Materials and methods: We used Hepa 1-6 and HUH-7 mouse and human hepatoma cell lines, respectively, to characterize the trafficking of the insulin receptor, in physiological conditions. For this, cells were stimulated with various insulin concentrations (50, 75 and 100 nM), during different time points, and processed for immunofluorescence, using phalloidin to label the actin cytoskeleton and antibodies against the receptor.

Results: Our results suggest that after insulin stimulation, hepatocytes form ring-shaped actin-rich structures known as Circular Dorsal Ruffles (CDRs). CDRs are dynamic and transient, forming exclusively on the dorsal surface of the cell, upon growth factor stimulation. The main function of these membrane-bound structures is the rapid internalization by macropinocytosis of tyrosine kinase receptors, like the insulin receptor. After this step, the receptors can be recycled back to the surface, following the recycling pathway or degraded in lysosomes. We observed that CDRs form as soon as 1 min after insulin stimulation. Furthermore, we found that the insulin receptor localizes to CDRs, suggesting it is internalized via this pathway.

Conclusion: Thus, our results suggest that the insulin receptors are rapidly internalized and recycled back to the plasma membrane through CDRs. This fast recycling might be crucial for the liver to fulfill its functions, especially the insulin clearance.

Lack of CD2AP disrupts Glut4 trafficking and attenuates glucose uptake

T.A. Tolvanen, S.N. Dash, Z. Polianskyte, V. Dumont, S. Lehtonen; Department of Pathology, University of Helsinki, Finland.

Background and aims: Glucose transporter 4 (Glut4) is the primary insulin responsive glucose transporter. In the absence of insulin, Glut4 resides in intracellular vesicles, and undergoes exocytosis upon insulin stimulation. CD2-associated protein (CD2AP) is a ubiquitously expressed cytoplasmic protein, which is necessary for the formation of slit diaphragms and glomerular ultrafiltration. Interestingly, CD2AP gene variants associate with end-stage renal disease in patients with type 1

diabetes. CD2AP functions as a scaffolding protein in different signaling and vesicle trafficking pathways, but it is not known whether it regulates glucose uptake into cells. In this study we investigated the role of CD2AP in insulin-dependent Glut4 trafficking and glucose uptake.

Materials and methods: Glucose uptake was measured in immortalized wildtype (WT) and CD2AP^{-/-} podocytes, and in HIRC and L6 cells transfected with CD2AP and control siRNAs, using tritium-labeled 2-deoxyglucose in basal, serum starved and insulin stimulated conditions. CD2AP^{-/-} and WT podocytes stably expressing HA-Glut4-GFP were surface-labelled with an antibody against HA to quantify the amount of Glut4 on the plasma membrane. HA-Glut4-GFP expressing podocytes were also used to study the trafficking of Glut4 by live cell imaging, and to quantify the circulation of Glut4 between the intracellular compartment and the plasma membrane in a time-dependent manner.

Results: In the basal state lack of CD2AP attenuated glucose uptake into podocytes by 20% compared to WT cells ($p < 0.05$). Also knockdown of CD2AP in HIRC and L6 cells by siRNA reduced glucose uptake by 25% ($p < 0.05$). Insulin stimulation induced glucose uptake into WT podocytes by 20% ($p < 0.05$), whereas CD2AP^{-/-} podocytes failed to respond. In line with this, insulin stimulation increased the amount of HA-Glut4-GFP on the plasma membrane by 50% in WT podocytes ($p < 0.01$), whereas no difference was observed in CD2AP^{-/-} podocytes. In WT podocytes, live cell imaging revealed dynamic trafficking of HA-Glut4-GFP in response to insulin, whereas in CD2AP^{-/-} podocytes HA-Glut4-GFP formed dense insulin unresponsive clusters. Quantification of HA-Glut4-GFP on the plasma membrane in a time-dependent manner after insulin stimulation revealed that in WT podocytes the amount of Glut4 on the plasma membrane increased by 30% after 5 minutes ($p < 0.01$), and by 270% after 30 minutes ($p < 0.001$). In CD2AP^{-/-} podocytes, however, there was no difference in the amount of HA-Glut4-GFP on the plasma membrane after insulin stimulation for 5 minutes. After 15 minutes, there was a 50% increase ($p < 0.001$), which did not significantly increase by 30 minutes ($p < 0.22$).

Conclusion: Our results indicate that CD2AP is essential for regulating glucose uptake into podocytes and other insulin responsive cells. CD2AP appears to be vital for sorting of endocytosed Glut4 to correct insulin sensitive compartments and insulin-responsive trafficking of Glut4 to the plasma membrane in podocytes.

MicroRNAs potentially regulators of GLUT4J.V.D. Esteves¹, C.Y. Yonamine¹, F. Gerlinger-Romero¹, D.C. Pinto-Junior¹, M.M. Okamoto¹, F.J. Enguita², U.F. Machado¹;¹Physiology and Biophysics, University of São Paulo, Brazil, ²University of Lisbon, Portugal.

Background and aims: Diabetes is a metabolic disease characterized by hyperglycemia associated with impaired glucose uptake, in which reduced GLUT4 protein expression (encoded by the SLC2A4 gene) plays an important role. The recently described microRNAs (miRNAs), which are small RNAs involved in gene regulation at the post-transcription level, usually by affecting the stability and degradation of mRNAs, have been described as involved in the pathophysiology of diabetes. However, the miRNAs participation in the reduction of GLUT4 expression, consequently in impaired glucose uptake, especially in skeletal muscle, remains unclear. Thus, the objective of this study was to investigate the expression of miRNAs potentially involved in the regulation of Slc2a4/GLUT4 expression in skeletal muscle of diabetic rats.

Materials and methods: Male Wistar rats (70-day old) were rendered diabetic by receiving streptozotocin (50 mg/kg, i.v.). After 13 days, 3 groups were formed: non-diabetic (ND), and diabetic treated with placebo (DP) or insulin (DI) (NPH insulin, 6U/day). Treatment was conducted for 7 days, totalizing 21 days of diabetes. At the end of the experimental

period, the animals were anesthetized, blood was collected and the soleus muscle was removed for evaluation of mRNA and protein expression. *In silico* analysis was used to select miRNAs predicted as potential regulators of Slc2a4/GLUT4 in rat. After that, based on previous description of diabetes-induced modulation of the miRNAs, and/or their participation in the skeletal muscle cell homeostasis, some miRNAs were selected for validation. The Slc2a4 mRNA and the miRNAs were analyzed by qPCR. The GLUT4 protein was assessed by Western blotting. The comparison among groups was performed by analysis of variance (ANOVA) followed by Bonferroni post-test.

Results: Diabetic rats developed hyperglycemia, glycosuria and increased plasma fructosamine; insulin treatment improved these parameters. Diabetes reduced ($P < 0.01$) by 60% and 40% the Slc2a4 mRNA and GLUT4 protein; insulin treatment was able to restore these parameters completely. *In silico* analysis scored 32 miRNAs, predicted by at least 3 algorithms, as potential regulators of Slc2a4/GLUT4 expression. From these, 10 miRNAs were selected for validation: miR-1, miR-29a, miR-29b, miR-31, miR-93, miR-106b, miR-133a, miR-133b, miR-199a and miR-206. Four of these miRNAs were modulated by diabetes in skeletal muscle: miR-1 and miR-29b were upregulated by 28% and 119%, respectively ($P < 0.05$ and $P < 0.01$), and miR-93 and miR-199a were down-regulated by 39% and 30%, respectively ($P < 0.05$). Insulin treatment was able to fully restore the expression of the miR-29b, miR-93 and miR-199, but had no effect upon miR-1.

Conclusion: This study shows that diabetes represses the Slc2a4/GLUT4 expression in soleus muscle, and that may be related to enhanced miR-1 and miR-29b and repressed miR-93 and miR-199 activity. Except by miR-1 overexpression, insulin treatment was able to reverse all the diabetes-induced regulations, which can be fundamental to improve the skeletal muscle glucose uptake in diabetes.

APPL1 promotes mechanical stretch induced glucose uptake through PKC ζ -Myosin IIa pathway in C2C12 myotubes

T. Saito, Y. Shimoda, Y. Tagaya, A. Osaki, E. Yamada, S. Okada, M. Yamada;

Molecular Science and Internal Medicine, Gunma University, Maebashi, Japan.

Background and aims: Adaptor protein, phosphotyrosine interaction, PH domain and leucine zipper containing 1 (APPL1) promotes insulin or adiponectin induced glucose uptake via protein kinase B (PKB/Akt) or 5' adenosine monophosphate-activated protein kinase (AMPK) dependent pathway. We have reported that APPL1 also promotes mechanical stretch induced glucose uptake through PKC ζ dependent pathway in C2C12 myotubes, but the mechanism was unknown. Therefore, this study aimed to investigate the mechanism of PKC ζ dependent pathway involved in glucose uptake stimulated by mechanical stretch.

Materials and methods: C2C12 myoblasts were grown on an elastic silicone chamber and induced differentiation. Differentiated C2C12 myotubes were stimulated by cyclic uniaxial stretch (10% of initial length, 10 cycle/min) for 5 hours. Plasmid DNA was transfected into C2C12 myoblasts by electroporation. Glucose uptake was measured by enzymatic assay and the localization of PKC ζ was examined by immunofluorescence. To find the binding partner of PKC ζ , PKC ζ was immunoprecipitated from cell lysates and analyzed by MS/MS.

Results: Mechanical stretch statistically increased PKC ζ phosphorylation by 30% and translocation to plasma membrane in APPL1 over-expressed myotubes compared to control cells. To investigate PKC ζ pathway, we have tried to find PKC ζ binding partner. Mass spectrometry analysis revealed non-muscle myosin IIa binds phosphorylated PKC ζ by immunoprecipitation in APPL1 over-expressed cells. This interaction was confirmed by western blotting. Furthermore, blebbistatin, myosin

IIa ATPase inhibitor, suppressed PKC ζ phosphorylation, translocation and glucose uptake to the basal level.

Conclusion: These results suggest that APPL1 promotes stretch induced glucose uptake through PKC ζ -myosin IIa pathway.

Favorable actions of Insulin-like Growth Factor Binding Protein (IGFBP)-1 and its RGD domain in insulin sensitivity and glucose regulation

N. Haywood, P. Cordell, N. Yuldasheva, J. Smith, M. Kearney, S. Wheatcroft;

LIGHT LABS, The University of Leeds, UK.

Background and aims: In prospective studies, low circulating levels of IGFBP1 predict the development of type 2 diabetes. We have previously shown that *in vivo* over expression of IGFBP1 improves insulin sensitivity and protects against atherosclerosis. IGFBP1 can impact on cellular functions via an RGD ($\alpha_5\beta_1$ integrin binding) motif independent of IGF binding. However, whether IGFBP1 is causally implicated in insulin sensitivity and glucose regulation and could be exploited therapeutically remains unexplored.

Materials and methods: C2C12 myotubes, 3 T3 adipocytes, HepG2 hepatocytes and INS823/13 pancreatic β -cells, were used to investigate the effects of acute treatment of rIGFBP1 and the synthetic hexapeptide GRGDTP (which binds $\alpha_5\beta_1$ integrin) on the insulin sensitivity and glucose regulation, through several complimentary *in vitro* assays. To examine whether the RGD motif of IGFBP1 is mechanistically implicated in glucose regulation, we administered GRGDTP peptide to both C57BL/6 mice with diet-induced obesity and KKAY diabetic Mice.

Results: Treatment of C2C12 myotubes with rIGFBP1 or GRGDTP, enhanced insulin stimulated IRS1, AKT phosphorylation and insulin stimulated glucose uptake ($P \leq 0.05$, ≤ 0.02 and $P \leq 0.01$ respectively). Enhanced insulin sensitivity is mediated through integrin engagement and focal adhesion kinase. Co-incubation with glucose and IGFBP1 or GRGDTP, increased glucose stimulated insulin secretion in INS823/13 pancreatic β -cells ($P \leq 0.01$ and ≤ 0.05 respectively) and is dependent upon integrin linked kinase. Acute administration of GRGDTP significantly improved glucose clearance and insulin sensitivity in mice with diet-induced obesity and KKAY diabetic mice ($P \leq 0.05$). Long term administration of GRGDTP had no detrimental effect.

Conclusion: We have shown that the RGD integrin-binding domain of IGFBP1 may play an important role in insulin sensitivity and glucose regulation and represents a potential novel therapeutic agent in the field of type 2 diabetes that requires further investigation.

Transcriptome profiling in lympho-monocytes of healthy subjects identifies a biomarker of early insulin resistance with potential implications in chronic heart failure

E. Derlindati¹, A. Matone², V. Spigoni¹, L. Marchetti², D. Ardigò¹, V. Curella¹, A. Dei Cas¹, I. Zavaroni¹, C. Priami², R.C. Bonadonna¹;

¹Dept. of Clinical and Experimental Medicine, University of Parma, ²Centre for Computational and System Biology (COSBI), The Microsof Research-University of Trento, Rovereto, Italy.

Background and aims: Gene expression profile (GEP) of peripheral blood mononuclear cells (PBMCs) is significantly affected by various diseases and may serve as biomarker of pathological changes occurring in other tissues. The aim of our study was to investigate whether insulin resistance (IR) per se is characterized by a specific pattern of GEP.

Materials and methods: 150 healthy young adults, were recruited in a cardiovascular risk assessment study (Multi-Knowledge project). Two groups of 10 subjects with extreme HOMAIR indices (High HOMA:4.0±2.8; Low HOMA:0.5±0.1), but with normal, similar BMI (22.2±2.6 vs 22.5±2.2 kg/m²), and comparable age (33.9±6.2 vs 40.2±11.3 years) and gender (7 M and 3 F in both groups) were selected. Standard anthropometric, hemodynamic, and metabolic variables were assessed. GEP of PBMCs from all subjects was evaluated using Agilent whole genome oligonucleotide mRNA microarrays. Data were analyzed with a novel ad-hoc rank-based classification method, optimized to extract a gene expression signature with highest power and statistical significance (p at least <0.005) to discriminate the two groups. Gene enrichment analysis was applied on the significant differentially expressed list of genes. All analyses were performed with R and Matlab.

Results: We identified a set of 512 probes corresponding to 321 annotated genes which summarize the characteristics of each sample and allow distinguishing Low HOMA and High HOMA subjects with an accuracy of 100%, according to a 5-fold cross-validation approach. Gene enrichment analysis of the 321 genes showed significant enrichment for the KEGG pathway “Adrenergic signaling in cardiomyocytes”, in which differentially expressed genes were compatible with a cluster of alterations, including increased intracellular cAMP and Ca²⁺ and accelerated apoptosis in the High HOMA group. We hypothesized that this pathway should biomark chronic heart failure (CHF), of which IR is a known risk factor. In two publicly available gene expression data sets (GSE21125 and GSE9128) we investigated whether the genes in the pathway of interest could differentiate between patients with CHF and controls. Two biomarkers (length 41 and 22, respectively) were found with high discriminant accuracy (95%), at a significant p value (p<0.02), overlapping with the “adrenergic signaling in cardiomyocytes” pathway.

Conclusion: GEP of the “adrenergic signaling pathway in cardiomyocytes” in lymphocytes is a fingerprint of IR and is implicated also as a biomarker of patients with CHF. This may be a major molecular platform linking IR to CHF.

Mitochondrial respiratory capacity of peripheral blood mononuclear cells associates with insulin resistance

K. Kaul¹, T. Jelenik¹, B. Menart¹, R. Rütter¹, B. Nowotny¹, J. Szendrodi^{1,2}, M. Roden^{1,2};

¹Institute of Clinical Diabetology, ²Department of Endocrinology and Diabetology, Medical Faculty, Heinrich-Heine University, Düsseldorf, Germany.

Background and aims: Subclinical inflammation contributes to the development of insulin resistance. In adipose tissue, infiltration by pro-inflammatory M1 macrophages has been linked to insulin resistance through release of tumor necrosis factor alpha and enhanced reactive oxygen and nitrogen intermediates. Pro-inflammatory M1 macrophages have higher non-oxidative respiration at resting stage, coupled with higher generation of reactive oxygen species. We aimed to study the association between whole-body insulin resistance and mitochondrial respiration in monocytes in circulation and systemic oxidative stress.

Materials and methods: Recently diagnosed type 2 diabetes patients (T2D) and lean individuals (CON) were recruited from the German Diabetes Center Study (GDS), and underwent thorough metabolic and blood analysis, including hyperinsulinemic-euglycemic clamps to assess whole-body insulin sensitivity (M-value). Leukocytes were isolated from fasting blood samples using density gradient centrifugation. Mitochondrial respiration was measured in isolated leukocytes using multiple substrate protocols and high-resolution respirometry. Tricarboxylic acid cycle activity was assessed by using saturating concentrations of malate, glutamate, succinate and adenosine diphosphate. Beta-oxidation was measured in response to octanoyl carnitine. Finally, maximal respiration capacity in the uncoupled state u was investigated using the uncoupler carbonyl cyanide-4-trifluoromethoxy phenylhydrazone (FCCP). Leak respiration was measured in response to ATPase inhibitor, oligomycin. The coupling efficiency of the mitochondrial complexes was assessed as the ratio of leak respiration to maximal respiration, known as the leak control ratio. Mitochondrial content was assessed by citrate synthase activity (CSA) in the leukocytes. Heparinized blood was used for the quantification of the ratio of CD11 positive M1 and CD 206 positive M2 macrophage subsets. Lipid peroxidation measured by thiobarbituric acid reactive substances assay (TBARS) was performed to assess systemic oxidative stress.

Results: Rates of oxygen consumption by leukocytes were markedly lower in patients with T2D than in CON (State u: 4.0±1 vs 8.3±1.3 pmol/s/mg protein, P<0.05). Maximal beta-oxidation was also lower in leukocytes of T2D (3.9±0.7 vs 6.2±0.6 pmol/s/mg protein, P<0.05). CSA did not differ between groups. The leak control ratio was higher in T2D indicating lower mitochondrial coupling efficiency and thus a source of reactive oxygen species (0.5±0.07 vs 0.2±0.04, P<0.05). The ratio of M1:M2 expression was also higher in leukocytes of T2D (0.2±0.01 vs 0.1±0.01, P<0.05) in line with a pro-inflammatory phenotype. TBARS in plasma was higher in T2D compared to CON (2±0.2 vs. 1±0.2 μM). Leukocyte state u respiration associated positively to whole-body insulin sensitivity (M-value: R=0.45, P<0.05) and negatively with TBARS (R=-0.49, P<0.005). Beta-oxidation also related positively to M-value (R=0.57, P<0.05) and negatively to total blood cholesterol (R=-0.47, P<0.05).

Conclusion: Lower mitochondrial respiration in circulating leukocytes may influence pro-inflammatory polarization of leukocytes and contribute to oxidative stress, which have been related insulin resistance.

Sclerostin and insulin resistance in prediabetes. Evidence of a cross-talk between bone and glucose metabolism

G. Daniele¹, D. Winnier¹, A. Mari², J. Bruder³, M. Fourcaudot¹, Z. Pengou¹, D. Tripathy¹, C. Jenkinson¹, F. Folli¹;

¹Medicine/Diabetes, UTHSCSA, San Antonio, USA, ²Medicine/Diabetes, Institute of Neuroscience, Padova, Italy, ³Medicine/Endocrinology, UTHSCSA, San Antonio, USA.

Background and aims: Sclerostin is a peptide inhibiting Wnt/ β -catenin signaling. Impaired glucose regulation (IGR), which includes impaired fasting glucose (IFG) and/or impaired glucose tolerance (IGT), is characterized by insulin resistance and altered insulin secretion, two key pathophysiological features preceding the development of type 2 diabetes. Our aims were to evaluate serum sclerostin levels in IGR subjects and to analyze its relationship with insulin-resistance and β -cell function

Materials and methods: In a cross-sectional study, 43 healthy normal glucose tolerant (NGT) individuals (12 male and 31 women; age=44.0 \pm 1.9 years; BMI=31.1 \pm 1.1 Kg/m²) and 79 individuals with impaired glucose regulation (IGR) (22 male and 57 women; age=46.0 \pm 1.4 years; BMI=31.9 \pm 1.2 Kg/m²) which included subjects with IFG (n=27), IGT (n=18) and combined IFG/IGT (n=34), underwent OGTT and DXA. Serum sclerostin levels were measured at fasting. β -cell function parameters were calculated using C-peptide deconvolution. Dynamic indexes of insulin sensitivity were calculated from OGTT. A subgroup (n=18 with NGT and n=30 with IGR) underwent to an euglycemic hyperinsulinemic clamp with 3-3H-glucose to estimate the endogenous glucose production (EGP) and the rate of insulin-mediated total body glucose disposal (TGD/SSPI)

Results: Sclerostin levels were higher in IGR as compared to NGT (50.8 \pm 2.4 vs. 38.7 \pm 2.3 pmol/l; p=0.01). IFG and combined IFG-IGT manifested higher sclerostin levels compared to NGT (55.8 \pm 2.9 and 50.8 \pm 5.1 vs. 38.7 \pm 2.3 pmol/l; p=0.02, respectively) while no difference was found between isolated IGT and NGT. In whole population serum sclerostin was correlated with HOMA-IR (r=0.62), OGIS (r=-0.38), Matsuda Index (r=-0.42), adipose tissue insulin resistance index (ATIRI) (r=0.61) and TGD/SSPI (r=-0.40) (all p<0.001) although subjects with isolated IFG were mostly accountable for the correlations with insulin sensitivity in skeletal muscle (r=0.63 HOMA-IR; r=-0.55; Matsuda Index; r=-0.64 OGIS; r=-0.57 TGD/SSPI), liver (r=0.61; fasting EGP) and adipose tissue (r=0.71 ATIRI) (all p<0.05). EGP, hepatic insulin resistance and ATIRI were correlated with sclerostin levels (r=0.48 and r=0.62; r=0.61; p<0.001). Fasting and OGTT insulin clearance were correlated with sclerostin serum levels (r=-0.52 and r=-0.44; both p<0.001) but no correlations were found with β -cell function parameters. In multiple linear regression analysis, sclerostin levels improved the r² associated to HOMA-IR (r²=0.192 to 0.247) to TGD/SSPI (r²=0.518 to 0.577). Sclerostin levels were positively correlated with fasting plasma glucose (r=0.22; p=0.01), fasting and 2-hours plasma insulin (r=0.63 and r=0.45 respectively; p<0.001) and HbA1c (r=0.18; p=0.04). IFG and combined IFG-IGT were accountable for the correlation between sclerostin levels and fasting plasma insulin (r=0.64 and r=0.52; p<0.01) and 2-hours plasma insulin (r=0.72; p<0.01 and r=0.29; p=0.08)

Conclusion: Sclerostin levels are increased in IGR individuals and correlated with insulin-resistance in skeletal muscle, liver and adipose tissue. These data suggest that sclerostin might play a role in determining insulin resistance possibly acting on insulin clearance and degradation

619

Elevated circulating microRNA-143-3p is associated with insulin resistance in the metabolic syndrome

X. Lin, D. Yu, Z. Xu, Q. Pan, X. Yin, J. Zhou, F. Zheng, H. Li;

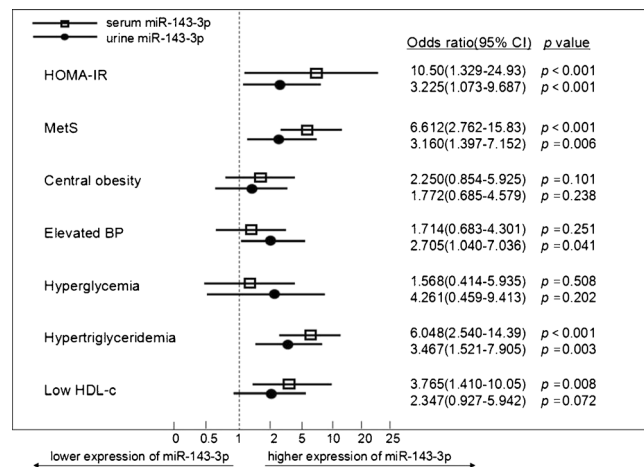

Department of Endocrinology, The Affiliated Sir Run Run Shaw Hospital, Zhejiang University, Hangzhou, China.

Background and aims: Metabolic syndrome (MetS) is a cluster of cardiovascular risk factors that includes obesity, diabetes, and dyslipidemia. Insulin resistance (IR) is the most accepted unifying theory explaining the pathophysiology of the metabolic syndrome. Accumulating evidence implies that circulating microRNAs (miRNAs) are involved in the regulation of MetS, but existing studies have yielded inconclusive results. Examining the associations of circulating miRNAs levels with MetS and insulin sensitivity in human may lead to improved insight.

Materials and methods: The genome-wide circulating miRNA profiles were detected via microarray in serum samples from 4 patients with MetS and 4 control without MetS. Elevated miR-143-3p was selected and validated in individual serum and urine samples from 50 MetS patients (52.0% men) and 50 control (48.0% men) subjects. Associations between circulating miR-143-3p levels and parameters related to adiposity, insulin resistance, lipid profiles and hepatic enzymes were further assessed.

Results: Eleven miRNAs were found to be expressed differently in the sera of MetS patients compared to control subjects (p<0.001). Further qRT-PCR analyses confirmed that circulating miR-143-3p was increased significantly in MetS compared with controls (p<0.001) both in the serum and urine samples. Serum and urine miR-143-3p levels were correlated with homeostasis model assessment of insulin resistance (HOMA-IR) (r=0.726, 0.624), high density lipoprotein-cholesterol (r=-0.321, -0.473) and percentage of body fat (Fat%) (r=0.307, 0.392, all p<0.001). After controlling for confounding factors, miR-143-3p remained an independent risk factor for insulin resistance (OR=10.500, 95% CI=1.329 - 24.93 for serum, OR=3.225, 95% CI=1.073 - 9.687 for urine, both p<0.001).

Conclusion: Elevated circulating miR-143-3p is positively associated with MetS and insulin resistance. These findings provide a better understanding regarding the role of circulating miRNAs in insulin sensitivity.

Bone turnover markers and prediabetes in humans

D. Winnier¹, G. Daniele¹, A. Mari², J. Bruder³, M. Fourcaudot¹, Z. Pengou¹, D. Tripathy¹, C. Jenkinson¹, F. Folli¹;

¹Medicine/Diabetes, UTHSCSA, San Antonio, USA, ²Medicine/Diabetes, Institute of Neuroscience, Padova, Italy, ³Medicine/Endocrinology, UTHSCSA, San Antonio, USA.

Background and aims: Recent studies have suggested a link between bone remodeling and glucose metabolism. The aim of the study was to examine the relationship between hormones involved in bone remodeling and glucose metabolism alterations in subjects with impaired glucose regulation (IGR), which is known to lead to type 2 diabetes mellitus

Materials and methods: We performed a cross-sectional study including 43 healthy normal glucose tolerant (NGT) individuals (12 male and 31 women; age=44.0±1.9 years; BMI=31.1±1.1 Kg/m²) and 79 individuals with impaired glucose regulation (IGR) (22 male and 57 women; age=46.0±1.4 years; BMI=31.9±1.2 Kg/m²) which included subjects with IFG (n=27), IGT (n=18) and combined IFG/IGT (n=34), undergoing OGTT and DXA. Osteopontin, Osteocalcin, Osteoprotegerin and PTH were measured at fasting. β -cell function parameters were calculated using C-peptide deconvolution. Dynamic indexes of insulin sensitivity were calculated from OGTT (SI, OGIS and Stumvoll). A subgroup (n=18 with NGT and n=30 with IGR) underwent in addition to an euglycemic hyperinsulinemic clamp with 3-3H-glucose to estimate the endogenous glucose production (EGP) and the rate of insulin-mediated total body glucose disposal (TGD/SSPI)

Results: Osteopontin levels were higher in IGR as compared to NGT (5.3±0.5 vs. 3.3±0.2 μ g/ml; p=0.008) while osteocalcin, osteoprotegerin and PTH were similar in both groups. Osteopontin levels were higher in isolated IGT as compared to isolated IFG and IFG/IGT (6.3±0.5 vs. 4.5±0.3 and 5.4±0.5 μ g/ml; p=0.02). Osteocalcin levels were similar between IFG and NGT (8.0±0.5 vs. 8.3±0.3 ng/ml; p=0.74) but lower in isolated IGT and IFG/IGT as compared to NGT (7.2±0.3 and 5.4±0.2 vs. 8.3±0.3 ng/ml; p<0.01). Osteoprotegerin and PTH levels were similar between glucose tolerance subgroups in IGR subjects. Osteopontin levels positively correlated with HbA1c, fasting and 2 h plasma glucose and PTH (r=0.20; r=0.21; r=0.26 and r=0.26; all p<0.05). Conversely, osteocalcin levels were negatively correlated with body fat, 2 h plasma glucose, insulin (r=-0.25; r=-0.18; r=-0.21, all p<0.05) and positively correlated with Stumvoll index (r=0.21; p<0.05). Osteoprotegerin levels correlated with TGD/SSPI (r=-0.29; p<0.05) and with EGP and Hepatic Insulin Resistance Index in IGR subjects (r=0.51 and r=0.43; p<0.01). PTH did not correlate with insulin sensitivity and β -cell function parameters

Conclusion: Osteopontin and osteocalcin were inversely correlated with glucose metabolism parameters. Interestingly, in IGR subjects osteoprotegerin levels were strongly associated with increased EGP and increased insulin resistance in skeletal muscle and liver. In prediabetes, hormone known to be involved in bone remodeling may directly affect glucose metabolism before overt type 2 diabetes occurs

621

The adipokine Zinc- α 2-Glycoprotein (ZAG) is downregulated with insulin sensitivity in polycystic ovary syndrome

Y. Chang^{1,2}, L. Li^{1,2}, G. Yang³;

¹Key Laboratory of Diagnostic Medicine (Ministry of Education) & Department of Clinical Biochemistry, ²College of Laboratory Medicine, ³Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, China.

Background and aims: Zinc-alpha2-glycoprotein(ZAG) is a novel adipokine, which can act locally to influence adipocyte metabolism. Recent studies have shown that ZAG decreases in type 2 diabetes mellitus,

which suggest that ZAG is likely to associate with insulin resistance(IR). Meanwhile, polycystic ovary syndrome (PCOS) characterized by androgen excess is also linked to IR. Currently, no report has demonstrated any relationships between ZAG and IR in a relative large population of PCOS. The aim of the current study is to investigate whether ZAG correlates with IR in PCOS women.

Materials and methods: 99 PCOS women and 100 healthy age-matched control subjects were recruited. Euglycemic- hyperinsulinemic clamps (EHCs) were performed to assess their insulin sensitivity, which was expressed as M-value. Circulating ZAG was measured with ELISA kit. Plasma glucose and HbA1c were measured by the glucose oxidase method and HPLC, respectively. Plasma insulin was detected by radioimmunoassay. Plasma TC, HDL, LDL, and TG were analyzed enzymatically using an autoanalyzer. The percentage of body fat (FAT%) was determined by bioelectrical impedance. HOMA-IR=fasting insulin (FIns, mU/L)×fasting blood glucose (FBG, mmol)/22.5. The area under the curve for glucose (AUC glucose) and insulin (AUC insulin) during the OGTT was calculated geometrically using the trapezoidal rule. The ROC curves of ZAG was analyzed to investigate the predictive value of ZAG for PCOS.

Results: Circulating ZAG and M-value were much lower in PCOS than in controls (35.3±18.3 vs. 53.9±15.3 mg/L for ZAG; 5.9±2.9 vs. 10.1±2.6 mg/kg/min for M-value, both P<0.01). Pearson correlations showed that in PCOS, ZAG correlated positively with M-value and negatively with BMI, FAT%, TG, FIns, HbA1c, HOMA-IR, AUCglucose and AUCinsulin. Multiple linear regression analysis revealed that only M-value and AUCglucose were independently related factors to ZAG in PCOS. Multivariate logistic regression analysis showed that ZAG was associated significantly with PCOS even after controlling for anthropometric variables, blood pressure, lipid profile and hormones. The ROC curve analyses revealed that the best cutoff value for ZAG to diagnose PCOS was 42.6 mg/L (sensitivity 84.0%, specificity 77.8%).

Conclusion: Circulating ZAG is reduced in PCOS and is associated with IR, which suggests that ZAG may play a role in the pathogenesis of IR in PCOS, and even become a marker of insulin resistance that predicts outcomes and therapeutic responses to assist clinical management of PCOS.

Acute exercise impacts kynurenine metabolism in type 2 diabetic and healthy people

J.M. Mudry¹, J.L. Ruas², S. Erhardt², K. Caidahl¹, J.R. Zierath¹, A. Krook², H. Wallberg-Henriksson²;

¹Molecular medicine and surgery, ²Physiology and Pharmacology, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Tryptophan (Trp) is an essential amino acid and a primary source for the synthesis of neurotransmitters and signalling peptides such as serotonin and kynurenine (KYN). KYN is the substrate for two different neuro-active metabolites with opposing effects: kynurenic acid (KYNA) or quinolinic acid (QUIN). Kynurenine aminotransferase (KATs) enzymes catalyse the conversion of KYN into KYNA. In contrast to KYN, KYNA does not cross the brain blood barrier. KYN entry into the brain is associated with psychiatric disorders such as schizophrenia or depression. Reductions in circulating KYN coupled to resistance to depression. Exercise and PGC1 α overexpression in skeletal muscle increases skeletal muscle KATs mRNA expression, thus enhancing conversion of KYN into KYNA in the periphery. Given that type 2 diabetic (T2D) patients are prone to depression, we determined whether resting and exercise-induced KATs expression and circulating KYN and KYNA concentration are altered compared to people with normal glucose tolerance (NGT).

Materials and methods: We recruited sedentary T2D age- and BMI-matched NGT volunteers. Subjects underwent clinical phenotyping and VO₂max testing. Subjects performed a 30 minute exercise bout on a cycle ergometer at 80% of VO₂max. A vastus lateralis muscle biopsies and plasma sample was collected at rest, after exercise and during recovery (3 hours post-exercise). Skeletal muscle mRNA expression of KATs and metabolism-related genes, as well as plasma measurement of Trp, KYN and KYNA were determined. Statistical analysis was performed using repeated measures two-way ANOVA with Bonferroni post-tests.

Results: Exercise increased PGC1 α mRNA expression in skeletal muscle as expected. Skeletal muscle mRNA expression of KAT1 and KAT2 was reduced in T2D, while acute exercise altered KAT4 expression in both NGT and T2D subjects. Plasma concentrations of Trp and KYN were decreased and KYNA increased in response to exercise.

Conclusion: mRNA expression of KATs is reduced in skeletal muscle from T2D patients. However, KATs mRNA was not correlated with acute variations in plasma levels of KYN or KYNA. Acute exercise (30 min) reduces plasma level of Trp and KYN and increases KYNA over 3 hours, indicating that exercise directly alters KYN/KYNA balance in the circulation.

Analysis of anti-insulin receptor antibody in two patients with rheumatoid arthritis and systemic lupus erythematosus

K. Fujioka¹, M. Asano¹, T. Ishizuka¹, H. Okada², I. Mori³, K. Kajita³, H. Morita³;

¹General Internal Medicine, Gifu Municipal Hospital, ²General Internal Medicine, Gifu Prefectural General Medical Center, ³General Internal Medicine, Gifu University Graduate School of Medicine, Gifu City, Japan.

Background and aims: Type B insulin resistance syndrome (IRS) proposed by Flier et al in 1976, is a rare autoimmune disease characterized by the presence of autoantibodies against the insulin receptor. The majority of the patients present marked hyperglycemia and compensated hyperinsulinemia, but some patients may present with hypoglycemia

caused by an insulin-like effect of the receptor autoantibodies. A common feature of type B IRS is the co-occurrence of autoimmune disorders, such as systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). We have reported here 2 cases of novel type B IRS presented with hypoglycemia and unstable diabetes control in a patient with SLE and RA, respectively.

Materials and methods: Two Japanese women were examined. One woman has RA and the other woman has SLE. We examined an insulin receptor antibody by immunoprecipitation method.

Results: Case1. 17 years old Japanese woman had both shoulders and cubital arthralgia, butterfly rash, stomatitis, photoallergy, and proteinuria were presented, suggesting SLE with lupus nephritis (WHO classII) diagnosed by renal biopsy. Moreover, hypoglycemia (less than 60 mg/dl) were appeared with hyperinsulinemia (IRI90.7 μ l/ml and CPR11.5 ng/ml). We examined an insulin receptor antibody by immunoprecipitation method. We identified the 95 kDa band which showed anti-insulin receptor β subunit antibody using patient's serum. When we treated with mycophenolate mofetil and prednisolone (30 mg/day), the hypoglycemia and pyrexia had been disappeared. Case2. 52 years old Japanese woman has been suffered with rheumatoid arthritis treated with salazosulfapyridine, methotrexate and tacrolimus. General fatigue and hyperglycemia (300 mg/dl) appeared. When intensive insulin therapy had been started, her glycemic control was poor with hyperglycemia (>400 mg/dl) and hypoglycemia (<40 mg/dl). We identified the 135 kDa band which showed anti-insulin receptor α subunit antibody. Etanercept treatment improves rheumatoid arthritis and glucose control in accordance with amelioration of insulin resistance and vanishing of hypoglycemia.

Conclusion: When hypoglycemia and unstable control of diabetes occurred in autoimmune disease such as SLE and rheumatoid arthritis, we should be suspicious of type B insulin resistance syndrome.

Association of faecal elastase 1 with non-fasting triglycerides in type 2 diabetes

J. Oscarsson¹, W. Rathmann², B. Haaster³, N. Berglind¹, B. Lindkvist⁴, N. Wareham⁵;

¹AstraZeneca R&D, Mölndal, Sweden, ²Institute for Biometrics and Epidemiology, Dusseldorf, ³mediStatistica, Neuenrade, Germany, ⁴Sahlgrenska Academy, Göteborg, Sweden, ⁵MRC Epidemiology Unit, Cambridge, UK.

Background and aims: Morphological alterations and moderate impairment of exocrine pancreatic function are present in patients with type 2 diabetes. Despite the fact that decreased pancreas lipase activity is a hallmark for pancreatic exocrine insufficiency, little is known about the impact of exocrine pancreatic function on plasma triglycerides. Moreover, studies specifically investigating the metabolic importance of a mild impairment of pancreatic exocrine function demonstrated as a low fecal elastase-1 (FE1) levels in patients with diabetes are lacking. We investigated the association between FE1 and non-fasting triglycerides in patients with type 2 diabetes and controls.

Materials and methods: Data from 544 patients with type 2 diabetes (age: 63 \pm 8 years) randomly selected from diabetes registers, and 544 matched controls (age, sex, practice) without diabetes were retrospectively analysed. FE1 (μ g/g stool) measurements were performed centrally. Non-fasting plasma triglycerides were centrally determined. Linear regression models were fitted using FE1 as dependent and log-triglycerides as independent variable adjusting for sex, age, body mass index, alcohol consumption, serum lipase, HbA1c, and smoking.

Results: FE1 concentrations were lower (mean \pm sd: 337 \pm 204 vs. 437 \pm 216 μ g/g, p <0.05) and plasma triglycerides were higher (geometric mean \times standard deviation factor: 2.2 \times :1.9 vs. 1.6 \times :1.8 mmol/l, p <0.05) in

patients with type 2 diabetes vs. controls, respectively. In type 2 diabetes, a 10% increase in plasma triglycerides was associated with 4.5 $\mu\text{g/g}$ higher FE1 concentrations ($p=0.001$) after adjusting for confounders. The model in controls comprised triglycerides (+10% increase: +4.5 $\mu\text{g/g}$ FE1, $p=0.005$), age, heavy alcohol drinking, HbA1c, serum lipase, and current and ex-smoking. Triglyceride levels and the confounders explained about 10% of the variance in FE1 in both groups. In contrast, patients with diabetes and controls with pathological FE1 (<100 $\mu\text{g/g}$) showed an inverse relation: low FE1 levels were associated with high plasma triglycerides, but the association was statistically significant only in controls ($p=0.012$ for controls, $n=20$, and $p=0.135$ for patients with type 2 diabetes, $n=65$).

Conclusion: Non-fasting triglycerides were positively related to FE1 in both patients with type 2 diabetes and control subjects, suggesting that impairment of exocrine pancreatic function is influencing plasma triglycerides. Marked loss of exocrine pancreatic function is associated with an opposite effect, resulting in higher plasma levels of plasma triglycerides. *Supported by: Unrestricted grant from AstraZeneca, Sweden for the analyses*

Balance between innate immunity pathways (MYD88/TRIF) is associated with insulin sensitivity in muscle and adipose tissue of obese post-menopausal women

C. Amouzou¹, C. Breuker¹, K. Lambert¹, F. Galtier², J. Cristol², A. Avignon², J. Mercier¹, A. Sultan^{1,2}, C. Bisbal¹;

¹INSERM U1046, ²CHU Lapeyronie, Montpellier, France.

Background and aims: During obesity, innate immune Toll like receptors (TLRs) activation in insulin dependent tissues such as adipose tissue (AT) and skeletal muscle (SM) is one of the key mechanisms involved in insulin resistance (IR) development. In fact, in obese subjects, the excess of free fatty acids (FFA) and lipopolysaccharides (LPS) at systemic level induced TLRs activation such as TLR4. TLR4 activation occurs via two pathways: - The myeloid differentiation primary response gene 88 “MYD88 pathway” which induces IR by activating nuclear factor κB (NF κB) transcription factor, inflammatory cytokines (TNF α , IL6) and inflammatory kinases. - The toll/interleukin-1-receptor-domain-containing adapter-inducing interferon β “TRIF pathways” which is less studied than “MYD88 pathway”, and involved interferon β (IFN β) production, and proteins such as oligoadenylate synthetase 2 (OAS2), the latent endoribonuclease (RNase L) and TLR3. The aim of this study was to identify the role of “TRIF pathway” in early mechanisms leading from obesity to IR in AT and SM of grade I obese women.

Materials and methods: We recruited 30 post-menopausal women (50-65 years old), with no personal or familial history of diabetes and any treatment that could interfere with IS. Among these subjects 10 were normal-weight control (CT) and 20 were grade I obese subjects. IS/IR was first assessed by HOMAIR index in order to classify grade I obese volunteers as obese insulin-sensitive OIS ($n=11$) or obese insulin-resistant OIR ($n=9$), and the accuracy of these method was then confirmed by glucose infusion rate (GIR) measurement determined by a hyperinsulinemic euglycemic clamp test. SM and AT of all volunteers were obtained respectively from biopsies in the vastus lateralis and abdominal subcutaneous adipose tissue. We analyzed tissues insulin response, inflammatory state at systemic level and innate immune MYD88 and TRIF pathways at tissues level (SM and AT).

Results: Our results show that at systemic level, there is no difference in cytokines levels between OIS and OIR. In AT, IS (measured by Phospho Akt/Akt ratio) was comparable in CT, OIS and OIR while it was significantly decreased in OIR’s SM compare to CT ($P=0.002$) and OIS ($P=0.002$). The preservation of IS in AT is associated with activation of “TRIF pathway” (up-regulation of OAS2, RNase L and TLR3 mRNA level and increase in IRF3 phosphorylation). On the other hand, alteration

of IS in OIR’s SM is associated with “MYD88 pathway” activation. In grade I obese subjects, IR occurs only in OIR’s SM. This muscular IR appears without any systemic inflammation but is associated with “MYD88 pathways activation”. On the other hand, preservation of IS in AT is associated with “TRIF pathway” activation. These results show that “TRIF pathways” activation seems to have positive effects on IS.

Conclusion: Further, the balance between MYD88 and TRIF pathways seems to be important for IS regulation.

The prevalence of pre-diabetes, insulin sensitivity indices and glucose levels are increased in patients with autoimmune thyroiditis

G. Boutzios¹, K. Alexandraki¹, S. Liatis², K. Makrilakis², E. Lampropoulou¹, G. Nikolopoulos¹, K. Paradeisi¹, G. Kaltsas¹;

¹Pathophysiology, ²First Department of Propaedeutic Medicine, National University of Athens, Greece.

Background and aims: The prevalence of thyroid autoimmunity in general population (positive tests for thyroglobulin antibodies (TgAb) and/ or thyroperoxidase antibodies (TPOAb) is increased up to 14.8% in men and 23.4% in women without palpable goiter. The prevalence of pre-diabetes is also increased and it is estimated up to 14.6%. The aim of the study was to investigate whether there is an association between thyroid autoimmunity and β -cell secretion in patients with impaired fasting glucose (IFG) and/ or impaired glucose tolerance (IGT).

Materials and methods: 609 patients (457 females) 46.8 \pm 14.5 years studied for pre-diabetes (defined as IGT either IFG or HbA1c \geq 5.7%) and autoimmune thyroiditis (AIT, TgAb and/or TPOAb positive) were included in the study. Characteristics recorded were age, gender, waist circumference (cm), BMI (Kg/m²). Fasting glucose (mg/dl) and insulin levels ($\mu\text{IU/ml}$), glucose 120 min post-oral glucose tolerance test (OGTT), HbA1c (%), HOMA and QUICKI insulin-resistance (IR) indices, and IR status as HOMA >2.16 and QUICKI <0.34 were also assessed. In 291 patients who had an oral glucose tolerance test (OGTT) with glucose and insulin measurement in five different time points, first, second phase insulin sensitivity index (ISI) and ISI were also assessed. Patients with hypothyroidism and DM2 were excluded from the study.

Results: Patients ($n=311$) who had AIT compared to non-AIT patients ($n=293$) were older [49.2 \pm 13.9 vs. 44.2 \pm 14.7 ($p<0.001$)], had larger waist [96 \pm 15.3 vs. 91.7 \pm 15.3 ($p=0.002$)], higher glucose levels [99.6 \pm 12 vs. 95.6 \pm 12.2 ($p<0.001$)], and higher pre-diabetes rates (71.2%) (chi-square=21.5, $p<0.001$) but similar rates of IR (44.6%). Pre-diabetic ($n=221$) patients with AIT had first phase ISI (1470.9 \pm 458.2), and ISI (0.1 \pm 0.03) higher to non-AIT (first phase ISI:1262.8 \pm 596.4, $p<0.001$; ISI:0.09 \pm 0.05, $p<0.001$).

Conclusion: Patients with AIT and impaired β -cell secretion had higher HbA1c levels with similar rate of insulin resistance and higher prevalence of pre-diabetes compared to non-AIT. Thyroid autoimmunity could be eventually a possible factor modifying β -cell secretion. Nevertheless further studies are needed to confirm these findings.

627

Insulin sensitivity with reactive hypoglycaemia: a metabolic subtype of polycystic ovary syndrome with reduced risks of type 2 diabetes and cardiovascular disease

J. Pinkney¹, A. Mari², A. Tura², K. Bond³, E. Stenhouse⁴, R.P. Vincent⁵, J. Tomlinson⁶;

¹Centre for Clinical Trials and Population Studies, Plymouth University, Peninsula Schools of Medicine and Dentistry, UK, ²Italian National Research Council Institute of Biomedical Engineering, University of Padua, Italy, ³Research and Development, Royal Cornwall Hospital, Truro, ⁴School of Nursing and Midwifery, Plymouth, ⁵Clinical Biochemistry, King's College Hospital, London, ⁶Pool Health Centre, Redruth, UK.

Background and aims: Polycystic Ovary Syndrome (PCOS) is associated with insulin resistance (IR) and is a risk factor for type 2 diabetes (T2D) and cardiovascular disease (CVD). However, Reactive Hypoglycaemia (RH) in PCOS has received little attention. This study aims to identify the frequency of RH in PCOS, its potential mechanisms and clinical significance.

Materials and methods: 48 women with PCOS (Rotterdam criteria) and 53 BMI-matched controls underwent a 6-point, 2-hour 75 g oral glucose tolerance test to identify beta cell function (computer modelling from glucose, insulin and C-peptide data) and Insulin Sensitivity Index (ISI) (Matsuda method). Central adiposity was measured by bioimpedance and anthropometry. Biochemical RH was defined as 2-hour glucose less than fasting.

Results: (1) There were no significant differences between PCOS and controls in beta cell glucose sensitivity (BCGS) (103.8 [69.1] vs 105.1 [54.9] pmol/min/mL/mmol; $p=0.91$) or ISI (0.94 [0.57] vs 1.17 [0.77]; $p=0.11$) but ISI was strongly associated with adiposity (BMI categories <24.9, 25-29.9, 30-34.9, >35 kg/m²; PCOS and controls, ANOVA both $p<0.001$). (2) RH was common in both PCOS (37%) and controls (52%) (Chi-square; $p=0.48$). Compared to women without RH, those with RH had lower increases in insulin levels from 0-120 mins (PCOS 171.6 [28.5-243.8] vs 340.6 [228.8-429.5] pmol/l; $p=0.005$; Controls 66.7 [8.7-122.1] vs 250.8 [165.8-504.4] pmol/l; $p<0.001$), and controls with RH also had higher ISI (1.68 [0.98] vs 0.89 [0.46]); ($p<0.001$). (3) In women with PCOS, glucose at 120 mins correlated with waist circumference ($r=0.40$, $p=0.008$), triglycerides ($r=0.33$, $p=0.03$), systolic ($r=0.32$, $p=0.03$) and diastolic blood pressure ($r=0.35$, $p=0.02$) and C-reactive protein ($r=0.31$, $p=0.04$), but these relationships were not present in controls. (4) Women with PCOS and poor insulin secretion (lowest quartile of BCGS), low waist circumference ($r=0.81$, $p=0.001$), low visceral fat ($r=0.82$, $p=0.001$) and high ISI ($r=-0.60$, $p=0.01$) were associated with lower 2 hour glucose levels. Women with PCOS in the lowest waist tertile (<87 cm) also had significantly lower 2 hour glucose (5.29 [1.07] mmol/l) vs) than those in the middle and upper tertiles (6.12 [1.85] mmol/l) ($p=0.005$). Finally, (5) women with PCOS who self-reported regular hypoglycaemic symptoms such as shakiness had higher ISI (1.14 [0.63] vs 0.77 [0.46]; $p=0.03$).

Conclusion: These new findings identify a common subtype of PCOS in which lower visceral fat and increased insulin sensitivity are associated with normal blood glucose despite poor insulin secretion. Waist circumference less than 87 cm and 2 hour glucose less than baseline, sometimes accompanied by symptoms of RH, identifies women with PCOS who may have lower risks of future T2D and CVD. These findings have significant implications for patient education, screening and prevention. *Supported by: Duchy Health Charity, Cornwall Centre for Endocrinology and Diabetes*

628

Metabolic flexibility and oxidative capacity independently predict insulin sensitivity in newly diagnosed patients with type 2 diabetes

M. Apostolopoulou^{1,2}, K. Strassburger^{2,3}, B. Knebel^{2,4}, J. Kotzka^{2,4}, J. Szendroedi^{1,2}, M. Roden^{1,2};

¹Institute for Clinical Diabetology, German Diabetes Center, ²German Center for Diabetes Research, ³Institute for Biometrics and Epidemiology, ⁴Institute for clinical biochemistry and pathobiochemistry, German Diabetes Center, Duesseldorf, Germany.

Background and aims: Inherited and acquired insulin resistance have been related to abnormal muscle mitochondrial function. Mitochondrial function should be reflected by maximal oxygen uptake (VO₂max) and metabolic flexibility, defined as the difference between fasting and insulin-stimulated respiratory quotient (Δ RQ). However it is unclear, whether impaired Δ RQ results from impaired mitochondrial function or decreased glucose uptake due to insulin resistance. We hypothesized that VO₂max and Δ RQ correlate with each other and with insulin sensitivity and that gender, genetic variations associated with higher insulin sensitivity or VO₂max in peroxisome proliferator-activated receptors and co-factors (PPAR γ , PPAR δ , PGC-1 α), NADH dehydrogenase 1 β subcomplex 6 (NDUFB6) or β -adrenergic receptor (ADRB) genes, glycemia or lipidemia would mediate such relationships.

Materials and methods: A total of 121 patients (85 males, 36 females), all participants of the GDS, within the first year of type 2 diabetes (T2D) diagnosis were included. The patients underwent comprehensive phenotyping including hyperinsulinemic-euglycemic clamps, indirect calorimetry and cycling spiroergometry as well as genotyping for PPAR γ , NDUFB6, PGC-1 α , PPAR δ and ADRB2 genes.

Results: Males and females had comparable age (51 \pm 10 vs 52 \pm 11 years) but different body mass (BMI; 30.3 \pm 5.5 vs 33.8 \pm 7.6 kg.m⁻², $p=0.01$) and VO₂max (29 \pm 5 vs 27 \pm 4 ml.min⁻¹.(kg fat free mass)⁻¹, $p=0.05$). Insulin sensitivity (M: 9.7(7.3,12.2) vs 9.7(7.1, 11.9) mg.(kg fat free mass)⁻¹.min⁻¹) and Δ RQ (0.11 \pm 0.06 vs 0.11 \pm 0.05, $p=0.99$) were nearly identical between males and females. Δ RQ and VO₂max did not correlate with each other, but both parameters associated with insulin sensitivity in both males and females (Δ RQ: males: $\beta=1.91$, $p=0.002$, females: $\beta=2.46$, $p=0.014$, VO₂max: males: $\beta=0.04$, $p<0.0001$, $\beta=0.04$ females: $p=0.02$). When we examined also the effect of body mass index, age, fat mass and waist-to-hip ratio performing multiple regression analysis, Δ RQ and VO₂max were remained independent predictors of insulin sensitivity in male ($\beta=1.56$, $p=0.004$ and $\beta=0.02$, $p=0.006$ respectively), but not in female participants. There was no association of the examined parameters with glycemic control, free fatty acids or tested gene variations.

Conclusion: The absence of a relationship between VO₂max and Δ RQ despite their independent association with insulin sensitivity suggest that metabolic flexibility and oxidative capacity are different features of muscle mitochondrial function. Moreover, neither glycemia and lipidemia nor variants in genes related to oxidative metabolism affected the relationship between VO₂max and Δ RQ in T2D patients.

Excess in haemoglobin glycation and glucose variability in obese patients without known dysglycaemia

P. Valensi, M. Fysekidis, A. Rezki, I. Banu, C. Pillegand, S. Chiheb, E. Cosson;

Department of Endocrinology, Diabetology, Nutrition, Paris Nord University, France.

Background and aims: We previously showed that, in obese patients without known dysglycemia, age was a determinant of hemoglobin glycation. A mathematical relation has been proposed between mean

glucose given by continuous glucose monitoring (CGM) and HbA1c levels. This study aimed to explore in overweight or obese patients the difference between the measured HbA1c level and HbA1c level predicted by this relation (ΔHbA1c), and the factors associated with this difference.

Materials and methods: We included 70 patients (46.5 ± 14.3 years, BMI 35.2 ± 6.8 kg/m²) without known dysglycemia. CGM was performed during 24 hours. Mean glucose and mean amplitude glycemic excursion (MAGE) were calculated. Predicted HbA1c level was calculated using the following formula (ADAG): mean glucose = $1.649 \times \text{HbA1c} - 2.645$, and the difference between measured and predicted HbA1c was calculated (ΔHbA1c). An OGTT was performed.

Results: Measured HbA1c was 5.1% to 7.4%. According to OGTT, 24 patients had prediabetes (fasting hyperglycemia and/or glucose intolerance) and 13 had diabetes whereas 49 patients had an HbA1c $\geq 5.7\%$. The population was separated in quartiles of measured HbA1c (Q1 to Q4). For every quartile, measured HbA1c was higher than predicted value of HbA1c ($p < 0.01$ to < 0.0001), and ΔHbA1c increased significantly from Q1 to Q4 ($0.60 \pm 0.23/0.77 \pm 0.34/0.85 \pm 0.25/1.13 \pm 0.31\%$; $p < 0.008$). In the overall population, ΔHbA1c correlated with age ($r = 0.536$, $p < 0.0001$) and MAGE ($r = 0.494$, $p < 0.0001$). In multivariate analysis, ΔHbA1c remained associated independently with age, MAGE and HbA1c quartiles ($p = 0.002$, 0.017 , 0.006 ; adjusted r^2 for the model = 0.43).

Conclusion: In obese patients with dysglycemia detected on OGTT in half of them, measured HbA1c is higher than HbA1c predicted by mean glucose given by CGM. This possible excess in hemoglobin glycation is noticeably determined by 24-hour glucose variability in addition to age and higher measured HbA1c. This may partly explain why the sensitivity of HbA1c is greater than OGTT to detect dysglycemia in this population.

PS 048 Food intake and weight regulation

Body composition, insulin resistance, and the effectiveness of orlistat versus metformin added to dietary treatment in obese premenopausal women

M. Łuczak¹, K. Musialik², M. Szulińska², E. Swora-Cwynar³, A. Kargulewicz³, M. Grzymisławski³, D. Pupek-Musialik¹, P. Bogdański²; ¹Department of Internal Medicine, Metabolic Disorders, and Hypertension, ²Department of Education and Obesity Treatment and Metabolic Disorders, ³Department of Internal Medicine, Metabolic Disorders and Dietetics, University of Medical Sciences, Poznań, Poland.

Background and aims: Clinical studies have determined a strong correlation between insulin resistance and the amount of total and intraabdominal fat. We aimed to evaluate the effects of treatment with metformin and orlistat on body composition with a focus on glucose-insulin homeostasis in obese premenopausal women.

Materials and methods: 73 obese premenopausal women aged 31.9 ± 9.4 years were randomized to open label treatments: diet + metformin 1000 mg/d ($n = 37$); or diet + orlistat 360 mg/d ($n = 36$). Anthropometric measurements, dual-energy X-ray absorptiometry, oral glucose tolerance test, insulin resistance by the homeostasis model assessment (HOMA-IR), and insulin sensitivity by the Matsuda Index (ISI) were evaluated at the baseline and after 3 months.

Results: Treatment with orlistat was superior to metformin regarding weight loss (-9.4 ± 2.3 vs. -4.9 ± 1.3 kg), fat mass (-5.41 ± 3.02 vs. -3.49 ± 0.68 kg), as well as an increase in the lean body mass (2.39 ± 1.87 vs. 0.09 ± 1.10 kg), improving the body composition. Similar reductions in the % of android and gynoid fat were achieved in both groups, with the greater decreases in android (-0.10 ± 0.06 vs. -0.69 ± 0.19 kg) and trunk fat (-3.83 ± 0.73 vs. -0.72 ± 0.68 kg), seen in the metformin group. Orlistat and metformin similarly improved the ISI (18.6 ± 10.3 vs. 17.5 ± 47.4) and postchallenge insulin (-19.0 ± 50.5 vs. -18.8 ± 40.2 nmol/L). High initial postload insulin and low ISI - though not HOMA-IR - correspond with reductions in total fat, trunk fat, waist in both groups as well as with the decrease in android fat in metformin group (table).

Conclusion: Orlistat treatment resulted in a greater weight loss and improvement in body composition, metformin - in a additional visceral fat reduction. Orlistat and metformin produced a comparable improvement in insulin/glucose homeostasis. High initial postload insulin and low ISI predict greater effects of treatment.

3-month change	Metformin group			Orlistat group		
	Log 120-insulin	Log ISI	Log HOMA-IR	Log 120-insulin	Log ISI	Log HOMA-IR
Waist cm	-0.40	0.38	-0.30	-0.51	0.40	NS
Fat %	-0.37	0.56	NS	-0.33	0.40	NS
Fat kg	-0.38	0.42	NS	-0.29	0.39	NS
Android fat kg	-0.38	0.31	-0.40	NS	0.30	NS
Android /gynoid fat	-0.40	0.35	-0.42	NS	NS	NS
Trunk fat kg	-0.40	0.47	-0.30	-0.30	0.31	-0.34

Table. Univariate regressions between 3-month changes in adiposity, and initial 120 OGTT insulin, ISI Matsuda, and HOMA-IR indices in both examined groups.

The effect of laparoscopic greater curvature plication and Roux-en-Y gastric by-pass on metabolic control in obese subjects with type 2 diabetes mellitus: a 2-year follow-up

P. Trachta¹, M. Mráz¹, P. Kavalkova¹, K. Dolezalova², J. Klouckova¹, A. Cinkajzlova¹, M. Kosak¹, D. Haluzikova³, J. Krizova¹, Z. Lacinova¹, M. Matoulek¹, M. Fried², S. Svacina¹, M. Haluzik¹;

¹3rd Department of Medicine, Charles University, ²OB Klinika, ³Department of Sports Medicine, Charles University, Prague, Czech Republic.

Background and aims: Bariatric surgery is considered one of the most effective options in the treatment of obesity and its co-morbidities, including type 2 diabetes mellitus (T2DM). The aim of our study was to assess the effect of laparoscopic greater curvature plication (LGCP) and Roux-en-Y gastric by-pass (RYGB) on anthropometric and biochemical parameters and metabolic control in obese subjects with T2DM.

Materials and methods: Forty-four subjects undergoing LGCP and 8 patients scheduled for RYGB were included into the study. Anthropometric, biochemical and hormonal examinations were performed before and 1, 6, 12 and 24 months after the procedure. In a selected subgroup of LGCP patients the postprandial incretin effect was assessed using a 2-hour liquid meal test (LMT - Fresubin Original 200 ml, Fresenius Kabi, Germany).

Results: Both LGCP and RYBP lead to a significant decrease in body weight that was sustained throughout the whole 24 months (BMI 42.4±0.9 vs. 37.1±1.8 kg/m², p<0.05 for LGCP and 50.3±4.2 vs. 37.1±3.6 kg/m², p<0.05 for RYGB). The same was true for glucose control (HbA1c 51.9±2.6 vs. 44.7±3.2 mmol/mol, p<0.05 for LGCP and 54.0±7.7 vs. 41.7±4.7 mmol/mol, p<0.05 for RYGB). Both procedures also partially improved the lipid profile (HDL cholesterol 1.17±0.04 vs. 1.27±0.07 mmol/l, p<0.05 for LGCP and 1.15±0.09 vs. 1.45±0.16 mmol/l, p<0.05 for RYGB). Additionally, LGCP was accompanied by a reduction in systemic low-grade inflammation (hsCRP 3.2±0.6 vs. 1.3±0.3 mg/l, p<0.05). The incretin effect was temporarily restored 1 month after LGCP (GLP-1 at min 30 of LMT: 10.37±3.77 vs. 26.48±7.70 pM, p<0.05).

Conclusion: Laparoscopic greater curvature plication as well as Roux-en-Y gastric by-pass rapidly and sustainably reduce body weight and improve glucose control during the first 24 months after surgery. Partial restoration of the incretin effect might play a role in these processes.

Insulin sensitivity indices derived from oral glucose tolerance tests: Are they valid after Roux-en-Y gastric bypass?

K.N. Bojsen-Møller^{1,2}, C. Dirksen^{1,2}, N.B. Jørgensen^{1,2}, V.B. Kristiansen³, J.J. Holst^{4,2}, E.A. Richter⁵, S. Madsbad¹;

¹Department of Endocrinology, Hvidovre Hospital, ²Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, ³Department of Surgical Gastroenterology, Hvidovre Hospital, ⁴Department of Biomedical Sciences, ⁵Department of Nutrition, Exercise and Sports Sciences, University of Copenhagen, Denmark.

Background and aims: Insulin sensitivity indices obtained from oral glucose tolerance tests (OGTTs) are frequently used in diabetes research and provide an easily obtained surrogate measure of insulin sensitivity. Roux-en-Y gastric bypass (RYGB) induces extensive weight loss and improvements in insulin sensitivity when evaluated by the hyperinsulinaemic clamp. Insulin sensitivity indices obtained from OGTTs have not been validated after RYGB and may be inaccurate due to surgical alterations of the gut resulting in accelerated glucose absorption and increased insulin secretion.

Materials and methods: We investigated insulin sensitivity in 20 obese subjects (10 with type 2 diabetes and 10 with normal glucose tolerance)

before, 3 months (mo) and 1 year (y) after RYGB using a 4 h hyperinsulinaemic (40 mU/m²/min) euglycaemic (5.5 mmol/L) clamp combined with [6,6-2H₂]-glucose tracer infusion as well as a 2 h 75 g OGTT. Fat free mass (ffm) was assessed by DEXA. Matsuda, Gutt and Oral Glucose Insulin Sensitivity (OGIS) indices were calculated from OGTTs and compared to the clamp-derived Rate of disappearance (Rd) of [6,6-2H₂]-glucose (in mg/min/kg ffm). Pearson test was used to evaluate correlations.

Results: Before RYGB, the three OGTT-based insulin sensitivity indices correlated significantly with Rd (Matsuda vs Rd: r=0.63, p<0.001, Gutt vs Rd: r=0.56 p=0.012 and OGIS vs Rd: r=0.62, p=0.005). After RYGB, the relative improvements in Matsuda and Gutt were substantially larger than improvements in Rd at 3 months (Rd: +36±13%, Matsuda: +86±17% p<0.05, Gutt: +91±9.7% p<0.01) and 1 year (Rd: +57±14%, Matsuda: +164±28% p<0.01, Gutt: +145±18% p<0.01). Furthermore, the relative changes in Matsuda and Gutt did not correlate significantly to the relative changes in Rd (%Matsuda vs %Rd: 3 mo: r=0.23, p=0.35, 1y: r=0.46, p=0.07; %Gutt vs %Rd: 3 mo: r=0.35, p=0.16, 1 y: r=0.46, p=0.06). In contrast, the relative changes in OGIS were comparable to the relative changes in Rd both at 3 mo (Rd +36±13%, OGIS +31±5.9%, p=0.34) and 1 year (Rd: +57±14%, OGIS: +46±5.9%, p=0.36) and correlations between the relative change in OGIS and Rd were significant (%OGIS vs %Rd: 3 mo: r=0.61, p=0.007; 1 y: r=0.50, p=0.04).

Conclusion: Insulin sensitivity indices obtained from oral tests may be inaccurate after RYGB. Compared to the gold standard hyperinsulinaemic clamp, OGIS seems to perform better than Matsuda and Gutt indices in assessing changes in insulin sensitivity within the first year after RYGB.

Metabolic improvements observed in subjects receiving EndoBarrier: a pooled analysis of clinical trials

J. Teare¹, C.W. Le Roux², E. Chiquette³, D. Maggs³, I. Janssen⁴;

¹Imperial College London, UK, ²Diabetes Complications Research Centre, Conway Institute, University College Dublin, Ireland, ³GI Dynamics, Lexington, USA, ⁴Rijnstate Hospital Arnhem Netherlands, Netherlands.

Background and aims: EndoBarrier therapy (EBT) involves the reversible endoscopic placement of an impermeable liner that anchors in the duodenum and bypasses the first two feet of the upper bowel, thus replicating features of bariatric surgery.

Materials and methods: EBT in obese subjects with ≥1 comorbidity (diabetes, hypertension, hyperlipidemia) or morbidly obese with or without comorbidities from 6 clinical trials (n=211, age 46 yrs, BMI 38.9 kg/m²) was evaluated.

Results: Significant metabolic improvements were observed with EBT (Table). At 12 months, 57% of subjects achieved ≥10% weight loss while 55% of those with T2DM reached an A1C of ≤7%. The improvement in glycemic control occurred despite a shift to decreased concomitant anti-diabetic medication use. Moreover, 37% of T2DM subjects achieved both a ≥0.5% A1C reduction and ≥10% weight loss at 12 months. Reported AEs were mild (event rate 85.0%) or moderate (event rate 14.5%) in severity and mostly GI in nature. Hypoglycemia was observed in patients on insulin or sulfonylurea, but no severe hypoglycemia occurred. EBT did not induce hypoglycemia in non-diabetic subjects, suggesting no innate hypoglycemia potential. Early device removal was due to anchor migration, GI distress, liner obstruction, or GI bleed; all resolved w/o permanent sequelae. SAEs were reported infrequently at a rate of 3%.

Conclusion: EBT elicits metabolic benefits, with an acceptable safety profile, in obese subjects with comorbidities.

Table. Mean Metabolic Changes from Baseline			
	Baseline	Month 12 ^a	Absolute Change
Total Weight, kg	108.1 ± 21.5	96.1 ± 19.9	-11.8 ± 8.6 ^b
A1C in T2DM, %	8.4 ± 1.2	7.2 ± 1.2	-1.2 ± 1.3 ^b
Lipid Panel			
Total cholesterol, mmol/L	4.8 ± 1.1	4.2 ± 0.9	-0.6 ± 0.8 ^b
LDL, mmol/L	2.8 ± 0.9	2.4 ± 0.8	-0.4 ± 0.7 ^b
HDL, mmol/L	1.2 ± 0.3	1.1 ± 0.3	-0.1 ± 0.2
Triglycerides, mmol/L	2.2 ± 1.8	1.7 ± 1.1	-0.4 ± 1.0 ^b
Blood pressure			
Systolic, mmHg	138.1 ± 16.7	128.4 ± 15.7	-9.2 ± 17.5 ^b
Diastolic, mmHg	83.5 ± 9.7	77.4 ± 11.0	-5.8 ± 11.9 ^b

Data presented as mean ± standard deviation; ^alast observation carried forward (LOCF) if data not available at 12 months; ^bp-value ≤ 0.05, baseline vs. Month 12 or LOCF.

Associations of glucagon-like peptide 1 with food processing in the brain are present in lean and obese humans

M. Heni^{1,2}, S. Kullmann^{3,2}, B. Gallwitz¹, H.-U. Häring^{1,3}, H. Preissl^{3,2}, A. Fritsche^{1,3};

¹Department of Internal Medicine IV, ²German Center for Diabetes Research (DZD e.V.), ³Institute for Diabetes Research and Metabolic Diseases of the Helmholtz Center Munich at the University of Tübingen, Germany.

Background and aims: Glucagon-like peptide 1 (GLP-1) is a peptide hormone that is released into the bloodstream after food intake. In addition to stimulating insulin release, it introduces satiety and contributes to the termination of food intake as indicated by research in animals and exogenous administration in humans. Here, we investigated whether endogenous GLP-1 associates with food-related brain activity and hunger.

Materials and methods: Twenty-four human volunteers underwent a 75 g oral glucose tolerance test that promotes GLP-1 secretion as part of another study. Food-cue induced brain activity was assessed by functional magnetic resonance imaging (fMRI) and GLP-1 concentrations were measured before and after glucose intake.

Results: The significant increase in GLP-1 levels negatively correlated with change in food-cue induced brain activity in the orbitofrontal cortex, a major reward area. This association was independent of concurrent alterations in insulin and glucose concentrations. Furthermore, GLP-1 was negatively correlated with hunger ratings. Both associations were present in lean and overweight participants. In contrast, postprandial insulin associated with orbitofrontal response only in lean individuals.

Conclusion: The postprandial release of GLP-1 alters reward processes in the orbitofrontal cortex and might thereby support the termination of food intake and reduce hunger. While obese persons showed brain insulin resistance, no GLP-1 resistance was observed. Our study provides novel insights in the central regulation of food intake by the incretin hormone GLP-1.

Luminal trans,trans-2,4-decadienal reduces gastric emptying in rats

A. Yahagi¹, T. Hira², S. Nishimura³, M. Sakaino³, T. Yamashita³, H. Hara²;

¹Division of Applied Biosciences, Graduate School of Agriculture, ²Division of Applied Biosciences, Research Faculty of Agriculture, Hokkaido University, Sapporo, ³Fundamental Research Laboratory, Research and Development Division, J-Oil Mills, Inc, Yokohama, Japan.

Background and aims: Postprandial glycemia and lipidemia are strongly affected by the rate of gastric emptying, and slowing of gastric

emptying contributes to reducing postprandial hyperglycemia and hyperlipidemia. Gut hormones including cholecystokinin (CCK) are major endogenous factors for reducing postprandial gastric emptying. We recently demonstrated that unsaturated aldehydes stimulated CCK secretion from murine enteroendocrine cell line, STC-1. Among various aldehydes tested, *trans,trans*-2,4-decadienal (decadienal) had a potent CCK-releasing activity, however, its effect *in vivo* has not been studied. In the present study, we investigated whether oral administration of decadienal affects the rate of gastric emptying (one of CCK-related physiological effects) in rats, by using the acetaminophen absorption test and the phenol red recovery method.

Materials and methods: In fasted Male Sprague-Dawley rats, test liquids containing acetaminophen with or without decadienal (50–100 mg/kg) were orally administered. Tail vein blood was collected with time until 120 min, and plasma acetaminophen concentration was measured. In separated experiments, decadienal was orally administered together with phenol red. Luminal contents in the stomach, the proximal and the distal small intestine were respectively collected 15 min after the administration. Amounts of luminal phenol red were measured and the rate of gastric emptying was calculated. By using the methods above, we compared various aliphatic compounds having the same chain length (C10) with decadienal, and further investigated the effect of an intraperitoneal administration of decadienal, on the rate of gastric emptying.

Results: Oral administration of decadienal dose-dependently reduced the appearance of acetaminophen in the peripheral blood. Luminal phenol red recovered from the stomach was greater in decadienal-treated rats than control rats, which resulted in lower gastric emptying rate in decadienal-treated rats (13%) compared to control rats (57%) (n=7, P<0.01). This was reflected by smaller amount of phenol red collected from the small intestine in decadienal-treated rats compared to control rats. Oral administrations of aliphatic compounds (decanal, decanol and decanoic acid) having the same chain length with decadienal, and an intraperitoneal administration of decadienal did not reduce the rate of gastric emptying, respectively.

Conclusion: These results demonstrate that orally administered decadienal has inhibitory effect on gastric emptying through acting in the intestinal lumen, possibly on enteroendocrine cells.

Mice on high fat diet or normal diet have different metabolic responses to rosuvastatin treatment

L. Eliasson¹, V.A. Salunkhe¹, T. Reinbothe^{1,2}, I.G. Mollet¹, A. Wendt¹, J. Vikman¹;

¹Dept Clinical Sciences Malmö, Lund University Diabetes Center, ²Department of Physiology, University of Gothenburg, Sweden.

Background and aims: Rosuvastatin (Ros) is a member of the cholesterol lowering statin family prescribed to reduce the risk of cardiovascular disease. The beneficial effects of statin treatment are well documented. However, several reports have also indicated diabetogenic effects of statins. The underlying mechanisms are poorly understood. Here we aim to investigate the effects of rosuvastatin on glucose homeostasis and insulin secretion in mice on high fat diet (HFD) or normal diet (ND).

Materials and methods: C57BL/6 mice were put on ND or HFD for 12 weeks. 4 weeks into the experiment a subset of the mice were given rosuvastatin (Ros) in the drinking water (0.2 mg/mice/day; 15 mice per group). Every 4 weeks the mice were subjected to an oral glucose tolerance test (OGTT) and samples were taken for *in vivo* measurements of glucose and insulin. In agreement with earlier studies HFD mice had higher blood glucose levels than ND mice and comparison was performed ND vs ND+Ros and HFD vs HFD+Ros. Every second week it was verified that Ros treatment resulted in lowered blood cholesterol levels. At the termination of the experiment tissues were collected for *in vitro* experiments. Insulin secretion was measured with RIA. Exocytosis was recorded as changes in membrane capacitance using the patch clamp technique. Intracellular calcium was monitored with fura-2.

Results: After 4 weeks of Ros treatment the OGTT revealed a glucose lowering effect of Ros in ND mice (delta15 min(glucose) was reduced ~50%; $p \leq 0.01$ and total AUC(glucose) was reduced ~20%; $p \leq 0.05$; N=14 ND; N=15 ND+Ros), but this was not accompanied by any changes in insulin response. In the HFD mice, that already had high blood glucose compared to the ND mice, total AUC or delta15 min for glucose was not altered after 4 weeks or 8 weeks of Ros treatment. However, acute insulin response during the OGTT was significantly decreased after Ros treatment for 8 weeks in the HFD group (delta15 min (insulin) was reduced ~65%; $p \leq 0.01$; n=15 HFD; n=13 HFD+Ros). On a cellular level, Ros treated mice, regardless of diet, had a ~20% ($p \leq 0.01$; n=24) lower insulin content. *In vitro* insulin secretion at 16.7 mM glucose was reduced by ~40% (n=4; $p \leq 0.05$) with Ros treatment in the ND mice. However, the insulin release relative to insulin content was not changed. No significant difference in insulin secretion by Ros from the HFD islets was detected. The exocytotic response from single beta-cells did not differ between the ND+Ros and ND (n=7). However, elevating glucose concentrations from 2.8 mM to 16.7 mM in isolated ND islets resulted in a delayed increase in intracellular calcium in the Ros treated group compared to ND alone. In addition, the dip in intracellular calcium preceding the increase in calcium was less prominent ($p < 0.001$; N=3) in ND+Ros islets, indicating a reduced uptake of calcium into the ER.

Conclusion: The integrated physiological response to glucose is intact after 8 weeks of rosuvastatin treatment. Interestingly, the acute insulin response to glucose in HFD mice is more vulnerable to rosuvastatin treatment than it is in ND mice. Taken together, our data suggests that the metabolic state of the individual could influence the effects of rosuvastatin treatment on glucose homeostasis. On a cellular level rosuvastatin reduced insulin content and disturbed calcium handling in the islets, which may perturb insulin secretion in the long term.

Adverse effect of ovariectomy on substrate utilisation in brown adipose tissue and on liver dicarbonyl stress in rats

H. Malinska, J. Trnovska, V. Skop, L. Kazdova;

Center for Experimental Medicine, Institute for Clinical and Experimental Medicine, Prague 4, Czech Republic.

Background and aims: Ovariectomy leads to increase in body weight, visceral adiposity, insulin resistance, fatty liver and other disorders of lipid and glucose metabolism. However, the underlying mechanism of these disorders remains unclear. Increasing evidence indicates that brown adipose tissue (BAT) modulates energy balance. It also suggests that increased accumulation of dicarbonyls in the liver may increase oxidative stress, activate the inflammatory pathway and can play a key role in the development of other metabolic disorders. In this study, we examined the effect of ovariectomy on the utilization of energetic substrate in interscapular brown adipose tissue and liver dicarbonyl and oxidative stress.

Materials and methods: Female Wistar rats were ovariectomized (OVX) or sham-operated (controls) at 8 weeks of age and fed a standard diet for 4 month, in order to fully develop disorders associated with ovariectomy. BAT activity was determined *ex vivo* according to the utilization of ¹⁴C-U-palmitic acid and ¹⁴C-U-glucose for oxidation (incorporation into CO₂) and incorporation of ¹⁴C-U-palmitic acid and ¹⁴C-U-glucose into BAT lipids. Lipolysis in BAT was measured by the release of free fatty acids. The concentrations of methylglyoxal and glutathione in the liver were determined using the HPLC-method with fluorescence detection.

Results: Compared with sham-operated control rats, OVX rats exhibited markedly increased body weight (+10%, $p < 0.05$) and visceral adipose tissue weight (+10%, $p < 0.05$). Insulin sensitivity of white visceral adipose and muscle tissue, measured according to ¹⁴C-U-glucose incorporation into lipids and glycogen, were significantly decreased ($p < 0.01$) in OVX rats compared to controls. However, plasma glucose, insulin and triglycerides were not different between OVX and control rats. Severe hepatic triglycerides accumulation (12.76±1.10 vs 5.44±0.85 μmol/g, $p < 0.001$) in OVX rats associated with significantly elevated level of methylglyoxal (12.78±2.7 vs 5.49±0.41 nmol/mg, $p < 0.01$) may have contributed to the development of liver steatosis. Ovariectomy led to impaired balance in the reduced and oxidised forms of glutathione in the liver (GSH/GSSG: 15.4±1.3 vs 28.4±1.4, $p < 0.01$), which may have increased oxidative and carbonyl stress. BAT of OVX rats exhibited a reduced fatty acid oxidation (-72%, $p < 0.05$), lipogenesis (-26%, $p < 0.05$) and decreased lipolysis (-25%, $p < 0.05$), despite the fact that BAT weight was significantly increased ($p < 0.05$) in OVX rats compared to controls.

Conclusion: Results indicate that reduced fatty acid and glucose utilization, together with lower lipolysis in brown adipose tissue in response to ovariectomy, may contribute to the development of obesity in the postmenopausal period. Severe liver steatosis induced by ovariectomy was associated with excessive formation of methylglyoxal and the reduced ratio of GSH/GSSG, which could participate in oxidative stress. Both low metabolic activity in BAT and liver dicarbonyls formation may be involved in the development of postmenopausal metabolic syndrome.

Interspecies scaling of dynamic glucose and insulin using a mathematical model approach

O. Alskär, M.O. Karlsson, M.C. Kjellsson;

Department of Pharmaceutical Biosciences, Uppsala University, Sweden.

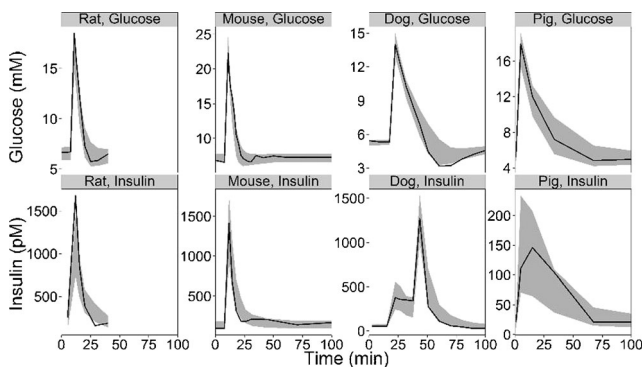

Background and aims: Mathematical models are useful tools in understanding complex relationships such as glucose homeostasis. The

integrated glucose insulin (IGI) model is a mathematical model that describes dynamic glucose and insulin concentrations in humans during glucose tolerance tests. The aim of this work was to investigate if the model can be scaled to describe intravenous glucose tolerance test (IVGTT) data from several preclinical species.

Materials and methods: Glucose and insulin concentrations from IVGTTs performed in healthy individuals of rats (n=16), mice (n=24), dogs (n=11), pigs (n=11) and humans (n=24) was available for analysis. In the first step allometric scaling based on individual body weights was investigated. The most suitable value for the allometric exponent was investigated for all parameters in the model, based on objective function value, parameter uncertainty and model complexity. In the second step species adaptations was investigated by scaling parameters with the weight of organs relevant to that parameter in each species. In the third step remaining species adaptations that could not be described by allometric scaling was investigated.

Results: Estimating one allometric exponent for clearances (0.85), one exponent for volumes (0.9) and fixing the exponent of rate constants to -0.25 described the data well and kept the scaling complexity low. Estimating the allometric exponent is of importance to be able to describe rodents well, since their body weights are far from humans. Of the investigated scaling relationships with species specific organ weights no relationship improved the fit for all animals. Dogs and pigs showed lower first phase secretion and stronger second phase secretion of insulin than the model predicted and these two parameters were estimated for dogs and pigs. Pigs also showed a slower first phase secretion and this parameter was also estimated for pigs. The model predicted slower glucose elimination in pigs than the data showed and insulin dependent glucose clearance was estimated separately for pigs. The result of the final model describing IVGTT in rats, mice, dogs and pigs is displayed in figure 1 (the solid line is the median based on the observed data. Shaded area is the 95% confidence interval around the median based on the simulated data).

Conclusion: The allometrically scaled IGI model developed in this project can accurately predict preclinical IVGTT data. In general glucose scales better than insulin, as insulin is a protein the kinetics are more complex and the amino acid sequence is not identical in the different species. When investigating animal models of diabetes it is of most importance that glucose scales well since insulin secretion often is diminished. The allometrically scaled IGI model can be used in drug development to facilitate better translations of preclinical research into clinic.

Moderate exercise prevents pituitary dysfunction induced by a sucrose rich diet

M.E. Mercou¹, E. Repetto¹, P. Arias², C.V. Finkelstein³, C.B. Cymering¹;

¹Dpto de Bioquímica Humana. FMED, UBA, CEFYBO-CONICET, Buenos Aires, ²Departamento de Fisiología. Facultad de Medicina. Universidad Nacional de Rosario, Argentina, ³Department of Biological Sciences. Virginia Polytechnic Institute and State University, Blacksburg, USA.

Background and aims: Increased consumption of sucrose, a major constituent of western diet, has been associated with the development of obesity and insulin resistance (IR). Altered hypothalamic-pituitary-adrenal axis function has been linked to IR, in animal models and patients. Studies from our group have shown morphological and functional changes in the adrenal cortex of rats fed a sucrose-rich diet (SRD). The aim of this study was to evaluate the effects of SRD on basal activity of the pituitary gland, the underlying cellular processes, and the effect of exercise (E) on these parameters.

Materials and methods: Adult male Wistar rats were randomized into 4 groups (n=5), two of which received 30% w/v sucrose in the drinking water (SRD) for 15 weeks. A subset of each dietary group was subjected to E protocol (C-E and SRD-E) (treadmill walk, 15 min/day, 5 day/week, for 15 weeks, at 0.8 km/h speed). The sedentary (C-S and SRD-S) subset of each dietary group did not perform any physical activity. Insulin sensitivity was assessed at the 7th week of treatment by i.p. ITT. Statistical analyses were performed using Student's t test or ANOVA and significant differences were studied with Tukey's post hoc test.

Results: Our results showed that serum metabolites (fasting glucose, triglycerides and free fatty acids (FFA)) were increased in SRD-S animals by the end of the 15th week of treatment. Animals from the SRD-S group showed significantly lower plasma levels of ACTH (C-S: 96.9±2.6, SRD-S: 52.6±0.5, pg/ml), decreased pituitary POMC mRNA levels (C-S: 1.02±0.04, SRD-S: 0.64±0.03, fold induction), and lower serum corticosterone concentrations (C-S: 13.61±2.66, SRD-S: 2.66±0.33, ng/ml) than those from the C-S group. Analysis of pituitary levels of antioxidant enzymes and autophagy markers suggested the activation of these cellular pathways in the SRD-S group. E was able to prevent the induction of autophagy and antioxidant defense systems in the pituitary gland of SRD-E animals. Analysis of POMC mRNA (C-E: 1.46±0.06, SRD-E: 1.43±0.18, fold induction), plasma ACTH levels (C-E: 142.0±8.6, SRD-E: 130.6±20.2, pg/ml) and of serum corticosterone concentrations (C-E: 28.05±4.8, SRD-E: 50.40±3.33, ng/ml) showed that E prevented the effects of SRD on HPA axis basal activity. Regarding the analyzed serum biochemical parameters, E was able to prevent the increase in serum FFA levels. Given this, we analyzed the effects of palmitic acid (PA) on POMC-ACTH production in AtT-20 corticotroph cell-line. Cells were transiently transfected with a POMC-luciferase reporter plasmid, and then incubated with 4% BSA+PA. Our results showed that 24 h treatment with 1 mM PA significantly inhibited POMC promoter activity (4% BSA: 1.00±0.07, 4% BSA + 1 mM PA: 0.75±0.04, A.U.), and induced autophagy and oxidative stress. Similar results on POMC promoter activity were obtained incubating the cells with Rapamycin or H2O2, suggesting a role for these cellular processes on POMC regulation.

Conclusion: Administration of a SRD shows a significant effect on cellular mechanisms that influence POMC transcription and ACTH production in corticotroph cells. We also hypothesize that sustained elevated FFA serum levels could contribute to the observed pituitary dysfunction. Supported by: PICT 2008-1034; CONICET PIP 2013-2015, UBACYT 2011-2014

A disrupted rhythm of appetite-regulating hormone is relevant to abnormal feeding behaviour in high fat diet induced obese mice

H. Mifune¹, Y. Tajiri², K. Hara², S. Iwata², Y. Nishi³, M. Kojima⁴, K. Yamada²;

¹Institute of Animal Experimentation, ²Department of Internal Medicine, Division of Endocrinology and Metabolism, ³Department of Physiology, Kurume University School of Medicine, Japan, ⁴Kurume University, Japan.

Background and aims: A number of appetite-regulating molecules have been identified and discussed in obese subjects and animals. Ghrelin is a representative orexigenic gut hormone produced in the stomach. Pathophysiological roles of ghrelin in obesity is, however, largely unknown together with its diurnal dynamics. Neuromedin U (NMU) is distributed in the brain and gut, including supra-chiasmatic nucleus (SCN) in the hypothalamus, a master biological clock. In contrast to ghrelin, NMU acts as an anorexigenic peptide. Because these two antagonistic peptides have never been discussed simultaneously, the aim of the present study is to explore the relevance of these peptides in the formation and progression of obesity, especially in relation to a diurnal rhythm of feeding and activity.

Materials and methods: Male C57BL/6J mice at 4 weeks old were housed in a control room under a 12 h light-dark cycle (light on 0700–1900) with ad libitum access to either control diet (CD: 10 kcal% fat) or high fat diet (HFD: 60 kcal% fat) for 12 weeks. At 16 weeks old, an individual mouse was transferred to a metabolic chamber (ARCO systems), and respiratory quotient (RQ), food consumption and locomotor activity (ACT) was measured on a minute by minute basis for 2 days. Then mice were sacrificed at 4 different time points (7:00, 13:00, 19:00, 25:00), and plasma for the determination of ghrelin by RIA and hypothalamus for NMU and stomach for clock genes such as BMA11 and PER2 by RT-PCR were retrieved. To further elucidate a role of ghrelin for the regulation of feeding and ACT, 16 weeks old ghrelin knockout (GKO) mice fed CD were housed in ARCO systems for 2 days same as wild type (WT) mice.

Results: Body weight in HFD group was significantly higher than that in CD group at 16 weeks old. Food consumption and ACT in CD group were mainly observed during dark phase (D) with a very small ACT during light phase (L). RQ in CD group showed a clear diurnal rhythm with being low during L and high during D. In contrast, these distinct diurnal rhythms of food consumption, ACT and RQ were severely disrupted in HFD group with an increase of these parameters during L. Although plasma ghrelin concentration revealed a bimodal rhythm with a zenith at 7:00, 19:00 and a nadir at 13:00, 25:00 in CD group, a completely reverse rhythm was observed in HFD group. On the other hand, NMU expression in the hypothalamus showed a diurnal rhythm with being high during L and low during D in CD group, and a completely reverse rhythm was observed in HFD group. Furthermore, a diurnal phase of stomach BMA11 expression shifted backward and PER2 shifted forward in HFD group compared to CD group. It is of interest that GKO mice fed CD showed indistinct rhythms of ACT and RQ, which are quite similar to those in WT mice fed HFD.

Conclusion: An indistinct rhythms of ACT and feeding observed in HFD group evokes abnormal binge eating in human obese subjects. Ghrelin may act as an initiator of feeding behavior from the results in GKO mice, and NMU may control circadian rhythms of clock genes taking its localization in SCN into account. It is suggested that abnormal diurnal rhythms of both appetite-regulating peptides in HFD group is quite relevant to the formation and progression obesity.

Dose-dependent stimulatory effect of leptin on Leydig cell steroidogenesis in leptin-deficient obese mice

S. Kralisch-Jäcklein^{1,2}, I.V. Wagner^{1,3}, G.M. Manjowk¹, A. Hoffmann², N. Klötting^{1,2}, T. Ebert^{1,2}, B. Jessnitzer², U. Loessner^{1,2}, R. Burkhardt⁴, M. Stumvoll², O. Söder³, K. Svehnikov³, M. Fasshauer^{1,2};

¹IFBAdiposityDiseases, ²Department of Endocrinology and Nephrology, University of Leipzig, Germany, ³Department of Women and Child Health, Karolinska Institutet, Stockholm, Sweden, ⁴Institute of Laboratory Medicine, University Leipzig, Germany.

Background and aims: Over the last decade, the evidence linking obesity to impaired male reproductive function has grown. Leptin is a known mediator and modulator of the hypothalamus-pituitary-testes axis, dysregulated in obesity; however, data have been inconsistent. The aim of the study was to elucidate the dose-dependent impact of leptin on male reproductive function and Leydig cell steroidogenesis in a mouse model of obesity.

Materials and methods: Leptin-deficient obese (ob/ob) male mice on a C57BL/6J LDLR^{-/-} background were treated with 0.1, 0.5, or 3 mg/kg body weight/d murine recombinant leptin or saline for 12 weeks starting at 8 weeks of age. The effect of leptin on testicular weight, spermatogenesis, intratesticular testosterone, Leydig cell morphology, and macrophages was elucidated.

Results: Testis weight which is mostly indicative of overall spermatogenic activity was significantly and dose-dependently up-regulated between control (saline-treated; 1.69 mg/g bodyweight (BW)) and leptin-treated animals (2.56, 2.76, and 3.28 mg/g BW at 0.1, 0.5, or 3 mg/kg body weight/d, respectively) ($p < 0.001$). Moreover, intratesticular testosterone content was restored dose-dependently after leptin treatment (314.4, 497.2, and 526.3 ng/g tissue at 0.1, 0.5, or 3 mg/kg body weight/d, respectively) compared to saline-treated mice (212.7 ng/g tissue) ($p < 0.001$). Restoration of intratesticular testosterone in leptin-treated animals was associated with a significant up-regulation of the steroidogenic enzymes Cyp11a1 and Cyp17. Testicular histology indicated that Leydig cells dose-dependently regain their usual morphology and clustering characteristic after leptin-treatment as compared to saline-treated animals. In contrast, macrophage markers were not different between leptin-treated and control mice.

Conclusion: The adipokine leptin might play an important role in the regulation of Leydig cell function and testicular physiology.

BACE2 suppression protects from High Fat Diet (HFD)-induced metabolic effects

G. Alcarraz-Vizán, C. Castaño, M. Visa, J. Montane, M. Obach, J.-M. Servitja, A. Novials;
Diabetes & Obesity Laboratory, IDIBAPS, Barcelona, Spain.

Background and aims: BACE2 (β -site APP-cleaving enzyme 2) is a protease that has been found in the brain, where it is thought to play a role in the development of Alzheimer's disease (AD). It has also been localized in the pancreas, where it seems to play a physiological role, since BACE2-deficient mice elicit better glucose tolerance than control littermates. However, despite the potential link between AD and glucose homeostasis deregulation in humans and rodents, the involvement of BACE2 in other metabolic disturbances, such as insulin resistance and obesity, has not been explored. Thus, the aim of the present study was to investigate the effect of BACE2 on whole-body glucose metabolism.

Materials and methods: BACE2-KO mice and their respective controls were used to analyze their phenotype after 16 weeks of high-fat diet (HFD) feeding. Insulin tolerance test (ITT) and glucose tolerance test

(GTT) were performed to evaluate metabolic phenotype, and the area under the curve (AUC) of the GTT was calculated as a measure of glucose homeostasis. The ability to secrete insulin in response to glucose (GSIS) was quantified with an ELISA kit. β -cell mass was analyzed by insulin immunostaining. mRNA expression of relevant genes from pancreatic islets, white adipose tissue and hypothalamus was analyzed by quantitative PCR.

Results: BACE2-KO mice fed with HFD showed a 32% reduction in body weight ($p < 0.05$), with respect to their wild type counterparts, whereas no changes in food intake were observed. Moreover, BACE2-KO mice fed with HFD presented better glucose homeostasis (28% decrease in AUC of GTT) and did not exhibit insulin resistance when compared to wild type animals with the same feeding. Interestingly, white adipose tissue from these animals presented a weight reduction of 25% ($p < 0.01$) and a lower expression of the inflammation marker ccl2. Furthermore, while wild type animals presented a remarkable decrease in the levels of hypothalamic anorexigenic markers *pomc* and *cartpt* when fed with HFD (65% reduction in the case of *pomc*, $p < 0.01$), BACE2-KO animals did not show changes in any of the neuropeptides studied with respect to the animals fed with a regular diet.

Conclusion: Altogether, these results indicate that the inhibition of BACE2 seems to protect against HFD. Thus, targeting BACE2 may represent a good therapeutic strategy to ameliorate the pathological effects of obesity.

Significant effects of HM11260C on body weight over 20 weeks in obese subjects without diabetes: a randomised, double-blind, placebo controlled study

R. Pratley¹, J. Kang², P. Kim², E. Kwak², O. Han², S. Kil², K. Gee², I. Choi², S. Kwon², M. Trautmann³, M. Hompesch³;

¹Florida Hospital Diabetes Institute, Orlando, USA, ²Hanmi Pharm. Co., Ltd., Seoul, Republic of Korea, ³Profil Institute for Clinical Research, Inc., Chula Vista, USA.

Background and aims: HM11260C (HM) is a novel long acting GLP-1R agonist with a $T_{1/2}$ of ~158 hrs resulting in a flat PK profile. This 20-week, randomized, double-blind, placebo (PBO) controlled, parallel group study was designed to evaluate the efficacy, safety, and tolerability of once a week (QW) or every other week (Q2W) doses of HM in obese subjects without diabetes.

Materials and methods: 297 subjects (mean age 43.4 yrs and BMI 35.5 kg/m²) were randomized to one of four HM doses (4 mg QW, 6 mg QW, 6 mg Q2W, or 8 mg Q2W) or to PBO. HM was administered subcutaneously for 20 weeks. The diet and exercise regimens remained unchanged during the study.

Results: The body weight loss with HM 4 mg QW, 6 mg QW, 6 mg Q2W and 8 mg Q2W was 6.2 kg, 7.8 kg, 7.0 kg and 7.1 kg (LS Mean, $p < 0.0001$ all HM treatment groups), whereas the body weight gain was observed with PBO (0.8 kg). More subjects in the HM treatment groups achieved significant body weight loss $\geq 5\%$ or $\geq 10\%$, and the mean reductions in BMI from baseline were greater, compared with PBO. Changes from baseline in waist circumference were -6.00 cm, -9.45 cm, -7.11 cm, -8.00 cm and -0.21 cm (LS Mean) with HM 4 mg QW, 6 mg QW, 6 mg Q2W, 8 mg Q2W and PBO. The most frequent adverse events were gastrointestinal events which were observed relatively frequently and increased injection site reactions which were less common (Table 1).

Conclusion: All doses of HM meaningfully reduced body weight and were well tolerated. These results warrant further studies to assess titration schemes as well as the long-term efficacy and safety of HM in obesity.

Table 1. Summary of efficacy and safety of HM11260C over 20 weeks (Interim analysis)

	Placebo (n=27)	HM11260C 4 mg QW (n=27)	HM11260C 6 mg QW (n=27)	HM11260C 6 mg Q2W (n=27)	HM11260C 8 mg Q2W (n=27)

MEDI0382 a novel GLP1/glucagon co-agonist induces profound body weight loss and improves metabolism in rodents and non-human primates

A. Konkar¹, P. Ambery², M. Bednarek², M. Fritsch-Fredin³, J. Grimsby¹, S. Henderson², D. Hornigold², R. Jackson², C. Rondinone¹, J. Trevasakis¹, L. Jemutus²;

¹MedImmune, Inc., Gaithersburg, USA, ²MedImmune, Inc., Cambridge, UK, ³Astrazeneca, Molndal, Sweden.

Background and aims: Oxyntomodulin (OXM), the endogenous GLP-1/Glucagon co-agonist peptide, is secreted from intestinal L-cells in response to meals. OXM reduces body weight in obese subjects and produces direct acute gluco-regulatory effects in type 2 diabetic patients. Due to its short lifetime in circulation, the clinical utility of this hormone is limited. We synthesized stable, lipidated analogs of OXM that possessed the *in silico* selected ratios of GLP-1:glucagon activity ideal for clinical utility.

Materials and methods: Chinese hamster ovary cells stably expressing human GLP-1 and glucagon receptors were used to evaluate the ability of MEDI0382 to stimulate cAMP production. C57Bl/6 mice fed a 60% high-fat diet, diabetic *db/db* mice and cynomolgus monkeys were used to evaluate the metabolic effects of subcutaneously injected MEDI0382.

Results: The lead molecule, MEDI0382, is a highly potent agonist of GLP-1 and glucagon receptors. Once-daily subcutaneous dosing with MEDI0382 (10 and 30 nmol/kg) reduced body weight by 24.5% and 32.5% in male diet-induced obese (DIO) mice, as compared with vehicle-treated DIO mice. The effect was superior to liraglutide (40 nmol/kg). Liraglutide had a greater effect on cumulative food intake than both doses of MEDI0382, suggesting that the effect of MEDI0382 on body weight may be partly mediated by increased energy expenditure. A significant improvement in glucose tolerance was observed in drug-treated mice in an intraperitoneal glucose tolerance test. In diabetic *db/db* mice, a single dose of MEDI0382 reduced glucose excursion following an intraperitoneal glucose challenge. Repeated daily dosing of MEDI0382 for 2 months in cynomolgus monkeys resulted in dose-dependent reductions in body weight of 5% to 12% compared to starting bodyweights at the end of the treatment period.

Conclusion: In summary, our data indicate that MEDI0382 shows significant promise as a weight loss drug in overweight and obese subjects and the potential to lower glucose in people with type 2 diabetes.

645

Early weight loss with liraglutide 3.0 mg is good predictor of clinically meaningful weight loss after 56 weeks

M. Blüher¹, K. Hermansen², F. Greenway³, K. Fujioka⁴, M. Donsmark⁵, C.B. Jensen⁵, J.P.H. Wilding⁶;

¹University of Leipzig, Germany, ²Aarhus University Hospital, Denmark, ³Pennington Biomedical Research Center, Baton Rouge, ⁴Scripps Clinic, La Jolla, USA, ⁵Novo Nordisk, Søborg, Denmark, ⁶University of Liverpool, UK.

Background and aims: Early identification of responders to weight loss (WL) medications is important in order to discontinue those unlikely to achieve WL targets; EU regulators are especially interested in identifying those unlikely to achieve $\geq 10\%$ WL at 1 yr. This subgroup analysis of SCALE Obesity and Prediabetes and SCALE Diabetes trials reports key efficacy and safety outcomes in adults achieving $\geq 5\%$ WL from baseline at Week (W) 16 on liraglutide (lira) 3.0 mg (early responders; ER), compared to those who did not (early non-responders; ENR). A WL target of $\geq 5\%$ at W16 demonstrated the best balance between negative predictive value and sensitivity in identifying those unable to achieve $\geq 10\%$ WL at W56.

Materials and methods: 2910 adults were randomized to lira as adjunct to diet & exercise (D&E): 2487 without T2D (BMI ≥ 30 or 27–29.9 kg/

m² ≥ 1 comorbidity; 45 yr; 21% male; BMI 38 kg/m²; 61% with prediabetes), and 423 with T2D (BMI ≥ 27 kg/m²; 55 yr; 52% male; BMI 37 kg/m²); 2159 and 365 adults without and with T2D respectively completed 16 W of treatment. Lira was increased weekly by 0.6 mg to a 3.0 mg maintenance dose. Efficacy data are for 56 W completers. Mean and categorical WL was estimated by ANCOVA or logistic regression model respectively. Efficacy data are LS means or estimated proportions, safety data are observed proportions.

Results: 67.5% of W16 completers without T2D were ER to lira 3.0 mg, with a mean WL of 11.5% at W56. Proportions of ER with $\geq 5\%$, $>10\%$ and $>15\%$ WL at W56 with lira were 88.2%, 54.8% and 24.2%, respectively. ENR without T2D achieved mean WL of 3.8% at W56, and 36.9%, 8.3% and 1.8% had achieved $\geq 5\%$, $>10\%$ and $>15\%$ WL, respectively. 50.4% of W16 completers with T2D were ER to lira 3.0 mg, with mean WL of 9.3% W56. Proportions of ER with $\geq 5\%$, $>10\%$ and $>15\%$ WL at W56 with lira were 80.1%, 44.6% and 11.6%, respectively. ENR with T2D achieved mean WL of 3.6% at W56, at which time 33.3%, 5.8% and 1.3% had achieved $\geq 5\%$, $>10\%$ and $>15\%$ WL, respectively. Pooled across trials 93.4% of ENR failed to achieve $\geq 10\%$ WL at W56. Across both trials, greater improvements in CV risk factors were seen in ER than ENR, consistent with greater WL. The overall safety profile was generally comparable between ER and ENR (Table). In those without T2D rates of hepatobiliary disorders appeared higher in ER than ENR. In patients with T2D rates of severe hypoglycaemia (ADA Criteria) were low in both ER and ENR (1.1% v 0.6%; all on SU) and the overall hypo rates (ADA criteria, documented symptomatic) were generally comparable between ER (28.3%) and ENR (21.0%).

Conclusion: Those failing to reach $\geq 5\%$ WL at W16 are unlikely to reach $\geq 10\%$ at W56. By contrast, ER to lira 3.0 mg as adjunct to D&E with and without T2D achieve a mean WL at W56 of 9.3% and 11.5%, respectively, with improvements in cardiometabolic markers with a similar safety profile to NR.

Table: Key efficacy and safety outcomes of early responders vs early non-responders on liraglutide 3.0 mg by trial

	SCALE Obesity and Prediabetes		SCALE Diabetes	
	Early responder N=1456	Early non-responder N=703	Early responder N=184	Early non-responder N=181
Change from baseline in cardiometabolic outcomes

Liraglutide 3.0 mg efficacy and safety by baseline BMI in the SCALE Diabetes trial: post-hoc analysis

J. Udden Hemmingsson¹, J. Rosenstock², M. Davies³, H. Bays⁴, A.-P. Cancino⁵, T.V. Skjøth⁵, V. Aroda⁶;

¹Capio St Gorans Hospital, Stockholm, Sweden, ²Diabetes & Endocrine Center, Dallas, USA, ³University of Leicester, UK, ⁴L-MARC Research Center, Louisville, USA, ⁵Novo Nordisk, Søborg, Denmark, ⁶MedStar Health Research Institute, Hyattsville, USA.

Background and aims: This analysis from the SCALE Diabetes trial compared efficacy and safety results for individuals with baseline BMI < or ≥35 kg/m² treated with liraglutide 3.0 mg for weight management or placebo.

Materials and methods: 846 adults were randomised (age 54.9 y, male 50%, BMI 37 kg/m², A1C 7.9%, T2D duration 7.3 years) 2:1:1 to liraglutide 3.0 mg, 1.8 mg, or placebo as adjunct to diet and exercise for 56 weeks. Data are LS means (efficacy) or observed means (LOCF).

Results: Overall withdrawals rates were 23.4% for liraglutide 3.0 mg vs 34.0% for placebo. At 56 weeks, greater mean and categorical weight loss, and greater improvements in glycaemic parameters, SBP, and IWQoL-Lite physical function score were seen with liraglutide 3.0 mg vs placebo in both subgroups. Treatment effects were independent of baseline BMI subgroup (p>0.05) (Table). BMI subgroups had broadly comparable adverse events (AEs). In both liraglutide 3.0 mg subgroups (BMI< or ≥35 kg/m²) a greater proportion of subjects had nausea (34 vs 32%) and vomiting (11% vs 20%) than placebo (nausea: 12 vs 15%; vomiting: 8% vs 4%). Documented symptomatic hypoglycaemia (FPG ≤3.9 mmol/L) rates were similar with liraglutide 3.0 mg in both BMI subgroups (1.07 vs 0.70 events/PYE), as was severe hypoglycaemia, seen in three subjects with concomitant sulphonylureas.

Conclusion: In summary, effects of liraglutide 3.0 mg, as adjunct to diet and exercise, on weight loss, associated metabolic effects and safety profile were consistent across predefined baseline BMI subgroups.

The impact of gastrointestinal adverse events on weight loss with liraglutide 3.0 mg as adjunct to a diet and exercise programme

C. le Roux¹, D.C.W. Lau², K. Fujioka³, I.D. Caterson⁴, A.-P. Cancino⁵, C.B. Jensen⁵, M.E.J. Lean⁶;

¹Diabetes Complications Research Centre, University College Dublin, Ireland, ²University of Calgary, Canada, ³Scripps Clinic, La Jolla, USA, ⁴University of Sydney, Australia, ⁵Novo Nordisk, Søborg, Denmark, ⁶University of Glasgow, UK.

Background and aims: To explore any associations between gastrointestinal adverse events (GI AEs) and weight loss with liraglutide 3.0 mg/

day in addition to a diet and exercise programme in individuals without type 2 diabetes who had obesity (BMI ≥30 kg/m²) or overweight (BMI 27-29.9 kg/m²) with at least one comorbidity.

Materials and methods: The SCALE Obesity and Prediabetes trial was a randomised, double-blind, multi-centre trial in which individuals (mean age 45.1 years, 78.5% female, mean weight 106.2 kg, mean BMI 38.3 kg/m², 61% with prediabetes) were enrolled in a long-term weight management programme and randomised to liraglutide 3.0 mg (n=2487) or placebo (n=1244). These data are from an exploratory analysis based on groups of individuals defined by occurrence of GI AEs (0-16 weeks, 0-56 weeks). Weight loss at week 56 is presented as least squares means using LOCF, with p-values denoting whether or not GI AEs had a significant effect on treatment.

Results: Overall, liraglutide 3.0 mg was associated with a greater weight loss from baseline than placebo (8.0% vs. 2.6%, respectively, p<0.0001). As expected, more individuals on liraglutide 3.0 mg (68.3%) compared with placebo (40.3%) reported GI AEs; the most prevalent GI AEs were nausea (40.2 vs. 14.7%), diarrhoea (20.9 vs. 9.3%), constipation (20.0 vs. 8.7%) and vomiting (16.3 vs. 4.1%), occurring mostly within the first 16 weeks of treatment. There was no significant difference in weight loss between individuals who did or did not experience ≥1 episode of nausea/vomiting during 0-56 weeks, regardless of treatment (liraglutide 3.0 mg: nausea/vomiting, -7.8%, no nausea/vomiting, -8.1%; placebo: nausea/vomiting -2.5%, no nausea/vomiting -2.6%, p=0.81). Similar results were seen if all other types of GI AE combined were included. Moreover, no significant differences were observed at week 56 for weight loss in individuals who experienced 0, 1, 2-3, or ≥4 GI AEs in the first 16 weeks (7.7-8.2% with liraglutide 3.0 mg vs. 2.3-3.0% with placebo, p=0.24), or during the entire 56 weeks of treatment (7.7-8.4% with liraglutide 3.0 mg vs. 2.4-3.2% with placebo, p=0.55). Although those experiencing 0 GI AEs appeared to perform slightly better than the other groups, this may be explained by the higher withdrawal rate as the number of GI AE increase. These results were further supported by comparable mean weight loss profiles over time across the 0, 1, 2-3, or ≥4 GI AE groups.

Conclusion: The weight loss observed with liraglutide 3.0 mg is not explained by the occurrence of GI AEs, including nausea/vomiting.

GLP-1 and GLP-2 responses to a fat-rich meal correlate to postprandial triglyceride-rich lipoproteins in obese men

N. Matikainen^{1,2}, S. Söderlund², C. Borén³, B. Eliasson³, K.H. Pietiläinen^{1,2}, L.H. Bogl², A. Rivellesse⁴, G. Riccardi⁴, J.-P. Després⁵, N. Almería⁵, J.J. Holst⁶, C.F. Deacon⁶, J. Borén³, M.-R. Taskinen²;

¹Endocrinology, Helsinki University Hospital, ²Research programs Unit, Diabetes and Obesity, University of Helsinki, Finland, ³Department of Molecular and Clinical Medicine/Wallenberg Laboratory, University of Gothenburg, Sweden, ⁴Department of Clinical Medicine and Surgery, Federico II University, Naples, Italy, ⁵Institut Universitaire de Cardiologie et de Pneumologie de Québec, Québec City, Canada, ⁶NNF Centre for Basic Metabolic Research, and Department of Biomedical Sciences, Faculty of Health and Medical Sciences, Copenhagen, Denmark.

Background and aims: Nutrients, mainly glucose and lipids stimulate the gut incretin hormones glucagon-like peptide (GLP) 1, GLP-2 and glucose-dependent insulinotropic peptide (GIP) that in animal models or if given in pharmacologic doses to humans regulate chylomicron secretion from the enterocytes. However, the effect of these gut incretins on human postprandial lipid metabolism is not fully clarified. We aimed to explore the responses of GLP-1, GLP-2 and GIP after glucose tolerance test (OGTT) or fat-rich meal, and the relationships between responses of incretins and postprandial triglyceride (TG)-rich lipoprotein after fat-rich meal.

Materials and methods: Glucose, insulin, GLP-1, GLP-2 and GIP were measured during OGTT (75 g glucose) and fat-rich meal (63 g carbohydrates, 56 g fat and 40 g protein) in 75 healthy obese (BMI 26–40 kg/m²) male subjects with mean age of 49 years, LDL-cholesterol 3.3 mmol/L, HDL-cholesterol 1.2 mmol/L and TG 1.6 mmol/l. TG, apoB48 and apoB100 in TG-rich lipoproteins (chylomicrons, VLDL1 and VLDL2) were measured after fat-rich meal. We measured postprandial responses [area under curve (AUC)] for glucose, insulin, GLP-1, GLP-2, GIP in plasma, and TG, apoB48 and apoB100 in plasma and TG-rich lipoproteins separated by gradient density ultracentrifugation.

Results: The GLP-1, GLP-2 and GIP responses after fat-rich meal and OGTT correlated strongly ($r=0.73$, $p<0.0001$; $r=0.46$, $p<0.001$ and $r=0.69$, $p<0.001$, respectively). Glucose and insulin AUCs were lower, but the AUCs for GLP-1, GLP-2 and GIP were significantly higher after fat-rich meal than OGTT. The peak value for all hormones appeared at 120 minutes after fat-rich meal, compared to 30 minutes after OGTT. After fat-rich meal, the AUCs for GLP-1, GLP-2 and GIP correlated significantly with TG, apoB48 and apoB100 in chylomicrons.

Conclusion: In obese males, GLP-1, GLP-2 and GIP responses to a fat-rich meal are greater than following an OGTT. The balance between responses of GLP-1 and GLP-2 to a fat-rich meal may be involved in regulating postprandial responses of TG-rich lipoproteins.

Effects of weight loss and long-term weight maintenance with diets varying in protein and glycaemic index on atrial natriuretic peptide in the Diet, Obesity, and Genes study

N.N. Rudovich^{1,2}, W. Bernigau³, O. Pivovarova^{1,2}, V. Murahovshi^{1,2}, M.A. Osterhoff¹, M.A. van Baak⁴, S.A. Jebb⁵, A. Valsesia⁶, J. Hager⁶, N. Viguier⁷, D. Langin⁷, W.H.M. Saris⁴, A. Astrup⁸, A.F.H. Pfeiffer^{1,2}, DiOGenes Study Group;

¹Clinical Nutrition, DIFE Potsdam-Rehbrücke, Nuthetal, ²Charité' Universitätsmedizin, Berlin, ³Epidemiology, DIFE Potsdam-Rehbrücke, Nuthetal, Germany, ⁴NUTRIM School for Nutrition, Toxicology, and Metabolism, Maastricht University Medical Centre, Netherlands, ⁵Medical Research Council Human Nutrition Research, Elsie Widdowson Laboratory, Cambridge, UK, ⁶Nestlé Institute of Health Sciences SA, Lausanne, Switzerland, ⁷Obesity Research Laboratory, Institute of Metabolic and Cardiovascular Diseases, Inserm, Paul Sabatier University, Toulouse, France, ⁸Faculty of Science, University of Copenhagen, Denmark.

Background and aims: Low atrial natriuretic peptide (ANP) concentrations are independently associated with risk of cardiovascular diseases and type 2 diabetes in obesity, while high natriuretic peptide levels appear to be protective. We tested the hypothesis that circulating ANP may be regulated by weight loss and dietary interventions.

Materials and methods: DiOGenes is a pan-European controlled dietary intervention study in overweight adults who first lost body weight on an 8-week low-calorie diet and were then randomized to 1 of 5 ad libitum diets for 26 weeks. The diets were either high (HPI) or low (LPI) protein or high (HGI) or low (LGI) glycemic index in 4 combinations or control. The concentrations of adiponectin and ANP (measured as mid-regional pro-atrial NP (MR-proANP)), were measured and analyzed together with anthropometrical and physiological parameters.

Results: Weight loss after 8-week low-calorie diet (mean±s.e.m; 11.2±3.5 kg; $p<0.001$) increased MR-proANP (from 49.7±20.3 pmol/l to 53.0±19.3 pmol/l; $p<0.001$) in the whole cohort and was pronounced in male subjects ($n=173$; 44.6±18.2 pmol/l vs. 52.5±21.0; $p<0.001$) than in women ($n=336$; 52.0±20.1 pmol/l vs. 52.8±18.2 $p=0.39$). During the 26-week weight maintenance period, MR-proANP decreased among the male subjects assigned to HGI diets (53.0±19.0 pmol/l vs. 47.0±19.0 $p=0.002$) as well as in groups with LGI diets (50.3±22.1 pmol/l vs. 45.2±19.4 $p=0.003$, $p=0.69$ for group comparison). A similar effect was observed in male subjects during HPI and LPI interventions (50.3±19.2 pmol/l vs. 45.6±16.6, $p=0.006$ for HPI; 53.5±22.3 pmol/l vs. 46.8±22.4, $p<0.001$ for LPI; $p=0.418$ for group comparison). No changes of MR-proANP were observed with all three types of diets in women (51.2±14.5 pmol/l vs. 49.7±15.8, $p=0.18$ for HGI; 54.3±21.4 pmol/l vs. 53.6±21.9, $p=0.63$ for LGI; $p=0.63$ for group comparison and 52.1±17.1 pmol/l vs. 51.0±19.9, $p=0.37$ for HPI; 53.7±20.1 pmol/l vs. 52.7±18.7, $p=0.45$ for LPI; $p=0.95$ for group comparison). Changes in circulating MR-proANP after weight loss correlated inversely with fasting insulin ($r=-0.12$, $p=0.01$), fasting glucose ($r=-0.18$, $p<0.0001$), waist circumferences ($r=-0.11$, $p=0.01$) and positively with adiponectin ($r=0.16$, $p=0.0004$) in the whole cohort.

Conclusion: Weight loss effectively increases circulating MR-proANP in male but not female subjects. The different types of diets were unable to prevent a decrease of ANP during the weight maintaining phase. Gender differences in the regulation of endogenous ANP may be causally associated with higher cardiovascular risk in males and could have implications for personalized medicine.

Impact of obesity on bone mass throughout adult life: influence of gender and severity of obesity

A. Sultan^{1,2}, A. Avignon^{1,2}, D. Mariano-Goulart¹, T. Mura¹, L. Maimoun^{3,2};

¹CHU Lapeyronie, ²INSERM U1046, ³CHU, Montpellier, France.

Background and aims: Cross-sectional studies have demonstrated that obesity improves areal bone mineral density (aBMD). However, it is not known if gender, aging or severity of obesity could modulate this effect and if bone sites are similarly impacted. The main aim of the study was to model the aBMD variation in obese patients from peak bone mass period until elderly age according to gender, bone localisation and severity of obesity. The secondary aim was to identify the relationship between aBMD and body composition during obesity.

Materials and methods: Obese patients were recruited in the Nutrition Clinic where they had been addressed for metabolic and physical assessment of their obesity. DXA (Hologic QDR-4500A, Hologic, Inc., Waltham, MA) measured the areal bone mineral density (BMD; g/cm²) of the whole body and at specific bone sites: the antero-posterior lumbar spine (L1-L4), the dominant arm radius and the hip. The soft tissue body composition, percentage of body fat mass and lean mass was derived from the whole body scan. We first estimated Z-scores of aBMD adjusted for age according to bone sites and gender using a linear mixed model. We then customized statistical tests to compare (1) the estimated value of Z-score (and change in Z-score with age) to 0 for each bone site for men and women, (2) the estimated value of Z-score (and change in Z-score with age) between men and women for each bone site, (3) the estimated value of Z-score (and change in Z-score with age) between each bone site for men and women. The effect of obesity grades was analyzed separately for men and women using the same type of linear mixed model and customized statistical tests. The relations between aBMD and age have also been studied for each bone site according to gender and grades of obesity using thin plate regression spline models. Statistical analyses were performed at the conventional two-tailed α level of 0.05 using SAS version 9.2

Results: Five hundred and four french obese patients (363 women and 141 men) with a mean BMI of 38.5 ± 6.0 kg/m², aged from 18.1 to 81.9 years (mean age 49.6 ± 14.6 years) were enrolled. Excepted at L1-L4 in men, Z-scores were significantly increased, above the age- and gender-related mean, both for women and men at WB (respectively 0.79 SD and 0.31 SD), hip (1.09 SD and 1.05 SD), radius (1.42 SD and 0.25 SD) and L1-L4 (0.85 SD for women only). The improvement of Z-scores appeared significantly more marked in women than in men in all bone sites, hip excepted. Further, differences with normal values were significantly accentuated by aging, without any depend-effect of gender. In women, whatever the BMI or the bone site, Z-scores were significantly higher than normal values, but difference appeared more marked at WB, L1-L4 and hip for those patients with a BMI above 40 kg/m². Lean mass, but not fat mass appeared an independent predictor of aBMD in men and women.

Conclusion: This study demonstrated for the first time that obesity induces an improvement of aBMD, which is however modulated by bone site localisation, severity of obesity, age and gender. The accentuation of peak bone combined to reduction of bone loss related to aging may explain that obese patients do present a lower prevalence of osteoporosis.

651

Visceral fat obesity and metabolic syndrome increase serum DPP-4 levels in type 2 diabetes mellitus

S. Tanaka, I. Kanazawa, M. Notsu, T. Sugimoto;
Shimane University Faculty of Medicine, Izumo City, Japan.

Background and aims: Dipeptidyl peptidase-4 (DPP-4) is a ubiquitously expressed transmembrane glycoprotein and separates N-terminal dipeptides from a variety of substrates including incretin such as glucagon-like

peptide 1 (GLP-1) and gastric inhibitory polypeptide. Recently, it has been shown that DPP-4 is one of adipokines expressed and secreted from adipose tissue, and that DPP-4 expression in visceral fat is greater than in subcutaneous fat. Previous studies showed that serum DPP-4 levels were significantly elevated in obese subjects compared to non-obese. However, it remains unclear whether or not serum DPP-4 levels are associated specifically with visceral fat mass and metabolic syndrome (Mets) in type 2 diabetes mellitus (T2DM). Therefore, the aim of this study was to examine the association of serum DPP-4 with visceral fat accumulation and the presence of Mets in patients with T2DM.

Materials and methods: This is a cross-sectional study with 135 Japanese male patients with T2DM. None of them had hepatic or renal dysfunction and had taken DPP-4 inhibitors or GLP-1 receptor agonists so far. Visceral and subcutaneous fat areas were evaluated by performing computed tomography scan at the level of the umbilicus. Serum DPP-4 concentration was measured by using commercially available ELISA kits. We defined more than 100 cm² of visceral fat area as visceral fat obesity as well as dyslipidemia (triglyceride ≥ 150 mg/dL, HDL < 40 mg/dL, or usage of statins and fibrates) and/or hypertension (systolic blood pressure (BP) ≥ 140 mmHg, diastolic BP ≥ 90 mmHg, or usage of anti-hypertensive drugs) accompanied by visceral fat obesity as Mets. We analyzed the relationships between serum DPP-4 levels and various parameters by multiple regression analyses and logistic analysis.

Results: Means of age and duration of T2DM were 57.4 years old and 9.8 years, respectively. Mean serum DPP-4 level was 809.1 ng/mL. Of 135 patients, 78 and 74 were visceral fat obesity and Mets, respectively. In multiple regression analysis adjusted for age, duration of T2DM, body mass index, serum creatinine, and HbA1c, DPP-4 was significantly and positively associated with visceral fat area ($\beta = 0.15$, $p = 0.01$), but not subcutaneous fat area ($\beta = -0.09$, $p = 0.14$). Un-paired Student *t*-test showed that serum DPP-4 was marginally higher in patients with visceral fat obesity than without it (832 ng/mL vs 778 ng/mL, $p = 0.09$), and that serum DPP-4 was significantly higher in patients with Mets than without it (838 ng/mL vs 775 ng/mL, $p = 0.04$). In logistic analyses adjusted for the confounding factors described above, serum DPP-4 was significantly and positively associated with visceral fat obesity and Mets [odds ratio (OR) = 1.34, 95% confidence interval (CI) = 1.04–1.72 per standard deviation (SD) increase, $p = 0.02$; OR = 1.87, 95% CI = 1.17–2.98 per SD increase, $p < 0.01$, respectively].

Conclusion: Although it is previously reported that serum DPP-4 levels were increased in obese patients, the present study showed for the first time that serum DPP-4 levels were associated positively and specifically with accumulation of visceral fat, which is evaluated by CT scan, in male patients with T2DM. In addition, serum DPP-4 levels were significantly increased in patients with Mets, suggesting that serum DPP-4 may be involved in not only glucose metabolism but also lipid metabolism and blood pressure.

Analysis of the intestinal microbiota composition and its relationship with type 2 diabetes in patients with overweight and obesity in level II

C. Taddei¹, J. McCulloch¹, T.B. Petry², M. Martinez¹, R. Cohen², J. Salles³;

¹University of São Paulo, ²Hospital Alemão Oswaldo Cruz, ³School of Medical Sciences Santa Casa, São Paulo, Brazil.

Background and aims: It is estimated that 11 million people are diabetic in Brazil, with a prevalence of T2DM. In recent years, studies indicate the gut microbiota as an important modulator of the disease. Environmental and genetic factors interact to control the host intestinal microbiota, triggering metabolic disorders such as obesity and insulin resistance. The objective of this study was to identify the fecal microbiota in adult diabetic patients and to evaluate changes in its composition after bariatric surgery. Two groups of eleven patients each were enrolled in this study.

Materials and methods: Group 1 were submitted to the Reducing gastroplasty in Roux-Y and fecal sample were collected before the surgery and after 6 and 12 months. Group 2 were followed through 6 and 12 months without surgery intervention and fecal samples were collected at inclusion in the trial and after 6 and 12 months. Fecal microbiota was analyzed using high throughput sequencing in MiSeq (Illumina) with v3-v4 16S rRNA primers.

Results: The fecal microbiota in a surgery group has an increase in bacterial abundancy and diversity when compared with non-surgery group. This data was observed with the genera belonging to the Phylum Bacteroidetes, with a remarkable increase of Bacteroides, and Actinobacteria, with an increase of Bifidobacterium in surgery group.

Conclusion: This data could contribute to a better understanding of the role of the microbiota in T2DM regulation.

Gliadin intake alters intestinal microbiota, glucose and lipid metabolism, and adipose tissue and liver immune cells

D. Andersen¹, L. Zhang², H.M. Roager², N. Danneskiold-Samsøe³, C.H.F. Hansen⁴, M.I. Bahl², A.K. Hansen⁴, S. Brix¹, L.I. Hellgren¹, T.R. Licht²;

¹Systems Biology, ²National Food Institute, Technical University of Denmark, Copenhagen, ³Department of Biology, University of Copenhagen, ⁴Department of Veterinary Disease Biology, University of Copenhagen, Denmark.

Background and aims: Dietary gluten induces type 1 diabetes and intestinal inflammation in celiac disease patients. Likewise, gluten has effects on intestinal inflammation and microbiota composition in non-celiac disease subjects. However, the effect of dietary gluten on metabolic performance in non-celiac disease conditions is still largely uncharacterised. Therefore, we aimed to elucidate the mechanisms involved in the development of gluten-induced metabolic dysregulation in obesity. We hypothesized that intake of the gluten component, gliadin, induces changes in the intestinal ecology compared to a gluten-free diet. This subsequently affects host physiology via changes in glucose and lipid metabolism, as well as leukocyte subsets in liver and adipose tissue, thus leading to a metabolic syndrome phenotype.

Materials and methods: Forty C57BL/6 mice were fed a high-fat diet with or without 4% gliadin for 22 weeks.

Results: Among the gliadin-fed mice, HbA1c levels and HOMA-IR were significantly higher, suggesting gliadin-dependent changes in glucose metabolism and development of insulin resistance. Analysis of RNA expression showed that the gluconeogenic enzyme Glucose-6-phosphatase (G6Pase) was upregulated in the liver, indicating that the increased blood glucose level was at least partly explained by increased hepatic glucose output. Principal coordinate analysis (PCoA) of intestinal content showed that gliadin-fed mice have an altered intestinal microbiota, which also was manifested as higher acetate and total levels of short-chain fatty acids in cecum. Since gliadin is known to be immuneregulating and obesity-induced insulin resistance rely strongly on immune cell signaling in metabolic organs, such as adipose tissue and the liver, we performed a deep-phenotyping of the immune cells in these tissues using flow cytometry. Monocyte subsets in blood showed no differences in systemic inflammation between treatments. However, significant alterations of the immune cell composition were evident in the epididymal adipose tissue and the liver. Total numbers of macrophages and T cells increased significantly in the adipose tissue of gliadin-fed mice. Furthermore, various T cell subsets in the adipose tissue exhibited a more pronounced inflammatory phenotype. Likewise, based on the major immune cells detected in the liver, gliadin-fed mice displayed

alterations in their immune cell composition allowing for a gliadin-dependent segregation using a principal component analysis (PCA).

Conclusion: Gliadin intake caused significant changes in glucose regulation, intestinal microbiota, and in the leukocyte phenotypes of adipose tissue and liver. Collectively, this suggests that gliadin-intake affects several of the systems involved in regulating insulin sensitivity. The exacerbation of an insulin resistant phenotype in obese mice by gliadin indicates that excessive gluten intake might increase the severity of metabolic syndrome. Further analyses of the relationship between these gliadin phenotypes are needed to identify the mechanisms mediating a response to gluten in the host.

Elevated plasma pigment epithelium-derived factor is reduced by metformin treatment

P. Zhang, Y. Bi, S. Shen, D. Zhu;

Endocrinology department, Drum Tower Affiliated to Nanjing University Medical School, China.

Background and aims: Pigment epithelium-derived factor (PEDF) was recently found to be closely associated with metabolic syndrome and insulin resistance. However, there is a lack of evidence quantitating PEDF levels in different glucose tolerance state and whether metformin treatment could influence it remains unknown. We aimed to investigate serum PEDF levels in subjects with different glucose tolerance and the effect of metformin treatment on PEDF levels in type 2 diabetic patients.

Materials and methods: Circulating PEDF levels and metabolic profiles were assessed in 517 Chinese participants with normal glucose tolerance (NGT), impaired glucose regulation (IGR) and type 2 diabetes mellitus (T2DM), based on the guideline of International Diabetes Federation. Body mass index (BMI) classification was according to the World Health Organization, underweight (BMI <18.5 kg/m²), normal weight (18.5 ≤ BMI <25 kg/m²), overweight (25 ≤ BMI <30 kg/m²), and obesity (BMI ≥30 kg/m²). 63 diabetic patients were treated with metformin (Bristol-Myers Squibb) for a period of 24 weeks, initially administered at 500 mg once daily and gradually titrated every two weeks to meet glycaemic targets (fasting plasma glucose ≤6.1 mmol/L) up to a maximum daily dose of 1500 mg. If the target was not achieved with maximum dose, then metformin was maintained as the maximum dose until the end of the 24 weeks. PEDF levels after 24-weeks metformin treatment in 63 patients with T2DM were also analyzed. Serum estradiol levels were determined in females.

Results: In all participants (42.6% men and 57.4% women, mean age was 49.7 ± 14.5 years), 186 had NGT, 216 had IGR and 169 had newly diagnosed diabetes. Serum PEDF level was significantly higher in subjects with IGR [9.51 (7.6 - 11.4) ug/ml] and T2DM [9.7 (7.9 - 11.7) ug/ml], compared with the controls [8.5 (7.1 - 10.7) ug/ml, p=0.010] and metformin treatment significantly decreased PEDF levels in T2DM patients with weight loss (p=0.027). Spearman correlation analysis demonstrated that PEDF levels were positively and significantly correlated with risk factors regarding metabolic syndrome and visceral obesity such as body mass index, waist circumference, waist-to-hip ratio, fasting and 2 h glucose (p<0.001). Multiple stepwise regression analysis revealed that PEDF was associated with alanine aminotransferase (p<0.001), triglycerides (p=0.002) and diastolic blood pressure (p=0.002) after adjustment for age and gender. Subjects with a higher tertile of PEDF concentration exhibited a higher prevalence of overweight or obesity than those in the lower tertile (p<0.001). Furthermore, men exhibited remarkably higher serum PEDF levels [9.58 (7.92-11.92) ug/ml] than women [8.88 (7.35-10.77) ug/ml, p=0.003] and this difference still existed even after adjusting for BMI, waist circumference and waist-to-hip ratio (p=0.009). We found that in post-menopause females, serum estradiol level

was negatively associated with PEDF ($r=-0.216$, $p=0.013$) and was an independent determinant of PEDF

Conclusion: PEDF concentration is significantly elevated in patients with IGR and could be reduced after metformin treatment in T2DM patients with weight loss. We for the first time identifying decreased estradiol level was an independent risk factor for the elevated PEDF and may contribute to the occurrence of T2DM in post-menopause females.

Effects of a novel potent and specific melanin-concentrating hormone receptor 1 antagonist, AZD1979, on body weight homeostasis in mice and dogs

D. Lindén¹, L. Benthem¹, D. Kakol-Palm¹, P. Gennemark¹, L. Andersson¹, M. Bjursell², J. Börjesson², L. Kärberg¹, M. Antonsson¹, A. Johansson¹, S. Iverson³, A. Turnbull¹, K. Ploj¹;

¹Cardiovascular & Metabolic Diseases iMed, ²Discovery Sciences, Transgenics, ³Drug Safety & Metabolism, AstraZeneca, Mölndal, Sweden.

Background and aims: Melanin-concentrating hormone (MCH) exerts an orexigenic response and while rodents express one receptor for MCH (Mchr1), humans, non-human primates and dogs express two MCH receptors (MCHR1 and MCHR2). MCHR1 antagonists have been developed for the treatment of obesity and they generally lower body weight in rodents. However, the relative contribution of the effect on food intake and energy expenditure as well as if MCHR1 antagonists can lower body weight in species expressing both MCH receptors are not fully understood. We have discovered a novel potent small molecule MCHR1 antagonist, AZD1979, and the aims of this study were to investigate the mechanism for weight loss in diet-induced obese (DIO) mice and to study the effect of AZD1979 on body weight in dogs expressing both MCH receptors.

Materials and methods: The effect of AZD1979 (20–60 $\mu\text{mol/kg}$ by oral gavage twice daily for up to 3 weeks) on food intake and body weight was compared to vehicle in DIO wildtype and mchr1 knock-out (KO) mice. The importance of food intake and energy expenditure for the effects was analyzed using continuous pair-feeding based on 30 min intervals in an automated system and by indirect calorimetry (CLAMS system). The effect of AZD1979 (22–216 $\mu\text{mol/kg}$ by oral gavage once daily for 4 weeks) on body weight was also studied in dogs.

Results: AZD1979 dose-dependently reduced body weight ($-17.1\pm 1\%$ vehicle adjusted, $p<0.001$ at 60 $\mu\text{mol/kg}$), body fat mass (60 $\mu\text{mol/kg}$, 19.2 ± 1.5 g vs. vehicle, 27.7 ± 1.7 g, $p<0.001$) and improved homeostasis model assessment (HOMA)-index of insulin sensitivity ($\text{mM glucose} \times \text{nM insulin}$) (60 $\mu\text{mol/kg}$, 4.9 ± 0.9 vs. vehicle, 9.8 ± 1.8 , $p<0.01$). Importantly, AZD1979 had no effect on food intake or body weight in Mchr1 KO mice. AZD1979 (60 $\mu\text{mol/kg}$) and pair-fed vehicle dosed DIO mice showed similar body weight reduction up to 11 days. Thereafter, AZD1979 dosed DIO mice had lower body weights compared to pair-fed vehicle dosed DIO mice (41.5 ± 1 g vs. 44.2 ± 1 g, $p<0.001$ dosing day 17), indicating a preserved energy expenditure. In line with this, AZD1979 (60 $\mu\text{mol/kg}$) had no effect on energy expenditure day 0–3 post initial dose but elevated energy expenditure during the light periods day 7–10 post initial dose ($p<0.05$). Finally, AZD1979 also dose-dependently reduced body weight in dogs ($-5.2\pm 1.6\%$ vehicle adjusted, $p<0.01$ at 216 $\mu\text{mol/kg}$).

Conclusion: We have discovered a novel potent and specific MCHR1 antagonist, AZD1979 that affects both food intake and energy expenditure leading to body weight loss in species expressing one or two MCH receptors.

656

FGF21 improves the adipocyte dysfunction related to seipin-deficiency

L. Dollet¹, T. Coskun², C. Levrel¹, C. Le May¹, A.C. Adams², R. Gimeno², J. Magré¹, B. Cariou¹, X. Prieur¹;

¹UMR 1087, Nantes, France, ²Lilly, Indianapolis, USA.

Background and aims: Berardinelli and Seip Congenital Lipodystrophy (BSCL) is a rare genetic disease characterized by an almost complete lack

of adipose tissue. Bi-allelic mutations in BSCL2, encoding seipin, are responsible for the most severe form of BSCL. Seipin function remains largely unknown, however, previous studies have shown that seipin deficiency affects adipogenesis.

Materials and methods: We used seipin knock-out (SKO) mice and we developed a new inducible seipine knock-down cell line (SKD). We use the FGF21 analog from LY2405319.

Results: SKO mouse model displays severe lipodystrophy with residual dysfunctional adipose tissues. Interestingly, by comparing the profile of these residual fat pads in 4 and 12-week-old mice, we highlighted a decrease in adiponectin mRNA and plasma levels with aging (3,25±0,41 vs 0,64±0,12 µg/mL in 4 vs 12-week-old mice), suggesting that beyond adipogenesis, seipin is involved in adipocyte maintenance. Aiming to prevent this impairment, we treated 6-week old SKO mice with an FGF21 analog (LY2405319, Eli-Lilly) known to target adipose tissue and to increase adiponectin secretion. FGF21 treatment during 28 days improved random fed glycemia (256±49 vs 147±28 mg/dL in control vs treated SKO), normalised insulin sensitivity, and increased adiponectin expression in adipose tissue and secretion (0,64±0,12 vs 1,53±0,47 µg/mL). To further decipher the molecular pathways altered by seipin deficiency in mature adipocytes, we developed a unique SKD cell-line from 3 T3-L1, with inducible expression of a shRNA targeting seipin mRNA. shRNA expression was induced after differentiation, and at day 9, the SKD cells and control cells exhibited similar Oil red O staining and mature adipocyte gene expression with a 60% decrease in seipin mRNA levels. At day 21, SKD cells displayed a strong decrease in Oil red O-positive cells and in mRNA levels of mature adipocytes markers. Importantly, FGF21 treatment significantly prevented this phenotype.

Conclusion: This study highlights an essential role of seipin in the maintenance of the mature adipocyte integrity, and identifies FGF21 as a potential therapeutic target for BSCL2. Our new cellular model is a useful tool to distinguish seipin function in the mature adipocyte as opposed to its established role in adipocyte differentiation.

Dose dependent effect of all-trans retinoic acid on weight and glucose homeostasis

S. Hasan¹, R. White², F.G. Hamel³, C.V. Desouza¹, R.G. Bennett³;

¹Diabetes, Endocrinology and Metabolism, University Of Nebraska Medical Center, Omaha, ²University Of Nebraska Medical Center, Omaha, ³VA Nebraska-Western Iowa Health Care System, Omaha, USA.

Background and aims: All-trans retinoic acid (ATRA) is a potent derivative of Vitamin A. In recent years, the importance of vitamin A in obesity and type 2 diabetes has become apparent. We previously showed that treatment (tx) of db/db mice with ATRA promoted the remodeling of WAT and attenuated inflammation by reducing macrophage infiltration. The objective of this study was to determine the effects of different doses of ATRA on weight, glucose homeostasis and body composition in obese, diabetic db/db mice.

Materials and methods: Three month old female mice were divided into 4 groups: high dose group was treated with 0.6 mg/mouse (ATRA-H), median dose group-0.2 mg/mouse (ATRA-M), low dose group-0.06 mg/mouse (ATRA-L) and control grp was treated with corn oil. Tx was 5 days/week for 12 weeks by voluntary oral feeding. Body weight and random glucose levels were determined weekly, and body composition analysis was performed at baseline, at week 6 and 12.

Results: Baseline body weights were similar in the 3 groups (46.3±0.8 g (ATRA-H) vs 46.4±0.8 g (ATRA-M) vs 46.8±0.9 g (ATRA-L). High dose group lost 4.6±1.9 g, with a significant difference at wk 10 (41.6±1.4 g (ATRA-H) vs 43.6±2.2 g (ATRA-M), 47.7±2.8 g (ATRA-L), p<.05), whereas no weight loss was observed in low dose group. After 10 weeks of tx, random glucose levels significantly decreased in the high

dose grp (239.5±32 mg/dL (ATRA-H) vs 407.8±32 mg/dL (ATRA-M) vs 418.5±28 mg/dL (ATRA-L), p<.05). High dose ATRA treatment significantly decreased fasting glucose levels at week 6 (277.3±32 mg/dL (ATRA-H) vs 445.6±17 mg/dL (ATRA-M) vs 420.7±46 mg/dL (ATRA-L), p<.05). Baseline % body fat was similar in all the groups, which significantly reduced after 6 wks of high dose ATRA treatment (56.6±0.9 (ATRA-H) vs 54.7±1.7 (ATRA-M) vs 57.1±1.5 (ATRA-L). The db/db mice developed hepatic steatosis, which was markedly reduced with high dose of ATRA. This change was reflected in the liver triglyceride content, which decreased significantly with ATRA (48.9±6.1 µg Triglycerides/mg Liver control vs 23.4±3.2 µg Triglycerides/mg Liver ATRA, p<0.05). Obesity is accompanied by downregulation of adipose PPAR-δ expression and activity, leading to weight gain and insulin resistance. ATRA increased PPAR-δ gene expression in visceral white adipose which was statistically significant (1.1±0.1 control vs 6.7±3.4 ATRA, p<0.001).

Conclusion: We have shown that ATRA promoted weight loss, improved glucose homeostasis and reduced hepatic steatosis by upregulating PPAR-δ expression suggesting that it may be an effective treatment for obesity-associated diabetes.

658

Role of cannabinoid receptor type 1 in glucocorticoid-induced lipolysis, insulin resistance and central obesity in human adipose tissue

C.O. Sidibeh¹, M.J. Pereira¹, J.L. Börjesson¹, P.G. Kamble¹, P. Katsogiannos¹, M. Sundbom², M.K. Svensson³, J.W. Eriksson¹;

¹Department of Medical Sciences, ²Department of Surgery, Uppsala University, ³Department of Molecular and Clinical Medicine, University of Gothenburg, Sweden.

Background and aims: Glucocorticoids and the endocannabinoid system are both involved in the regulation of energy balance. Cannabinoid receptor type 1 (CNR1) is highly expressed in the central nervous system. However, it is also expressed in adipose tissue. CNR1 antagonistic drugs such as rimonabant have previously been developed and marketed in efforts to treat obesity and metabolic comorbidities. However, psychiatric side-effects, notably depression, lead to its withdrawal from the market. We recently showed that CNR1 is upregulated in human adipose tissue by the synthetic glucocorticoid dexamethasone. Here, we study the involvement of CNR1 in glucocorticoid-induced lipolysis and insulin resistance in human adipose tissue.

Materials and methods: Human subcutaneous (sc) and omental (om) adipose tissue, obtained from non-diabetic volunteers (13 M/30 F, 24-66 yr, BMI 20.7-55.5 kg/m²) undergoing kidney donation or bariatric surgery, was incubated with or without dexamethasone (0.003-3 µM, 24 h). In addition, sc adipose tissue acquired from non-diabetic volunteers (5 M/17 F, 23-72 yrs, BMI 21.3-32.8 kg/m²) by needle biopsies from the lower abdomen was incubated with or without dexamethasone (0.3 µM, 24 h) in the presence or absence of the CNR1 antagonist/inverse agonist AM281 (1 µM) during the last 4 h of incubation. In adipose tissue, CNR1 expression as well as sc adipocyte lipolysis and glucose uptake was assessed following the incubations above.

Results: Dexamethasone increased CNR1 expression dose-dependently in adipose tissue (p<0.001 sc: by 14-fold, om: by 29-fold). CNR1 gene expression was higher in sc than om adipose tissue in overweight-obese subjects, while levels were similar between depots in normal-weight subjects. Furthermore, CNR1 gene expression in both depots correlated positively with markers of insulin resistance and central obesity such as fasting plasma levels of insulin (sc: r=0.52, p<0.001; om: r=0.40, p<0.05), HOMA-IR (r=0.56, p<0.001; r=0.38, p<0.05) and waist circumference (r=0.62, p<0.001; r=0.44, p<0.01). In subcutaneous adipose tissue, pre-treatment with dexamethasone (0.3 µM) for 24 h increased the rate of isoprenaline-stimulated lipolysis by about 50%, compared with control (p<0.01), whereas AM281 prevented this effect (p<0.01).

Moreover, incubation of subcutaneous adipose tissue for 24 h with only the CNR1-specific agonist ACEA (1 μ M), increased isoproterenol-stimulated lipolysis in adipocytes by about 20% ($p < 0.01$). Dexamethasone also reduced the rate of basal glucose uptake in sc by about 40% ($p < 0.001$) and insulin-stimulated glucose uptake by about 24% ($p < 0.01$). However, treatment with AM281 did not prevent these effects.

Conclusion: Our findings suggest that CNR1 is upregulated in states of insulin resistance and central obesity. Its expression may therefore be associated with the metabolic syndrome. Furthermore, CNR1 may be a mediator involved in glucocorticoid-regulated lipid metabolism in human adipose tissue. This study gives further support for a role of the peripheral endocannabinoid system in central obesity and insulin resistance. It supports the potential of peripherally restricted CNR1 antagonists for future treatment of type 2 diabetes.

Peripheral oxytocin administration activates vagal afferent nerves to suppress feeding, ameliorating hyperphagia and obesity in diabetic db/db mice

T. Yada^{1,2}, Y. Iwasaki¹, Y. Maejima¹, S. Suyama¹, M. Yoshida³, T. Arai¹, K. Katsurada¹, P. Kumari¹, M. Kakei³

¹Physiology, Jichi Medical University, Tochigi; ²Developmental Physiology, National Institute for Physiological Sciences, Aichi; ³Saitama Medical Center, Jichi Medical University, Saitama, Japan.

Background and aims: Hyperphagia and obesity cause type 2 diabetes and hamper dietetic treatment. Oxytocin (Oxt) is produced in the paraventricular nucleus and supraoptic nucleus of hypothalamus and, as a classic neurohypophysial hormone, promotes labor and lactation. Oxt is also released as a neurotransmitter within various brain regions and plays a critical role in regulation of food intake and body weight, as well as social behavior and stress responses. Peripheral administration of Oxt, as well as central administration, suppresses feeding and ameliorates obesity and metabolic syndrome in high fat diet-induced obese mice. However, peripheral Oxt reportedly little enters the brain through blood-brain barrier. Hence, the route through which peripheral Oxt informs the brain is unclear. In this study, we aimed to clarify whether vagal afferents mediate the sensing and anorexigenic effect of peripherally injected Oxt in healthy and diabetic *db/db* mice.

Materials and methods: To evaluate the direct action of Oxt on vagal afferents, we measured the cytosolic Ca^{2+} concentration ($[Ca^{2+}]_i$) in single nodose ganglion neurons isolated from mice, by using fura-2 ratiometric analysis. To examine the involvement of vagal afferents in Oxt-induced anorexigenic effect, we measured food intake after intraperitoneal injection of Oxt in the mice received systemic capsaicin treatment, subdiaphragmatic vagotomy or sham-operation.

Results: Oxt evoked membrane depolarization, increased action potential firings, and increased $[Ca^{2+}]_i$ in single nodose ganglion neurons. The Oxt-induced $[Ca^{2+}]_i$ increases were inhibited by Oxt receptor antagonist. Majority of Oxt-responsive nodose ganglion neurons also responded to cholecystokinin-8, a postprandial gastrointestinal hormone known to reduce food intake via direct interaction with vagal afferents. Moreover, around 80% of Oxt-responsive nodose ganglion neurons contained cocaine- and amphetamine-regulated transcript (CART) as the neurotransmitter. Intraperitoneal injection of Oxt suppressed food intake and induced c-Fos expression in the nucleus tractus solitarius (NTS) of medulla, to which vagal afferents project. This feeding suppression and c-Fos expression in NTS were blunted by subdiaphragmatic vagotomy or capsaicin treatment. In obese diabetic *db/db* mice, leptin failed to but Oxt increased $[Ca^{2+}]_i$ in nodose ganglion neurons. Moreover, sub-chronic administration of Oxt decreased feeding and body weight gain.

Conclusion: Peripheral injection of Oxt suppresses food intake by direct activation of vagal afferents. Oxt exerts these effects in leptin-resistant obese diabetic *db/db* mice, and its sub-chronic administration suppresses feeding and body weight gain. This “vagal afferent-mediated peripheral Oxt signaling to brain” may provide a novel effective route to treat hyperphagia and obesity in diabetes.

A monoclonal anti-aP2 antibody treats diabetes and fatty liver disease in obese mice

M.F. Burak^{1,2}, K. Inouye¹, A. White¹, C. Doyle³, D. Lightwood³, L. Howells³, G. Odede³, H. Hailu³, S. West³, A. Clargo³, H. Neale³, R. Garlish³, A. Moore³, G.S. Hotamisligil¹

¹Department of Genetics & Complex Diseases and Sabri Ülker Center, Harvard T. H. Chan School of Public Health, Boston, ²Medicine, Mount Auburn Hospital, Harvard Medical School, Cambridge, USA, ³UCB Pharmaceuticals, Slough, UK.

Background and aims: The lipid chaperone aP2/FABP4 has been implicated in the pathology of many immunometabolic diseases, such as diabetes and atherosclerosis. While multiple lines of evidence also supports its involvement in human disease, targeting aP2 for therapeutic applications have not yet been accomplished. Recent studies in our laboratory have shown that aP2 is not simply an intracellular protein binding lipids but an active adipokine that contributes to hyperglycemia by promoting hepatic gluconeogenesis and interfering with peripheral insulin action. Multiple groups have now demonstrated that serum aP2 levels are markedly elevated in mouse models of obesity, and human serum aP2 levels strongly correlate with BMI, insulin resistance, dyslipidemia, and cardiovascular risk. Importantly, blocking aP2 in preclinical models showed strong anti-diabetic activity. These observations raised an exciting new strategy for targeting serum aP2 to treat metabolic disease with a monoclonal anti-aP2 antibody. Here, we report the identification of a highly effective, anti-aP2 mAb, CA33, and the characterization of its effects in vivo.

Materials and methods: In hyperinsulinemic-euglycemic clamp studies, we found that the anti-diabetic effect of CA33 was predominantly linked to the regulation of hepatic glucose output and peripheral glucose utilization. We also examined the properties of this antibody by structural and biochemical studies, identified its target epitopes, and demonstrated its target specificity.

Results: Treatment of mice with dietary or genetic obesity with CA33 lowered fasting blood glucose levels, improved glucose metabolism, increased systemic insulin sensitivity and reduced fat mass and liver steatosis.

Conclusion: We conclude that development of an anti-aP2 monoclonal antibody-mediated therapeutic is a feasible approach and would constitute a strong candidate for the treatment of diabetes and fatty liver disease.

Prevention of progression from prediabetes to diabetes in 109 hypogonadal men treated with testosterone for up to 8 years

F. Saad^{1,2}, A. Haider³, A. Yassin⁴, G. Doros⁵, A. Traish⁶

¹Global Medical Affairs Andrology, Bayer Pharma AG, Berlin, Germany, ²Gulf Medical University School of Medicine, Ajman, United Arab Emirates, ³Private Urology Practice, Bremerhaven, ⁴Institute for Urology and Andrology, Norderstedt, Germany, ⁵Boston University School of Public Health, ⁶Boston University School of Medicine, USA.

Background and aims: While short-term studies using testosterone replacement therapy (TRT) in hypogonadal men with type 2 diabetes mellitus (T2DM) have yielded mixed results, long-term treatment has

shown beneficial effects of TRT. There is no information, however, whether TRT has benefits in hypogonadal men with prediabetes.

Materials and methods: Men presenting to urological offices with various complaints were screened for the presence of hypogonadism and, if found hypogonadal, offered TRT. Those who had received at least 1 year of treatment with TU were entered into two independent, prospective, observational, cumulative registry studies. 109 men with prediabetes, defined as a baseline HbA_{1c} from 5.7 to 6.4%, were analysed. TU was administered in 3-month intervals for up to 8 years. At each or each other visit, anthropometric and metabolic parameters were measured. Patients whose TRT was temporarily interrupted were excluded from the analysis. **Results:** Mean age was 57.37±8.99 years. Mean weight decreased from 96.15±13.05 to 84.14±6.98 kg. Change from baseline was -14.58±0.68 kg, percent change from baseline -14±0.65%. Waist circumference decreased from 103.8±6.88 to 94.32±4.53 cm. Change from baseline was -9.62±0.44 cm. BMI decreased from 30.55±4.35 to 27.04±2.55 kg/m², change from baseline -4.66±0.23 kg/m². Waist-to-height ratio decreased from 0.58±0.04 to 0.53±0.03. All anthropometric measures were statistically significant vs. baseline ($p<0.0001$) and improved progressively with statistical significance compared to the previous year for 6 to 7 years. Fasting glucose decreased from 5.43±0.68 to 4.63±0.6723 mmol/L ($p<0.0001$), change from baseline -0.94±0.11 mmol/L reaching a plateau after 1 year. HbA_{1c} decreased from 5.9±0.21 to 5.38±0.26% ($p<0.0001$), change from baseline -0.59±0.04% with statistical significance compared to the previous year for the first 3 years. The triglyceride to HDL ratio, considered a surrogate parameter of insulin resistance, declined from 5.62±2.61 to 2.6±0.74 ($p<0.0001$). The product of fasting glucose and triglycerides (TyG Index), another surrogate for insulin resistance, improved from 4.04±0.17 to 3.81±0.14. No patient progressed from prediabetes to T2DM. All but 4 patients' last measured HbA_{1c} was <5.7%. Lipid patterns as well, blood pressure, liver transaminases and C-reactive protein all improved significantly. 3 patients dropped out, 2 due to relocation to a different city, 1 was lost to follow-up. There were no major adverse cardiovascular events during the full observation time.

Conclusion: Hypogonadal men with prediabetes defined by HbA_{1c} from 5.7 to 6.4% showed clinically meaningful and sustainable weight loss as well as improvements in glycaemic control when receiving long-term treatment with testosterone. No patient advanced from prediabetes to overt T2DM. TRT seems to be effective to improve anthropometric and metabolic parameters in hypogonadal men and in preventing progression from prediabetes to T2DM, thereby potentially reducing cardiometabolic risk.

Effect of apelin on duodenal contraction: consequences on the gut-to brain axis in the control of glucose metabolism

A. Fournel¹, A. Drougard¹, T. Duparc², A. Marlin¹, N. Cenac³, N. Vergnolle³, P. Valet¹, P. Cani², C. Knauf¹;

¹INSERM U1048, I2MC / Neuromicrobiota, European Associated Laboratory (EAL), Toulouse, France, ²Université catholique de Louvain, Louvain Drug Research Institute / Neuromicrobiota, European Associated Laboratory (EAL), Brussels, Belgium, ³INSERM U1043, CPTP, Toulouse, France.

Background and aims: In the gut, the enteric nervous system (ENS) controls intestinal contractility allowing postprandial absorption of nutrients. In diabetic human and mice, ENS function is profoundly altered resulting in intestinal hyper-contraction. Our original concept is that “ENS/intestinal contraction” coupling, could also permit to modulate central nervous system activity (via afferent nervous messages), and in particular the hypothalamus, a key area able to control glucose utilization

in peripheral tissues. In this study, we aim at demonstrating that apelin, a bioactive peptide present in the intestinal lumen, could target ENS neurons and so control activity of “ENS/intestinal contraction” coupling. These potential modifications could have consequences on hypothalamic Nitric Oxide release (NO, a neurotransmitter strongly involved in the control of glucose metabolism) leading to variations of glucose utilization in peripheral tissues.

Materials and methods: Animals were handled in accordance with the principles and guidelines established by the National Institute of Health and Medical Research. Male C57BL6/J mice are fed on normal or high-fat diet. ENS neurons expressing APJ, the apelin receptor, are identified by immunohistochemistry. Effects of apelin on duodenal contractility are measured ex vivo with an isotonic transducer (Krebs-Ringer is used as control), and in vivo by telemetry (water is used as control). Hypothalamic release of NO in response to apelin infusion in the digestive tract, is recorded in vivo via specific amperometric NO probe implanted in the hypothalamus (water is used as control). Peripheral glucose utilization is assessed following oral gavage of apelin coupled with tritiated glucose (water is used as control).

Results: Immunohistochemistry experiments reveal that APJ is expressed in ENS neurons. In normal mice, low-dose of apelin stimulates ex vivo duodenal mechanical activity (151±15,55% of basal contraction amplitude vs 90±11, 14 for control; $P<0,05$) and in vivo duodenal electrical activity (123±0,67 (fold increase) vs 114±0,56 for control; $P<0,001$). Average frequency of NO hypothalamic release is significantly reduced following infusion of low-doses of apelin in the digestive tract (0,11±0,003 Hz vs 0,12±0,002 for control; $P<0.001$) associated with a significant decrease in muscle glucose utilization (158±17,3 Log₁₀[dpm/g tissue] vs 267±33,1 for control; $P<0.05$). In contrast, higher concentrations of apelin inhibit in vivo duodenal electrical activity, restore hypothalamic NO release and improve glucose utilization and tolerance in normal and obese/diabetic mice.

Conclusion: We demonstrate that apelin could target the ENS activity in order to modify hypothalamic NO release and then to control muscle glucose entry. Decrease the activity of the duodenum by acting on ENS neurons via bioactive peptides could be considered as a new therapeutic strategy for metabolic diseases.

PS 053 Adipokines and novel proteins in adipose tissue

663

siRNA-mediated silencing of DPP4 improves insulin sensitivity of human primary adipocytes

D. Röhrborn, H. Sell, J. Eckel;

German Diabetes Center, Düsseldorf, Germany.

Background and aims: DPP4 is a ubiquitously expressed cell surface protease which is also released to the circulation as soluble DPP4 (sDPP4). DPP4 is able to clip numerous substrates e.g. the incretin hormones, and therefore represents an important drug target for the treatment of type 2 diabetes. Recently, we identified DPP4 as a novel adipokine oversecreted in obesity and thus potentially linking obesity to the metabolic syndrome. Furthermore, we could show that sDPP4 impairs insulin signaling in an autocrine and paracrine fashion in different cell types. However, it is still unknown which functional role DPP4 plays within adipose tissue. The aim of this study was to elucidate the influence of siRNA-mediated knockdown of DPP4 on differentiation and functionality of adipocytes.

Materials and methods: Primary human adipocytes were silenced with a specific DPP4 siRNA one day prior to start of differentiation. Markers of differentiation, inflammation and adipocyte functionality were measured by Western Blot, qRT-PCR and ELISA. Furthermore adipokine profiler arrays were performed with supernatants from day 14 of differentiation to monitor changes in the secretome. In these arrays the relative level of 58 human adipokines can be determined simultaneously. On day 14 of differentiation, cells were stimulated with 100 nM insulin and parameters of insulin signaling were monitored.

Results: Very high silencing efficiency was achieved at the DPP4 mRNA level ($68 \pm 15\%$) which remained stable over the whole differentiation. DPP4 protein expression was diminished substantially to about 50% at day 14 of differentiation. DPP4 knockdown had no effect on protein or mRNA expression of the differentiation marker PPAR γ . Functional adipocyte markers like HSL and Glut4 were slightly but not significantly reduced at the level of protein expression on day 14. Of the 58 adipokines spotted on the membrane of the profiler arrays, 31 proteins were detectable. Most of them were unaffected by DPP4 silencing in adipocytes. Slight changes were found in the secretion of Cathepsin L, MIF and IGFBP-6, which seemed to be decreased whereas IL-10 secretion seems to be upregulated. mRNA expression and release of adiponectin and MCP-1 were unchanged by silencing, whereas mRNA expression of IL-6 was significantly reduced in adipocytes with reduced DPP4 expression. Most interestingly, at the level of insulin signaling DPP4 knockdown affected the insulin-stimulated phosphorylation of the insulin receptor (Tyr1150/1151) and expression of the insulin receptor substrate 1 (IRS1) which are increased by about 60% and 40%, respectively. In accordance to that, silencing induced a significant 1.7-fold higher insulin-stimulated phosphorylation of Akt (Ser473) compared to control whereas basal levels remained similar. Further experiments to elucidate the underlying mechanisms and consequences of altered insulin signaling are ongoing at the moment.

Conclusion: In conclusion, knockdown of DPP4 improves the responsiveness towards insulin in primary human adipocytes without affecting adipocyte differentiation and secretory function. Taken together with our previous observation that sDPP4 induces insulin resistance in adipocytes and higher adipose DPP4 levels in obese insulin-resistant patients, DPP4 might be a potential marker of adipose tissue insulin sensitivity.

664

A new role for GLP-2 in human adipose tissue: effects on differentiation and adipocyte metabolism

M. Ejarque, C. Serena, C. Nuñez-Roa, K. Roche, J.J. Vendrell, S. Fernandez-Veledo;

Institut d'Investigacions Sanitàries Pere Virgili (IISPV), Tarragona, Spain.

Background and aims: Glucagon-like peptide-2 (GLP-2) is a proglucagon-derived peptide structurally related to GLP-1 that is released by enteroendocrine L cells, which plays an important role in the regulation of intestinal growth and function. Unlike GLP-1, GLP-2 has not been reported to modulate insulin secretion, however, meal-related GLP-2 secretion suggests a putative role for GLP-2 in metabolism regulation beyond its well-established intestinal function. The GLP-2 receptor (GLP-2R) shows significant homology with GLP-1R, but its expression has been described largely restricted to intestine, lungs and hypothalamus. Interestingly, our group has observed GLP-2R expression in human adipose tissue. This work aims to gain insight into the molecular function of GLP-2/GLP-2R axis on energetic metabolism, focusing on its potential modulatory function on adipose tissue.

Materials and methods: Clinical studies. Visceral (VAT) and subcutaneous (SAT) adipose tissue samples from lean and obese individuals with different degrees of insulin resistance were obtained during a scheduled surgical procedure (27 women and 21 men, aged 42.4 ± 11.3 years and BMI range 23.3 to 42.4 kg/m²). Stroma-vascular (SVF) and adipocyte fractions were also obtained. Gene and protein expression studies were performed. In vitro studies. SGBS cell line was used as a model of human subcutaneous pre-adipocytes. Human adipocytes (hADSC) were isolated from adipose tissue from lean and obese patients. Effects of GLP-2 on proliferation, viability, gene expression and adipocyte metabolism were analysed.

Results: GLP-2R is expressed in SAT and VAT of lean and obese individuals mainly in the adipocyte fraction. Patient classification according to HOMA-IR shows a GLP-2R down-regulation in SAT on high-IR individuals, with independence on BMI, suggesting a putative relationship between insulin sensitivity and GLP-2R expression on AT. Accordingly, GLP-2R expression is down regulated at mRNA and protein level on adipocytes derived from hADCS isolated from obese patients. In vitro studies demonstrate no effects on adipocytes proliferation and viability during differentiation, but GLP-2 administration produce an increase on lipids accumulation with an up-regulation of lipogenic genes in differentiated adipocytes.

Conclusion: Our data suggest that adipose tissue may be a new target for GLP-2 activity, influencing the adipogenic and functional capacity of human adipocytes. Understanding the role of GLP-2 in the metabolic events that take place in AT may help to define more precisely new potential indications of clinical usefulness in metabolic imbalance.

Adiponectin is required for adaptive thermogenesis by enhancing the browning of white adipose tissues in mice

A. Xu, X.-Y. Hui, P. Gu;

State Key Laboratory of Pharmaceutical Biotechnology, The University of Hong Kong, China.

Background and aims: Adiponectin is a major adipocyte-secreted adipokine with multiple protective effects against a cluster of obesity-related cardiometabolic diseases. Plasma levels of adiponectin are inversely associated with obesity and insulin sensitivity. However, its role in adaptive thermogenesis remains unclear. This study aims to investigate whether adiponectin regulates thermogenic activity of adipose tissues in mice.

Materials and methods: Adiponectin-knockout mice and wild-type littermates were exposed to cold temperature to induce thermogenesis. The browning phenotypes of different adipose depots were analyzed by immunocytochemistry and real-time PCR. The thermogenic activity of adipose tissues was measured with the Seahorse analyzer.

Results: Chronic cold exposure caused a dramatic and selective elevation of adiponectin in stromal vascular fraction of subcutaneous white adipose tissue (scWAT), but not in classical brown adipose tissue. In scWAT, adiponectin co-localized with alternatively-activated M2 macrophages in response to cold challenge. Chronic cold exposure-induced accumulation of M2 macrophages, activation of beige cells and thermogenesis were obviously impaired in scWAT of adiponectin-knockout mice, whereas these impairments were reversed by replenishment with recombinant adiponectin. Further analysis found that adiponectin bound to the cell surface of M2 macrophages via its co-receptor T-cadherin and promoted the cell proliferation by activation of Akt, thereby leading to beige cell activation by secreting catecholamines.

Conclusion: Adiponectin is a key mediator for cold-induced browning and adaptive thermogenesis of white adipose tissue, by facilitating the crosstalk between adipocytes and immune cells.

FNDC5 (irisin) expression is increased in subcutaneous adipose tissue in obese patients with type 2 diabetes one year after bariatric surgery
J. Muenzker¹, A. Harger¹, A. Tuca¹, L. Lindheim¹, V. Zachhuber¹, E. Svehlikova¹, O. Freisinger², J. Fruhmant², F. Tadler³, B. Obermayer-Pietsch¹, T.R. Pieber¹;

¹Division of Endocrinology and Metabolism, ²Department of Surgery, Medical University of Graz, ³Department of Surgery, Krankenhaus der Elisabethinen Graz, Austria.

Background and aims: Gastric bypass surgery improves glycaemic control, but the underlying mechanisms including potential changes in adipoinular axis are incompletely understood. The aim of this study was to investigate potentially causal or associated alterations in gene expression of adipokines, myokines and hormones in the subcutaneous adipose tissue of diabetic and non-diabetic obese patients before and after gastric bypass.

Materials and methods: Biopsy specimens from the subcutaneous adipose tissue of 12 diabetic and 12 non-diabetic patients at and one year after gastric bypass were analyzed with quantitative real-time PCR for the expression levels of various adipokines and myokines.

Results: Non-diabetic subjects were found to express significantly higher levels of FNDC5 (irisin) in the subcutaneous adipose tissue than diabetic subjects before gastric bypass ($p=0.0167$). FNDC5 expression in the subcutaneous adipose tissue of diabetic patients was significantly increased one year after surgery ($p<0.001$). In non-diabetic subjects, there was no significant increase observable ($p=0.158$). The increase in FNDC5 in diabetic subjects correlated with reduction in BMI (Pearson's $r=0.718$, $p=0.009$). No correlation was observed between FNDC5 expression and early insulin response or insulin sensitivity index.

Conclusion: To the best of our knowledge, this is the first study to investigate the role of the novel myokine irisin in bariatric surgery mediated weight loss in diabetic patients. The results of this study demonstrate that exercise-independent weight loss significantly increases irisin expression levels in subcutaneous adipose tissue of diabetic subjects.

Microdialysis and proteomics of the subcutaneous interstitial fluid reveals abundance of galectin-1 in type 2 diabetes patients

E. Fryk¹, J. Perman Sundelin¹, L. Strindberg¹, M. Pereira², M. Federici³, N. Marx⁴, P.-A. Svensson¹, J.W. Eriksson², J. Borén¹, P.-A. Jansson¹;

¹Molecular and clinical medicine, Medicine, Gothenburg University, ²Department of Medical Sciences, Medicine, Uppsala University, Sweden, ³Systems Medicine, Medicine, University of Rome "Tor Vergata", Italy, ⁴Division of Cardiology, Medicine, University Hospital RWTH Aachen, Germany.

Background and aims: It is well established that adipose tissue dysfunction conveys insulin resistance and type 2 diabetes (T2D). We have previously used microdialysis for in vivo studies of adipose tissue metabolism in human subjects. Our aim was to identify novel proteins in insulin resistant adipose tissue by applying a combination of subcutaneous microdialysis and proteomics in T2D patients and healthy controls.

Materials and methods: Eight newly diagnosed male T2D patients and 7 male healthy participants were recruited. Microdialysis was performed in the subcutaneous adipose tissue (SCAT) and the obtained dialysates were analysed with a tandem MS. For validation of our results, dialysates and serum samples were quantified for galectin-1 using ELISA. Moreover, isolated adipocytes were prepared from biopsies and cell size and galectin-1 gene expression were determined. In a larger group of T2D patients ($n=31$) and healthy controls ($n=20$) serum levels of galectin-1 were measured. Furthermore, another group of obese patients ($n=24$) was subject to a very low calorie diet (VLCD) for 16 weeks and galectin-1 gene expression was measured at week 0, 8, 16 and 18. In addition, SCAT biopsies were obtained from non-diabetic participants where glucose uptake, GLUT 1 and GLUT 4 expression were measured in the presence of galectin-1. Finally, insulin signalling was quantified in cultured endothelial cells through Western blot in the presence of galectin-1.

Results: Thirty-six different proteins differed significantly when comparing dialysates obtained from SCAT in T2D patients and healthy controls. One of these proteins showing a significant over-expression in T2D patients compared with the controls, was galectin-1. This was validated by ELISA analyses of the dialysate samples ($p<0.05$) and qPCR of isolated adipocytes ($p<0.05$). Moreover, circulating galectin-1 levels correlated with subcutaneous adipocyte size and waist/hip ratio ($p<0.05$, respectively). In the expanded groups there was also a significant difference in circulating galectin-1 levels when comparing T2D patients and healthy controls ($p<0.05$). In this larger sample, we also observed linear correlations between serum galectin-1, fasting glucose and fasting insulin at concentrations below 10 mmol/L and 10 mU/L respectively. The correlations were not observed in participants with higher fasting glucose or insulin levels. Furthermore, a VLCD diet reduced galectin-1 gene expression in adipose tissue biopsies ($p<0.05$). In addition, adipocytes showed a 20% reduction ($p<0.05$) in basal and insulin-stimulated glucose uptake after pre-incubation with galectin-1 for 24 h and GLUT4, but not GLUT1 mRNA expression was reduced. Finally, endothelial cells pre-incubated with galectin-1 for 24 hrs showed a significant decrease in AKT phosphorylation after 5 min of insulin stimulation ($p<0.05$).

Conclusion: Galectin-1 is an abundant protein in subcutaneous adipose tissue of T2D patients, with effects on both insulin signalling and glucose uptake. Circulating galectin-1 levels may be a biomarker for an insulin-resistant adipose tissue indicating an increased diabetes risk.

Clock genes are implicated in the regulation of energy homeostasis in humans

O. Pivovarova^{1,2}, Ö. Gögebakan^{1,3}, S. Sucher¹, J. Groth¹, V. Murahovschi^{1,2}, K. Kessler^{1,2}, M. Osterhoff¹, N. Rudovich^{1,2}, A. Kramer⁴, A.F.H. Pfeiffer^{1,2},

¹Dept. of Clinical Nutrition, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, ²Dept. of Endocrinology, Diabetes and Nutrition, Campus Benjamin Franklin, Charité University Medicine, ³Dept. for Radiology and Interventional Therapy, Vivantes Klinikum Neukölln, ⁴Laboratory of Chronobiology, Institute for Medical Immunology, Charité University Medicine, Berlin, Germany.

Background and aims: The circadian clock coordinates numerous metabolic processes to adapt physiological responses to light-dark and feeding regimens. The implication of the circadian clock in the control of energy balance, and consequently in the regulation of body weight, is widely studied in rodents, but not in humans. Here, we investigated (1) whether the expression of clock genes in human adipose tissue is changed by weight loss and weight regain and (2) whether these alterations are associated with metabolic parameters.

Materials and methods: Subcutaneous adipose tissue samples were collected before and after 8 weeks of weight loss on a 800 kcal/d hypocaloric diet (Modifast, Nutrition et Santé, France plus 200 g/d vegetables) and again after 6 month of weight maintenance at the same time of day. Only participants who achieved a weight loss of at least 8% after 8 weeks were selected for the study (n=50, age 40.8±0.9 years, BMI 34.2±0.6 kg/m², mean ± SEM). The expression of core clock genes, and key metabolic and inflammatory genes was determined by quantitative real-time PCR.

Results: The mean weight loss for the group was 10.8% of initial weight after the hypocaloric phase and 8.0% after the weight maintenance phase. The expression of core clock genes PER2 and NR1D1 was increased in the hypocaloric phase (p=7×10⁻⁶ and p=0.031, respectively). Expression of BMAL1 and CLOCK did not change in the hypocaloric phase, but decreased during the weight maintenance period (p=0.014 and p=0.012, respectively). Clock gene expression levels and their weight loss-induced changes strongly correlated with each other at all investigation days (p<0.001). The expression levels of PER2, but not its weight loss-induced alterations, negatively correlated with BMI and body fat percentage (p<0.05). Moreover, BMAL1, CLOCK, and PER2 demonstrated a large number of correlations with genes involved in the inflammatory response (TLR4, NFKB, NFKBIA, NLRP3), energy metabolism (SIRT1) and fat metabolism (FASN, CPT1A, LPL, PPARG, PGC1A), as well as with adiponectin gene expression (ADIPOQ).

Conclusion: Clock gene expression in human subcutaneous adipose tissue is regulated by the body weight changes and associated with BMI, body fat percentage and expression of metabolic and inflammatory genes. This suggests that clock genes are implicated in the regulation of energy homeostasis in humans.

Role of lipocalin 2 in human adipose tissue metabolism and glucocorticoid-induced insulin resistance

P.G. Kamble¹, M.J. Pereira¹, C.O. Sidibeh¹, S. Ammini¹, M. Sundbom², J.W. Eriksson¹;

¹Medical Sciences, ²Surgical Sciences, Uppsala University, Sweden.

Background and aims: Lipocalin 2 (Lcn2), a peptide produced by adipose tissue (AT), has been reported to be linked to obesity and related metabolic disorders. Agents promoting insulin resistance like glucocorticoids can induce Lcn2 expression and this can be reversed by

thiazolidinediones. However, the role of Lcn2 in glucose and lipid metabolism is not fully explored in humans. We aimed to study effects of Lcn2 on glucose and lipid metabolism in human AT.

Materials and methods: Paired samples of human subcutaneous (SC) and omental (OM) AT obtained from non-diabetic subjects undergoing elective surgery (12 M/29 F, 24-66 yrs, BMI 20.7-55.5 kg/m²) were incubated with Dexamethasone (Dex), a synthetic glucocorticoid, (0.03-3 μM, 24 hr) to measure Lcn2 gene expression. Adipose tissue samples from non-diabetic subjects (3 M/19 F, 22-71 yrs, BMI 21.2-29.4) were treated with recombinant human (RH) Lcn2 (100 ng/ml, 24 hr) and used for gene (n=11) and protein expression (n=7). Isolated adipocytes were used for glucose uptake (n=8) and lipolysis (n=11) assays. Fasting blood samples were taken to measure the levels of plasma glucose, insulin and lipids, and anthropometric measurements were done.

Results: When considering both males and females, Dex significantly increased the Lcn2 gene expression in SC AT by 2.5 fold (p<0.05) in a dose-dependent manner. However, in OM AT, there was only a tendency to an increased Lcn2 expression by 1.4 fold (NS). Gender comparison shows that Dex increased Lcn2 expression in SC AT from females by 3.5 fold (p<0.05), but had no effect in males. No effect on Lcn2 expression in OM AT was seen in either gender. RH-Lcn2 treatment reduced the basal and insulin-stimulated (1000 μU/ml) glucose uptake in SC adipocytes by 18% and 25% respectively (p<0.01), similar in both genders. In addition, Lcn2 reduced the protein content of the glucose transporters GLUT1 and GLUT4 by ~40% (P<0.01) in SC AT. In paired samples, Lcn2 gene expression in OM depot was ~7.5 fold higher than in SC depot (p<0.001). Lcn2 expression in both SC and OM AT showed a tendency to be correlated with BMI (NS). The basal Lcn2 expression in SC AT was positively correlated with fasting glucose (r=0.32, p<0.05), SC adipocyte size (r=0.509, p<0.002) and OM adipocyte size (r=0.397, p=0.017). In OM AT, Lcn2 expression was positively correlated with fasting insulin (r=0.359, p=0.034) and HbA1C (r=0.376, p=0.031). In a stepwise multivariate analysis, glucose (r=0.457, p<0.01) and HbA1C (r=0.377, p<0.05) remained significant predictors of Lcn2 gene expression in SC and OM AT, respectively. In human SC AT, Lcn2 reduced PPARγ gene expression by 24% (p<0.05) and its target gene adiponectin by 34% (p<0.01). Finally, RH-Lcn2 did not affect basal or isoproterenol stimulated lipolysis in adipocytes.

Conclusion: Our results suggest that glucocorticoids increase Lcn2 expression in SC AT from females, and that this inhibits glucose uptake and reduces expression of GLUT1 and GLUT4 in adipocytes. Decreased PPARγ expression by Lcn2 suggests a possible role in the regulation of human adipogenesis. Lcn2 expression in AT is also positively correlated with blood glucose levels. In conclusion, the adipokine Lcn2 can contribute to development of insulin resistance in human AT, and it may be a mediator of metabolic adverse effects of glucocorticoid excess.

Adipose tissue miR-15b, miR-20a, miR-20b, miR-27b, miR126, miR-130a, miR210, miR296 and Let-7f expression profile in relation to obesity and type 2 diabetes

A.-M. Gentile¹, L. Coín-Aragüez², S. Lhamyani², W. Oliva Olivera², M. Murri³, F. Tinahones², R. El Bekay²;

¹UMA/IBIMA, ²ISCIII/CIBERobn/HUVV, Málaga, ³ISCIII/CIBERDEM/IRYCIS, Madrid, Spain.

Background and aims: Adipose tissue expandability is an important factor determining the appearance of insulin resistance and Type 2 diabetes (T2D) associated to obesity. Several studies revealed the importance of miRNAs in the post-transcriptional regulation of adipose tissue functionality. MiR-15b, miR-20a, miR20b, miR-27b, miR126, miR130a, miR210, miR-296 and Let-7f have shown a differential expression profile between lean and obese subjects and between metabolically healthy and

type 2 diabetes subjects in visceral adipose tissue (VAT). These microRNAs are principally involved in adipogenic, angiogenic and apoptotic regulation. Bioinformatic's analysis highlighted 50 target genes of these microRNAs; 16 among them: CDKN1A, E2F3, ESR1, GLUL, GPI, HIF1A, HIST2H3A, LRIG3, MYC, MEF2D, NUP210, STAT3, SERTAD2, UBA1, VMP1, VEGFA, showed significant expression differences in visceral adipose tissue in relation to obesity and type 2 diabetes. In summary, our data highlight the potential involvement of miR-15b, miR-20a, miR20b, miR-27b, miR126, miR130a, miR210, miR-296 and Let-7f in the regulation of apoptosis, adipogenesis and angiogenesis in adipose tissues and to have an association with obesity and type 2 diabetes.

Materials and methods: MicroRNAs and mRNA were extracted from visceral and subcutaneous adipose tissue biopsies from the following subjects: Lean (n=10), T2D lean subjects (n=10) obese (n=10), T2D obese subjects (n=10). MicroRNAs miR-15b, miR20a, miR.20b, miR-27b, miR-126, miR-130a, miR-210, miR-296 and Let-7 were extracted and analyzed by qPCR from visceral and subcutaneous adipose tissues. In silico prediction of target genes was carried out using miRTarBase, Panther and David. The network and visualization using Cytoscape software.

Results: MiR-15b, miR-20a, miR20b, miR-27b, miR126, miR130a, miR210, miR-296 and Let-7f have shown a differential expression profile between lean and obese subjects and between metabolically healthy and T2D subjects in VAT. A prediction in silico by miRTarBase, Panther and David showed that 50 target genes share connections with at least two or three of the studied miRNA. 16 among them: CDKN1A, E2F3, ESR1, GLUL, GPI, HIF1A, HIST2H3A, LRIG3, MYC, MEF2D, NUP210, STAT3, SERTAD2, UBA1, VMP1, VEGFA, showed statistically significant expression differences in visceral adipose tissue in relation to obesity and type 2 diabetes

Conclusion: Our data highlight the potential involvement of MiR-15b, miR-20a, miR20b, miR-27b, miR126, miR130a, miR210, miR-296 and Let-7f in the regulation of apoptosis, adipogenesis and angiogenesis in adipose tissues and to have an association with obesity and type 2 diabetes.

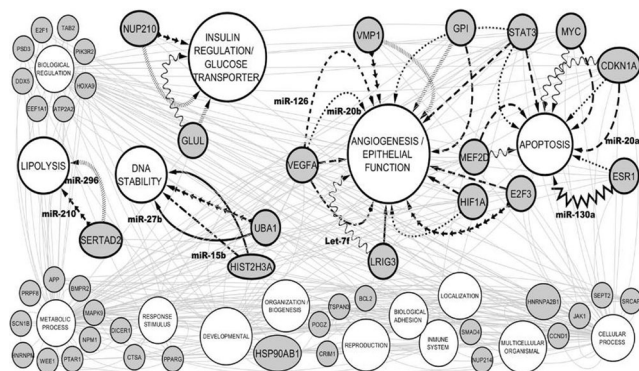

Fig. 1 Mapping of target genes that were shared by miRNAs studied to biological processes. Biological network were created using the Cytoscape software. This network is made of 50 gray nodes for target genes, 16 white nodes for biological processes and 317 edges that show regulations between 9 miRNAs and 50 target gene. The 16 target genes: CDKN1A, E2F3, ESR1, GLUL, GPI, HIF1A, HIST2H3A, LRIG3, MYC, MEF2D, NUP210, STAT3, SERTAD2, UBA1, VMP1, VEGFA, that were differentially expressed in visceral adipose tissue in relation to obesity and type 2 diabetes are shown through miRNA involved in each process

Hyperinsulinaemia increases proinflammatory factors genes expression in subcutaneous adipose tissue in young healthy subjects

N. Matulewicz^{1,2}, M. Stefanowicz^{1,2}, A. Nikořajuk², M. Strączkowski^{1,2}, M. Karczewska-Kupczewska^{1,2};

¹Medical University of Białystok, ²Institute of Animal Reproduction and Food Research, Polish Academy of Sciences, Olsztyn, Poland.

Background and aims: In obese and type 2 diabetic subjects adipose tissue is characterized by a chronic low-grade inflammation which is correlated with an increased secretion of proinflammatory cytokines, such as macrophage inhibitory factor (MIF), monocyte chemoattractant protein-1 (MCP-1) and IL-18, which might contribute to insulin resistance. Hyperinsulinemia, frequently present in type 2 diabetes and obesity, might be one of the drivers of the enhanced production of proinflammatory adipokines, however this issue remains controversial. It is also unclear if the alternations in expression of proinflammatory factors genes in adipose tissue are already present in young subjects with increased adiposity but without overt metabolic disturbances. The aim of the present study was to assess the regulation of proinflammatory factors genes expression in subcutaneous adipose tissue by hyperinsulinemia and its relationships with adiposity and insulin sensitivity in young subjects.

Materials and methods: We examined 150 young (age 23.39 ± 2.93 years) apparently healthy subject with normal glucose tolerance, 83 lean (BMI < 25 kg/m²) and 67 with overweight or obesity (BMI between 25 and 40 kg/m²). In all subjects insulin sensitivity was evaluated by the 2 h euglycemic-hyperinsulinemic clamp. Additionally, in 20 subjects, clamp was prolonged to 6 hours. Biopsy of subcutaneous adipose tissue was performed before each clamp and after 6-hour clamp. Adipose tissue mRNA expression of MIF, MCP-1, IL-18 and subunits of nuclear factor κ B (NFκB) was analysed with Real-Time PCR.

Results: Obese subjects had higher adipose tissue MIF, MCP-1, IL-18, NFκB1 expression (all p < 0.05). 6 h hyperinsulinemia increased the adipose tissue expression of MIF by 22% (p = 0.009). Furthermore, 6 h hyperinsulinemia resulted in an increase in the expression of NFκB1 by 35% (p = 0.004) and NFκB2 by 54% (p = 0.008) in subcutaneous adipose tissue. We found positive correlations between adipose tissue MIF, MCP-1, IL-18 expression and BMI (r = 0.17, p = 0.04; r = 0.29, p = 0.001 and r = 0.35, p < 0.0001, respectively), waist circumference (r = 0.21, p = 0.01; r = 0.22, p = 0.009 and r = 0.34, p < 0.0001, respectively) at baseline. Adipose tissue MIF and IL-18 expression was negatively related to insulin sensitivity (r = -0.17, p = 0.04; r = -0.18, p = 0.03, respectively) in the baseline state.

Conclusion: Our data show that 6 h hyperinsulinemia resulted in an increased expression of the proinflammatory factors in adipose tissue. This expression is already increased in young healthy people with excess body fat.

Plasma chemerin is elevated in type 2 diabetes, is associated with impaired kidney function, and is predictive for cardiovascular events
A. Leihner^{1,2}, A. Muendlein¹, P. Rein^{1,3}, K. Geiger¹, P. Fraunberger^{2,4}, H. Drexel³, C.H. Saely^{1,3};

¹Vorarlberg Institute for Vascular Investigation and Treatment (VIVIT), Feldkirch, Austria, ²Private University of the Principality of Liechtenstein, Triesen, Liechtenstein, ³Medicine and Cardiology, Academic Teaching Hospital Feldkirch, ⁴Medical Central Laboratories, Feldkirch, Austria.

Background and aims: The association of the novel adipokine chemerin with cardiovascular event risk is unclear and is addressed in the present study.

Materials and methods: We measured plasma chemerin levels in 495 patients undergoing coronary angiography for the evaluation of established or suspected stable CAD.

Results: Chemerin was higher in patients with type 2 diabetes mellitus (T2DM, $n=111$) than in non-diabetic subjects (192 ± 73 vs. 170 ± 65 ng/ml, $p=0.001$). Further, chemerin was significantly and independently associated with the glomerular filtration rate (GFR) in analysis of covariance using age, sex, and BMI as covariates ($F=49.6$, $p<0.001$). Prospectively, we recorded 186 cardiovascular events during a 8-year follow-up. Chemerin both univariately and after multivariate adjustment including baseline GFR significantly predicted cardiovascular events, with hazard ratios of 1.72 [95%CI 1.19–2.47], $p=0.004$ and 1.51 [1.03–2.23], $p=0.037$ for the top tertile of chemerin versus the first and second tertiles, respectively. A cardiometabo-chip-analysis revealed an association of two nearby located SNPs in TP53BP1 and CAPN3 rs2444030 nominal p -value= 5.2×10^{-9} , and rs3098423 nominal p -value= 9.6×10^{-8} with chemerin concentration. Haplotype analysis for these two SNPs revealed a significantly impaired GFR associated with the fully mutated haplotype compared to all other haplotypes (OR=0.63, $p=0.006$).

Conclusion: We conclude that high chemerin is characteristic of T2DM, is associated with impaired kidney function, and is predictive for cardiovascular events.

The role of the nuclear receptor FXR in obesity-induced adipose tissue inflammation

A. Marino, D. Mogilenko, H. Dehondt, D. Dombrowicz, S. Caron, B. Staels;
UMR1011, Lille, France.

Background and aims: Obesity plays a central role in the development of metabolic syndrome and related diseases. Understanding the mechanism behind the development is necessary to adopt the right clinical approach to prevent and treat metabolic disorders. Obesity is characterized by a state of low-grade inflammation consisting of a progressive infiltration of immune cells in adipose tissue. The molecular mechanisms

and the contribution of the different cell types involved are still not clear. Recent observations suggested that adipocytes themselves may exert immunological functions. The nuclear receptor FXR plays major role in regulating bile acid metabolism, but it plays also a role in maintaining systemic glucose/lipid homeostasis. Although lower than in liver, FXR is expressed in adipose tissue and regulates adipocyte differentiation and function. FXR-KO mice, in the lean state, show impaired glucose tolerance and peripheral insulin resistance. By contrast, in mouse models of obesity (ob/ob and high fat diet (HFD)), FXR-deficiency protects from obesity. Recently, has been shown that FXR plays a role in hepatocyte inflammation. The aim of this study was to elucidate the role of FXR in adipocytes on the development of obesity-induced inflammation.

Materials and methods: WT and FXR KO mice were fed a low fat diet (LFD) or a HFD. After 12 weeks, epididymal white adipose tissue (e-WAT) was collected and inflammatory phenotype was analyzed. Cytofluorimetric analysis was used to evaluate number and phenotype of immune cells infiltrating WAT. mRNA was isolated from WAT to analyze the expression of inflammatory mediators by quantitative PCR. In vitro differentiated primary adipocytes from WT and FXR KO mice were stimulated with cytokines (TNF α 20 ng/ml, IFN γ 20 ng/ml), LPS (100 ng/ml) or palmitic acid (PA, 0.5 mM). mRNA and proteins has been isolated to evaluate the expression of genes and proteins involved in adipocyte inflammation, respectively by quantitative PCR and western blot. Cytokines secretion in cell culture medium was evaluated using ELISA kits.

Results: HFD-induced accumulation of macrophages in e-WAT, measured by the number of macrophages per gram of WAT, was significantly lower in FXR-KO mice ($p<0.05$) compared to WT after 12 weeks of HFD. Moreover, gene expression of the macrophage marker EMR1 (F4/80) was lower in WAT of FXR-KO mice compared to WT on HFD ($p<0.05$). HFD drove M1 polarization of e-WAT macrophages in WT but not FXR-KO mice. Indeed, we found a significant decrease in CD11c+ M1 macrophages ($p<0.001$) and a significant increase in CD206+ M2 macrophages ($p<0.005$) in e-WAT of FXR KO mice. Gene expression analysis revealed a significantly decreased of inflammatory marker (TNF α , IL6, NLRP3, caspase1) ($p<0.05$) in WAT from HFD feeding FXR-KO mice. Our in vitro results showed a decreased inflammatory response of FXR-KO adipocytes. Gene expression analysis showed that FXR deficiency impairs the inflammatory response of adipocytes, in terms of gene expression of different cytokines (TNF α , IL-1 β) ($p<0.005$) and of inflammasome proteins encoding genes (NLRP3 and caspase-1) ($p<0.05$). Moreover FXR-KO adipocytes did not show any increase of SOCS3 gene expression in response to cytokines. Furthermore, FXR-KO adipocytes stimulated with LPS and PA showed decreased IL1 β secretion compared to WT ($p<0.05$).

Conclusion: Our results clearly suggest a role of FXR in the inflammatory response of adipocytes and in the crosstalk between adipocytes and immune cells in adipose tissue in the context of obesity-induced inflammation.

674

Linagliptin-mediated DPP4 inhibition controls both macrophage migration and alternative activation and improves insulin resistance in diet-induced obese mice

T. Ota, F. Zhuge, Y. Ni, L. Xu, M. Nagashimada, N. Nagata, S. Kaneko;
Brain/Liver Interface Medicine Research Center, Kanazawa University, Japan.

Background and aims: Obesity activates the innate immune system with subsequent recruitment of immune cells such as macrophages and T cells into metabolic tissues, leading to the development of insulin resistance. In particular, macrophage recruitment and polarization are pivotal in obesity-induced inflammation and insulin resistance. Dipeptidyl peptidase-4 (DPP4), also known as CD26, is widely expressed, including

in immune cells. However, the role of DPP4 in macrophage-mediated inflammation is unclear. In the present study, we showed that linagliptin, a DPP4 inhibitor, attenuates whole-body insulin resistance by regulating macrophage migration and alternative activation in both the adipose tissue and liver of high-fat diet (HFD)-induced obese (DIO) mice.

Materials and methods: Eight-week-old C57BL/6J mice were fed a HFD or a HFD containing linagliptin (HFD + Lina; 3 mg/kg body weight) for 8 weeks. The histological characteristics and DPP4 activity in the epididymal white adipose tissue (eWAT) and liver as well as insulin sensitivity were examined. To quantify DPP4+ macrophages in lean and obese mice, fluorescence-activated cell sorter (FACS) analysis was performed on stromal vascular (SV) cells from the eWAT and liver of DIO mice.

Results: DPP4 mRNA expression was significantly higher in the SV fraction than in the adipocyte fraction from the eWAT of DIO mice. Furthermore, an immunofluorescence study of eWAT in DIO mice revealed that F4/80+ macrophages expressed DPP4 in crown-like structures. FACS analysis showed that only a small percentage of adipose tissue macrophages (ATMs) and liver macrophages (LMs) co-expressed DPP4 in wild-type (WT) mice. However, the percentage of DPP4+ cells was significantly higher in both ATMs and LMs of DIO mice. Importantly, DPP4 activity in the eWAT and liver of DIO mice were 1.7-fold and 1.4-fold higher, respectively, than in WT mice ($p < 0.01$), whereas linagliptin markedly reduced the DPP4 activity by 89% and 88% ($p < 0.01$) in the eWAT and liver of DIO mice, respectively. Linagliptin administration improved HFD-induced glucose intolerance, hyperinsulinemia (HFD, 1.1 ± 0.3 vs. HFD + Lina, 0.5 ± 0.08 ng/mL; $p < 0.05$, fasting state) and hepatic steatosis. Linagliptin also enhanced insulin signaling assessed by IR β and Akt phosphorylation in both the eWAT and liver of DIO mice. F4/80+ macrophage migration into eWAT and liver as well as crown-like structure formation in eWAT were lower in HFD + Lina mice than in HFD mice, although adiposities were similar. These findings were associated with decreased mRNA expression of chemokine systems (MCP-1-CCR2 and RANTES-CCR5) and proinflammatory cytokines (IL-1 β , IL-6, and TNF α) in eWAT and liver of HFD+Lina mice. Furthermore, FACS analysis revealed that HFD + Lina mice had 35% and 36% fewer CD11c+CD206-(M1) ATMs and LMs, respectively, and 25% and 164% more CD11c-CD206+(M2) ATMs and LMs, respectively, than HFD mice, resulting in predominance of the M2 over M1 ATM and LM population. However, the predominance of the Ly6C- over the Ly6Chi monocyte population was not observed in the peripheral blood or bone marrow of HFD+LY mice.

Conclusion: Linagliptin-mediated DPP4 inhibition reduces M1-polarized macrophage migration and induces a M2 dominant shift of macrophages within adipose tissue and liver, thereby attenuating obesity-induced inflammation and insulin resistance.

The SUCNR1-pathway couples obesity-induced metabolic stress to the development of adipose tissue inflammation and diabetes

J.A. van Diepen¹, J.H. Robben², G. Hooiveld³, C. Carbone², M. Bekkenkamp-Grovenstein², M.G. Netea¹, C.J. Tack¹, R. Stienstra¹, P.M.T. Deen²;

¹Internal Medicine, ²Physiology, Radboud UMC Nijmegen, ³Nutrition, Metabolism and Genomics Group, Wageningen University, Netherlands.

Background and aims: Adipose tissue of obese animals and humans is characterized by adipocyte hypertrophy, oxidative stress, macrophage infiltration and enhanced production of pro-inflammatory cytokines. The enhanced inflammatory state of the adipose tissue significantly contributes to the development of insulin resistance and development of type 2 diabetes mellitus (T2DM). However, mechanisms by which local metabolic disturbances in adipose tissue in obesity lead to macrophage infiltration and the onset of chronic inflammation are not fully understood.

The TCA cycle intermediate succinate has recently emerged as a metabolic signal induced by pro-inflammatory stimulations. In the present study, we aimed to investigate the role of succinate and its receptor SUCNR1 in obesity-induced inflammation and insulin resistance in type 2 diabetes mellitus (T2DM).

Materials and methods: To study the role of the SUCNR1-pathway, both animal and human studies were combined with various *in vitro* approaches. Human plasma samples of T2DM patients (n=58) and non-diabetic subjects (n=76) were used to determine circulating succinate levels. In addition, adipose tissue inflammation as well as glucose tolerance were determined in SUCNR1^{-/-} and Wildtype (WT) mice that were fed a high fat diet (HFD) or low fat diet (LFD) for 16 weeks.

Results: Circulating levels of succinate were elevated in humans diagnosed with T2DM as compared to non-diabetic subjects (+60%; $P < 0.01$). Interestingly, *ex vivo*, both hypoxia and hyperglycemia appeared to drive the release of succinate from adipose tissue. Therefore, we set out to evaluate the significance of the SUCNR1 in adipose tissue. Feeding mice a high fat diet (HFD) increased expression of SUCNR1 in the stromal vascular fraction (SVF) of the adipose tissue (4-fold; $P < 0.01$), pointing towards a role of the SUCNR1 in immune cell function in enlarged adipose tissue. In response to HFD, WT and SUCNR1^{-/-} mice had a similar increase in total body weight and adipose tissue mass. However, absence of the SUCNR1 in HFD-fed mice led to a reduction in total adipose tissue macrophage numbers (-39%; $P < 0.05$) and Crown Like Structures (CLS; -53%; $P < 0.01$), further confirmed by reduced F4/80 and Cd68 mRNA expression. *In vitro*, absence of the SUCNR1 in bone marrow derived macrophages strongly reduced the chemotaxis potential towards medium derived from apoptotic/hypoxic 3 T3 adipocytes (-59%; $P < 0.05$). *In vivo*, the reduced macrophage infiltration in adipose tissue of obese SUCNR1^{-/-} mice was accompanied by a significantly improved glucose tolerance as compared to WT mice (AUC -28%; $P < 0.01$).

Conclusion: Overall, our results have identified succinate and its receptor as a driver of obesity-induced inflammation and an important contributor to the migration of macrophages into adipose tissue leading the systemic glucose intolerance in obesity-induced type 2 diabetes. As such, our data put the SUCNR1 forward as a promising therapeutic target to combat obesity-induced diabetes.

MIP-1 α ablation prevents insulin resistance induced by high-fat feeding or leptin deficiency

M. Nagashimada, Y. Ni, L. Xu, N. Nagata, S. Kaneko, T. Ota; Brain/Liver Interface Medicine Research Center, Kanazawa University, Japan.

Background and aims: Monocyte chemoattractant protein-1 (MCP-1) and its receptor CCR2 play a central role in the recruitment of adipose tissue macrophages (ATMs) and subsequent development of insulin resistance; however, a deficiency in either CCR2 or MCP-1 is insufficient to overcome obesity-induced ATM recruitment and insulin resistance. We have previously shown that other chemokine receptors, such as CCR5, also promote adipose tissue inflammation and insulin resistance in obese mice. The expression of macrophage inflammatory protein-1 α (MIP-1 α or CCL3), a ligand of CCR5, is elevated markedly in the white adipose tissue (WAT) of obese mice, although the mechanism by which MIP-1 α affects insulin resistance and glucose homeostasis remains poorly understood. Here, we investigated the role of MIP-1 α in obesity-induced adipose tissue inflammation and whole-body insulin resistance induced by high-fat (HF) feeding or leptin deficiency.

Materials and methods: Gene expression and the localization of chemokines and their receptors were examined in the WAT of genetically (ob/ob) and HF diet-induced obese (DIO) mice. To determine whether MIP-1 α is required for obesity-induced ATM recruitment and insulin

resistance in vivo, we examined the metabolic phenotype of MIP-1 α -/- mice. We also performed bone marrow transplantation (BMT) of MIP-1 α -/- mice or wild-type (WT) C57Bl/6J mice donor cells into irradiated WT recipient mice to generate myeloid cell specific chimeric mice.

Results: MIP-1 α expression was increased markedly compared to that of MCP-1 in the WAT of both DIO (MIP-1 α , 5.9-fold; MCP-1, 3.2-fold; $p < 0.05$ vs. WT) and ob/ob mice (MIP-1 α , 17.5-fold; MCP-1, 4.1-fold; $p < 0.05$ vs. WT) at 15 weeks of age. Immunofluorescence staining of WAT in DIO mice revealed strong MIP-1 α expression in the crown-like structures (CLS) of F4/80+ macrophages. MIP-1 α -/- mice fed normal chow had slightly better glucose tolerance. MIP-1 α -/- mice fed a HF diet showed decreased macrophage infiltration and CLS formation in WAT compared with WT mice at 16 weeks, although the weight gain was similar in both groups. The HF diet-induced glucose intolerance and hyperinsulinemia (MIP-1 α -/- vs. WT; 0.6 ± 0.1 ng/mL vs. 2.3 ± 0.3 ng/mL, $p < 0.01$) were improved significantly in MIP-1 α -/- mice. These findings were associated with decreased inflammatory cytokine expression (TNF α and iNOS), attenuated endoplasmic reticulum stress evaluated by XBP-1 splicing, and reduced hepatic steatosis. Next, we introduced a MIP-1 α deficiency into ob/ob mice to generate double-knockout (DKO) mice. The DKO mice were strikingly resistant to the development of both insulin resistance and fatty liver disease. The DKO mice also exhibited decreased ATM recruitment and CLS formation, along with slightly reduced adipocyte size compared to ob/ob littermates. Importantly, mRNA expression of MIP-1 α and other CCR5 ligands in WAT was higher in the stromal vascular fraction relative to the adipocyte fraction from DIO mice at 16 weeks. Furthermore, chimeric mice lacking MIP-1 α in myeloid cells were protected from HF diet-induced hyperinsulinemia (MIP-1 α -/-BMT 2.6 ± 0.3 vs. WT-BMT 5.1 ± 1.1 ng/mL, $p < 0.05$), glucose intolerance, and hepatic steatosis.

Conclusion: MIP-1 α deficiency prevents insulin resistance caused by either HF feeding or leptin deficiency, indicating a crucial role for MIP-1 α in ATM recruitment and the subsequent development of insulin resistance independent of MCP-1/CCR2.

Inflammation triggers specific microRNA profiles in human adipocytes and macrophages and in their supernatants

F.J. Ortega¹, M. Moreno¹, J.M. Mercader², J.M. Moreno-Navarrete¹, M. Sabater¹, W. Ricart¹, J.M. Fernandez-Real¹;

¹Department of Diabetes, Endocrinology and Nutrition (UDEN), Institut d'Investigació Biomèdica de Girona (IdIBGi), Girona, ²Joint IRB-BSC program on Computational Biology, Barcelona Supercomputing Center, Spain.

Background and aims: The potential relevance of microRNAs (miRNAs) in adipose tissue is increasingly recognized, being intrinsically linked to different pathways, including obesity-related inflammation. In this study, we aimed to characterize the changes induced by inflammation on the miRNA pattern of human adipocytes and macrophages.

Materials and methods: An extensive profile of 759 common miRNAs was assessed in cells (human primary mature adipocytes, and the macrophage-like cell line THP-1) and in their supernatants (SN) using TaqMan low-density arrays. This profile was evaluated at the baseline and after administration of lipopolysaccharide (LPS, 10 ng/ml) and LPS-conditioned medium from M1 macrophages (MCM, 5%). Those miRNA that experienced the most dramatic changes were also studied in subcutaneous human adipose tissue before and ~2 years after bariatric surgery-induced weight loss.

Results: Differentiated adipocytes expressed 169 miRNAs, being 85 detectable in the SN. In M1 macrophages, 183 miRNAs were detected, being 106 present also in the SN. MCM and LPS led to increased number of detectable miRNAs in cells and SN in both adipocytes (+8.3% and +

24.7%) and M1 macrophages (+1.4% and +5%, respectively). Under inflammatory conditions, adipocytes and M1 macrophages shared the expression of 147 (+9%) miRNAs, and 100 (+41%) common miRNAs were also shared in their SN. Twelve of these “inflammatory” miRNA were linked to inflammation in adipose tissue from obese subjects. Interestingly, miR-221 (2-fold, $p = 0.002$), miR-222 (2.5-fold, $p = 0.04$) and miR-155 (5-fold, $p = 0.015$) were increased not only in inflamed adipocytes but also in their SN (15, 6 and 4-fold, respectively, all $p < 0.001$). The expression of these specific miRNAs in human adipose tissue concordantly decreased after weight loss (-51%, $p = 0.003$, -49%, $p = 0.03$, and -54.4%, $p = 0.005$, respectively).

Conclusion: Inflammation induces a specific miRNAs pattern in adipocytes and M1 macrophages with impact on the physiopathology of obesity-induced inflammation of adipose tissue. Variations regarding the cluster miR-221/222 and the miR-155 may participate in the crosstalk between obesity-related inflammation and AT/adipocytes impaired glucose uptake.

The transcription factor Prep1 is a molecular link between insulin-resistance and inflammation in adipose tissue

F. Oriente¹, A. Liotti¹, S. Cabaro¹, I. Cimmino¹, S. Ricci¹, G. Perruolo¹, M. Ciccarelli¹, F. Ariemma¹, C. Procaccini¹, G. Matarese², P. Formisano¹, F. Beguinot¹;

¹Department of Translational Medicine, University of Naples “Federico II”; IEOS/CNR & URT “Genomica del Diabete”, ²University of Salerno, Italy.

Background and aims: Mounting evidence have highlighted that the chronic low-grade systemic inflammation accompanying obesity impairs insulin signaling by secreting adipokines and may contribute to the development of insulin-resistance and type 2 diabetes mellitus. We have previously identified Prep1 as a homeodomain transcription factor, which plays an important role in glucose homeostasis. Prep1 hypomorphic heterozygous mice (Prep1i/+) expressing low levels of protein are protected from streptozotocin-induced diabetes and show improved insulin sensitivity both in muscle and in liver. Moreover, these mice feature reduced lipotoxicity and diet-induced steatohepatitis. In this study, we have focused our attention on the role of Prep1 on adipose tissue function.

Materials and methods: Adipose tissue of WT and Prep1i/+ mice have been characterized by histological analysis and Western blot and qRT-PCR experiments have been used to measure adipocyte protein and mRNA expression. Adipose tissue immune-phenotyping has been performed by cytofluorimetric analysis and metabolic profile of adipocytes has been evaluated by extracellular flux analyzer.

Results: Prep1 hypomorphic heterozygous mice feature a 23% reduction of total body lipid content compared to the WT littermates while the fresh weight of the epididymal fat pads was found 25% lower in Prep1i/+ mice ($p < 0.01$). Histological analysis in adipose tissue of WT and Prep1i/+ mice revealed that Prep1 hypomorphic adipocytes feature a reduced cell volume compared to the adipocytes of WT mice. More detailed analysis of Prep1i/+ adipose tissue indicated increased number of small adipocytes, which are more insulin responsive, and a reduction of enlarged adipose cells that promote immune-inflammatory responses. Indeed, insulin receptor tyrosine and akt/PKB phosphorylation was markedly increased in Prep1 deficient mice and, in parallel, glucose uptake was 3-fold higher in Prep1i/+ animals ($p < 0.05$). In addition, adipose tissue from Prep1 hypomorphic heterozygous mice showed reduced T cells infiltration and leptin, TNF- α and IL-8 expression, while adiponectin levels were increased.

Conclusion: All together, these data indicate that Prep1 deficiency reduces immune-inflammatory response improving glucose homeostasis in adipose tissue.

PS 055 The inflammatory language of diabetes

The role of tight glycaemic control on inflammation factors and vasoactive substances in newly diagnosed type 2 diabetes mellitus

A.A. Makina¹, P. Mitrou², M. Chrisanthakopoulou¹, A. Theofanou³, P. Georgoutsou³, T. El Xasman¹, Z. Aleksiou¹, G. Dimitriadis²;

¹2nd Department of Internal Medicine, General Hospital, Eleusina, ²2nd Department of Internal Medicine and Research Institute Athens University Medical School, General Hospital, Attikon University Hospital, ³Haematology Laboratory of General Hospital of Eleusina, Athens, Greece.

Background and aims: In conditions with insulin resistance, a low-grade inflammation in adipose tissue activates macrophages that together with adipocytes produce various inflammatory adipokines, procoagulant and vasoactive substances. Considering the crosstalk between inflammatory pathways and insulin signalling cascade, these molecules may represent a link between inflammation and metabolic signals and mediate, at least in part, insulin resistance in peripheral tissues. However, little is known about the effect of intensive therapy targeting in tight glycaemic control on these factors. In our study we aimed to investigate circulating levels of inflammatory markers including hsCRP, interleukin (IL)-6, IL-18 and von Willebrand factor (vWF) in patients with newly diagnosed type 2 diabetes, before and after 6-months intensive antidiabetic therapy resulting in tight glycaemic control.

Materials and methods: 52 newly diagnosed T2DM (29 males, age: 54.7±2.1 years) were selected. None of the subjects had coexistent autoimmune or other inflammatory disease. Venous blood was obtained on admission (1st baseline sample without any medication therapy) and 6 months later (2nd sample under antidiabetic therapy with oral agents and/or insulin) for measurements of hsCRP, IL-6, IL-18 and vWF.

Results: After 6 months therapy (compared to baseline): 1) HbA1c decreased (6.01±0.1 vs 7.91±0.26, $p<0.05$) 2) BMI decreased (31.1 kg/m² vs 34.5±1 kg/m², $p=0.0001$) 3) hsCRP serum levels decreased (4.20±1.3 vs 9.29±1.51 mg/l, $p<0.05$) 4) IL-6 serum levels decreased (2.44±0.41 vs 3.45±0.26 pg/ml, $p<0.05$) 5) IL-18 serum levels decreased (77.57±6.64 vs 99.54±8.0 pg/ml, $p<0.05$) and vWF plasma levels decreased (97.14±8.58 vs 137.28±25.08%, $p<0.69$) 6) There were no statistically significant differences between different therapies.

Conclusion: Tight glycaemic control with oral agents and/or insulin decreases the inflammatory factors, with additional beneficial effects on endothelial dysfunction which may reduce procoagulant imbalance seen in untreated patients with type 2 diabetes.

Impact of glucose-loading on the variation of CD4+ and CD8+ T cells

A. Miya¹, A. Nakamura¹, H. Miyoshi¹, Y. Takano¹, K. Sunagoya², K. Hayasaka², C. Shimizu², Y. Terauchi³, T. Atsumi¹;

¹Division of Rheumatology, Endocrinology and Nephrology, ²Division of Laboratory and Transfusion Medicine, Hokkaido University, Sapporo, ³Department of Endocrinology and Metabolism, Graduate School of Medicine, Yokohama City University, Japan.

Background and aims: Chronic inflammation is involved in the pathogenesis of obesity and type 2 diabetes. Obesity and diabetes were associated with the peripheral blood T cell composition as well as total peripheral white blood cell and leukocyte count. However, little is known about the effect of acute change of glucose metabolism by glucose-loading on the peripheral blood T cell compartment. The aim of this study is to examine the fluctuation of CD4+, CD8+ T cells and natural CD4+

CD25+FoxP3+ T-regulatory (Treg) cell variation following oral glucose tolerance test (OGTT) in patients with or without type 2 diabetes and its relation to fluctuation in glucose, insulin and free fatty acid (FFA) caused by OGTT.

Materials and methods: Twenty Japanese patients with type 2 diabetes (DM group) and 20 without diabetes (non DM group) were recruited into the present study. After obtaining the approval of the institutional review board and written informed consent from the subjects, a 75-g OGTT was performed. The plasma glucose and insulin levels were measured after an overnight 12-h fast and during a 75-g OGTT at 30, 60, 90 and 120 min. Cell numbers of leucocyte, lymphocytes and T cell compartment such as CD4+, CD8+, and Treg were calculated from their blood after an overnight 12-h fast and during a 75-g OGTT at 60 and 120 min. Insulin sensitivity was estimated using the Matsuda index and homeostasis model assessment of insulin resistance (HOMA-IR). Glucose-stimulated insulin secretion was evaluated based on the insulinogenic index and oral disposition index.

Results: Age was significantly higher, whereas insulinogenic index and oral disposition index were significantly lower in the DM group compared with those in the non DM group. There were no significant differences in sex, body mass index, Matsuda index, nor HOMA-IR between these two groups. Before glucose-loading, there were no differences in cell numbers of leucocyte (6466.7±2332.9/μL in the DM group vs 6290.0±1587.1/μL in the non DM group), lymphocytes (2001.2±636.7/μL vs 2336.6±1173.7/μL), CD4+ (896.5±290.9/μL vs 1036.2±429.0/μL), CD8+ (582.7±277.8/μL vs 622.6±290.5/μL), and Treg (78.6±38.1/μL vs 88.9±40.2/μL) between these two groups. The proportion of lymphocytes (DM group: 31.8±7.3% to 30.2±7.4/μL; $p<0.01$, and non DM group: 37.5±16.0% to 36.9±15.5%; $p<0.01$) and CD8+ (DM group: 28.4±7.4% to 26.3±6.4/μL; $p<0.01$, and non DM group: 27.1±4.9% to 25.3±5.6%; $p<0.01$) significantly decreased, whereas the proportion of CD4+ significantly increased (DM group: 45.2±6.1% to 47.6±5.9/μL; $p<0.01$, and non DM group: 46.3±9.0% to 47.7±9.8%; $p<0.01$) after 120 min of glucose-loading in both groups. The proportion of Treg was not affected. Furthermore, significant positive correlation was observed between the area under the curve for CD8+ and the change of FFA following OGTT ($r=0.40$, $p<0.05$), but not that of glucose nor insulin.

Conclusion: Although Treg population was not quantitatively different, CD4+ T cells were increased and CD8+ T cells decreased after glucose loading in both subjects with and without diabetes. These findings suggest that glucose loading dynamically affects the balance of circulating T lymphocyte subset regardless of glucose tolerance.

Association of low-grade inflammation with early changes of glycaemic control, insulin sensitivity and secretion in recent-onset type 1 and type 2 diabetes

K.S. Weber^{1,2}, B. Nowotny^{1,2}, K. Strassburger^{3,2}, G. Pacini⁴, J. Szendroedi^{1,5}, K. Müsigg^{1,5}, C. Herder^{1,2}, M. Roden^{1,5}, for the GDS Group;

¹Institute for Clinical Diabetology, German Diabetes Center at Heinrich Heine University, Leibniz Institute for Diabetes Research, ²German Center for Diabetes Research, Partner Düsseldorf, ³Institute for Biometrics and Epidemiology, German Diabetes Center at Heinrich Heine University, Leibniz Institute for Diabetes Research, Düsseldorf, Germany, ⁴Metabolic Unit, Institute of Biomedical Engineering, National Research Council, Padua, Italy, ⁵Department of Endocrinology and Diabetology, Medical Faculty, Heinrich Heine University, Düsseldorf, Germany.

Background and aims: Low-grade inflammation affects insulin sensitivity and beta-cell function already before the onset of diabetes and can contribute to the development of both type 1 (T1D) and type 2 diabetes (T2D). We hypothesized that biomarkers of low-grade inflammation also associate with the early progression of recent-onset T1D and T2D.

Materials and methods: In the prospective GDS study, new-onset T1D (n=42) and T2D (n=94) patients underwent detailed metabolic characterization within the first year after diabetes diagnosis and 2 years thereafter. Associations between changes of markers of low-grade inflammation with changes of HbA1c, insulin sensitivity and secretion as measured by intravenous glucose tolerance test were assessed using multivariable linear regression analysis adjusted for age, sex, body mass index (BMI), smoking status, as well as for 2-year changes of BMI, smoking status, and glucose-lowering treatment.

Results: Both T1D and T2D patients exhibited good glucometabolic control at baseline (mean HbA1c $7.1\pm 1.6\%$ and $6.4\pm 1.0\%$) and after 2 years (mean HbA1c $7.0\pm 1.2\%$ and $6.6\pm 1.1\%$). Two-year increases of high-sensitive C-reactive protein, soluble E-selectin and soluble intercellular adhesion molecule-1 in T2D and of interleukin-18 in T1D were associated with absolute increases of HbA1c by +0.5%, +0.9%, 1.7% and +1.2% (all $P<0.01$; changes per doubling of biomarker levels between baseline and 2-year follow-up). A comparable 2-year increase of sE-selectin associated with a relative decrease in pre-hepatic beta-cell function by -34.9% ($P<0.05$) in T2D.

Conclusion: During the initial course of disease, low-grade inflammation relates to worsening of glycemia in both T1D and T2D, whereas endothelial activation may contribute to decreasing beta-cell function in T2D.

Metformin decreases TLR4 expression in type 2 diabetic patients monocytes and inhibits leptin secretion in peripheral blood mononuclear cells (PBMC)

A. Coppola^{1,2}, M. Caputo^{1,2}, D. Pastore¹, B. Capuani¹, F. Pacifici¹, R. Arriga¹, S. Caratelli^{1,3}, A. Bellia^{1,2}, S. Tartaglione⁴, A. Galli⁴, M. Romano⁴, P. Sbraccia¹, D. Della Morte^{1,2}, G. Sconocchia⁵, D. Lauro^{1,2};

¹University of Rome, ²University Hospital 'Fondazione Policlinico di Tor Vergata', ³Institute of Translational Pharmacology, National Research Council, ⁴University Hospital 'Fondazione Policlinico di Tor Vergata', ⁵Institute of Translational Pharmacology, National Research Council, Roma, Italy.

Background and aims: Several studies argue the importance of inflammation as key component of Type 2 Diabetes Mellitus (T2D). Among cytokines involved in T2D pathogenesis, serum levels of Leptin and High Mobility Group Box (HMGB1) were found increased in T2D patients: Leptin modulates cytokines secretion in monocytes and CD4+ T-cells while HMGB1 activates immune system by promoting T-cell and B-cell reactivity. Moreover, HMGB1 receptors Toll like receptor 2 and 4 (TLR2 and 4) were found increased in monocytes of newly diagnosed T2D patients. Metformin represents the T2D first line therapy, and it can decrease both HMGB1 and Leptin blood levels. We aimed to investigate the effects of Metformin therapy on TLR expression in T2D patients and to explain its anti-inflammatory mechanism.

Materials and methods: 50 Caucasian subject were recruited and divided in 3 groups: 10 healthy controls (HC), 20 T2D patients in therapy with Metformin (MET-T2D), and 20 newly diagnosed T2D patients without pharmacological treatment (Naïve-T2D). MET-T2D and Naïve-T2D showed BMI ≤ 28 , glucose value < 126 mg/dl and HbA1c values were $< 6\%$. Monocyte percentage was evaluated by flow cytometry and confirmed with complete blood count (CBC) analysis. TLR2 and TLR4 expression or mean fluorescence intensity (MFI) of each cohort were evaluated by flow cytometry. PBMCs of each group were isolated by Ficoll gradient, activated with IL-2 (200U/ml) for 72 h and treated with HMGB1 (2 ug/ml) for 48 h. Leptin levels were evaluated by ELISA assay. Results were analyzed with t-test and P values < 0.05 were considered statistically significant.

Results: CBC analysis showed no variation in monocytes count among our groups. We, thus, analyzed TLR2 and TLR4 expression: we found Naïve-T2D showed an increase in amount of TLR2+/TLR4+ subpopulation compared to HC. Conversely, MET-T2D showed a dramatic decrease in TLR4 compared to Naïve-T2D and HC while TLR2 expression is not affected by Metformin. We confirmed these data by MFI analysis. To assess biological significance to TLR4 inhibition by Metformin, PBMCs from HC, Naïve-T2D and MET-T2D were isolated, activated with IL-2 and treated with HMGB1. We established that HMGB1 increases Leptin secretion in IL-2 activated HC PBMCs, while MET-T2D PBMCs showed no variations in Leptin secretion after HMGB1 treatment and IL-2 activation. Nevertheless, HMGB1/IL-2 tandem treatment increased Leptin secretion only in TLR4+ PBMC in Naïve-T2D patients, in fact we found a small percentage of Naïve-T2D in which TLR4 expression is highly deregulated. MET-T2D and TLR4- Naïve-T2D did not show any variation in Leptin secretion after HMGB1/IL-2 treatment.

Conclusion: Our data shows that Metformin therapy is associated with TLR4 deregulation in T2D patient's monocytes. The lack of TLR4 suggests a minor susceptibility to inflammatory stimuli in terms of Leptin secretion, providing a potential mechanism to explain Metformin anti-inflammatory pleiotropic effect.

683

Effects of empagliflozin in a murine model of diet-induced insulin resistance: A role for NLRP3 inflammasome inhibition?

E. Benetti¹, G. Vitarelli¹, M. Collino¹, R. Mastrocola², J.C. Cutrin³, F. Chiazza¹, D. Nigro², R. Fantozzi¹;

¹Dipartimento di Scienza e Tecnologia del Farmaco, ²Department of Clinical and Biological Sciences, ³Department of Biotechnology and Sciences for the Health - University of Turin, Italy.

Background and aims: Empagliflozin is a potent and selective inhibitor of the sodium glucose co-transporter (SGLT)-2, approved as a new oral treatment for type 2 diabetes. However, to date, the potential ability of empagliflozin to affect the chronic inflammatory response associated with diabetes and recently recognized as a primary pathogenic factor in the development of insulin resistance, has not been investigated. Aim of this study was to evaluate the effects of a chronic treatment with empagliflozin in a murine model of diet-induced insulin resistance, focusing on inflammatory response in liver and kidney. In particular, as NLRP3 (nucleotide-binding and oligomerization domain [NOD]-like receptor [NLR] pyrin domain-containing 3) inflammasome has been recognized playing a key role in insulin-resistance and obesity-induced inflammation, the effect of empagliflozin on diet-induced NLRP3 activation was evaluated.

Materials and methods: Male C57BL/6 mice (n=20 per group) were provided with a standard (control group) or a high fat-high sugar (HFHS group) diet for 4 months. Over the last 2 months, subsets of animals were treated with empagliflozin (1-10 mg/kg) added to the diet. Body weight, water/food intake were recorded weekly. Insulin, interleukin (IL)-1 β , IL-18, IL-6 and tumor necrosis factor (TNF) levels and albumin/creatinine ratio (ACR) were measured by ELISA. Phosphorylation of insulin signaling intermediates, NLRP3 expression and caspase-1 activation were evaluated by western blot on tissue specimens.

Results: In comparison to mice fed with standard diet, animals provided with HFHS diet exhibited a significantly bigger final body weight (25.2 ± 0.8 vs 34.6 ± 3.0 g, $p<0.001$), higher fasting glycaemia (111.3 ± 11.8 vs 171.3 ± 21.4 mg/dl, $p<0.001$) and plasma total cholesterol (102.3 ± 24.3 vs 138.9 ± 10.9 mg/dl, $p<0.05$). HFHS mice shown hepatic steatosis and tubular vacuolar degeneration in the kidney. Moreover, a 4-fold higher liver triglyceride level ($p<0.01$), a 5-fold higher ACR ($p<0.001$) and a marked increase of NLRP3 expression ($p<0.01$) in liver and kidney were also measured in HFHS mice. A 10% reduction of body weight was induced by 10 mg/kg empagliflozin ($p<0.001$), and a dose-dependent

effect on fasting glycaemia, liver steatosis and renal tubular damage was measured in animals treated with the drug. Interestingly, the diet-related overexpression of NLRP3 was attenuated by empagliflozin in a dose dependent manner, and this effect was associated with a significant decrease in tissue caspase-1 activation and IL-1 β production. Empagliflozin evoked a significant reduction of plasma TNF, liver IL-6 and ACR starting from 1 mg/kg.

Conclusion: The deleterious effects of a HFHS diet were reverted by empagliflozin in a dose-dependent manner. Our results clearly demonstrated the ability of the drug to affect NLRP3 inflammasome signaling, suggesting that this inhibition may contribute to the therapeutic effects exerted by empagliflozin.

Hypoglycaemic episodes are associated with inflammatory status in patients with type 1 diabetes

B. Kiec-Wilk¹, B. Matejko¹, U. Razny², A. Polus², T. Klupa¹, J. Skupien¹, M.T. Malecki¹;

¹Metabolic Diseases Department, ²Clinical Biochemistry Department, Jagiellonian University Medical College, Krakow, Poland.

Background and aims: It is well documented that glycemic control is associated with inflammatory status in type 1 diabetes (T1DM) patients. The hyperglycemia-induced oxidative stress plays a key pathophysiological role in damaging endothelial function in diabetes. However, the individual contribution of different parameters and indices, for example glucose variability or hypoglycemic episodes, is not clear. The aim of the study was to examine the association of glycemic control parameters and selected blood markers of endothelial function and inflammation in T1DM patients.

Materials and methods: We included 101 patients with T1DM on insulin pumps (mean age - 28.7+10.8 years, mean T1DM duration - 8.5 +/- 2 years). All subjects completed a standardized questionnaire. Other sources of information included medical records, downloads from glucose meters and personal pumps. The list of glycemic control parameters included HbA1c, mean glucose level, standard deviation and four other indices based on self-monitoring blood glucose as well as the number of hypoglycaemias (glucose <55 mg/dL) from the period of last 7 days. Blood was collected for 4 inflammatory markers: interleukin 6 (IL-6), Vascular Cell Adhesion molecule 1 (VCAM), Intercellular Adhesion Molecule 1 (ICAM), E-selectin. Appropriate statistical analyses were performed for differences and associations. In forward stepwise multiple linear regression analysis, inflammatory factors were dependent variables, while as independent variables we used seven glycemic control indices and selected clinical as well as biochemical parameters.

Results: The examined cohort was characterised by good glycemic control as the mean HbA1c level was 7.1+0.8%, mean daily glucose - 141.5+27.1 mg/dL. Standard deviation reached 65.6+16.9, while number of hypos 5.6+4.0 over the observation period. In forward stepwise multiple linear regression analysis we observed that the number of hypoglycaemias was consistently an independent predictor of the level of all investigated markers - sICAM (p=0.0019), VCAM (p=0.021), E-selectin (p=0.048) and IL-6 (p=0.027), respectively. None of the other glycemic parameter turned out to independently predict the inflammatory status of examined T1DM patients.

Conclusion: For the first time, we report the association between the number mild hypoglycemic episodes over the period of one week and the level of several inflammatory markers in T1DM patients with good glycemic control.

Characterisation of the complement system among hospitalised type 2 diabetic patients with community acquired bacterial infections

L.J. Barkai, E. Sipter, D. Csuka, Z. Nebenfuhrer, Z. Prohaszka, I. Karadi, N. Hosszufalusi;

3rd Department of Internal Medicine, Semmelweis University, Budapest, Hungary.

Background and aims: Infections are more frequent and severe in patients with type 2 diabetes mellitus (T2DM) than in nondiabetic population. The complement cascade is a complex protein system, which can be activated via different enzymatic pathways and plays an important role in response to pathogens. The goal of our study was to determine predictive association between increased risk of community-acquired bacterial infections and lectin complement pathway member ficolin-3 among patients with type 2 diabetes mellitus.

Materials and methods: In our prospective, matched pairs study 40 subjects with T2DM according to WHO criteria and 12 nondiabetic subjects were investigated. Patient inclusion criteria were clinical diagnosis of acute community acquired bacterial infections. Immunological, hematological, oncological illnesses were excluded. Activity of the ficolin- and MBL-lectin complement pathway member ficolin-3 and mannose binding lectin (MBL), activity of the alternative complement pathway, concentrations of classical complement pathway member C1q and complement activation end product C4d were measured from blood samples using standardized ELISA kits. Complement and laboratory parameters of 26 subjects from the T2DM and 9 subjects from the nondiabetic group were reassessed after a minimum of three-month infection-free period. Statistical analysis and correlations between C1q/WBC, C4d/WBC, C4d/CRP, F3/WBC and F3/CRP were performed using GraphPad Prism 5.

Results: We found higher HbA1c levels in the T2DM group (17/40 men; median [percentile 25-75] age: 73 [66.3-80.8] years, HbA1c: 7.6 [6.2-8.1]%, CRP: 146 [74.6-248.3] mg/l, white blood cell count (WBC): 10.2 [8.1-14] G/l; sepsis: 17/40; mortality: 8/40) than in the nondiabetic group (8/12 men; median [percentile 25-75] age: 74.5 [59.3-82] years, HbA1c: 5.5 [5.4-6] %, CRP: 118.7 [74.7-159.7] mg/l, white blood cell count (WBC): 10.95 [8.5-13.4] G/l; sepsis: 4/12; mortality: 1/12). Among T2DM subjects during acute infection no change was found in the MBL activity, however ficolin-3 activity, alternative complement pathway activity were higher (p=0.0061 and p=0.0447, respectively), C4d concentrations were lower (p=0.0138) than in an infection-free period. During infection, C4d concentrations were also lower in the T2DM group than in the nondiabetic group (p=0.025), however no difference was found in the MBL and ficolin-3 activity, alternative complement pathway activity, and C1q concentrations. In the absence of infection, lower C1q levels were found in T2DM than in nondiabetic subjects (p=0.0212), however during infection this difference could not be seen. Interestingly, between C1q and WBC during infection-free period a positive (p=0.0087, Spearman r=0.51), while having an infection a negative correlation (p=0.0054, Spearman r=-0.53) was found.

Conclusion: Our results show that T2DM may be associated with an alteration of not only the ficolin- and MBL-lectin, but also the classical and the alternative complement pathways. This could be a possible cause of the increased risk of infection among patients with T2DM.

PS 056 Fatty acid metabolism: new insights

686

Free fatty acid uptake in different abdominal adipose tissue compartments

P. Dadson¹, L. Landini^{1,2}, J.C. Hannukainen¹, M.-J. Honka¹, H. Immonen¹, M. Soinio³, P. Salminen⁴, J. Pihlajamäki⁵, P. Iozzo⁶, P. Nuutila^{1,3};

¹Turku PET Center, University of Turku, Finland, ²Institute of Clinical Physiology, National Research Council, Pisa, Italy, ³Department of Endocrinology, ⁴Acute and Digestive Surgery, Turku University Hospital, ⁵Clinical Nutrition and Obesity Center, University of Eastern Finland, Kuopio, Finland, ⁶Institute of Clinical Physiology, National Research Council, Pisa, Italy.

Background and aims: Abdominal adipose tissue (AT) contains subcutaneous (SC) deep and superficial layers and intraperitoneal and extraperitoneal visceral AT. There is limited information about differences and the effect of surgery in fatty acid uptake (FAU) in these compartments. We therefore aimed to study tissue-specific FAU in abdominal adipose tissue compartments before and after obesity surgery and compare the results to non-obese subjects.

Materials and methods: A total of 27 severely obese females (BMI 41.4 ± 4.0 kg/m², age 42 ± 9 yrs, 11 T2D and 16 non-T2D) undergoing bariatric surgery and 15 age-matched non-obese healthy women (BMI 22.6 ± 2.8 kg/m²) were recruited into the study. FAU in superficial and deep abdominal SC AT and extra- and intraperitoneal visceral AT was assessed using PET with [¹⁸F] fluoro-6-thia-heptadecanoic acid ([¹⁸F] FTHA). Studies were repeated in obese subjects 6 months after surgery. The controls were studied once.

Results: During the follow-up, both BMI (41.4 ± 4.0 vs 31.8 ± 4.2 kg/m², p < 0.001) and body fat % (50.0 ± 3.7 vs 42.8 ± 4.3%, p < 0.001) decreased, but remained abnormal. Before surgery obese had higher fasting glucose and FFA levels compared to controls, and FFA remained at the same level postoperatively. In obese, abdominal fat FAU (μmol*min⁻¹*100 g⁻¹) was higher in intraperitoneal than extraperitoneal AT (0.81 ± 0.44 vs 0.46 ± 0.29, p < 0.001) and in deep than superficial SC AT (0.38 ± 0.18 vs 0.30 ± 0.16, p < 0.001). Similarly, deep vs superficial AT (0.30 ± 0.16 vs 0.25 ± 0.14, p < 0.01) and intra- vs extraperitoneal AT (0.56 ± 0.27 vs 0.43 ± 0.25, p < 0.01) differed in controls, but no differences were found in tissue-specific FAU between obese and controls, when FAU was expressed per kilogram AT. The FAU per depots of AT was in obese 6-fold higher before surgery and 4-fold higher postoperatively as compared to controls. Surprisingly, the distribution of FAU between SC, and intra- and extra-abdominal depots was similar in obese and controls. Baseline SC FAU correlated with fasting glucose (r = 0.41, p = 0.03) and intraperitoneal FAU with high-sensitivity C-reactive protein (r = 0.47, p = 0.02).

Conclusion: Fatty acid uptake in abdominal AT depots is markedly enhanced in obesity and remains elevated after bariatric surgery. FAU per volume of AT differs between different abdominal AT depots, but remains similar in morbidly obese before and after bariatric surgery. Surgery did not alter FAU in the metabolically distinct abdominal fat compartments. The enhanced metabolic activity in intraperitoneal fat coupled with its association with a marker of low-grade inflammation may be the major contributing factor to the unfavorable glucose homeostasis observed in obese subjects before surgery.

Respective roles of ATGL and HSL on adipose tissue lipolysis-mediated control of glucose metabolism and insulin sensitivity

E. Mouisel, L. Monbrun, P. Morigny, J. Personnaz, M. Houssier, V. Barquissau, G. Tavernier, D. Langin; Obesity Research Laboratory, Institute of Metabolic and Cardiovascular Diseases, Toulouse, France.

Background and aims: We and others showed that pharmacological and genetic inhibition of the neutral lipases, Adipose Triglyceride Lipase (ATGL) or Hormone-Sensitive Lipase (HSL), responsible of adipose tissue lipolysis, improves whole-body glucose metabolism and insulin sensitivity. The underlying mechanisms are not perfectly understood. Recently, our laboratory showed a potentially beneficial upregulation of adipose de novo lipogenesis (DNL) following HSL down regulation in vitro in human adipocytes (see abstract from Morigny et al, EASD 2015). Here, we aimed at deciphering in vivo the roles of ATGL and HSL haploinsufficiency on insulin sensitivity.

Materials and methods: ATGL^{+/+}-HSL^{+/+}, ATGL^{+/+}-, HSL^{+/+}- and wildtype (WT) male C57BL/6J mice were fed 3 months either a chow or a 60% high fat diet and phenotyped at various time points.

Results: Whole-body insulin sensitivity, measured by QUICKI, indicated a higher sensitivity in ATGL^{+/+}-HSL^{+/+}- fed a chow diet in comparison to WT mice (0.47 ± 0.01 vs 0.41 ± 0.01, respectively, p = 0.02). When challenged 3 months with high fat diet, ATGL^{+/+}- (0.36 ± 0.01, p = 0.02), HSL^{+/+}- (0.36 ± 0.01, p < 0.01) and double haploinsufficient mice (0.38 ± 0.01, p < 0.001) showed a significantly higher insulin sensitivity in comparison to WT mice (0.33 ± 0.01). Compared to WT mice fed high fat diet, lipase haploinsufficiency resulted in an improvement of insulin signalling pathway (AktSer473 phosphorylation) and increased expression of master regulator genes of glucose metabolism and DNL in white adipose tissue (WAT). The improvement was more pronounced in ATGL^{+/+}-HSL^{+/+}- mice. There was no difference in fat mass and WAT inflammation between genotypes. In the liver, glycogen content was increased and hepatic steatosis was decreased. Measurements of respiratory quotient suggested a shift from fat to glucose metabolism in the haploinsufficient mice.

Conclusion: Altogether these results shed new light on the role of adipose neutral lipase in the control of glucose metabolism and insulin sensitivity. Whether the mechanisms mediating these improvements are similar or different following ATGL and HSL inhibition is currently under investigation.

Partial inhibition of hormone-sensitive lipase improves insulin sensitivity by induction of de novo lipogenesis and elongase ELOVL6 in human adipocytes

P. Morigny¹, M. Houssier¹, S. Caspar-Bauguil¹, D. Beuzelin¹, A. Mairal¹, E. Mouisel¹, C. Postic², H. Guillou³, D. Langin¹; ¹INSERM U1048 I2MC, Toulouse, ²CNRS UMR 8104, Institut Cochin, Paris, ³INRA UMR 1331, TOXALIM, Toulouse, France.

Background and aims: Partial inhibition of Hormone-Sensitive Lipase (HSL) improves in vivo and in vitro insulin sensitivity. In human adipocytes, HSL inhibition improves glucose metabolism and increases de novo lipogenesis (DNL). Recent studies report a close relationship between adipose DNL, under the control of the transcription factor Carbohydrate Responsive Element Binding Protein (ChREBP), and insulin sensitivity. Consequently, we hypothesized that the improvement of insulin sensitivity observed during HSL inhibition is driven by an increase of DNL.

Materials and methods: In human hMADS adipocytes (human multipotent adipose-derived stem cells), downregulation of HSL (siHSL),

ChREBP (siChREBP), Elongation of Very-Long-Chain Fatty Acids 6 (siELOVL6) or, as control, Green Fluorescent Protein (siGFP) expression has been achieved by siRNA transfection. Glucose metabolism has been measured by radiolabelled glucose. Insulin signaling has been assessed by Western Blot. Fatty acid (FA) composition of phospholipids (PL) has been determined by gas chromatography.

Results: siHSL adipocytes show improved glucose transport, oxidation and DNL in parallel to an increase of ChREBP gene expression (+32%, $p < 0.001$). These cells also present an improved insulin signaling. All these beneficial effects are lost with dual inhibition of HSL and ChREBP. HSL downregulation promotes an increase in PL oleate (+18%, $p < 0.001$) combined with a slight decrease of PL palmitoleate whereas the opposite profile is observed in siChREBP adipocytes. Among ChREBP-induced genes, the elongase ELOVL6 gene expression shows the highest induction in siHSL cells (+93%, $p < 0.001$). Inhibition of ELOVL6 decreases PL oleate in favor of an important increase of PL palmitoleate and results in a significant reduction of the beneficial effects of HSL inhibition on insulin sensitivity.

Conclusion: We have demonstrated that partial inhibition of HSL improves insulin sensitivity and increases DNL pathway through ChREBP induction. ChREBP by a positive control of ELOVL6 is responsible of an increase in oleate synthesis. Increased PL oleate by ELOVL6 could modify plasma membrane fluidity and thereby improve insulin signaling.

Mitochondrial oxidative pathways are downregulated in adipocytes in obesity - a twin study

S. Heinonen¹, M. Muniandy¹, A. Hakkarainen², J. Lundbom^{2,3}, N. Lundbom⁴, J. Kaprio^{5,6}, A. Rissanen¹, K. Pietiläinen^{1,7};

¹Obesity Research Unit, Diabetes and Obesity Research Programs Unit, ²Helsinki Medical Imaging Center, University of Helsinki, Finland, ³Institute for Clinical Diabetology, Leibniz Center for Diabetes Research, Heinrich Heine University, Düsseldorf, Germany, ⁴University of Helsinki, Helsinki Medical Imaging Center, ⁵Department of Health, National Institute for Health and Welfare, Helsinki, ⁶Department of Public Health, ⁷Department of Endocrinology, Abdominal Center, University of Helsinki, Finland.

Background and aims: Low mitochondrial activity in adipose tissue is suggested to be an underlying factor in obesity and its metabolic complications. However it is still unknown whether this is due to malfunction of adipocytes or of other cells in adipose tissue.

Materials and methods: We studied young adult monozygotic (MZ) Finnish twin pairs discordant ($n=14$, $\Delta\text{BMI}>3$ kg/m²) and concordant ($n=5$, $\Delta\text{BMI}<3$ kg/m²) for obesity, aged 22–36-years by assessing abdominal body fat distribution (MRI), liver fat content (MR spectroscopy), insulin sensitivity (OGTT) and global gene expression (Affymetrix U133 plus 2.0 chips) of isolated adipocytes, collagenase digested and washed from subcutaneous abdominal adipose tissue biopsies.

Results: The obese (mean BMI 30.0 ± 1.0 kg/m²) and lean (BMI 23.9 ± 0.8 kg/m²) co-twins of the discordant pairs had a mean 17.6 ± 1.9 kg, $p < 0.001$ difference in body weight. The obese co-twins had more subcutaneous (6068.9 ± 437.4 vs. 3526.1 ± 293.6 cm³, $p < 0.001$), intra-abdominal (1193.1 ± 169.4 vs. 540.5 ± 81.9 cm³, $p < 0.001$) and liver fat (2.93 ± 0.79 vs. $0.62 \pm 0.07\%$, $p < 0.001$), and were more insulin resistant (HOMA-index 1.6 ± 0.2 vs. 1.1 ± 0.2 , $p < 0.01$; Matsuda-index 6.4 ± 0.7 vs. 8.3 ± 0.9 , $p = 0.02$). The concordant pairs were very similar in their measures. The significantly differentially expressed genes in adipocytes between the discordant co-twins (2538 transcripts, adjusted p -value, FDR < 0.05) were related to mitochondrial oxidative phosphorylation, branched chain amino acid catabolism, glucocorticoid receptor signaling and IL-8 signaling. More than one-tenth of these transcripts ($n=278$) were mitochondria-related and almost all of them downregulated (244/278, 88%) in the obese

co-twins. Pathway analysis of the mitochondria-related transcripts revealed reduced oxidative phosphorylation, TCA-cycle, fatty acid beta oxidation, branched chain amino acid degradation and ketone body production and breakdown (all $p < 0.001$) in the obese co-twins. These down-regulated pathways correlated negatively with intra-abdominal and liver fat, HOMA-index, hs-CRP and positively with adiponectin ($p < 0.05$ all) in individual twins.

Conclusion: We report global downregulation of mitochondrial oxidative pathways in obese adipocytes, associating with metabolic disturbances, in young adult MZ twins.

The adipokine adipocyte fatty acid-binding protein in high altitude T. Ebert^{1,2}, J. Pichler Hefti^{3,4}, T.M. Merz³, U. Hefti⁵, A. Hoffmann^{1,2}, M. Stumvoll¹, M. Fasshauer^{1,2}, S. Kralisch^{1,2};

¹Department of Endocrinology and Nephrology, University of Leipzig, ²IFB AdiposityDiseases, Leipzig University Medical Center, Germany, ³Department of Intensive Care Medicine, ⁴Department of Pneumology, University Hospital and University of Bern, ⁵Swiss Sport Clinic, Bern, Switzerland.

Background and aims: Different adipose tissue-secreted adipokines are dysregulated in hypoxia *in vitro*. However, the *in vivo*-effect of prolonged hypobaric hypoxia on serum levels of the insulin resistance-inducing and proatherogenic adipokine adipocyte fatty acid binding-protein (AFABP) has not been comprehensively studied in humans, so far.

Materials and methods: AFABP serum levels were quantified in all participants of the High Altitude Medical Research Expedition Himlung 2013 ($N=39$) by enzyme-linked immunosorbent assay. This expedition is an observational cohort study of human adaption to hypobaric hypoxia and has measured clinical and anthropometric data of the subjects at six time points at different altitudes, i.e. pretest: 550 m; base camp 1: 4800 m; camp 2: 6025 m, base camp 2: 4800 m; camp 3: 7050 m; post: 550 m (Figure 1). Associations were studied using multivariate regression models with relative changes (ratios=parameter at maximum altitude / parameter at start altitude) of the respective parameters.

Results: Median [interquartile range] AFABP serum concentrations increased during the ascent from 11.2 [6.6] $\mu\text{g/l}$ at pretest to a maximum of 34.2 [16.1] $\mu\text{g/l}$ at the peak level, i.e. 7050 m ($p < 0.05$). Barometric pressure was the strongest and negative predictor of AFABP after adjustment for age, gender, and body mass index ($p = 0.003$). In accordance with these findings, altitude was the strongest positive predictor of AFABP when included in this multivariate model instead of barometric pressure ($p = 0.004$). Interestingly, serum levels of the control and obesity-associated adipokine leptin decreased during the ascent (2.8 [4.8] $\mu\text{g/l}$ at pretest as compared to 1.1 [1.7] $\mu\text{g/l}$ at 7050 m) ($p = 0.003$) but no independent associations with relative changes of leptin could be demonstrated.

Conclusion: Circulating AFABP is increased during a high altitude ascent and is independently associated with barometric pressure, as well as with altitude level. These data are in accordance with the hypothesis that hypoxia could contribute to an adverse metabolic profile in humans. Further studies need to elucidate the pathophysiological significance of AFABP upregulation in high altitude/hypoxia.

Human brown adipose tissue oxygen consumption after meal is similar to cold activated consumption

M. U Din¹, J. Raiko¹, T. Saari¹, N. Kudomi², R. Parkkola³, P. Nuutila^{1,4}, K.A. Virtanen¹;

¹Turku PET Centre, Turku University Hospital and University of Turku, Finland, ²Department of Medical Physics, Faculty of Medicine, Kagawa University, Kita-gun, Japan, ³Medical Imaging Centre of Southwest Finland, ⁴Department of Endocrinology, Turku University Hospital, Finland.

Background and aims: Diet-induced thermogenesis in human brown adipose tissue (BAT) has not been widely examined. Therefore, we aimed to compare BAT oxygen consumption during cold activation and after standardised meal.

Materials and methods: Healthy lean and obese study subjects (n=14, age: 36.2±12.0 years, BMI range: 23.3 - 34.2 kg/m²) of both genders (10 F/4 M) were studied at two different scanning sessions, 1) after standardised meal (542 kcal, 58% carbohydrates, 25% fats, 17% proteins) at room temperature (RT) and 2) after overnight fasting during acute cold exposure, using PET-CT. Radioactive oxygen [¹⁵O]O₂ and [¹⁵O]H₂O were given to measure oxygen consumption and perfusion in BAT, respectively. Indirect calorimetry was performed to assess the differences in whole body resting energy expenditure (REE) and whole body substrate oxidation between post-prandial state and cold exposure.

Results: Supraclavicular BAT oxygen consumption during cold was 1.7±0.6 ml/100 g/min while after standardised meal it was 2.0±1.0 ml/100 g/min (p=0.81). There was no relation between BAT oxygen consumption measured during cold and post prandial state (r=-0.15; p=0.66). As expected, post-prandial plasma insulin level was higher than plasma insulin levels during fasting and cold exposure (p<0.001). Whole body REE during cold and post-prandial state was at the same level (7.7±1.0 MJ/day and 7.4±0.9 MJ/day, p=0.50, respectively). During post-prandial state whole body glucose oxidation was higher than in cold (p<0.001), while in cold whole body fat oxidation was higher compared to post-prandial state (p<0.001). Post-prandial BAT oxygen consumption correlated negatively with waist circumference (r=-0.77; p=0.006).

Conclusion: Similar oxygen consumption in post-prandial state and in cold suggests that human BAT has diet-induced thermogenic capacity. However, mechanism of action and substrate utilisation responsible for enhanced BAT oxygen consumption in these two states appear to be different. Since BAT is insulin sensitive we speculate that BAT oxygen consumption in post-prandial state is potentially due to insulin mediated substrate utilisation.

Clinical and laboratory characteristics of 14 patients with Berardinelli-Seip syndrome

R.M. Montenegro Jr¹, A.D.R. Montenegro¹, V.O. Fernandes¹, L.A.S. Karbage¹, C.M.M. Ponte¹, M.C.G. Castelo¹, M.M.D. Carvalho¹, D.D. Gadelha¹, M.L. Aragão¹, S.C. Lopes¹, A.A.M. Sales¹, C.B.R. Liberato¹, L.B. Aguiar¹, A.P. Moraes², C.B. D'Alva¹;

¹Faculty of Medicine - Federal University of Ceara, ²São José Hospital of Infectious Diseases, Fortaleza, Brazil.

Background and aims: Congenital generalized lipodystrophy (CGL) or Berardinelli-Seip syndrome (BS) is a rare disease that affects 1: 10.000.000 live births. This condition is inherited in an autosomal recessive pattern. These individuals have total or near total absence of subcutaneous tissue since birth. This condition is associated to severe insulin resistance and, in general, these patients develop early metabolic disorders such as diabetes and hypertriglyceridemia. Others clinical manifestations are hepatic steatosis and hepatic cirrhosis, muscle hypertrophy and acanthosis nigricans. The aim of this study was to describe the clinical and laboratory characteristics of patients with BS residents in the state of Ceara-Brazil.

Materials and methods: We studied 14 patients with BS. They performed a complete clinical evaluation, image exams and collected laboratory tests for metabolic evaluation. Data were analyzed in STATA 11.2 program. Results were expressed as mean±standard deviation (SD).

Results: 71.43% of patients were women; the mean age was 10.78±8.29 years old. BS family history was present in 21.43% and inbreeding in the family 64.29%. All patients had muscle hypertrophy, prominence of veins, acanthosis nigricans and no clinical evidence of peripheral adipose tissue. The mean body fat percentage of these individuals, rated by bioelectrical impedance analysis, was 8.56±3.53%. Diabetes was present in 50% of subjects. The age mean in diabetes diagnosis was 7.73±6.52 years old. After adjusted for sex, age and height, 88.89% had high blood pressure; 69.23% hypertriglyceridemia; 84.62% low HDL-c and 25% hypercholesterolemia. Imaging studies showed hepatomegaly in 92.86%, hepatic steatosis in 28.57%, splenomegaly in 35.71%, nephromegaly in 61.54% and left ventricular hypertrophy in 40% of the subjects. Laboratory findings were: A1C: 7.06±2.30%, fasting glucose: 109.14±78.60 mg/dL, insulin: 28.04±31.18 µUI/mL, HOMA-IR: 3.83±3.21, total cholesterol: 192.46±179.83 mg/dL, HDL-c: 29.84±8.73 mg/dL, LDL-c: 80.82±28.04 mg/dL, triglycerides: 188.08±186.09 mg/dL, leptin: 1.19±0.26 ng/mL and albumin/creatinine ratio: 85.80±113.20 mg/g.

Conclusion: The patients with BS have important metabolic disturbances since childhood, with multiple cardiovascular risk factors. Thus, it is necessary an early therapeutic intervention in this population to minimize the complications inherent to these condition.

PS 057 The cancer connection

Type 2 diabetes and a reduced risk of prostate cancer: a case for a spurious association

E.L. Badrick¹, M. Sperrin¹, T. Moran², I. Buchan¹, A. Renehan¹;
¹Institute of Population Health, University of Manchester, ²Cancer Registry, Manchester, UK.

Background and aims: Several studies from western populations indicate that men with Type 2 Diabetes (T2D) are paradoxically at reduced risk of developing incident prostate cancer (PC), but recent data from Asian-Pacific populations indicate that, here, there is a positive association between T2D and PC. In addressing aetiological inference, we hypothesise that such contrasting relationships reflect methodological rather than biological mechanisms.

Materials and methods: We used the Salford Integrated record database linked with the Northwest Cancer Intelligence service (UK) (1995-2010). We identified incident male cohorts with (N=5,069) and without T2D (N=41,812), who were matched (1: 3) by year of birth and smoking status. We explored two broad methodological models to estimate risk: (A) a fixed ever/never method based on prevalent T2D in 1999 (commonly used in the literature); and a (B) time-varying approach allowing for date of T2D diagnosis to be a varying exposure, until the diagnosis of PC. Risk estimates were expressed as hazard ratios (HRs) and their 95% confidence intervals (CIs) using a split-interval approach and age as the timescale.

Results: Using model A, there were 1,098 new diagnoses of PC, the risk of incident PC in men with T2D was reduced (HR: 0.54, 95% CIs: 0.31, 0.94), similar to estimates reported in the literature. Using model B, mean follow-up time was 6.80 years we observed that within 6 months following T2D diagnosis, there was an increased 'spike' co-diagnosis of PC. Analysing beyond 2 years, the association between T2D was null (HR: 0.96, 95% CIs: 71, 1.29).

Conclusion: These findings support the hypothesis that the apparent protective association between T2D and risk of PC might be spurious, and reflect methodological rather than true biological mechanisms. These analyses need to be repeated in a larger independent dataset.

Deterioration of glycaemic control as a clue to finding occult cancer

A. Reiko, H. Eguchi, Y. Ueda, Y. Tahara, S. Kaneko;
 Diabetes, Endocrinology and Life-related Disease, Takatsuki Red Cross Hospital, Japan.

Background and aims: Hyperglycemia, insulin resistance and hyperinsulinemia have been implicated in promoting carcinogenesis. On the other hand, cancer associated factors worsen insulin resistance, and glycemic control of cancer bearing diabetic patients often deteriorates. Either way, deteriorated glycemic control is believed to be an important clue to finding occult cancer in patients with diabetes.

Materials and methods: We tried to confirm whether deteriorated glycemic control was a clue to finding occult cancer in patients with diabetes and investigated whether it applies to every type of cancer. We investigated the medical records for diabetic patients with cancer going back over a period of 8 years. Their trends in glycemic control in relation to types and stages of cancer were analyzed.

Results: During 8 years from 2006 to 2013, 755 diabetic patients were newly diagnosed with cancer. Lung cancer was most common and found in 167 patients, followed by 114 colorectal, 110 gastric, 72 prostate, 40 pancreas, 36 hepatocellular, 26 kidney or urethra-bladder, 24 breast cancers and 20 uterine cancers. Cancers with diagnosed patient numbers

under 20 were excluded for analysis. HbA1c significantly elevated in gastric cancer as the stage advanced. However, gastrointestinal bleeding causes apparent decrease in HbA1c regardless of glycemic control, and should be given attention. HbA1c of patients with pancreatic cancer rose significantly in stage 2. Although statistically not significant, HbA1c of patients with hepatocellular carcinoma tended to increase as the stage advanced. HbA1c of patients with kidney or urethra-bladder elevated in stage 0 or 1 more significantly than stage 4. In patients with uterus cancer, HbA1c rose significantly as the stage 0 to 1 advanced. On the other hand, HbA1c of lung or prostate cancer-bearing patients was not elevated even in advanced stages.

Conclusion: Deterioration of glycemic control can be a promising clue to detect occult gastric, pancreatic, kidney or urethra-bladder, and uterus cancers. However, lung or prostate cancers had little effect on glycemic control. Keeping good glycemic control is not only essential for prevention of diabetic complication, but also helps early detection of pancreatic cancer, improvement of personal prognosis and the saving of medical economics.

695

p38 MAPK inhibitor suppresses diabetic pancreatic tumour growth and epithelial-mesenchymal transition-mediated metastasis via reducing inflammation

L. Wang, J. Zhou;
 Department of General Surgery, Zhongda Hospital, Medical School, Southeast University, Nanjing, China.

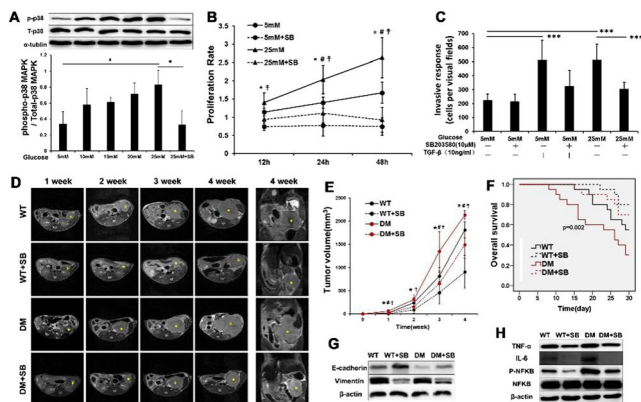

Background and aims: Diabetes contributes to chronic inflammation and promotes tumor progress. p38 mitogen-activated protein kinase (MAPK), as an essential kinase of inflammation, plays an important role in tumor growth. However, the effects of p38 MAPK on epithelial-mesenchymal transition (EMT)-mediated diabetic pancreatic cancer metastasis remains unclear. The aim of this study was to investigate the effects of p38 MAPK inhibitor on pancreatic cancer growth and metastasis in diabetic animals.

Materials and methods: C57BL/6 mice were intra-peritoneally administered with streptozotocin for 5 days and then fed with high fat diet in following 3 weeks to establish animal models of type 2 diabetes. p38 MAPK inhibitor, SB203580, was intravenously injected into pancreatic cancer mice for 7 consecutive days after surgical orthotopic implantation.

Results: Glucose does-dependently increased the phosphorylation of p38 MAPK ($P < 0.05$, Fig. A) and time-dependently increased the proliferation ($P < 0.05$, Fig. B) of pancreatic cancer cells which were both significantly reduced by SB203580. Transwell assay showed that SB203580 significantly inhibited both high glucose and TGF- β induced cancer cell invasion ($P < 0.001$, Fig. C). The orthotopically implanted tumors in wild-type controls and diabetic mice treated with SB203580 or saline were monitored by MRI in 1, 2, 3 and 4 weeks ($n = 20$ /group, Fig. D). Tumor volume measurement showed that the diabetic cancers grew much more rapidly than non-diabetic controls ($P < 0.05$, Fig. E), while SB203580 treatment significantly suppressed the tumor growth both in non-

diabetic and diabetic mice ($P < 0.05$, Fig. E). Survival curves showed that SB203580 could significantly increase the survival of diabetic and non-diabetic pancreatic cancer mice ($P = 0.02$, $n = 20/\text{group}$, Fig. F). In addition, Western blot analysis of tumors showed that diabetes decreased the expression of E-cadherin while increased the expression of vimentin; however, SB203580 treatment could reverse the above EMT process ($P < 0.05$, $n = 6/\text{group}$, Fig. G). Furthermore, the pro-inflammatory factors (IL-6, TNF- α , NF κ B) in diabetic pancreatic tumors were significantly reduced in SB203580-treated groups ($P < 0.05$, $n = 6/\text{group}$, Fig. H).

Conclusion: Diabetes induced the phosphorylation of p38 MAPK and inflammation, which promoted the proliferation and EMT-mediated metastasis of pancreatic cancers; while SB203580 suppressed the diabetes-induced tumor growth and EMT. Our results indicate that p38 MAPK inhibitor may provide a novel intervention strategie for diabetic pancreatic cancer patients.

Differential expression of the E2F family in the carcinogenesis accelerated by liver steatosis

K. Tanaka¹, S. Otabe¹, S. Kakino¹, E. Soejima¹, X. Yuan¹, H. Nakayama¹, O. Nakashima², K. Hara¹, T. Ohki², N. Wada¹, T. Hashinaga¹, T. Egashira¹, Y. Tajiri¹, K. Yamada¹;

¹Endocrinology and Metabolism, ²Clinical Laboratory Medicine, Kurume University, Japan.

Background and aims: Obesity and type 2 diabetes are major risk factors for non-alcoholic steatohepatitis (NASH) and hepatocellular carcinoma (HCC). Although various factors including insulin resistance and oxidative stress have been implicated in the development of HCC, the precise mechanism of the carcinogenesis remains to be determined. The E2F family is a group of transcription factors that plays pivotal roles in the regulation of cellular proliferation and apoptosis. The family is currently divided into pro-proliferative (E2F1-E2F3) and anti-proliferative (E2F4-E2F8) members. We tested a hypothesis that the differential regulation of the E2F family is involved in the development of HCC associated with steatosis.

Materials and methods: We used wild-type C57BL/6 mice, adipocyte-specific nSREBP-1c transgenic mice that exhibit liver steatosis and insulin resistance, and liver-specific cyclin D1 (Cnd1) transgenic mice that develop HCC at around the age of 60 weeks or later. A Cnd1/nSREBP-1c double transgenic mouse line was generated to assess the effect of liver steatosis on the development of HCC. Gene expressions were measured by DNA microarray analysis and quantitative RT-PCR. Protein expressions were determined by the Western blot analysis.

Results: Wild-type mice fed a high-fat/high-sucrose diet from the age of 8 weeks became obese and developed diabetes before the age of 20 weeks. The expression of E2f2 was higher in the liver compared with mice fed normal chow, while that of E2f8 was lower. Similarly, the expressions of

E2f2 and E2f8 were increased and decreased, respectively, in the liver from nSREBP-1c transgenic mice. However, in Cnd1 transgenic mice that had no liver steatosis, the expressions of E2f2 and E2f8 were comparable to those of wild-type mice. At the age of 52 weeks, small hepatic tumors were detected in 10 of 48 Cnd1 transgenic mice. In contrast, Cnd1/nSREBP-1c double transgenic mice that had liver steatosis developed multiple hepatic tumors with histological features corresponding with those of human HCC (34 of 34 mice, $p < 0.00001$). The expressions of E2f2, Ccna2 and Ccnb1 were significantly increased in the background liver tissue, whereas the expression of E2f8 was markedly reduced. Immunohistochemical analysis showed that the proliferating cell nuclear antigen was positive in the nuclei of the non-tumor tissue.

Conclusion: We demonstrated that steatosis accelerated carcinogenesis in the liver of the cancer-susceptible mice. Both Ccna2 and Ccnb1 are target genes of E2F2 and E2F8; E2F2 enhances the expression of the cyclin genes whereas E2F8 represses it. Although the expression levels of E2F members in human HCC and their association with prognosis are still controversial, these observations suggest that the up-regulation of E2F2 and the down-regulation of E2F8 may be involved in the development of HCC in patients with obesity and type 2 diabetes, probably through the modulation of cyclin gene expression.

Glucose-induced CCL5 release by human adipocytes promotes breast cancer invasiveness and distant metastasis

V. D'Esposito¹, D. Liguoro¹, M.R. Ambrosio¹, M. Cantile², F. Collina², G. Mosca¹, A. Buonomo¹, M. Lecce¹, L. Albano¹, F. Beguinot¹, M. Di Bonito², R. Franco², P. Formisano¹;

¹Department of Translational Medicine, University of Naples "Federico II"; IEOS/CNR & URT "Genomica del Diabete", ²National Institute of Tumors, Foundation "G. Pascale", Naples, Italy.

Background and aims: Type 2 diabetes (T2D) is associated with an excess risk of several forms of cancer. In particular, women with diabetes have a statistically significant 20% increased risk of breast cancer. Additionally, patients with breast cancer and preexisting diabetes have an increased of metastasis and of all-cause mortality compared with their nondiabetic counterparts. Breast cancer grows and metastasizes to a predominantly adipocyte-dominated host environment. T2D induces adipocyte alterations leading to an imbalanced adipokine production that in turn may promote cancer phenotypes. We have studied the mechanisms by which adipocytes integrate inputs from T2D-induced alterations and promote breast cancer cell motility and invasiveness.

Materials and methods: Human Stromal Vascular cells were isolated by adipose tissue biopsies, differentiated in adipocytes and incubated in the presence of different concentrations of glucose. Adipocyte conditioned media and co-cultures were established to investigate MDA-MB-231 breast cancer cell motility and invasiveness. Adipocyte-released factors were determined by ELISA multiplex. CCL5 and IGF1 expression in peritumoral adipose tissue was evaluated by immunohistochemistry.

Results: We have obtained evidence that human adipocytes exposed to high glucose concentration (25 mM) induce breast cancer cell proliferation, migration and invasion. Screening for several cytokines revealed that adipocytes cultured in high glucose medium release 1.5 and 2-fold higher amount of IGF1 and CCL5, respectively, compared to those cultured in low glucose medium (5.5 mM glucose). Moreover, adipocyte-released factors control IGF1, but not CCL5 expression in cancer cells. Inhibition of IGF-1 pathway almost completely prevented the effect of adipocytes on breast cancer cell growth but only slightly interfered with cancer cell motility. At variance, inhibition of CCL5 action by specific peptides and antibodies reduces adipocyte promoting effect on breast cancer cell migration and invasion. Interestingly, CCL5/RANTES expression in peritumoral adipose tissue of women with Triple Negative

Breast Cancer correlated with lymph node (p-value=0.04) and distant metastases (p-value=0.001). A positive correlation was also observed between CCL5 expression and T2D. Finally, Kaplan-Meier curves showed a significant negative correlation between CCL5 staining in the peritumoral adipose tissue and overall survival of patients (p-value=0.039).

Conclusion: Hyperglycemia induces adipocyte release of CCL5 that, in turn, contributes to cancer cell motility, cancer lymph node and distant metastases, which may contribute to reduce the overall survival of patients.

Chronic hyperglycaemia enhances the malignant molecular communication between the human pancreatic stellate and cancer cells

G. Firneisz¹, K. Kiss², K. Baghy², S. Spisak³, S. Szanyi⁴, Z. Tulassay¹, A. Zalatnai², J.-M. Löhr⁵, R. Jesenofsky⁶, I. Kovalszky²;

¹2nd Department of Medicine, ²1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary, ³Children's Hospital, Harvard Medical School, Boston, USA, ⁴Semmelweis University, Budapest, Hungary, ⁵Karolinska Institutet, Stockholm, Sweden, ⁶Medical Campus Mannheim, Dept. of Medicine II, University of Heidelberg, Mannheim, Germany.

Background and aims: The association between diabetes mellitus (DM) and pancreatic cancer (PaC) was established by epidemiologic studies. It was concluded that DM is not only an early manifestation, but also an etiologic factor of PaC. We hypothesized a role for pancreatic stellate cells (PSC) in the hyperglycemia induced deterioration of pancreatic cancer. Therefore studied two human cell lines (RLT-PSC, T3M4) in hyperglycemic environment.

Materials and methods: In case of 'chronic hyperglycemia' (CHG) exposure RLT-PSC cells were cultured in a medium containing 15.3 mmol/L glucose for 21 days. Subsequently, cells were starved for 24 hours in FBS-free medium and thereafter for 48 hours in FBS-free medium either with or without TGFβ1. The effect of CHG on PSCs was studied using mRNA expression array (GeneChip PrimeView, Affymetrix) with real-time PCR (ABI Gene Expression TaqMan®) validation and bioinformatic pathway analysis (MetaCore, Thomson Reuters). Main results were also confirmed using protein studies (ELISA, WB, IC). The effect of PSC-conditioned media and hyperglycemia on T3M4 pancreatic cells was assessed in proliferation and migration assays.

Results: The stress fiber formation (IC αSMA) indicated that PSCs tend to trans-differentiate to a myofibroblast-like state after CHG exposure. Glucose transporters (types-1, -2, and -3) were expressed on RLT-PSC and T3M4 cells. The phosphorylation of p38 and ERK1/2 was increased with a consecutive upregulation of CDC25, SP1, cFOS and p21, and with downregulation of PPARγ after PSCs were exposed to chronic hyperglycemia.

CXCL12 levels increased significantly in PSC supernatant after cells were exposed to CHG regardless of TGF-β1 treatment (3.09-fold with and 2.73-fold without TGF-β1, p<0.05). Treatment of PSCs - kept in normal glucose concentration with TGF-β1 treatment in a 2.69-fold increase of CXCL12 levels. When the TGF-β1 treatment was applied subsequently after that PSCs were exposed to CHG it resulted in a significant (3.78 fold, p<0.05) IGFBP2 protein level elevation in the supernatant. In cancer cells, hyperglycemia induced an increased expression of CXCR4, a CXCL12 receptor that was also induced by PSC's conditioned medium. The receptor-ligand interaction increased the phosphorylation of ERK1/2 and p38. Conditioned medium of PSC increased pancreatic cancer cell proliferation and this effect could be partially inhibited by a CXCR4 inhibitor (AMD3100). The PSC conditioned medium (even under normal glucose concentration) could increase the ERK1/2 and p38 phosphorylation.

Conclusion: Hyperglycemia induces increased CXCL12 production by the human PSCs, and its receptor, CXCR4 on cancer cells. The ligand-receptor interaction activates MAP kinase signaling that further increases the cancer cell proliferation and migration. The upregulation of the SP1 transcription factor in PSCs after CHG exposure may result in the increased CXCL12 and IGFBP2 production.

Insulin and IGF-1 promote pancreatic stellate cells activation and galectin-3 expression: potential role in promotion of pancreatic cancer

X. Zhu¹, R. Waldron^{2,3}, A. Lugea^{2,3}, L. Li^{1,3};

¹Department of Endocrinology, affiliated ZhongDa Hospital of Southeast University, Nanjing, China, ²Cedars-Sinai Medical Center, ³VA Greater Los Angeles Healthcare System, University of California, Los Angeles, USA.

Background and aims: Epidemiological studies indicate that the risk of pancreatic cancer (PC) is increased in type 2 diabetic patients. Insulin and insulin-like growth factor (IGF-1) play an important role in carcinogenesis. Insulin resistance and associated hyperglycemia, hyperinsulinemia, and abnormalities in insulin/IGF receptor pathways have been suggested to be the underlying mechanisms contributing to development of diabetes-associated pancreatic cancer. Activated pancreatic stellate cells (PSCs) are key stroma cells responsible for pancreatic fibrogenesis and pancreatic cancer progression. The aim of this study was to elucidate PSCs functional responses to insulin and IGF-1.

Materials and methods: In primary mouse PSCs and a novel immortalized mouse pancreatic stellate cell line (impSCs), we examined the effects of insulin and IGF-1 on PSCs activity. Cells were stimulated with 100 nmol/L insulin or 10 nmol/L IGF-1. We determined expression of α-smooth muscle actin (α-SMA) and galectin-3, measured matrix synthesis of collagen I (Col-I) and fibronectin (FN), and analyzed the expression of insulin/IGF-1 signaling pathway components and their operation as profibrotic and/or proliferative pathways and assessed the potential contributions of PSCs to a procarcinogenic microenvironment.

Results: PSCs express receptors for both insulin (IR) and insulin-like growth factor 1 (IGF-1R), and respond to insulin/IGF-1 stimulation with increased tyrosine phosphorylation at specific autophosphorylation sites. Akt/mTOR/p70S6K signaling were activated. α-SMA expression were induced when PSCs were incubated with either insulin (1.75±0.06 of control, P<0.01) or IGF-1 (8.16±0.04 of control, P<0.01). Galectin-3 production of PSC was enhanced after incubation with insulin (1.83±0.07 of control, P<0.01) or IGF-1 (9.80±0.06 of control, P<0.01). Col-I and FN production were also increased (P<0.05). IGF-1 was four to five times more potent than insulin. Results in impSCs were in accordance with primary mouse PSCs.

Conclusion: Our study suggests that insulin and IGF-1 play an important role in the activation of PSCs and progression of fibrosis. Increased expression of galectin-3 and abnormalities in insulin/IGF receptor signaling network may be involved in development and progression of diabetes-associated pancreatic cancer.

The postprandial glucose response is not a good reflection of the actual rate of glucose release from a starchy food: an exploratory study using dual stable isotope technique

H.P.F. Peters¹, H.M. Boers¹, T.H. van Dijk², C. Eelderink³, H. Hiemstra¹, A.R. Hoogenraad¹, D.J. Mela¹, M.G. Priebe³;

¹Unilever R&D, Vlaardingen, ²Dept of Laboratory Medicine, University of Groningen, University Medical Center Groningen, ³Center for Medical Biomics, University Medical Center Groningen, Netherlands.

Background and aims: We have shown that guar gum added to a flat bread flour lowers postprandial blood glucose and insulin dose-dependently, probably due to the viscosity-inducing effects of the fibre. However, the glucose influx rate from a starchy food source is not established by measuring only total blood glucose, as this is the net result of glucose absorption, glucose disposal into tissues and hepatic glucose production rates. The aim of this study was therefore to measure the actual rate of glucose release from the food and related glucose fluxes, and to obtain more insight into the mechanism of glucose lowering, by using the dual isotope technique and measuring incretin hormones.

Materials and methods: In a double-blind, randomized, placebo-controlled, cross-over design, 12 healthy males consumed each of three flatbread test products labelled with ¹³C-wheat flour: a control (C), or C with the incorporation of 15% chickpea with either 2% (GG2) or 4% (GG4) guar gum. By a 6 h primed-continuous infusion of D-[6,6-²H₂] glucose the appearance of exogenous glucose (RaE), endogenous glucose production (EGP) and glucose clearance (GCR) rates could be calculated. Plasma glucose, insulin, GIP and GLP-1 were measured for 4 h postprandially. All data were calculated as 2 h and (except glucose) 4 h area-under-the-curve (AUC). As the study was explorative, statistical significance was assessed by comparing the confidence intervals of the changes after GG2 and GG4 compared to C.

Results: Compared to C, GG2 reduced glucose by 14% (NS) and insulin by 16% (P<0.05), while 4 h AUC values for RaE, GCR and EGP were reduced slightly by 3, 5 and 3%, respectively (all NS). Changes after GG4 were more distinct and all significant (all P<0.05): glucose was reduced by 26% and insulin by 23%, while RaE, GCR and EGP were reduced by 11, 12 and 64%, respectively. The 2 h and 4 h effect sizes were similar for RaE and GCR, but the 2 h values for EGP were bigger, namely 36 and 80% greater suppression after GG2 and GG4 respectively (both P<0.05) compared to C. Postprandial changes in GIP and GLP-1 did not differ significantly between products.

Conclusion: Using the dual isotope technique, we found that the lower glucose response to GG2 and GG4 was not clearly dominated by a reduced absorption rate, as might be expected for a viscous fibre, but was perhaps even more due to post-absorptive effects (GCR and EGP). The data suggest that small initial changes in RaE could potentially result in larger post-absorptive effects. The lower GCR was in accordance with the lower insulin response after the test meals, but EGP was not. EGP was paradoxically more suppressed after the test meals than after the control, especially during the first 2 h, which could also not be explained by the other incretin hormones. These data reinforce the view that the rate of glucose release from carbohydrate-rich foods cannot be assumed from the postprandial glucose response, but must be measured using labelled tracers.

Metabolic and molecular effects of a high-protein diet in subjects with type 2 diabetes

M. Markova¹, S. Hornemann¹, S. Sucher¹, O. Pivovarova^{1,2}, A. Pfeiffer^{1,2};

¹Clinical Nutrition, German Institute of Human Nutrition (DIfE), Nuthetal, ²Department of Endocrinology, Charité University Medicine, Berlin, Germany.

Background and aims: Previous studies reported both favourable and adverse impacts of high-protein diet in type 2 diabetes. In our clinical study we compared effects of two isocaloric high-protein diets of animal (AP) and plant (PP) origin on metabolic markers, liver fat content and signalling pathways in white blood cells and adipose tissue.

Materials and methods: Individuals with type 2 diabetes (age 65±6 years, BMI 30.5±3.6 kg/m², HbA1c 7.0±0.6%, n=30) were randomized to either high-animal (meat and dairy foods) or high-plant (dietary pulses) protein diet (30% protein, 40% carbohydrates, 30% fat) for 6 weeks. Before and after the diet intervention, magnetic resonance imaging, hyperinsulinemic euglycemic clamps, and meal tolerance tests were performed, and blood and subcutaneous adipose tissue samples were collected. Key proteins of the Akt/mTOR signalling pathway were analysed in isolated white blood cells and adipose tissue using PathScan Antibody Array (Cell Signaling).

Results: Levels of liver parameters (AST, ALT, GGT) in blood improved after diet intervention in both groups. Liver fat content and HbA1c levels were reduced in all subjects (AP: -43.6%, p<0.001; PP: -37.1%, p<0.001, and AP: -0.58%, p<0.05; PP: -0.41%, p<0.001, respectively). The clamp-derived insulin sensitivity improved significantly only in the AP group (Δ M-value=0.88 mg/kg BW/min, p<0.05). In the PP group there was a significant reduction of plasma creatinine (-7.79 μ mol/l, p<0.01) and improvement of the glomerular filtration rate (from 75.95 to 88.15 ml/min/1.73 m², p<0.001) which was not found in the AP group. We did not observe any alteration of the Akt/mTOR pathway in white blood cells after the dietary intervention. However, in adipose tissue the phosphorylation of AMPK, Erk1/2 and 4E-BP1 was approximately 2-fold higher in the AP group, whereas in the PP group the phosphorylation of Bad and PDK1 was significantly increased.

Conclusion: In diabetic subjects, the 6-week high-protein diet leads to an improvement of glucose metabolism and decrease of liver fat content independently from the protein origin. The high-protein diet has no adverse effects on kidney parameters, moreover the kidney function improved in the plant protein group. On molecular level, we observed the dietary-induced increase of the phosphorylation of some proteins of Akt/mTOR pathway in subcutaneous adipose tissue, but not in blood cells, indicating a differential modulation of intracellular signalling pathways.

Effects of medium-chain saturated dairy fat on the body composition of abdominal obese subjects (DairyHealth): a 12-week, randomised, double-blinded, intervention study

M. Bohl¹, A. Bjørnshave¹, M.K. Larsen², S. Gregersen¹, K. Hermansen¹;

¹Department of Metabolism and Endocrinology, Aarhus University Hospital, ²Department of Food Science, Aarhus University, Tjele, Denmark.

Background and aims: Obesity, reduced insulin sensitivity and hypertension are important risk factors for cardiovascular disease (CVD) and type 2 diabetes (T2D). These risk factors are influenced by the dietary behavior. Thus the consumption of dairy products e.g. whey protein and medium-chain saturated fatty acids (MC-SFA) may have a beneficial impact.

Materials and methods: We conducted a 12-week randomized, double-blinded, parallel controlled, diet intervention study in 63 abdominal obese subjects. Subjects were randomized into one of four diets in a 2×2 factorial square design: 60 g/day of whey or casein combined with 63 g/day of milk fat with either high (8.5 g/day) or low content of MC-SFA (6.9 g/day). Body composition was assessed by dual-energy x-ray absorption scan at baseline and after intervention. We estimated insulin sensitivity using the homeostatic model assessment (HOMA-IR) and the Matsuda Index. In addition, diurnal blood pressure (24-h BP) was measured. Two-way ANOVA analysis was used to examine the difference between the whey and casein supplementation and between the high and low MC-SFA supplementation, as well as to elucidate potential interactions between the protein and the MC-SFA.

Results: Fifty-two subjects completed the intervention. We found that lean body mass increased by 981 g (95%CI: 248, 1713; $p=0.010$) by the diet supplemented with milk fat high rather than low in MC-SFA, whereas total body fat percentage was lowered by 0.70% (95%CI: 0.10, 1.31; $p=0.024$). These changes were independent of the protein type. We found no difference in HOMA-IR, the Matsuda Index, glycated hemoglobin, or 24-h BP between protein type or fat composition.

Conclusion: In conclusion, supplementation with milk fat enriched in MC-SFA via a feasible cattle feeding regimen resulted in increased lean body mass and lower total body fat percentage in abdominal obese subjects underlining the importance of the fat quality in dairy products.

Differential effects of carbohydrate vs fat overfeeding on liver fat content and lipid metabolism in healthy overweight males

C. Chee¹, P. Mansell², F. Stephens¹, S. Cordon¹, M. Kavani³, S. Bawden³, C. Hoad³, P. Gowland³, I. Macdonald¹;

¹University of Nottingham, ²Nottingham University Hospitals NHS Trust, ³Sir Peter Mansfield MRI Centre, Nottingham, UK.

Background and aims: Ectopic fat accumulation is thought to be an important contributor to insulin resistance and diabetes. Excess energy consumption has been shown to increase liver fat content and reduce insulin sensitivity, but it is unclear to what extent this is influenced by dietary composition. We investigated the degree to which liver fat, liver and lipid markers are affected by 2 weeks of overfeeding at 25% excess energy given as either carbohydrate or fat.

Materials and methods: After 1 week of ingesting an isocaloric diet, 21 overweight but healthy males (40.3±2.5 yrs; BMI 31±1.0 kg m⁻²) underwent 3 T H1Magnetic Resonance Spectroscopy (H1 MRS, Philips Achieva) of their liver and magnetic resonance imaging (MRI) of their abdomen to measure liver fat content and visceral fat respectively. Fasting serum insulin, glucose, triacylglyceride (TAG), free fatty acids (FFAs), lipoproteins, total cholesterol and liver function were also obtained. Subjects were then randomised into 2 groups of ingesting either a hyperenergetic (25% excess) high fat (HF) n=11, (42.2±2.4 yrs, BMI 30.5±0.9 kg m⁻²) or high carbohydrate (HC) n=10, (38.3±2.4 yrs, BMI 31.5±1.0 kg m⁻²) diet for two weeks. The diets comprised either high carbohydrate (65% CHO, 20% Fat, 15% Prot) or high fat (38% CHO, 47% Fat, 15% Prot). After two weeks, H1MRS liver, MRI abdomen and fasting bloods were repeated.

Results: After 2 weeks of excess energy consumption, there was an overall main effect of time on liver fat content (increased by 2.2±0.8%; $p<0.05$) which approached significance in the high carbohydrate group (increased by 2.8±1.8%; $p=0.06$) but not in the high fat group (increased by 1.6±1.1%; $p=0.3$). Fasting TAG in the whole group increased by 0.33±0.13 mmol/l ($p<0.05$), and this was notably higher in the high carbohydrate group where TAG increased by 0.45±0.14 mmol/l ($p<0.05$). In the whole group both Apolipoprotein A and B increased by 0.08±0.01 g/L, $p<0.01$ and 0.07±0.01 g/L $p<0.01$ respectively. The increase in

Apolipoprotein A and B was greater in the high fat group (0.13±0.03 g/dL and 0.10±0.03 g/L; $p<0.01$ respectively). There were no changes in body mass, visceral fat, HOMA-IR, or fasting insulin, glucose, FFAs, total cholesterol or liver function after 2 weeks of overfeeding in either the whole group or between dietary groups.

Conclusion: Two weeks excess energy consumption increased liver fat content, TAG, Apolipoprotein A and B. This deleterious effect of overfeeding on liver fat and markers of liver function and lipid appears to be more pronounced in the high carbohydrate-fed group.

Angiotensin converting enzyme increases in response to a high fat diet

R. Schüler¹, M.A. Osterhoff^{1,2}, T. Frahn¹, A.-C. Seltmann¹, L. Xu¹, A. Busjahn³, S. Kabisch^{1,2}, S. Homemann¹, M. Kruse¹, A.F.H. Pfeiffer^{1,2};

¹Clinical Nutrition, German Institute of Human Nutrition Potsdam-Rehbrücke (DIfE), Nuthetal, ²Department of Endocrinology, Diabetes and Nutrition, Charité-University Medicine, ³HealthTwiSt GmbH, Berlin, Germany.

Background and aims: Angiotensin-converting enzyme (ACE) catalyzes the conversion of angiotensin I to angiotensin II which leads to vasoconstriction. Pharmaceutical inhibition of ACE serves as effective treatment in hypertension and cardiovascular diseases, but also improves insulin sensitivity. On the contrary, carriage of the D-allele of the ACE insertion/deletion (I/D) polymorphism is associated with increased ACE serum levels and impaired glucose tolerance. ACE is not only expressed in vascular endothelial cells but also in adipose tissue and its levels are altered in conditions of obesity and weight loss. We aimed to investigate effects of an isocaloric high-fat diet (HF) on ACE considering possible nutrigenetic influences.

Materials and methods: In the NUGAT (NUTriGenomic Analysis in Twins) study 46 healthy twin pairs went from a 6-week carbohydrate-rich low-fat diet (LF) to a 6-week HF diet under isocaloric conditions. Clinical investigation days took place after 6 weeks LF and after 1 and 6 weeks of HF (HF1, HF6). At each investigation day subcutaneous adipose tissue biopsies were taken for gene expression analysis on Agilent 8×60K microarrays. Serum parameters were analyzed in blood samples using ELISA. To assess insulin sensitivity intravenous glucose tolerance tests (ivGTT) were performed and incremental areas under the curve (AUC) calculated. Genomic DNA extracted from whole blood was genotyped using Illumina HumanOmniExpressExome BeadChips. For heritability estimates the 'ACE' structural equation model was applied.

Results: Heritability estimates >80% prove a high genetic component of circulating ACE levels ($p<0.001$). After six weeks HF circulating ACE levels increased by 15% (HF6 161±49 ng/ml vs. LF 139±41 ng/ml; $p<0.001$) paralleled by an increase in adipose tissue gene expression (1.41-fold, $p<0.001$). 34% of the increase in circulating ACE levels as regulatory response to the HF diet is explained by additive genetic factors ($p<0.01$). Interestingly, in homozygous carriers (GG) of the rs4343 polymorphism, which serves as a surrogate marker for ACE I/D polymorphism, the increase in serum levels was nearly double that of non-carriers (AA) or heterozygous carriers (AG) ($p<0.001$). Whereas no change in glucose tolerance was observed for AA/AG-carriers, glucose tolerance significantly declined in GG-carriers after six weeks of HF (Δ AUC_{glucose}, recessive model: $p=0.009$).

Conclusion: Despite the known strong heritable component for ACE levels, we could show a considerable increase in ACE serum levels and gene expression in adipose tissue in response to a high fat diet. These results point out that ACE potentially constitutes a molecular link between dietary fat intake and cardiovascular diseases as well as impaired glucose metabolism. The extent of this relationship seems to be nutrigenetically modulated.

High fat diet induced association of anti-inflammatory phospholipid and CRP levels in human adipose tissue in the NUGAT study

M.A. Osterhoff^{1,2}, T. Frahnow¹, A.-C. Seltmann¹, A.S. Mosig^{3,4}, K. Heisig³, S. Sales⁵, J.L. Sampaio⁶, S. Hornemann¹, M. Kruse¹, A.F.H. Pfeiffer^{1,2};

¹Clinical Nutrition, German Institute of Human Nutrition, Potsdam-Rehbruecke, Nuthetal, ²Endocrinology, Diabetes and Nutrition, Charité - University Medicine Berlin, ³Molecular Haemostaseology, ⁴Center for Sepsis Control and Care, Jena University Hospital, ⁵Max Planck Institute of Molecular Cell Biology and Genetics, ⁶Lipotype GmbH, Dresden, Germany.

Background and aims: Lipid metabolism and signaling might be either controlled genetically or by environmental factors. The aim of the study was to correlate lipidomic and genomic data of human subjects to identify specific gene-modules responsible for the regulation or connected with the function of specific lipid metabolites.

Materials and methods: In the NUGAT-Study 46 healthy mono- and dizygotic twin-pairs first were standardized for their nutritional behavior by a carbohydrate-rich low-fat diet for 6 weeks (LF), immediately followed by a high-fat diet for 1 week (HF1) and additional 5 weeks (HF6). At each CID periumbilical fat biopsies were taken for determination of gene expression on Agilent 8×60K gene micro Arrays. Plasma was measured for lipid metabolites and cytokines (ELISA). Weighted gene Co-Expression Network Analysis (WGCNA) and regularized Canonical Covariance Analysis (rCCA) were used for identification of co-expressed gene-networks and their correlation with lipidome data.

Results: Analysis of the 5000 strongest regulated genes revealed a gene-module highly correlated with CRP ($r=0.31$; $p=6\times 10^{-4}$) and highly associated ($r=-0.32$, $p<0.0004$) with an anti-inflammatory/anti-bacterial lysophosphatidylethanolamine specimen (LPE18:1). Application of rCCA showed an increasing association of a set of genes involved in lysophosphatidic acid (LPA) receptor signaling with the decreasing concentrations of LPE specimen. When stratifying the cohort for individuals with a $CRP<1$ or $CRP\geq 1$ at HF6, LPE18:1 levels decrease more pronounced in individuals with high CRP ($p=0.042$). Remarkably, in individuals with low CRP the detected inflammatory gene-module is not associated with LPE18:1 ($r=-0.04$; $p=0.7$) while highly associated in people with high CRP ($r=-0.6$; $p=0.008$).

Conclusion: Our data show for the first time in humans that high-fat diet induces a gene set with inflammatory character which might be involved in lysophosphatidic acid (LPA) receptor signaling. Specifically we identify down regulation of the anti-inflammatory phospholipid LPE and increasing synchronization of LPE concentration with gene expression patterns as a mediator of inflammatory processes in the adipose tissue in a CRP associated manner.

Dysregulation of sirtuins and key metabolic genes in skeletal muscle of pigs with intrauterine growth restriction is associated to alterations of circulating IGF-1

L. Pirola¹, S. Chriett¹, I. Le Huërou-Luron², H. Vidal¹;

¹Medical Faculty, INSERM Unit1060, Oullins, ²INRA - UR 1341 ADNC, Saint-Gilles, France.

Background and aims: Prenatal and early postnatal lives are important determinants of future health, and intrauterine growth restriction (IUGR)-associated low birth weight predisposes to the development of metabolic and cardiovascular disease in adult life, but the mechanisms are largely unknown. We hypothesize here that IUGR might confer gene expression alterations, predisposing to metabolic disease.

Materials and methods: Using a porcine model of spontaneous IUGR, we determined in utero (71, 112 days post-conception) and early-postnatal (2 days post-birth) IGF-1, insulin and leptin levels, and in parallel we investigated skeletal muscle (Longissimus dorsi) gene expression of sirtuins and key metabolic genes (IRS1, GLUT4, HK2 and GAPDH). **Results:** In IUGR, we observed impaired IGF-1, insulin and leptin serum levels. Gene expression of sirtuin 1, 5, 6, 7, GLUT4 and HK2 exhibited significant correlations with gestational age or fetus/newborn body weight. SIRT1 and HK2 expression displayed an age- and weight-dependent downregulation in controls, which was lost in IUGR pigs. Conversely, SIRT2 and GLUT4 were upregulated in IUGR pigs. Within the set of genes studied, we found a significant correlation between IGF-1 levels and gene expression, indicating that IGF-1 is limiting in IUGR. IUGR-dependent gene alterations were partly linked to epigenetic changes on histone H3 acetylation and methylation.

Conclusion: Our observations indicate that several sirtuins and metabolic genes display specific gene expression trajectories during fetal and early postnatal life, which are altered in IUGR, and are related to hormonal dysregulations observed in IUGR. Given the importance of these genes in metabolic control, their perinatal alterations might contribute to the predisposition to metabolic disease and diabetes in adulthood.

Association between eating rate and obesity: a systematic review and meta-analysis

T. Ohkuma¹, Y. Hirakawa², U. Nakamura³, Y. Kiyohara², T. Kitazono³, T. Ninomiya¹;

¹Center for Cohort Studies, ²Department of Environmental Medicine, ³Department of Medicine and Clinical Science, Kyushu University, Fukuoka, Japan.

Background and aims: Considering the epidemic and deleterious impact of obesity and its complication such as type 2 diabetes, a better understanding of the association between diet therapy and obesity would be beneficial from both clinical and public health care perspectives. Epidemiological evidence has shown that diet therapy based on not only the types and amounts of foods, but also eating behaviours play an important role in the management of obesity. Recently, several epidemiologic studies have reported the significant association between eating rate and obesity. However, the influence of eating rate on the obesity remains inconclusive. Therefore, we undertook a systematic review with a meta-analysis of published epidemiological studies to provide a reliable estimate of the association between eating rate and obesity.

Materials and methods: A systemic search of MEDLINE, EMBASE and CINAHL was conducted to identify studies that reported quantitative estimates for indices of obesity based on the category of eating rate. Interventional studies or those conducted for children were excluded. The reference lists of identified articles were manually scanned to identify other relevant studies. Two independent researchers extracted the data. A summary estimate was calculated using a random-effects model. Subgroup analyses were conducted to identify the sources of heterogeneity.

Results: Twenty-three published studies were eligible for inclusion, of which 20 were cross-sectional studies, 2 were longitudinal studies and 1 provided results from both study designs. Twenty one cross-sectional studies were included in the meta-analysis. The mean difference in BMIs between individuals who ate quickly and those who ate slowly was 1.78 kg/m² (95% CI, 1.53–2.04 kg/m²). The pooled odds ratio of eating quickly on the presence of obesity was 2.15 (95% CI, 1.84–2.51). There was evidence of significant quantitative heterogeneity in the magnitudes of the association across studies ($I^2=78.4\%$, P value for heterogeneity < 0.001 for BMI, $I^2=71.9\%$, P value for heterogeneity < 0.001 for obesity), which may be partially explained by differences in the type of study population (a weaker association was observed for BMI in individuals with diabetes than in those without; mean difference 1.32 kg/m² [95% CI, 0.90–1.74 kg/m²] versus mean difference 1.89 kg/m² [95% CI, 1.64–2.15 kg/m²], respectively, P value for heterogeneity = 0.038). A funnel plot showed a symmetric pattern, and formal statistical testing did not identify the presence of publication bias. Three longitudinal studies also showed that a faster eating rate was associated with increased BMI and a higher risk of incident obesity over time.

Conclusion: Eating quickly is positively associated with excess body weight. Although further studies are needed to conclude a causal relationship between eating rate and obesity, more emphasis may be placed in clinical practice on slowing the speed of eating.

The effect of meal frequency in a reduced-energy regimen on the gastrointestinal and appetite hormones in patients with type 2 diabetes: a randomised crossover study

L. Belinova, J. Veleba, H. Kahleova, H. Malinska, O. Topolcan, J. Vrzalova, O. Oliyarnyk, L. Kazdova, M. Hill, T. Pelikanova;

Department of Diabetes, Institute for Clinical and Experimental Medicine, Praha 4, Czech Republic.

Background and aims: Appetite and gastrointestinal (GI) hormones participate in energy homeostasis, feeding behavior and regulation of body weight. We demonstrated previously the superior effect of two meals a day, breakfast and lunch (B2) on body weight, hepatic fat content, insulin sensitivity and feelings of hunger compared to the same diet divided into six smaller meals a day (A6). The aim of this secondary analysis was to investigate the effect of frequency of meals on the appetite and GI hormones.

Materials and methods: In a randomized, crossover study, we assigned 54 patients with T2D to follow two regimens of a hypocaloric diet, each for 12 weeks: either 6 meals (A6) or two meals (B2). The diet in both regimens had the same macronutrient and energy content. After each regimen participants underwent a standard meal test. The concentrations of glucagon-like peptide-1 (GLP-1), gastric inhibitory peptide (GIP), pancreatic polypeptide (PP), peptide YY (PYY), amylin, leptin and ghrelin were determined using multiplex immunoanalyses. For statistical analysis 2×2 crossover ANOVA was used.

Results: Body weight decreased in both regimens ($p<0.001$), more in B2 ($p<0.001$). Fasting leptin and GIP decreased (both $p<0.05$) in response to both regimens with no difference between the treatments. Fasting ghrelin decreased in A6 ($p<0.001$), with a trend toward an increase ($p=0.08$) in B2 ($p<0.05$). Fasting PP increased in B2 ($p<0.05$) with a trend toward an increase in A6 ($p=0.09$) with no significant difference between both regimens. Neither GLP-1 nor PYY did change in either regimen. The decrease in body weight correlated negatively with changes in fasting ghrelin ($r=-0.4$, $p<0.05$) and the postprandial suppress of ghrelin correlated positively with its fasting level ($r=0.9$, $p<0.001$).

Conclusion: We demonstrated that a hypocaloric diet with lower meal frequency leads to greater decrease in body weight in patients with T2D and the changes in body weight correlated negatively with changes in fasting ghrelin. The effect of meal frequency on other measured GI peptides was not proven.

Effect of different diurnal patterns of meal composition on metabolic parameters in healthy men

K. Kessler^{1,2}, S. Hornemann¹, C. Sticht³, N. Gretz³, A. Kramer⁴, O. Pivovarova^{1,2}, A.F.H. Pfeiffer^{1,2};

¹Dept. Clinical Nutrition, German Institute of Human Nutrition Potsdam-Rehbruecke (DIfE), Nuthetal, ²Dept. Endocrinology, Diabetes and Nutrition, Charité University Medicine, Berlin, ³Center for Medical Research (ZMF), Medical Faculty Mannheim at Heidelberg University, Mannheim, ⁴Laboratory of Chronobiology, Institute for Medical Immunology, Charité University Medicine, Berlin, Germany.

Background and aims: A recent animal study has shown a potential benefit of a fat-rich diet at the beginning of the active phase and a carbohydrate-rich diet at the end (versus the opposite order) on glucose tolerance, beta-oxidation and body weight. We therefore aim to determine the effects of two different diurnal patterns of meal composition on metabolic parameters and circadian gene expression in subcutaneous adipose tissue (SAT) in humans.

Materials and methods: In a cross-over study, 20 men (age 46.4 ± 14 years, BMI 27.5 ± 4 kg/m²) consumed isocaloric carbohydrate-rich meals in the morning and fat-rich meals in the evening (diet A) or isocaloric fat-rich meals in the morning and carbohydrate-rich meals in the evening (diet B) for four weeks each. At the end of each intervention period, two 850 kcal meal tolerance tests, a carbohydrate-rich (MTT HC) or a fat-rich (MTT HF), were performed at 09.00 am and 03.40 pm, respectively, according to the participant's previous dietary regimen. Insulin, C-peptide, glucose, and other routine lipid, liver and kidney markers were determined in plasma. Gene expression in SAT was measured at three time points (08.45 am, 12.15 pm and 07.00 pm) during each investigation day using quantitative real-time PCR.

Results: Mean body weights were not affected by the diets. Both diets decreased fasting blood glucose, insulin, and total cholesterol levels. As expected, MTT HC induced a larger increase in glucose and insulin levels than MTT HF. Postprandial glucose, insulin and C-peptide levels were higher in the afternoon compared to the morning for both MTT HC and MTT HF. In the afternoon, postprandial peak of insulin secretion was delayed and insulin excursion pattern showed a second peak independent of the meal composition. Postprandial NEFA levels were significantly higher in the afternoon compared to the morning only for MTT HC. Analysis of core clock gene expression in SAT (BMAL1, CLOCK, PER1-3, CRY1-2, NR1D1 and RORA) revealed profound reorganization of circadian oscillations induced by the change of the diurnal pattern of meal composition.

Conclusion: Our results show that glucose tolerance decreases in the afternoon independent of meal composition. Still, different diurnal patterns of meal composition induce large differences in circadian oscillations in SAT underlining the important role of food composition for the entrainment of peripheral circadian clocks in humans.

Extension of overnight fast until noon, triggers increased postprandial hyperglycaemia and reduced and delayed insulin response after lunch and dinner in type 2 diabetes

D. Jakubowicz¹, J. Wainsten¹, B. Ahrén², Z. Landau¹, Y. Bar-Dayán¹, O. Froy³,

¹Diabetes Unit, E. Wolfson Medical Center, Holon, Israel, ²Clinical Science, Lund University, Sweden, ³Agriculture Food and Environment, The Hebrew University of Jerusalem, Rehovot, Israel.

Background and aims: Reduction of postprandial hyperglycemia is a major target in the treatment of type 2 diabetic patients. Skipping breakfast has been consistently associated with higher HbA1c and overall PPHG in T2D. We aimed to explore the effect of eating vs. skipping breakfast on PPHG after subsequent isocaloric lunch and dinner.

Materials and methods: In a crossover design, 22 type 2 diabetic patients, since 7.79 ± 2.1 yrs, aged 58.7 ± 4.9 yrs, BMI 28.4 ± 2.8 kg/m² and HbA1c $7.7 \pm 0.394\%$ were randomly assigned to 2 meal test days: one day with breakfast, lunch and dinner (YesB) and another day the breakfast was omitted and only lunch and dinner were consumed (NoB). Postprandial plasma glucose, insulin, free fatty acids (FFA), glucagon and intact glucagon-like peptide-1 (iGLP-1) after isocaloric (700 kcals; % CH:protein:fat 50:30:20) lunch and dinner were assessed and calculated as AUC180min.

Results: Compared with YesB, AUC180 after lunch in the NoB group was higher by 37% for glucose (41804 ± 310 vs 30566 ± 185 mg/dl*min, $p < 0.0001$), lower by 17% for insulin (5156 ± 86 vs 6213 ± 116 μU/ml*min, $p < 0.0001$) and lower by 19% for iGLP-1 ($p < 0.0001$). Plasma FFA and glucagon were suppressed by 41.3% and 14.8%, respectively ($p < 0.0001$). Insulin peaked 30 min after lunch in the YesB group vs 60 min after lunch in the NoB group. After dinner, in the NoB vs YesB, AUC180 increased by 26.6% for glycemic response (47310 ± 88 vs $37368 \pm$

247 mg/dl*min, $p < 0.0001$), reduced by 7.9% for insulin (5150 ± 99 vs 5593 ± 147 μU/ml*min, $p < 0.0001$) and reduced by 16.5% for iGLP-1 ($p < 0.0001$). Plasma FFA and glucagon were less suppressed by 29.6% and 11.5%, respectively ($p < 0.0001$) in the NoB compared with the YesB group. Insulin peaked 60 min after dinner in the YesB group vs 90 min after dinner in the NoB group. Glycemic response AUC after lunch and dinner positively correlated with AUC180 for FFA ($R^2 = 0.78$, $p < 0.0001$) and with AUC180 for glucagon ($R^2 = 0.73$, $p < 0.0001$) and was inversely correlated with AUC180 iGLP-1 ($R^2 = 0.79$, $p < 0.0001$).

Conclusion: Skipping breakfast increased postprandial hyperglycemia after lunch and dinner. This was accompanied in NoB, by less iGLP-1, lower and delayed prandial insulin release, and less suppressed plasma FFA and glucagon. Breakfast consumption should be a strategy toward reduction of postprandial hyperglycemia in type 2 diabetic individuals.

Dietary habits and physical activity of Greek children in relation to the presence of diabetes in a household member

S. Kalantzi¹, G. Karamanakos¹, I. Pagkalos², A. Abrahamian³, I. Kaklamanos³, E. Kapantais³, T. Tzotzas³, M. Hassapidou⁴, S. Liatis¹;

¹First department of Propaedeutic Internal Medicine, University Medical School, Laiko General Hospital, Athens, ²Department of Electrical & Computer Engineering, Aristotle University, Thessaloniki, ³Hellenic Medical Association for Obesity, Athens, ⁴Alexander Technological Educational Institute, Thessaloniki, Greece.

Background and aims: To explore the relationship between dietary habits and amount of physical activity of Greek children aged 6-9 years old and the presence of diabetes in a family member living in the same household.

Materials and methods: Analysis was based on cross-sectional data obtained from the Greek arm of the second round of the Childhood Obesity Surveillance Initiative (COSI) study, established by the World Health Organization. The study population was nationally representative and consisted of primary school children aged 6-9 years old. A family record form was used to gather information on a voluntary basis on simple indicators of the children's dietary intake and physical activity/inactivity patterns, the family's socioeconomic characteristics and the presence of diabetes on a household member. Univariate and multivariate relationships between variables were studied using Chi-square and logistic regression tests.

Results: A total of 1821 children (884 boys and 937 girls) were included in the analysis. There were 104 children (5.7%) reporting a family member with diabetes in their household. Mean BMI was similar between children of families with and without diabetes in the household (18.8 ± 3.4 Kg/m² vs. 18.7 ± 3.3 Kg/m² respectively). The presence of a household member with diabetes was associated with less frequent breakfast consumption ($p = 0.04$), lower consumption of fresh fruits ($p = 0.051$) and fish ($p = 0.053$), higher consumption of diet soft drinks ($p < 0.001$), flavored milk ($p = 0.016$), foods like potato chips, corn chips, popcorn or peanuts ($p = 0.003$) and foods like pizza, fried potatoes, hamburger, sausage or meat pies ($p = 0.001$). In addition, it was associated with lower participation in sport or dancing clubs ($p = 0.002$ and $p = 0.007$ respectively), fewer hours spent playing outside ($p = 0.008$) and more hours spent on computer games ($p < 0.001$). The above associations remained significant after adjustment for BMI and socioeconomic status.

Conclusion: The presence of diabetes in a household member is associated with several unhealthy nutritional and physical activity habits in Greek children aged 6-9 years old, despite no difference in BMI and even after adjustment for family socioeconomic status. These findings may be attributed to the transition of unhealthy lifestyle choices of parents with diabetes to their children.

712

Nutritional regulation of incretin secretion in controls, impaired glucose tolerance and type 2 diabetes

F. Keyhani Nejad^{1,2}, M. Kemper^{1,2}, R. Schueler¹, O. Pivovarova^{1,2}, N. Rudovich^{1,2}, A.F.H. Pfeiffer^{1,2};

¹Department of Clinical Nutrition, German Institute of Human Nutrition, Nuthetal, ²Department for Endocrinology, Diabetes and Nutrition, Charité – University of Medicine, Berlin, Germany.

Background and aims: While studies suggest that excessive sugar intake is associated with the development of type 2 diabetes (T2DM) and non-alcoholic fatty liver, it is unclear whether this is primarily related to sugar metabolites such as glucose and fructose or to the postprandial hormonal responses, particularly incretins, glucose-dependent insulinotropic peptide (GIP) and glucagon like peptide-1 (GLP-1). We investigated the effects of sucrose and its isomer Palatinose ingestion on endogenous GIP and GLP-1 release and their relation to hepatic insulin clearance (HIC) in normal (NGT), impaired glucose tolerant (IGT) and T2DM participants.

Materials and methods: In a randomized, within-subject crossover study 15 NGT (control), 10 IGT and 10 T2DM subjects were studied for 180 min consuming 50 g either Palatinose or sucrose solutions which are dimers of glucose and fructose but resorbed either distally or proximally due to different 1,6 vs 1,2 linkage to evaluate glucose and insulin responses. Postprandial GIP and GLP-1 levels were assessed and related to HIC.

Results: Following oral sucrose, blood glucose levels peaked significantly ~2 fold after 30 min which were 38% ($p<0.001$) and 26% ($p<0.05$) higher than Palatinose intake in NGT and IGT subjects, respectively. In T2DM, maximal postprandial glucose excursions after sucrose and Palatinose intake were at 60 min and were ~20% significantly lower with Palatinose ingestion ($p<0.01$). Palatinose intake resulted in similar insuliniAUC levels in NGT, IGT and T2M (10.44 ± 2.2 , 10.9 ± 2.3 and 11.5 ± 3.3 nmol/l x180 min, respectively). InsuliniAUC levels after sucrose ingestion were 88%, 32% and 55% higher than Palatinose intake in NGT, IGT and T2DM ($p<0.01$, $p<0.05$ and $p=0.1$, respectively). Following sucrose intake, plasma concentrations of GIP increased significantly with 4.1, 3.1 and 2.8 fold in NGT, IGT and T2DM subjects, respectively. It reached its peak after 15 min sucrose load, while by Palatinose intake GIP levels peaked at 60 min with 2 fold increase in NGT and IGT and 1.5 fold increase in T2DM subjects compared to baseline. Palatinose intake compared with sucrose increased secretion of active GLP-1 (GLP-1iAUC) ~77% ($p<0.01$), 85% ($p<0.01$) and 84% ($p<0.05$) in NGT, IGT and T2DM groups, respectively. Sucrose caused only minor increases. Compared with sucrose, Palatinose intake improved HIC rate ~32% ($p<0.001$), 30% ($p<0.05$) and 37% ($p<0.05$) in NGT, IGT and T2DM, respectively. Across all groups, there was an inverse association between GIPiAUC and HIC ($r=-0.44$, $p<0.001$). In contrast, GLP-1iAUC was positively associated with the increased HIC ($r=0.4$, $p=0.001$).

Conclusion: Palatinose possesses a favorable profile for diabetes nutrition by lowering postprandial endogenous GIP levels, increasing GLP-1 concentrations and saving insulin secretion which ultimately results in improved management of blood glucose. Palatinose improves HIC in IGT and T2DM subjects. An inverse relationship between HIC and postprandial GIP concentrations and positive association between GLP-1 nad HIC suggest that the pattern of incretin secretions determines the rate of HIC. In particular, modulation of GIP secretion can be considered as a potential therapeutic target for improving hepatic glucose metabolism and the treatment of fatty liver.

Clinical Trial Registration Number: NCT02219295

Altered mitochondrial metabolism is involved with increased amplifying pathways modulation of insulin secretion in protein malnourished obese mice

C.C. Zoppi, N.C. Leite, R.C.S. Branco, F.M.M. Paula, P.C. Borck, J.F. Vettorazzi, E.M. Carneiro;

Structural and Functional Biology, University of Campinas, Brazil.

Background and aims: Glucose-induced insulin secretion (GIIS) stimulates dependent and independent mechanisms of KATP channels. Low protein and high-fat diets, during important stages of development favor obesity progress inducing several changes in pancreatic islets. The changes on the independent mechanisms of KATP channels, also called amplifying pathways, induced by the combination of these two treatments are unknown. Our aim was investigating the role of these pathways on GIIS modulation of malnourished obese mice.

Materials and methods: After weaning, 21 days old male C57BL-6 mice were randomly assigned into the control group (C) which received a normo-protein diet (14% protein) during 105 days; the control-high fat diet (HFD) (CH) received normo-protein diet for 45 days and after that was treated with a HFD (60% fat) for 60 days. The protein restricted R and RH groups were fed with a low protein diet (LPD) (6% protein), receiving the same HFD treatment. Insulin tolerance was assessed by euglycemic-hyperinsulinemic clamp. In order to investigate amplifying pathways control of insulin secretion, we incubated islets with glucose (G2.8; 11.1; 22.2 mM) in the presence of K⁺ (30 mM) and diazoxide (250 μ M). Insulin content was measured by radioimmunoassay. Protein kinases A and C and mitochondrial metabolism were also assessed.

Results: HFD decreased glucose uptake ($C=25.6\pm 2.1/CH=15.9\pm 2.36$; $R=50.0\pm 5.1/RH=18.18\pm 3.9$ mg/kg/min). GIIS was higher in animals fed with HFD ($G22.2 C=1.58\pm 0.18/CH=3.0\pm 0.3$; $R=1.08\pm 0.12/RH=1.8\pm 0.3$ ng/mL/hour/islet). The influence of amplifying pathways in insulin secretion was lower in R animals ($G22.2 C=0.757\pm 0.1$; $R=0.33\pm 0.09$ ng/mL/hour/islet). There were no differences among C and CH in all glucose concentrations. Additionally, the role of amplifying pathways was higher in RH ($G22.2 R=0.33\pm 0.09$; $RH=1.67\pm 0.22$). Whereas PKA and PKC content were not altered, ATP production displayed a trend to be reduced in RH. Basal mitochondrial membrane potential and glutamate dehydrogenase (GDH) protein content were nearly 40 and 50% higher, respectively.

Conclusion: Higher amplifying pathway modulation of insulin secretion of obese protein malnourished mice is associated with impaired mitochondrial function and GDH content. This could be one of the mechanisms reprogrammed by early protein malnutrition, since this effect does not appear in animals fed with a normal protein plus HFD.

Metformin associated lactic acidosis-incidence in the years of 2004-2012

A. Aharaz¹, T. Frøslev², R. Thomsen², H.T. Sørensen², H. Beck-Nielsen^{1,3};

¹Dpt. of Endocrinology, Odense University Hospital, ²Dpt. of Clinical Epidemiology, Aarhus University Hospital, ³Dansk Center for strategisk forskning i type 2 diabetes, Odense, Denmark.

Background and aims: Over the last decade Metformin has become frontline treatment in the overwhelming majority of patients with type 2 diabetes, including in elderly patients with possible increased risk of adverse effects. We examined if the annual incidence of lactic acidosis (LA) overall and associated with metformin use has increased in Denmark over a 9-year period.

Materials and methods: We conducted a nationwide cross-sectional study in Denmark in the period of 2004-2012, using population-based hospital and prescription registries. We identified all people in Denmark exposed to metformin in this period, and assessed first-time hospital contacts with LA (ICD-10 diagnosis code E87.2A) from the Danish National Patient Register. For each calendar year, we assessed the annual incidence rate (IR) of first-time LA events per 100,000 person-years among metformin-exposed people and among Denmark's entire background population.

Results: As shown in the Figure below the annual IRs for LA in Denmark increased substantially over time, both for LA in the entire background population (LA_IR, red graph) and for LA among metformin exposed individuals (MELA_IR, blue graph). In the general population, the incidence of LA increased from 0.01-0.1 per 100,000 person years in the early study years 2004-2006 to 3.0 per 100,000 person years in 2012. Among metformin users, the incidence of LA increased from 0.0-5.9 per 100,000 person years in the early study years 2004-2006 to 33.0 per 100,000 person years in 2012, corresponding to a 11-fold higher incidence of LA in metformin users versus the general population.

Conclusion: During the last decade, there has been a substantial rise in the incidence of LA among metformin users in Denmark, as well as in the background population. These findings raise concern that caregivers may not always comply with contraindications for metformin use.

Metformin inhibits pancreatic stellate cells proliferation and migration

C. Wu, X. Zhu, L. Li;

Department of Endocrinology, ZhongDa Hospital of Southeast University, Nanjing, China.

Background and aims: Metformin treatment is associated with a decreased risk and better prognosis of pancreatic cancer (PC) in patients with type 2 diabetes. The effects of metformin are mediated by activation of AMPK and a reduction in mTOR signaling in cancer cells. Activated pancreatic stellate cells (PSCs) are key stroma cells responsible for pancreatic fibrogenesis and PC progression. However, the impact of metformin on PSCs has not been studied. Assuming a protective role of metformin, we investigated its effects on PSCs.

Materials and methods: In primary mouse PSCs and a novel immortalized mouse pancreatic stellate cell line (imPSCs), cells were cultured with different concentrations of metformin (2.5, 5, 10 mmol/L). Cell proliferation was determined by MTT assay. PSCs migration was assessed by a wound healing assay. AMPK and mTOR, the important regulatory molecules responsible for metformin action, were investigated for their possible involvements in metformin-induced proliferation and migration.

Results: Metformin dose- and time-dependently decreased PSCs proliferation (78±3% of control, P<0.01). Metformin inhibited PSCs migration (73±4% of control, P<0.01). Metformin addition induced AMPK phosphorylation, reaching a maximum within 24 hours (4.52±0.03 of control, P<0.01). Metformin application showed inhibition of phosphorylated Akt (0.38±0.06 of control, P<0.01), mTOR (0.12±0.05 of control, P<0.01) and P70S6K (0.18±0.02 of control, P<0.01), maximal inhibitory effects were achieved at 48 hours.

Conclusion: Our findings indicated that metformin inhibited the proliferation and migration of PSCs. Metformin activated AMPK and reduced AKT/mTOR/P70S6K phosphorylation. Further studies designed to characterize the possible molecular mechanisms by which metformin affects PSCs are awaited.

716

Once-daily delayed release metformin in the morning is superior in efficacy to evening and twice-daily administration but at lower systemic exposures

M. Fineman, A. Baron, C. Burns, S. Skare;
Elcelyx Therapeutics, Inc., San Diego, USA.

Background and aims: Metformin delayed-release (MetDR) is a gut-restricted formulation designed to release drug only when it reaches the ileum, a region of the gut where GLP-1 secreting L-cells are abundant and absorption is poor, leading to low bioavailability. MetDR was previously shown to have glucose-lowering activity comparable to immediate-release and extended-release metformin (both of which are absorbed in the upper bowel with ~50% bioavailability) but with ~40% lower doses and significantly lower (>75%) systemic exposure, consistent with the gut being metformin's primary site of action. As the intestine is a major site of Met accumulation (300-1000X plasma), timing and frequency of daily metformin delivery to the lower bowel may not be important with repeated dosing (ie, at steady-state, the intestine effectively becomes a metformin reservoir that provides sustained activity). We tested this in the present study by comparing the pharmacokinetics (PK) and glucose-lowering efficacy of a total daily dose of 1000 mg MetDR administered twice-daily (BID) or once-daily (QD) in the morning (QAM) or evening (QPM).

Materials and methods: 1000 mg MetDR QAM or QPM were compared to 500 mg MetDR BID in a 7-day randomized crossover design (n=26, mean FPG 168 mg/dL) in subjects with T2D not on Met ≥2 wks prior to dosing. All treatments were administered with meals and were separated by a 6- to 12-day washout.

Results: PK results indicate a diurnal effect in both the rate and extent of metformin absorption with QAM having the fastest gut transit time and the lowest plasma exposure compared to QPM. The time to reach the ileum was 4.5–5.8 h for morning dosing vs 7.1–8.5 h for evening dosing. QAM resulted in a 29% decrease in 24-h Met plasma exposure (AUC) compared to QPM and BID ($p < 0.005$ for both). Despite these differences in exposure, QAM dosing resulted in the greatest reduction (9%) in plasma glucose AUC0–24 from baseline ($p = 0.003$) compared to a 5% reduction for both QPM ($p = 0.002$) and BID ($p = 0.099$). QAM dosing also resulted in a 10% reduction in 24-h maximum plasma glucose (C_{max}) from baseline ($p = 0.0006$) compared to a 9% reduction for QPM ($p = 0.0007$) and a 6% reduction for BID ($p = 0.039$). All treatments were well tolerated consistent with previous studies of MetDR.

Conclusion: Met DR delivered once-daily in the morning results in lower Met plasma exposure but the greatest reduction in plasma glucose compared to evening or BID administration. The observation that MetDR provides 24-h glucose lowering with once daily administration supports the previous findings that Met works predominantly in the lower bowel and that the contribution of systemic exposure to glucose lowering is small at best. As MetDR is being developed to limit metformin exposure in patients with renal impairment, once-daily morning administration of MetDR is the preferred dosing regimen.

Clinical Trial Registration Number: NCT01804842

Optimisation of metformin discontinuation in diabetic patients explored with 18 F-FDG PET/CT

B. Pérez-Pevida¹, L. Sancho Rodríguez², E.F. Guillén Valderrama², F.J. Escalada San Martín¹, M.J. García Velloso², E. Pascual Corrales¹, G. Gutiérrez Buey¹, M. Llaveró Valero¹, J.C. Galofré Ferrater¹, J.A. Richter², J. Salvador Rodríguez¹;

¹Endocrinology and Nutrition, ²Nuclear Medicine, Clínica Universidad de Navarra, Pamplona, Spain.

Background and aims: It is known that metformin increases 18 F-FDG PET/CT intestinal uptake and that it is reduced after its discontinuation for 3 days. The aim of this study was to determine if in patients with type 2 diabetes mellitus (T2D), 24 or 48 h metformin discontinuation could be useful to reduce 18 F-FDG PET/CT intestinal uptake keeping patient's glucose levels (GL) in normal range and improving PET/CT quality.

Materials and methods: 101 T2D patients referred to a 18 F-FDG PET/CT study were included. Drug regimen included metformin in 81 patients (group A) and other oral antidiabetic drugs (OAD) in 20 patients (group B). 30 patients without T2D served as the control group (group C). Group A was divided in three subgroups: 31 patients (group A1) were taking metformin, 21 patients (group A2) were asked to discontinue metformin for 24 h before 18 F-FDG PET/CT and the remaining 29 patients (group A3) were asked to discontinue metformin for 48 h. 18 F-FDG PET/CT intestinal uptake was assessed both, qualitatively (normal, mild, moderate or intense) and semi-quantitatively, using SUV_{max} values and tissue-to-background ratio (TBR). Results were compared among the groups. GL were assessed before PET/CT performance in all patients.

Results: Intense intestinal uptake in group A3 (17%) was significantly lower ($p < 0.001$) than in group A2 (32%) and A1 (68%) and comparable to group B (15%) and C (7%). Intestinal 18F-FDG uptake in group A was reduced after metformin discontinuation for 24 hours (TBR A1=2,32 vs TBR A2=3,24; $p = ns$) and significantly after 48 hours (TBR A3=1,82 vs A1 y A2; $p < 0.001$). There were no significant differences among A3 (TBR=1, 82), B (TBR=1, 69) and C (TBR=1,40). There were also no significant differences in age and body mass index (BMI) among the different groups. GL were higher in group A (122±19) than in groups B (119±19) and C (95±11) ($p < 0.01$).

Conclusion: Metformin discontinuation for 48 hours is feasible and better than 24 hours to reduce 18 F-FDG intestinal uptake in T2D and it

significantly improved PET/CT studies quality. Although GL increased with discontinuation, they were in normal range according to guidelines.

Development of oedema is associated with an improved glycaemic response in patients initiating thiazolidinediones: a MASTERMIND study

J.M. Dennis¹, A.T. Hattersley¹, M. Weedon¹, C. Angwin¹, L. Rodgers¹, E.R. Pearson², W.E. Henley¹, B.M. Shields¹;

¹University of Exeter Medical School, University of Exeter, ²Ninewells Hospital and Medical School, University of Dundee, UK.

Background and aims: Oedema is a common and serious side effect of thiazolidinedione therapy. A stratified medicines approach would aim to give thiazolidinediones to patients likely to have a good glycaemic response but to not develop oedema. We investigated whether oedema was associated with glycaemic response to thiazolidinedione therapy.

Materials and methods: We retrospectively studied 11,459 patients initiating a thiazolidinedione from UK primary care data (Clinical Practice Research Datalink), and identified medical records of new oedema in the subsequent twelve months. Response was defined as change in HbA1c at twelve months and was adjusted for baseline HbA1c, baseline BMI, gender and compliance (medication possession ratio). In secondary analyses we restricted oedema classification to patients with concomitant weight gain. As a comparison the same analysis was performed in 13,089 patients initiating a sulfonylurea.

Results: The 5% of patients with recorded oedema on thiazolidinediones had a mean (CI) 2.2 (1.1–3.2)mmol/mol greater fall in HbA1c ($p < 0.001$) compared to thiazolidinedione patients without oedema. This improved response increased when oedema was associated with weight gain, with a 2.5 (1.1–4)mmol/mol greater HbA1c fall when weight gain > 3 kg ($p < 0.001$) and a 3.6 (1.8–5.4)mmol/mol greater fall when weight gain > 5 kg ($p < 0.001$). Oedema was recorded in 3.7% of sulfonylurea patients and was not associated with response (HbA1c fall difference 1 (-0.5–2.5)mmol/mol, $p = 0.2$), even when associated with weight gain > 3 kg ($p = 0.19$).

Conclusion: Patients with Type 2 diabetes who develop oedema on initiating thiazolidinediones have an improved glycaemic response, and more severe oedema may be associated with greater reductions in HbA1c. An association between oedema and glycaemic response was not observed in patients initiating sulfonylureas. This supports glycaemic lowering and fluid retention being mediated by a common pathway of thiazolidinedione drug action.

Combined intervention with pioglitazone and n-3 fatty acids in metformin-treated diabetic patients

J. Kopecký¹, J. Veleba¹, P. Janovská², O. Kuda², O. Horaková², H. Malinská¹, L. Kazdová¹, J. Olza³, P. Calder³, A. Gardlo^{4,2}, E. Fiserová⁴, J. Jensen⁵, M. Bryhn⁶, J. Kopecky sr.², T. Pelikanová¹;

¹Institute for Clinical and Experimental Medicine, ²Department of Adipose Tissue Biology, Institute of Physiology Academy of Sciences of the Czech Republic, Prague, Czech Republic, ³Human Development & Health Academic Unit Faculty, Medicine University of Southampton, UK, ⁴Department of Mathematical Analysis and Applications of Mathematics, Faculty of Science, Palacky University in Olomouc, Czech Republic, ⁵University of Oslo, Norway, ⁶Silentia A.S., Svelvik, Norway.

Background and aims: Marine n-3 fatty acids eicosapentaenoic (EPA) and docosahexaenoic (DHA) acids help in primary prevention of cardiovascular disease, but their impact on glucose homeostasis in type 2

diabetic (T2D) patients remains unclear. We aimed to evaluate the effect of a combination intervention using EPA+DHA and a suboptimal doses of insulin-sensitizing drug pioglitazone on insulin resistance, body weight, serum lipid concentrations and compensation of diabetes in obese patients with T2D already treated with metformin.

Materials and methods: In a double-blind, placebo-controlled trial, 69 patients, 38–70 years of age (66% men) were randomly assigned to 24-week-intervention using: (i) corn oil (5 g/day; Placebo), (ii) pioglitazone (15 mg/day; Pio), (iii) EPA+DHA (2.75 g/day; Omega3), or (iv) pioglitazone and EPA+DHA (Pio+Omega3). The primary endpoints were the changes from baseline in insulin sensitivity and in triacylglycerol clearance assessed using hyperinsulinemic-isoglycemic clamp and a meal test. Secondary endpoints included changes in fasting glycemia and HbA1c, glucose and NEFA clearance and inflammatory markers and adipokines.

Results: Omega3 and Pio+Omega3 increased EPA+DHA content in plasma phospholipids. Pio and Pio+Omega3 increased body weight and adiponectin levels. Both fasting glycemia and HbA1c were increased by Omega3, but unchanged by Pio + Omega3. Insulin sensitivity was improved by Pio + Omega3. Triacylglycerol and NEFA clearance were increased by Pio+Omega3. See table.

Conclusion: Besides preventing a modest negative effects of Omega-3 on glycemic control, the combination of pioglitazone and EPA+DHA can be used to increase insulin sensitivity and postprandial lipid clearance in T2D patients on stable metformin therapy.

Table: Differences (Δ) between week 24 and baseline values for BMI, HbA1C, metabolic clearance of glucose (M) and adiponectin. Differences (Δ) between week 24 and baseline values for triacylglycerol and NEFA clearance calculated as area under the curve (AUC)

	Placebo	Pio	Omega3	Pio+Omega3
Δ BMI (kg/m ²)	-0.4 (0.8)	0.4 (0.9) ^{ac}	-0.5 (1.3)	0.7 (0.9) ^{bc}
Δ HbA1C (%IFCC)	0.00 (0.60)	0.00 (0.60)	0.65(1.20) ^{ab}	0.00 (0.45) ^c
Δ M (mg/kg.min)	-0.60 (1.84)	0.29 (1.64)	-0.58 (1.12) ^b	0.53 (1.13) ^c
Δ ADIPONECTIN (ug/ml)	0,4 (1,0)	3,5 (2,3) ^{ac}	0,9 (0,7)	3,7 (2,2) ^{ac}
Δ NEFA AUC	12 (7)	-4 (4)	5 (3)	-9 (5) ^a
Δ TG AUC	-8 (17)	-44 (45)	-27 (25)	-95 (26) ^{ac}

Significant differences (1-way ANOVA) compared with Placebo(a), Pio(b), and Omega3(c)

Single-dose colesevelam has no effect on postprandial GLP-1 levels, but increases CCK levels and decreases gallbladder refilling and gastric emptying in type 2 diabetes

E. Bahne¹, M. Hansen^{1,2}, D.P. Sonne^{1,2}, J.F. Rehfeld³, J.J. Holst², T. Vilsbøll¹, F.K. Knop^{1,2};

¹Center for Diabetes Research, Gentofte Hospital, University Copenhagen, Hellerup, ²NNF Center for Basic Metabolic Research and Department of Biomedical Sciences, Faculty of Health and Medical Sciences, University Copenhagen, ³Department of Clinical Biochemistry, Rigshospitalet, University Copenhagen, Denmark.

Background and aims: The well-established antidiabetic effect of the bile acid sequestrant, colesevelam (COL) has been proposed to be glucagon-like peptide-1 (GLP-1)-dependent since long-term COL treatment seems to increase postprandial GLP-1 levels in rodents and patients with type 2 diabetes. We evaluated the acute effect of oral COL on postprandial plasma GLP-1, insulin and glucose levels as well as plasma cholecystokinin (CCK), gallbladder volume, gastric emptying, appetite and food intake.

Materials and methods: In this placebo-controlled, double-blinded study we included twelve patients with type 2 diabetes (age: 60.8 \pm 8.8 years [mean \pm SD]; BMI: 29.8 \pm 3.0 kg/m²; HbA1c: 6.5 \pm 0.5% (48 \pm 6 mmol/mol)). On 2 separate days, after 1-week washout of antidiabetic drugs, the patients received COL (3.75 g) or placebo suspended in a 302 kcal-liquid meal with 1.5 g paracetamol (for evaluation of gastric emptying). At baseline and during 240 min blood was sampled, gallbladder volume was evaluated by ultrasound and appetite was evaluated by visual analogue scale. At the end of each day ad libitum food intake was evaluated.

Results: Acute administration of COL did not affect postprandial plasma responses (incremental AUCs) of GLP-1 (995 \pm 678 vs 1156 \pm 845 min \times pmol/l, p=0.78), insulin (3112 \pm 4252 vs 3115 \pm 2396 min \times pmol/l, p=0.99) or glucose (321 \pm 197 vs 350 \pm 255 min \times mmol/l, p=0.91), but significantly increased the postprandial CCK response compared to placebo (760 \pm 262 vs 391 \pm 248 min \times pmol/l, p=0.005). Meal-induced gallbladder emptying (AUC0-60 min for gallbladder volume) was not affected by COL whereas gallbladder refilling (AUC60-240 min) was significantly reduced. COL significantly reduced gastric emptying vs placebo whereas food intake and appetite was unaffected.

Conclusion: Acute administration of COL does not seem to affect postprandial plasma levels of glucose, GLP-1 or insulin, appetite or food intake in patients with type 2 diabetes, but appears to have a pronounced stimulatory effect on postprandial CCK levels, which may explain the reduced gallbladder refilling observed, and an inhibitory effect on gastric emptying. Whether these changes contribute to the long-term antidiabetic effect of COL remains to be elucidated.

Effects of pentoxifylline on proteinuria and glucose control in patients with type 2 diabetes

S. Han¹, H. Kim¹, D. Kim¹, C. Chung², C. Ahn³, K. Kim⁴, S.-K. Kim⁵, S. Park⁵, Y.-W. Cho⁵, S. Kim⁶, C. Kim⁷, J. Lee⁸, T. Kim⁹, S.-Y. An¹⁰, K. Lee¹;

¹Endocrinology and metabolism, Ajou University Hospital, Suwon, ²Internal Medicine, Yonsei University Wonju College of Medicine, ³Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, ⁴Endocrinology and metabolism, Dongtan jeil Women's Hospital, Hwasung, ⁵Internal Medicine, CHA Bundang Medical Center, CHA University, Seongnam, ⁶Internal Medicine, Kwandong University College of Medicine, Suwon, ⁷Internal Medicine, Hallym University Sacred Heart Hospital, Hallym University College of Medicine, Anyang, ⁸Endocrinology and metabolism, Myongji Hospital, Ilsan, ⁹Division of Endocrine and Metabolism, Department of Internal Medicine, Seoul Medical center, ¹⁰Endocrinology and metabolism, Hongik Hospital, Seoul, Republic of Korea.

Background and aims: Pentoxifylline is a methylxanthine derivative with significant anti-inflammatory, anti-fibrotic, and anti-proliferative properties. Some studies demonstrated that pentoxifylline might have renoprotective effects in chronic kidney disease. However, these studies had limitations due to the small sample sizes and the heterogeneity of patients' characteristics. Therefore, we investigated whether pentoxifylline could reduce proteinuria further in patients with diabetic nephropathy and residual proteinuria despite receiving adequate therapy with an angiotensin-converting enzyme inhibitor (ACEI) or an angiotensin II receptor blocker (ARB). We also studied the effects of pentoxifylline on glycemic control and insulin resistance.

Materials and methods: This was a prospective, randomized, double blinded, active control, multicenter study. The ethics committee of the Ministry of Food and Drug Safety approved the study protocol. A total of 174 patients with type 2 diabetes and albuminuria >30 mg/g of creatinine

during treatment with ACEI or ARB were assigned randomly to receive pentoxifylline (1200 mg, daily ($n=87$) or placebo ($n=87$). The study endpoint was the effect of pentoxifylline on proteinuria and glucose control, renal function, and inflammatory parameters.

Results: Six months of treatment with pentoxifylline did not change the amount of proteinuria. Although the estimated glomerular filtration rate (eGFR) decreased in the control group, there was no significant difference from the pentoxifylline group. However, pentoxifylline reduced fasting plasma glucose, HbA1c, and homeostatic metabolic assessment (HOMA-IR) significantly.

Conclusion: Although we did not find any beneficial effects regarding reducing proteinuria or preserving renal functions when pentoxifylline was added to ACEIs or ARBs, pentoxifylline therapy improved glucose control and insulin resistance in patients with type 2 diabetic nephropathy.

PS 061 Treating with tablets 1: type 2 diabetes oral antidiabetic drugs update

Implementing an optimised glucose-lowering strategy in daily medical practice with first- and second-line gliclazide MR 60 mg

N.P. Trubitsyna¹, M.V. Shestakova¹, M. Piletič², I. Satman³, L.A. Leiter⁴;

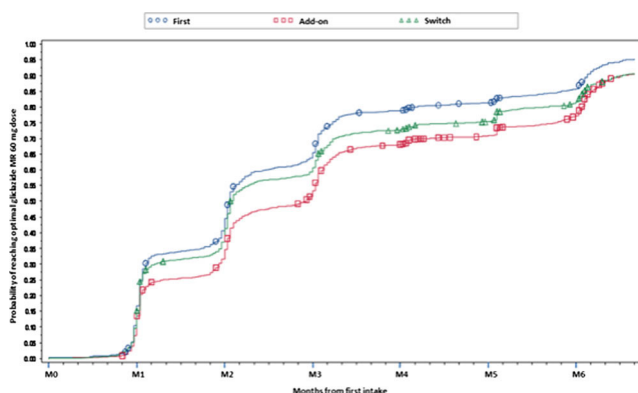

¹Institute of Diabetes Mellitus, Moscow, Russian Federation, ²General Hospital Novo Mesto, Slovenia, ³Istanbul University, Turkey, ⁴University of Toronto, Canada.

Background and aims: Intensive glucose control with gliclazide modified release (MR) has been reported to significantly reduce major macrovascular or microvascular events in people with type 2 diabetes (T2D). A new and convenient scored formulation (MR 60 mg) has been developed to facilitate medication adherence. This study explored the temporal titration profile of gliclazide MR 60 mg when used as either a first- or second-line prescription.

Materials and methods: This was a 6-month long, international, multicentre, non-comparative, open-label observational study. Between 7/2011 and 2/2014, 7170 individuals aged ≥ 35 years with T2D, HbA1c $\geq 7.5\%$ and not on insulin were enrolled. At Visit 1, they were prescribed 30-120 mg once daily (QD) of the gliclazide MR 60 mg formulation as a first line (FIRST - newly diagnosed and/or pharmacotherapy naïve), add-on (ADD) or switch from a previous oral antihyperglycaemic treatment strategy (SWITCH). At months 1, 2 and 3, gliclazide MR 60 mg dose was uptitrated (≥ 120 mg) based on fasting plasma glucose (FPG) and at the discretion of the investigator. The primary evaluation criterion was the time between first gliclazide MR intake and first occurrence of optimal glycaemic control (usually HbA1c $< 7\%$). Values are mean(SD); significance set at $P < 0.05$.

Results: Women comprised 58.5% of the cohort. Baseline (BL) age was 58.9(10.6) years, BMI 30.1 (5.0) kg/m², and T2D duration 5.1(4.4) years. FIRST ($n=1911$), ADD ($n=2831$) and SWITCH ($n=1683$) groups had BL HbA1c 8.83(1.39)%, 8.77(1.25)% and 8.75(1.30)% respectively. Probability of the entire cohort reaching optimal gliclazide MR dosing at months 1, 2, 3 and 6 was 0.15, 0.39, 0.59 and 0.92 respectively. Similar trends were observed in the three groups (Fig). Mean HbA1c changes from BL to month 6 were FIRST: -1.98(1.36)%, ADD: -1.74(1.28)% and SWITCH: -1.61(1.33)% (all $P < 0.01$); these corresponded with 71.8%, 65.0% and 57.7% of the respective groups documenting an HbA1c $\leq 7\%$. Overall, 65.3% achieved an HbA1c $\leq 7.0\%$ with an average time to efficient dose of 80.1 days. Weight loss occurred across the board (kg differences between BL and month 6 — FIRST -1.45(4.31), ADD -1.27(5.01) and SWITCH -1.30(4.22)). Severe hypoglycaemic incidents were rare, with 4 (0.06%) participants experiencing an episode. The majority (95.5%) indicated a greater likelihood of adherence with the gliclazide MR 60 mg QD regime vs their previous therapy.

Conclusion: Within 6 months, progressive gliclazide MR 60 mg QD titration produced a significant mean 1.78% improvement in HbA1c with $\sim 90\%$ optimal dose achievement. There was concomitant weight loss and few severe hypoglycaemic incidents. In this large, real world study, progressive uptitration with gliclazide MR 60 mg QD appears to be efficacious and safe in people with uncontrolled T2D independent of their prior antihyperglycaemic treatment.

Efficacy and safety of repaglinide added to sitagliptin in Japanese patients with type 2 diabetes: a randomised 24 week open-label trial A. Nishimura^{1,2}, S. Usui¹, N. Kumashiro¹, H. Uchino¹, A. Yamato², D. Yasuda², M. Okubo², Y. Mori², T. Hirose¹;

¹Division of Diabetes, Metabolism and Endocrinology, Department of Internal Medicine, Toho University School of Medicine, ²Toranomon Hospital, Tokyo, Japan.

Background and aims: Although sitagliptin (SITA) improves glycaemic control without increasing risk of hypoglycemia and is weight-neutral, SITA can't ameliorate postprandial glucose sufficiently in many patients with type 2 diabetes. Repaglinide (REPA), a potent insulin secretagogue has been reported to increase early insulin secretion and improve postprandial hyperglycemia, and might be effective in combination with SITA. However, there has been no report that shows the efficacy of REPA in combination with SITA, previously. The aim of this study is to investigate the efficacy and safety of REPA as add-on to SITA, compared with switching to REPA in Japanese type 2 diabetes patients poorly controlled with SITA.

Materials and methods: Thirty patients inadequately controlled with SITA 50 mg once daily [range of glycated hemoglobin (HbA1c) was 7.0–8.5%] were randomized 1:1 to REPA as add-on therapy to SITA (0.5 mg of REPA thrice daily and 50 mg of SITA once daily, n=15: AD group) or switch from SITA to REPA (0.5 mg of REPA thrice daily, n=15: SW group). A meal tolerance test was carried out at weeks 0 and 24. All data are expressed as mean±standard deviation (SD).

Results: Treatment groups were balanced at baseline (HbA1c, 7.6±0.4% in AD group and 7.6±0.4% in SW group; fasting plasma glucose, 8.5±1.4 mmol/L in AD group and 8.5±1.7 mmol/L in SW group; body weight, 66.4±8.0 kg in AD group and 71.4±15.1 kg in SW group). The mean HbA1c changes from baseline to week 24 were -0.8±0.7 and -0.2±0.4% in AD and SW groups, respectively, and the difference between two groups was significant (P=0.008). The mean changes in area under the curve (AUC) of glucose from 0 to 180 min from baseline to week 24 in AD group was -271.1±200.2 mmol*min/L in AD group compared with those in SW group (-31.2±342.6 mmol*min/L) (P=0.032). Mean insulin secretion relative to glucose elevation (ISG) (ISG: AUC0-180 insulin / AUC0-180 glucose) in AD group significantly increased in comparison with that in baseline (P=0.020) and tended to be higher than that in SW group, but the differences are not statistically significant (mean changes from baseline to week 24 were 1.23±1.24 μIU/mmol in AD group and those in SW group were 0.35±1.19 μIU/mmol; P=0.069). The mean change in AUC0-180 of glucagon decreased in AD group and increased in SW group, but the difference was not significant (-5485±9633 pg*min/mL in AD group and 2915±

12050 pg*min/mL in SW group; P=0.058). There was no significant difference in changes in bodyweight between the two groups (AD group 0.4±1.6 kg, SW group 0.5±1.3 kg; P=0.807). The incidence of hypoglycemic events was low (three in AD group), and none of the patients developed severe hypoglycemia or severe.

Conclusion: The combination therapy of SITA and REPA is effective and well tolerated in Japanese type 2 diabetes without significant weight gain and severe hypoglycemia.

Within-sulfonylurea-class evaluation of the time to intensification with insulin or triple oral therapy (ZODIAC-43)

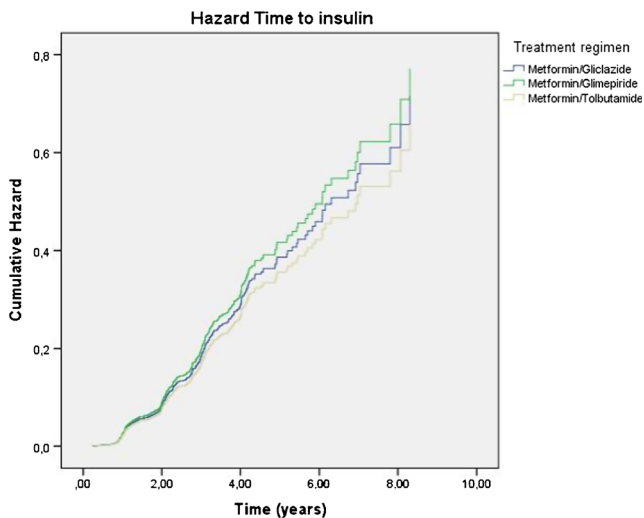

G.W.D. Landman^{1,2}, D. Schrijnders¹, K.H. Groenier^{1,3}, H.J.G. Bilo^{1,4}, N. Kleefstra^{1,4};

¹Diabetes Centre Isala, Zwolle, ²Dept. of Internal Medicine, Gelre Hospital, Apeldoorn, ³Dept. of General Practice, University Medical Center Groningen, ⁴Dept. of Internal Medicine, University Medical Center Groningen, Netherlands.

Background and aims: The Dutch type 2 diabetes mellitus (T2DM) guideline advises sulfonylureas (SUs), specifically gliclazide, as the first intensification step after metformin and the addition of insulin as a second intensification step. There is evidence for important within-class SU differences, but data are lacking concerning within-class SU differences and the time to a second intensification with either insulin or a third oral agent in daily practice. This study aims to investigate the relationships between three different SUs, either gliclazide, glimepiride or tolbutamide, used as dual therapy next to metformin, and the time needed for treatment intensification with either insulin or oral triple therapy in patients with T2DM. **Materials and methods:** From a large prospective cohort study (the ZODIAC cohort, n=82.167), patients were selected who used monotherapy with metformin for at least one year and subsequently intensified with one out of three SUs (gliclazide, glimepiride or tolbutamide), the so called new users. Patients with an eGFR below 30 mL/min per 1.73 m² were excluded. Time-dependent Cox proportional hazard analyses, adjusted for age, gender, diabetes duration, updated mean eGFR and BMI were used to evaluate the primary outcome, first receipt of insulin, and the secondary outcome, first receipt of insulin or triple oral therapy.

Results: From the 3507 selected patients 47.0% were female, the mean age (SD) 61.0(11.4), median diabetes duration (interquartile range (IQR)) 6.8 years (IQR 4.5–9.4), median HbA1c 6.8 (IQR 6.4–7.4), median BMI 29.7 (IQR 26.8–33.3) and the mean eGFR 83.2 mL/min per 1.73 m² (20.0). 2.5 and 5 years after intensification 13% and 32% of patients were using insulin. The cumulative hazard ratio (HRs) for the primary endpoint is shown in figure 1. Metformin/gliclazide was taken as a reference category. HR for time to insulin or triple oral therapy (the secondary endpoint) for metformin/glimepiride was 1.042 (95% CI 0.778–1.394) and for metformin/tolbutamide 0.845 (95% CI 0.632–1.129). There were no significant between group differences in both primary and secondary outcome.

Conclusion: In this study, intensification with either gliclazide, glimepiride or tolbutamide on top of metformin, was not associated with a difference in risk for need for a second intensification with insulin or triple oral therapy. 87% and 68% of patients were without insulin 2.5 and 5 years, respectively, after starting a SU. In this large Dutch primary care population, there were no within-SU-class differences concerning the time for the need of further treatment intensification with either insulin or a third oral agent.

725

Low baseline beta cell function is associated with higher rates of hypoglycaemia with glimepiride in elderly patients with type 2 diabetes inadequately controlled with metformin

S. Perl, W. Cook, C. Wei, P. Ohman, B. Hirshberg;
AstraZeneca, Gaithersburg, USA.

Background and aims: Elderly patients with type 2 diabetes (T2D) pose a challenge for management of glycemia owing to excess fragility and risk of adverse outcomes during hypoglycemia episodes. We therefore sought to identify risk factors for the development of hypoglycemia (any reported symptomatic event and events of plasma glucose concentration <54 mg/dL regardless of symptoms) in elderly patients when saxagliptin (SAXA) or glimepiride (GLIM) is added to metformin.

Materials and methods: A post hoc analysis of data from the GENERATION trial that enrolled 720 patients aged ≥ 65 years was conducted. β -cell function was assessed using HOMA-2% β .

Results: The proportion of patients experiencing any hypoglycemia event was lower with SAXA vs GLIM (5.8% vs 34.8%). Regardless of treatment, patients with baseline HOMA-2% $\beta \leq$ median value of 39.1% had a higher event rate of hypoglycemia of 1.27 events/patient year compared with patients with baseline HOMA-2% $\beta >$ median, 0.82 events/patient year (RR=1.300 [95% CI, 1.084, 1.560]). In the GLIM-treated patients, the hypoglycemia event rate in patients with baseline HOMA-2% $\beta \leq$ median was higher (2.29 events/patient year) compared with patients with baseline HOMA-2% $\beta >$ median (1.60 events/patient year; RR=1.278 [95% CI, 1.057, 1.545]); corresponding SAXA hypoglycemia event rates were too low to draw meaningful conclusions at 0.16 vs 0.09 events/patient year (RR=1.446 [0.687, 3.043]), respectively. The association between lower β -cell function at baseline and increased incidence of hypoglycemia was particularly strong for patients ≥ 75 years (RR=2.572 [95% CI: 1.787-3.701], $P < 0.001$).

Conclusion: In patients with lower β -cell function, the addition of a sulfonylurea is associated with increased risk of hypoglycemia compared with patients with higher β -cell function. These findings are especially relevant to elderly patients in whom hypoglycemia associated morbidity is higher.

Comparative efficacy of anti-diabetic agents on nonalcoholic fatty liver disease in patients with type 2 diabetes mellitus: a systematic review and meta-analysis

W. Tang, Y. Bi, S. Shen, D. Zhu;

Endocrinology department, Drum Tower Hospital Affiliated to Nanjing University Medical School, China.

Background and aims: Nonalcoholic fatty liver disease (NAFLD) has a high prevalence in patients with type 2 diabetes mellitus (T2DM). It deteriorates abnormal glucose and lipid metabolism, and accelerates the development of diabetic complications. In this study, we sought to provide a comprehensive assessment regarding the effects of anti-diabetic agents on NAFLD in patients with T2DM.

Materials and methods: MEDLINE, EMBASE and the Cochrane Central Register of Controlled Trials were searched for both randomized and non-randomized clinical trials focused on T2DM patients with NAFLD. Thiazolidinediones (TZDs), glucagon-like peptide-1 receptor (GLP-1R) agonists, dipeptidyl peptidase-4 inhibitors, sodium-glucose transport proteins type 2 inhibitors, sulfonylureas, insulin and metformin were explored, regardless of comparing with placebo, each other or non-treated controls. Observational trials were also recruited to expand exploration. Relative changes of hepatic fat content (HFC) and liver histology were evaluated as primary outcomes. We also assessed body composition, glucose and lipid metabolism, and inflammatory factors. Data was collected and analyzed by STATA.

Results: 1,196 participants from 19 randomized controlled trials (RCTs) and 14 non-randomized studies were included. Evidence from RCTs and observational studies suggested TZDs for 12-72 weeks were associated with greater HFC reduction (WMD -22.27%, 95%CI -26.98 to -17.56, $p=0.000$, as compared with placebo; WMD -27.88%, 95%CI -47.41 to -8.35, $p=0.005$, as compared with metformin; -35.7% vs. -7.69%, $p < 0.05$, as compared with glibenclamide; a range of -30% to -52.1%, all $p < 0.05$, in observational studies) and improved liver histology (including steatosis, ballooning necrosis, inflammation and NAFLD score as compared with placebo and metformin, all $p < 0.05$). GLP-1R agonists had beneficial effects on HFC after 26-50 weeks intervention (-61% vs. -41% for exenatide/pioglitazone combination vs. pioglitazone monotherapy, $p < 0.05$; 0.1 vs. 0 for liraglutide vs. glimepiride, $p=0.045$, changes from baseline of CT value), and insulin/metformin combination with 3-7 months improved HFC (a range of -17.6% to -48%, all $p < 0.05$, compared with baseline). Nevertheless, initiating metformin alone showed no benefit on HFC or liver histology, at least in 16-48 weeks. Neither did dapagliflozin for 24 weeks. Additionally, nateglinide for 18 months was reported in a small sample-size RCT to ameliorate HFC (-27%, p value was unavailable) and liver histology (steatosis and portal inflammation, both $p < 0.05$). Sitagliptin therapy of one year also provided benefit on nonalcoholic steatohepatitis score ($p=0.04$) in an observational study. What's more, we observed the reduction of TG, improvement of HbA_{1c} and alleviation of inflammation all paralleled to the amelioration of NAFLD. In spite that weight loss has been proved beneficial on NAFLD, it is definitely not the mere factor that contributed, since TZDs could still improve HFC and liver histology significantly with greater weight gain than placebo and metformin.

Conclusion: For T2DM with NAFLD, administering TZDs and GLP-1R agonists seems providing more identified advances in attenuating HFC. Further RCTs with high quality, long-term duration and large-size samples are warranted to assess the efficacy of various hypoglycemic agents on clinical outcomes associated with NAFLD in T2DM.

A network meta-analysis to assess options for treatment intensification for patients with type 2 diabetes inadequately controlled on dual therapy

M. Schroeder¹, V. Taieb², M. Pacou³, S. Ho², A.T. Nielsen⁴, A. Schubert⁵, C. Neslusan⁶;

¹Janssen UK, High Wycombe, ²Amaris, London, UK, ³Amaris, Paris, France, ⁴Janssen-Cilag, Birkerød, Denmark, ⁵Janssen-Cilag, Warsaw, Poland, ⁶Janssen Global Services LLC, Raritan, USA.

Background and aims: Augmenting existing therapies with medicines that have alternative modes of action in terms of glucose lowering and benefits in terms of other micro- and macrovascular risk factors beyond HbA1c reduction (e.g. weight loss and blood pressure reduction) may improve outcomes. In the absence of direct evidence comparing antihyperglycaemic agents (AHAs) in triple therapy, indirect comparisons can be used to inform clinical and policy decisions. A network meta-analysis (NMA) was conducted to assess the relative efficacy of canagliflozin (CANA), an agent that inhibits sodium glucose co-transporter 2 (SGLT2), compared to other non-insulin AHAs as add-on to metformin plus sulphonylurea (MET+SU) and as add-on to MET plus pioglitazone (MET+PIO).

Materials and methods: Two separate networks of evidence informed by a systematic literature review were constructed to estimate the relative efficacy of CANA in combination with MET+SU or MET+PIO in lowering HbA1c at 26±4 weeks via Bayesian NMA. After screening the trials for appropriateness of pooling, comparisons of CANA were feasible versus dapagliflozin (DAPA), empagliflozin (EMPA), liraglutide (LIRA), exenatide (EXEN), sitagliptin (SITA), linagliptin (LINA), saxagliptin (SAXA), PIO and insulin in the MET+SU network and EMPA, EXEN, and LINA in the MET+PIO network. Relative efficacy was evaluated based on absolute differences (Δ) and Bayesian pairwise probabilities (P); $P \leq 30\%$ and $P \geq 70\%$ were chosen to indicate a smaller and larger effect, respectively.

Results: As add-on to MET+SU, HbA1c reductions (%) were higher for CANA 300 mg compared to EMPA 10 and 25 mg ($\Delta = -0.36$ to -0.41 , $P = 100\%$), DAPA 10 mg ($\Delta = -0.32$, $P = 99\%$), EXEN 5 μg ($\Delta = -0.23$, $P = 96\%$), and SITA, SAXA, and LINA ($\Delta = -0.20$ to -0.39 , $P = 100\%$) and comparable to LIRA 1.8 mg ($\Delta = 0.08$, $P = 31\%$) and EXEN 10 μg ($\Delta = -0.01$, $P = 53\%$). HbA1c reductions with CANA 100 mg were greater compared to EMPA 10 and 25 mg ($\Delta = -0.11$ to -0.16 , $P \geq 81\%$), SAXA, and LINA ($\Delta = -0.10$ to -0.14 , $P \geq 75\%$), similar compared to DAPA 10 mg ($\Delta = -0.07$, $P = 68\%$), EXEN 5 μg , and SITA ($\Delta = 0.02$ to 0.05 , $P \geq 33\%$), and lower compared to LIRA 1.8 mg ($\Delta = 0.33$, $P = 3\%$). As add-on to MET+PIO, CANA 300 mg was associated with greater HbA1c reductions versus all comparators: EMPA 25 and 10 mg ($\Delta = -0.17$ to -0.27 , $P \geq 88\%$), LINA ($\Delta = -0.20$, $P = 84\%$), and EXEN 10 μg ($\Delta = -0.24$, $P = 96\%$). CANA 100 mg conferred HbA1c reductions greater than EMPA 10 mg ($\Delta = -0.13$, $P = 81\%$) and EXEN 10 μg ($\Delta = -0.10$, $P = 76\%$), and were deemed similar compared to EMPA 25 mg ($\Delta = -0.03$, $P = 58\%$) and LINA ($\Delta = -0.06$, $P = 62\%$).

Conclusion: An NMA of add-on therapies to MET+SU indicates that glycaemic reductions at 26 weeks were greater for CANA 300 mg and at least as large for CANA 100 mg compared to EXEN, other SGLT2 inhibitors, and dipeptidyl peptidase-4 (DPP-4) inhibitors. CANA 300 mg was found to be comparable to LIRA 1.8 mg in terms of HbA1c reduction. An NMA of add-on therapies to MET+PIO indicates that CANA 300 mg was associated with consistently greater HbA1c reductions versus EMPA, EXEN, and LINA, while CANA 100 mg was deemed at least similar. These results suggest that CANA may be a good therapeutic option as an add-on to common dual therapies for T2DM.

The impact of delaying treatment intensification in type 2 diabetes: evidence from UK general practice

R. Das¹, L. Watson², R. Farquhar², H. Langerman¹, A.H. Barnett³;
¹Merck Sharp & Dohme, Hoddesdon, ²EpiPharmaCo, Buxton, ³Heart of England NHS Foundation Trust, Birmingham, UK.

Background and aims: A key objective of treating type 2 diabetes mellitus (T2DM) is obtaining and maintaining good glycaemic control, generally based on measurement of glycated haemoglobin (HbA1c). Keeping HbA1c below target levels, which vary across international and local guidelines, reduces the risk of vascular complications. Evidence from UK, Europe and USA, however, indicates that health care professionals are commonly slow to intensify treatment in patients with poor glycaemic control (often termed “clinical inertia”). Our study aimed to evaluate longitudinal clinical changes and resource burden in patients intensified at varying times after loss of glycaemic control in the UK.

Materials and methods: Adults with incident T2DM were identified in the UK Clinical Practice Research Datalink during the period 1 January 2000 to 31 March 2014. Patients who were newly initiated on metformin monotherapy and who had lost good glycaemic control on medication (HbA1c > 7%) were included. Patients were grouped according to time to intensification of second line therapy: Group A, rapid intensification within 365 days of treatment failure; Group B, delayed intensification from day 366 to 1824 post treatment failure; Group C, never intensified post treatment failure. Patients were followed up from day 365 (index date) post first treatment failure for five years, until end of study, switch to insulin, migration or death. The study evaluated a variety of longitudinal clinical changes including HbA1c, weight and diabetes prescribing.

Results: 6,710 patients with T2DM met the study inclusion criteria. Key baseline characteristics of the evaluated patients are described below. There was a delay in treatment intensification to second-line therapy or no treatment intensification in 60.5% of patients in the 5-year follow-up period. Group A achieved a significant decline in HbA1c from baseline 1 year post index date compared to Groups B & C (-1.13% Group A; +0.26% Group B, +0.16% Group C). A significantly higher proportion of patients achieved HbA1c target < 7% in Group A (Group A (45.8%); Group B (19.1%), $p < 0.0001$). Using an adjusted hazard model, Group A was found to achieve the HbA1c target from the index date significantly faster than Group B (hazard ratio 3.25 (95% CI 2.87, 3.69)). The most commonly used second-line intensification agent was sulphonylureas in both Groups A and B throughout the observation period but was associated with significant weight gain (+1.3 kg per patient) in the adjusted models. Similar results were seen with thiazolidinediones users (+1.0 kg). Only patients taking DPP-4 inhibitors had consistent weight loss over 5 years of -0.6 kg.

Conclusion: There was a substantial level of clinical inertia. Patients that were rapidly intensified post treatment failure achieved a significant reduction in HbA1c and got to target faster. A significantly higher proportion achieved the HbA1c target < 7% in Group A compared with Group B, despite a higher baseline HbA1c.

Patient preferences for attributes of type 2 diabetes mellitus treatments in Germany

M. Sikirica¹, C. Mansfield², A. Pugh², C. Poulos², A. Martin¹, V. Unmuessig¹;
¹GSK, King of Prussia, ²RTI, RTP, USA.

Background and aims: Understanding T2DM patients' preferences for attributes of T2DM treatments may help to explain how each of these attributes differentially affect patients' perception and behavior. Our aim was to quantify the relative preferences of a set of attributes describing T2DM treatments for T2DM patients in Germany.

Materials and methods: A stated-preference discrete-choice experiment (DCE) survey was designed to elicit preferences for T2DM treatment attributes among patients in Germany taking a prescription T2DM medication for >2 years. The survey collected background characteristics and information on respondent demographics, health history, current health status (EQ-5D), and experience with T2DM and T2DM treatments. The DCE included a series of 8 choices between pairs of hypothetical T2DM treatments defined by these seven attributes: chance of reaching target HbA1c (A1c), reduction in risk of serious heart attack or stroke, frequency of hypoglycemia, risk of gastrointestinal side effects (GI SEs), weight change, mode of administration (MoAdmin; pill or injection), and dosing frequency. Random-parameters logit was used to analyze the DCE data. Interactions between patient characteristics and preference estimates were explored and results for prespecified subgroups analyzed. A preference for an attribute was dominant if a respondent always selected the medicine with the better level of that attribute. Minimum additional benefit (MAB) was defined as the minimum increase in probability of reaching target HbA1c for which respondents would accept a worse level of another attribute.

Results: Of 1,198 individuals that responded to the survey, 531 (44.3%) were eligible to participate, and 474 consented and completed the survey and were included in this analysis. Mean age was 61 years, 58% male, and 54% with T2DM diagnosed >7 yrs ago. Based on the DCE analysis, Figure 1 below, GI SEs were most important to patients, followed by weight changes, MoAdmin and A1c. Eighteen percent of respondents always selected the treatment administered by pills, 7% dominated on weight change, and 4% on A1c. Based on the DCE, the MAB analysis found that patients would require that the probability of reaching their target HbA1c is 56 additional percentage points higher to change from a 0% to 30% risk of having GI SEs. Other high MAB levels were reported by moving from 2-kg weight loss to 2-kg weight gain (MAB of 44), moving from 0% to 20% risk of GI SEs (43) and moving from pill to injection (42).

Conclusion: Our findings suggest that this sample of German T2DM patients was willing to trade-off efficacy for improved GI SEs and a better mode of administration (pills). Patients focused on reduction in the risk of T2DM-related GI-SEs, weight changes and mode of administration as key attributes that they value highly. Given the variety of T2DM medications available, the results suggest that careful discussion about patient preferences could help improve patient satisfaction with T2DM drugs.

Figure 1: Relative importance of the attributes over the ranges presented to respondents

GI = gastrointestinal; HbA1c = glycated hemoglobin; hypo = hypoglycemic event.

Note: All levels are different from each other within attributes at the 5% level except "once a week" and "once a day" ($P = 0.48$); "once a week" and "twice a day" ($P = 0.06$); and "twice a day" and "more than twice a day" ($P = 0.16$), in the dosing frequency attribute.

Dapagliflozin decreases post-prandial glucose without an increase in C-peptide or insulin

T. Forst¹, K. Rohwedder², E. Johnsson³;¹Profil Institute for Metabolic Research, Mainz, ²AstraZeneca, Wedel, Germany, ³AstraZeneca, Mölndal, Sweden.

Background and aims: Control of postprandial glucose (PPG) is important for type 2 diabetes mellitus (T2DM) management and risk reduction. The combination of PPG, insulin and C-peptide are measures of β -cell function, insulin resistance and success of glycaemic control.

Materials and methods: In a small subgroup of patients from a 4-year, phase 3 trial of dapagliflozin (DAPA, ≤ 10 mg/d) vs glipizide (GLIP, ≤ 20 mg/d) as add-on to metformin (MET) in patients with T2DM, PPG was assessed by oral glucose tolerance test at 52 and 104 weeks.

Results: At 52 weeks, mean area under the curve (AUC0-180 mins) for PPG was reduced from baseline in both groups, but was more pronounced with DAPA compared with GLIP (-636.44 [76.4] mmol/L/min vs -398.31 [82.67] mmol/L/min, respectively). Reductions were sustained at 104 weeks (DAPA, -517.12 [104.93] mmol/L/min; GLIP, -404.6 [107.0] mmol/L/min). At both time points, DAPA-mediated reductions in PPG were not associated with an increase in AUC for circulating insulin; this finding was the opposite for GLIP. In addition, increases in C peptide AUC were greater with GLIP than with DAPA at both time points (Table).

Conclusion: Compared with GLIP, DAPA is associated with a sustained reduction in PPG and improvement in glycaemic control without an increase in C-peptide or insulin over 2 years, suggestive of a potential protective effect of β -cell function and alleviation of β -cell stress and insulin resistance.

Combined treatment with saxagliptin + dapagliflozin improves beta cell function and reduces insulin levels by increased insulin clearance

E. Ekholm¹, L. Hansen², N. Iqbal², B. Carlsson¹, H. Chen³, B. Hirshberg³;¹AstraZeneca, Mölndal, Sweden, ²Bristol-Myers Squibb, Princeton, USA, ³AstraZeneca, Gaithersburg, USA.

Background and aims: Dapagliflozin (DAPA) alone and in combination with saxagliptin (SAXA+DAPA) reduced, while SAXA increased, insulin levels during a meal tolerance test (MTT). We asked if this was driven by increased insulin clearance.

Materials and methods: C-peptide/insulin ratio was used as a marker for insulin clearance during an MTT and β -cell function was assessed by HOMA-2 in a study testing SAXA 5 mg+DAPA 10 mg vs SAXA and DAPA alone in patients with type 2 diabetes poorly controlled with metformin.

Results: At week 24, SAXA+DAPA and SAXA increased mean (95% CI) C-peptide AUC from baseline, whereas no change was observed for DAPA (SAXA+DAPA: 40.2 [9.2, 71.3 ng/mL]; SAXA: 95.4 [63.4, 127.4] ng/mL; DAPA: 14.5 [-17.6, 46.8] ng/mL). In contrast, change from baseline in insulin AUC was reduced with SAXA+DAPA (-1120.4 [-1633.9, -606.9] μ U/mL), and DAPA (-1018.6 [-1550.5, -486.8]), but increased with SAXA (661.2 [131.1, 1191.3] μ U/mL). Curves for C-peptide/insulin at baseline were similar between the 3 treatment groups. At week 24, C-peptide/insulin was unaltered by SAXA but increased similarly after SAXA+DAPA and DAPA (Figure), mainly due to decreased insulin AUC with DAPA. All treatments improved β -cell function compared with baseline (SAXA+DAPA: 20.6% [16.5, 24.8]; DAPA: 17.0% [12.7, 21.4]; SAXA: 11.0% [6.6, 15.5]).

Conclusion: The data suggest that at 24 weeks, SAXA+DAPA and DAPA improved β -cell function and increased insulin clearance in patients with type 2 diabetes poorly controlled with metformin.

Baseline fasting plasma glucose may predict response to dapagliflozin when added to metformin

K. Rohwedder¹, E. Johnsson²;¹AstraZeneca Pharmaceuticals LP, Wedel, Germany, ²AstraZeneca Pharmaceuticals LP, Mölndal, Sweden.

Background and aims: Dapagliflozin (DAPA) is a highly selective, orally active sodium-glucose co-transporter 2 (SGLT2) inhibitor that increases urinary glucose excretion and reduces hyperglycaemia independently of insulin.

Materials and methods: In a 52-week, double-blind, active-controlled, non-inferiority trial, patients with type 2 diabetes mellitus (T2DM) inadequately controlled on metformin were randomised to DAPA (≤ 10 mg/d; n=406) or glipizide (GLIP; ≤ 20 mg/d; n=408). As previously reported, the response rate (reduction in HbA1c and body weight from baseline to 52 weeks) was significantly higher in the DAPA group (66.9 vs 21.3% [difference, 45.7%; 95% CI, 39.3-51.6%]). We report the results of a post hoc analysis of baseline factors, which may predict response to DAPA (C-peptide; fasting plasma glucose [FPG]; C-peptide:FPG ratio; estimated glomerular filtration rate).

Results: In both arms, response rate increased as baseline FPG increased (Table). Differences in response rate between baseline FPG categories were significant for DAPA categories <7.8 vs ≥9.6 mmol/L (<141 vs ≥173 mg/dL [difference, 20.0%; $P<0.001$]) and for ≥7.8–<9.6 vs ≥9.6 mmol/L (≥141–<173 vs ≥173 mg/dL [difference, 11.8%; $P=0.044$]) but not for any GLIP categories. In both groups (full analysis set), greater HbA1c decreases occurred with higher baseline FPG. Body weight change showed no obvious pattern with baseline FPG.

Conclusion: These data suggest that baseline FPG may predict the likelihood of combined HbA1c and body weight reduction in DAPA-treated T2DM patients.

Initial combinations of empagliflozin and metformin in patients with type 2 diabetes

S. Hadjadj^{1,2}, A. Jelaska³, S. Zhang³, T. Meinicke⁴, H.J. Woerle⁵, U.C. Broedl⁵;

¹Centre Hospitalier Universitaire Poitiers, ²INSERM CIC 1402, Poitiers, France, ³Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, USA, ⁴Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, ⁵Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany.

Background and aims: Metformin (MET) is the recommended first-line therapy for patients with type 2 diabetes (T2DM), but initial combination therapy may provide more robust glucose-lowering efficacy.

Materials and methods: In this Phase III study, 1364 drug-naïve patients with T2DM were randomized to empagliflozin (EMPA) 12.5 mg bid+MET 1000 mg bid (n=170), EMPA 12.5 mg bid+MET 500 mg bid (n=170), EMPA 5 mg bid+MET 1000 mg bid (n=172), EMPA 5 mg bid+MET 500 mg bid (n=170), EMPA 25 mg qd (n=168), EMPA 10 mg qd (n=172), MET 1000 mg bid (n=171) or MET 500 mg bid (n=171). The primary endpoint was change from baseline in HbA1c at week 24. Key secondary endpoints were changes from baseline in fasting plasma glucose (FPG) and weight.

Results: EMPA+MET bid led to statistically superior and clinically meaningful reductions in HbA1c vs EMPA qd and MET bid doses (Table). EMPA+MET bid led to significant reductions in FPG vs EMPA qd and MET bid and in weight vs MET bid (Table). Adverse events (AEs) were reported in 56.7–66.3% of patients across groups. The percentage of patients with confirmed hypoglycaemic AEs (plasma glucose ≤70 mg/dL and/or requiring assistance) was low in all groups (0–1.8%); none required assistance.

Conclusion: EMPA+MET bid significantly reduced HbA1c vs EMPA qd and MET bid and was well tolerated.

Efficacy and safety of canagliflozin monotherapy: results from 2 studies in patients with type 2 diabetes mellitus

E. Jodar¹, J. Rosenstock², L. Chuck³, M. González-Ortiz⁴, C. Tong⁵, G. Capuano⁵, M. Alba⁵, R. Qiu⁵;

¹Department of Endocrinology, Hospital Quiron, Madrid, Spain, ²Dallas Diabetes and Endocrine Center at Medical City, Dallas, ³Diablo Clinical Research Inc, Walnut Creek, USA, ⁴Institute of Experimental and Clinical Therapeutics, Physiology Department, Health Science University Center, University of Guadalajara, Mexico, ⁵Janssen Research & Development, LLC, Raritan, USA.

Background and aims: Canagliflozin (CANA) is an SGLT2 inhibitor approved for the treatment of type 2 diabetes mellitus (T2DM). The efficacy and safety of CANA monotherapy was assessed in patients with T2DM inadequately controlled with diet and exercise enrolled in 2 randomised, double-blind, Phase 3 studies.

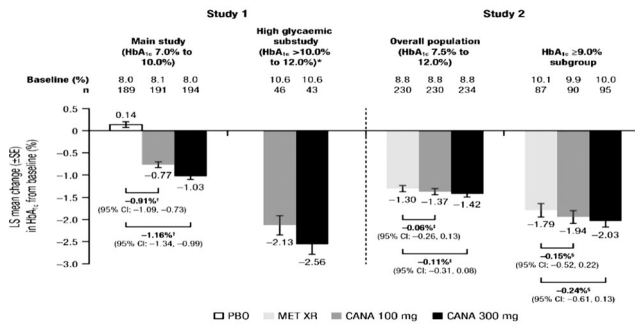

Materials and methods: In Study 1, the efficacy and safety of canagliflozin 100 and 300 mg versus PBO were assessed at Week 26 (N=584; mean age, 55.4 y; HbA1c, 8.0%; BMI, 31.6 kg/m²); change in HbA1c was also assessed in a separate substudy of patients with high baseline HbA1c (HbA1c >10.0% to ≤12.0%; N=91) that was not PBO controlled. In Study 2, the efficacy and safety of canagliflozin 100 and 300 mg versus metformin extended release (MET XR) were assessed at Week 26 (N=712; mean age, 55.0 y; HbA1c, 8.8%; BMI, 32.6 kg/m²); change in HbA1c was also assessed in a subset of patients with baseline HbA1c ≥9.0% (n=280). The proportion of patients achieving HbA1c <7.0% was evaluated in both studies at Week 26. Safety was assessed based on adverse event (AE) reports.

Results: In Study 1, CANA 100 and 300 mg provided significant reductions in HbA1c from baseline at Week 26 versus PBO (least squares [LS] mean changes of -0.77% and -1.03% vs 0.14%); HbA1c reductions were -2.13% and -2.56% with CANA 100 and 300 mg in patients with baseline HbA1c >10.0% to ≤12.0% in the substudy of Study 1 (Figure). In Study 2, CANA 100 and 300 mg showed noninferiority in lowering HbA1c versus MET XR at Week 26 (LS mean changes of -1.37%, -1.42%, and -1.30%, respectively); HbA1c reductions were -1.94%, -2.03%, and -1.79%, respectively, in patients with baseline HbA1c ≥9.0% (Figure). In Study 1, a greater proportion of patients achieved HbA1c <7.0% with CANA 100 and 300 mg versus PBO at Week 26 (44.5% and 62.4% vs 20.6%). In Study 2, the proportion of patients achieving HbA1c <7.0% at Week 26 with CANA 100 and 300 mg and MET XR was 38.8%, 42.8%, and 43.0%, respectively. In Study 1, the overall AE incidence was 61.0%, 59.9%, and 52.6% with CANA 100 and 300 mg and PBO, respectively. In Study 2, the overall AE incidence was 37.1%, 39.9%, and 37.6% with

CANA 100 and 300 mg and MET XR, respectively. In both studies, the incidence of serious AEs and AEs related to discontinuation was low across groups. Rates of genital mycotic infections were higher with CANA in both studies; rates of osmotic diuresis-related AEs were low overall but higher with CANA.

Conclusion: CANA provided reductions in HbA_{1c} and was generally well tolerated over 26 weeks as monotherapy in patients with T2DM inadequately controlled with diet and exercise, including those with high baseline HbA_{1c}.

Figure. Change from baseline in HbA_{1c} at Week 26.

Canagliflozin is superior to sitagliptin in reducing both HbA_{1c} and body weight in patients with type 2 diabetes mellitus

G. Schernthaner¹, L. Hieronymus², H. Jodon³, U. Vijapurkar⁴, G. Meininger⁴, W. Canovatchel⁴;

¹Rudolfstiftung Hospital-Vienna, Austria, ²DiabetesCare & Communications, Lexington, ³Metabolic Disease Associates, Erie, ⁴Janssen Research & Development, LLC, Raritan, USA.

Background and aims: Many patients with type 2 diabetes mellitus (T2DM) are obese or overweight, so treatments that improve glycaemic control and reduce body weight (BW) may be beneficial. Canagliflozin (CANA), a sodium glucose co-transporter 2 (SGLT2) inhibitor approved for the treatment of T2DM, inhibits renal glucose absorption by lowering the renal threshold for glucose and increasing urinary glucose excretion, resulting in lowered plasma glucose levels and a net caloric loss. CANA has been shown to provide reductions in HbA_{1c} and BW compared with sitagliptin (SITA) in 2 studies as add-on to metformin (MET) or MET plus sulphonylurea (SU). This analysis evaluated the proportion of patients who responded to treatment in terms of both HbA_{1c} and BW in these studies at Week 52.

Materials and methods: This analysis used data from two, 52-week, randomised, double-blind, Phase 3 studies of CANA 100 and 300 mg versus SITA 100 mg as add-on to MET (Study 1: N=1,284; mean baseline HbA_{1c}, 7.9%; BW, 87.2 kg) and CANA 300 mg versus SITA 100 mg as add-on to MET plus SU (Study 2: N=755; mean baseline HbA_{1c}, 8.1%; BW, 88.3 kg).

Results: In Study 1, least squares (LS) mean changes from baseline in HbA_{1c} at Week 52 were -0.73%, -0.88%, and -0.73% with CANA 100 and 300 mg and SITA 100 mg, respectively; LS mean percent changes in BW were -3.8%, -4.2%, and -1.3%, respectively. In Study 2, LS mean changes from baseline in HbA_{1c} were -1.03% and -0.66% at Week 52, and LS mean percent changes in BW were -2.5% and 0.3% with CANA 300 mg and SITA 100 mg, respectively. A greater proportion of patients in Study 1 had reductions in both HbA_{1c} and BW with CANA 100 and 300 mg versus SITA 100 mg (67.7%, 74.7%, and 50.6%, respectively;

differences [95% confidence interval (CI)] of 17.1% [9.7, 24.5] and 24.2% [17.1, 31.3], respectively; Figure). Similar to Study 1, a greater proportion of patients in Study 2 had reductions in both HbA_{1c} and BW with CANA 300 mg (70.6%) versus SITA 100 mg (37.8%; difference [95% CI] of 32.8% [25.7, 39.8]). The overall incidence of adverse events (AEs) was similar across treatment groups in both studies; CANA was associated with increased rates of genital mycotic infections and osmotic diuresis-related AEs compared with SITA. In Study 1, the incidence of documented hypoglycaemia (≤ 3.9 mmol/L) was 7%, 7%, and 4% with CANA 100 and 300 mg and SITA 100 mg, respectively; in Study 2, the incidence of documented hypoglycaemia was 43% and 41% with CANA 300 mg and SITA 100 mg, respectively.

Conclusion: CANA provided greater attainment of reduction in both HbA_{1c} and BW compared with SITA at 52 weeks and was generally well tolerated in patients with T2DM as add-on to MET or MET plus SU.

Figure. Change from baseline in both HbA_{1c} and BW with CANA versus SITA at Week 52 (Study 1).

Canagliflozin provides reductions in HbA_{1c}, body weight, and blood pressure in patients with type 2 diabetes on metformin with or without other antihyperglycaemic agents

P. Hollander¹, C. Mathieu², C. Tong³, W. Canovatchel³, G. Meininger³;
¹Baylor University Medical Center, Dallas, USA, ²Clinical and Experimental Endocrinology, KU Leuven, Belgium, ³Janssen Research & Development, LLC, Raritan, USA.

Background and aims: Canagliflozin (CANA) is a sodium glucose co-transporter 2 (SGLT2) inhibitor developed for the treatment of adults with type 2 diabetes mellitus (T2DM). This post hoc analysis evaluated the efficacy and safety of CANA in patients with T2DM inadequately controlled with metformin +/- other antihyperglycaemic agents (AHAs; ie, sulphonylurea or pioglitazone) based on pooled data from Phase 3 studies.

Materials and methods: Data were pooled from 3 randomised, double-blind, placebo (PBO)-controlled studies (N=1,729; mean age, 56.2 years; HbA_{1c}, 8.0%; body mass index, 32.2 kg/m²; estimated glomerular filtration rate, 88.5 mL/min/1.73 m²). Patients received CANA 100 or 300 mg or PBO once daily for 26 weeks. Efficacy endpoints were evaluated at 26 weeks; safety was assessed based on adverse event (AE) reports.

Results: Relative to PBO, CANA 100 and 300 mg provided least squares (LS) mean reductions in HbA_{1c} (-0.65% and -0.82%), body weight (-2.2% and -2.8%), and systolic blood pressure (BP; -4.0 and -4.4 mmHg) at Week 26 (Table). Overall AE rates were 59.9%, 59.0%, and 62.3% with CANA 100 and 300 mg and PBO, respectively; serious AE rates were 3.1%, 3.1%, and 4.0%, respectively. Over 26 weeks, higher rates of genital mycotic infections in males and females and osmotic diuresis-related AEs were seen with CANA 100 and 300 mg versus PBO. Rates of urinary tract infections were higher with CANA 100 mg versus CANA 300 mg and PBO. Rates of volume depletion-related AEs were low and similar across groups.

Conclusion: CANA improved glycaemic control and reduced body weight and BP compared with PBO, and was generally well tolerated in patients with T2DM as add-on to metformin +/- other AHAs.

Table. Summary of Efficacy Endpoints at Week 26 (mITT, LOCF)

Parameter*	PBO (n = 454)	CANA 100 mg (n = 638)	CANA 300 mg (n = 637)
Baseline HbA _{1c} , %	8.0 (0.9)	8.0 (0.9)	8.0 (0.9)
Change, %	-0.22 (0.04)	-0.87 (0.03)	-1.04 (0.03)
Difference vs PBO		-0.65 (-0.75, -0.56)	-0.82 (-0.92, -0.72)
Baseline body weight, kg	90.0 (22.6)	90.9 (22.4)	89.0 (22.4)
% change	-0.6 (0.2)	-2.8 (0.1)	-3.4 (0.1)
Difference vs PBO		-2.2 (-2.7, -1.8)	-2.8 (-3.2, -2.4)
Baseline systolic BP, mmHg	128.8 (12.9)	128.3 (12.9)	128.9 (12.9)
Change, mmHg	-0.5 (0.5)	-4.5 (0.5)	-5.0 (0.5)
Difference vs PBO		-4.0 (-5.3, -2.6)	-4.4 (-5.8, -3.1)

mITT, modified intent to treat; LOCF, last observation carried forward; SD, standard deviation; SE, standard error; ANCOVA, analysis of covariance; CI, confidence interval. Mean (SD) baseline, LS mean (SE) change from baseline using ANCOVA and PBO-subtracted LS mean (95% CI).

Changes in HbA_{1c} and weight in type 2 diabetes patients initiating dapagliflozin treatment in routine UK primary care

J.P.H. Wilding¹, C.J. Bailey², U. Rigney³, B. Blak³, W. Beekman⁴, C.E. Emmas³;

¹Diabetes & Endocrinology Research Group, Clinical Sciences Centre, Liverpool, UK, ²Life and Health Sciences, Aston University, Birmingham, UK, ³RWE, AstraZeneca UK, Luton, UK, ⁴Medical, AstraZeneca NL, Zoetermeer, Netherlands.

Background and aims: Dapagliflozin is a sodium-glucose co-transporter-2 (SGLT2) inhibitor that lowers blood glucose in type 2 diabetes (T2DM) by reducing renal glucose reabsorption. This study

examines the characteristics of patients initiating dapagliflozin treatment in routine clinical care and assesses subsequent changes in HbA1c and body weight.

Materials and methods: This retrospective observational study was conducted using the Clinical Practice Research Datalink which contains records from 684 primary care practices in the UK. The study cohort consisted of patients with T2DM given a first prescription for dapagliflozin between Nov 2012 and Sept 2014 who were registered ≥ 6 months prior to that prescription and remained registered for ≥ 3 months after dapagliflozin initiation. Changes in HbA1c and weight were reported for patients with a measure pre-initiation and at least one measure during dapagliflozin treatment (up to 12 months follow-up).

Results: Of 2401 patients with ≥ 1 prescription for dapagliflozin, 1732 fulfilled the inclusion criteria. Mean age was 57.5 (SD:10.5) years, weight was 103.1(SD:23.0) kg, HbA1c was 80.1(SD:17.9) mmol/mol and time since T2DM diagnosis was 9.5 (SD:6.0) years: 58% of patients were male. A history of retinopathy was present in 36.9%, nephropathy in 9.8% and neuropathy in 20.4%. The most common usages of dapagliflozin treatment were dual therapy with metformin (435, 25%), triple therapy (480, 28%) and add-on to insulin (332, 19%). 1091 patients had HbA1c values and 970 had weight recorded before initiation of dapagliflozin and on treatment. Reductions in HbA1c and weight were observed with each of the more common treatment combinations and overall (see table). A greater reduction was observed in patients with higher baseline HbA1c (upper tertile, 17.8 (15.4–20.1) mmol/mol) compared to those with a lower baseline (lower tertile, 2.6 (1.3–3.2) mmol/mol) as measured 14–90 days post-initiation.

Conclusion: Reductions in HbA1c and weight observed in a routinely treated UK T2DM population were consistent with results from the dapagliflozin clinical trial program. Reductions were observed with dapagliflozin in combination with metformin, two glucose-lowering agents and insulin.

PS 063 SGLT-2 inhibitors: long-term and advanced combination therapy

738

Simultaneous reduction in both HbA_{1c} and body weight with canagliflozin compared with glimepiride in metformin-treated patients with type 2 diabetes mellitus over 104 weeks

G. Langset¹, L.A. Leiter², U. Vijapurkar³, M. Davies³, W. Canovatchel³; ¹Lipid Clinic, Oslo University Hospital, Norway, ²Keenan Research Centre in the Li Ka Shing Knowledge Institute of St. Michael's Hospital, University of Toronto, Canada, ³Janssen Research & Development, LLC, Raritan, USA.

Background and aims: Canagliflozin (CANA), a sodium glucose co-transporter 2 (SGLT2) inhibitor developed to treat type 2 diabetes mellitus (T2DM), lowers the renal threshold for glucose and increases urinary glucose excretion, leading to decreased plasma glucose levels and a net caloric loss. Glimepiride (GLIM) is a sulphonylurea that stimulates insulin secretion. In patients with T2DM on background metformin (MET), CANA showed durable glycaemic improvements and reductions in body weight (BW) versus GLIM over 104 weeks; this post hoc analysis evaluated the proportion of patients who had decreases in both HbA1c and BW with CANA versus GLIM.

Materials and methods: In this randomised, double-blind study, patients with T2DM (N=1,450; mean baseline HbA1c, 7.8%; BW, 86.6 kg) received CANA 100 or 300 mg or GLIM as add-on to MET over a 52-week core period, followed by a 52-week extension (n=1,050). Using individual patient data, the proportion of patients achieving both change from baseline in HbA1c <0% and BW <0 kg was assessed at Weeks 52 and 104.

Results: At Week 52, least squares (LS) mean changes from baseline in HbA1c were -0.82%, -0.93%, and -0.81% with CANA 100 and 300 mg and GLIM, respectively; LS mean percent changes in BW were -4.2%, -4.7%, and 1.0%. At Week 104, LS mean changes from baseline in HbA1c were -0.65%, -0.74%, and -0.55% with CANA 100 and 300 mg and GLIM, respectively; LS mean percent changes in BW were -4.1%, -4.2%, and 0.9%. The proportion of patients with HbA1c reductions at Week 52 was 83.9%, 86.9%, and 81.9% with CANA 100 and 300 mg and GLIM, respectively; 84.1%, 87.3%, and 32.3% had reductions in BW. A greater proportion of patients had reductions in both HbA1c and BW at Week 52 with CANA 100 and 300 mg versus GLIM (72.4%, 78.5%, and 26.8%, respectively; differences [95% confidence interval (CI)] of 45.6% [39.7, 51.5] and 51.7% [46.0, 57.3]). The proportion of patients with HbA1c reductions at Week 104 was 75.7%, 79.7%, and 72.6% with CANA 100 and 300 mg and GLIM, respectively; 83.1%, 85.2%, and 34.6% had reductions in BW (Figure). A greater proportion of patients at Week 104 had reductions in both HbA1c and BW with CANA 100 and 300 mg versus GLIM (65.5%, 71.1%, and 26.8%, respectively; differences [95% CI] of 38.7% [32.6, 44.7] and 44.3% [38.4, 50.2]). At Week 104, the overall incidence of adverse events was 73%, 78%, and 78% with CANA 100 and 300 mg and GLIM, respectively. The incidence of documented hypoglycaemia (≤ 3.9 mmol/L) at Week 104 was lower with CANA 100 and 300 mg versus GLIM (7% and 8% vs 41%).

Conclusion: CANA provided greater attainment of reduction in both HbA1c and BW compared with GLIM at 52 and 104 weeks and was generally well tolerated in patients with T2DM as add-on to MET.

Figure. Change from baseline in both HbA_{1c} and BW with CANA 100 and 300 mg versus GLIM at Week 104.

Distribution of weight loss with canagliflozin in patients with type 2 diabetes mellitus over 104 weeks

K. Stenlöf¹, L. Blonde², A. Fung³, J. Xie³, W. Canovatchel³, G. Meininger³;

¹Clinical Trial Center, Sahlgrenska University Hospital, Gothenburg, Sweden, ²Department of Endocrinology, Diabetes, and Metabolic Diseases, Ochsner Medical Center, New Orleans, ³Janssen Research & Development, LLC, Raritan, USA.

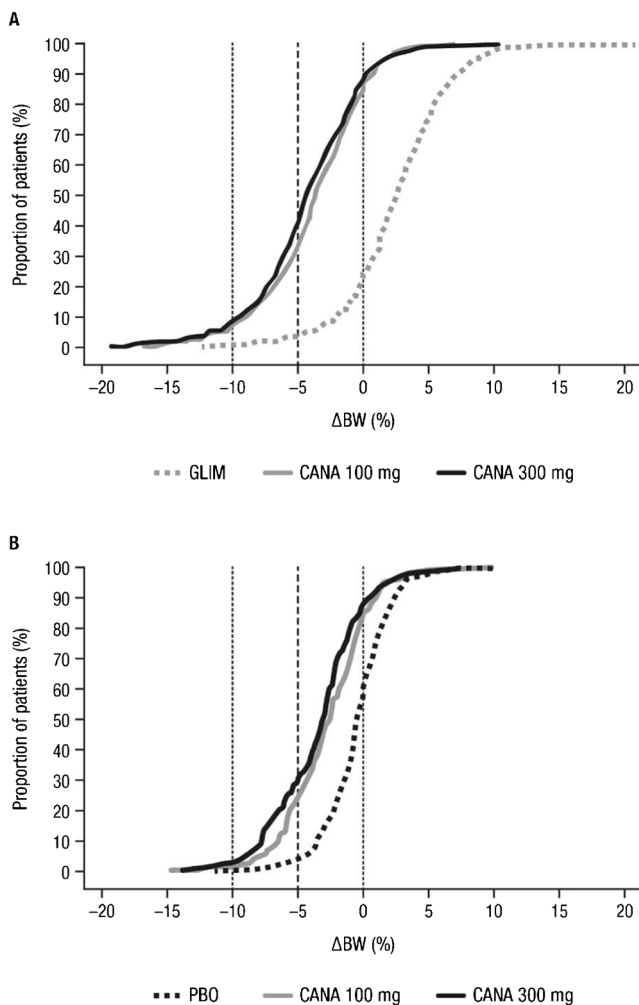

Background and aims: Canagliflozin (CANA), a sodium glucose co-transporter 2 inhibitor, lowers plasma glucose levels in patients with type 2 diabetes mellitus (T2DM) by increasing urinary glucose excretion. This also results in a mild osmotic diuresis and net caloric loss, which leads to reductions in body weight. This analysis assessed the distribution of body weight changes in two randomised, double-blind, Phase 3 studies of CANA.

Materials and methods: Study One assessed CANA 100 and 300 mg versus glimepiride (GLIM) as add-on to metformin in a 52-week core period, followed by a 52-week extension period (N=1,450; mean age, 56.2 y; HbA_{1c}, 7.8%; body weight, 86.6 kg). Study Two assessed CANA 100 and 300 mg versus placebo (PBO) in older patients (55–80 years) on various background antihyperglycaemic therapies in a 26-week core period, followed by a 78-week extension period (N=714; mean age, 63.6 y; HbA_{1c}, 7.7%; body weight, 89.5 kg). Percent change from baseline in body weight was a key endpoint in both studies. The cumulative distribution of body weight changes for each study was determined, as well as the proportion of patients with $\geq 5\%$ and $\geq 10\%$ weight loss.

Results: In Study One, body weight reductions were seen with CANA 100 and 300 mg versus an increase with GLIM at Week 52 (-4.2%, -4.7%, and 1.0%); these changes were sustained at Week 104 (-4.1%, -4.2%, and 0.9%). In Study Two, CANA 100 and 300 mg and PBO provided body weight reductions at Week 26 (-2.4%, -3.1%, and -0.1%) and at Week 104 (-3.0%, -3.8%, and -0.6%). In both studies, a greater proportion of patients in the CANA 100 and 300 mg groups experienced weight loss compared with those in the comparator groups (Figure). In Study One, approximately 85% to 90% of patients treated with CANA and approximately 30% to 35% of patients treated with GLIM had a reduction in body weight at Weeks 52 and 104. The proportion of patients with $\geq 5\%$ body weight reduction with CANA 100 and 300 mg and GLIM was 33%, 43%, and 6% at Week 52, and 35%, 40%, and 7%, at Week 104. In Study Two, approximately 80% to 85% of patients treated with CANA and approximately 60% of patients treated with PBO experienced weight loss at Weeks 26 and 104. The proportion of patients with $\geq 5\%$ body weight reduction with CANA 100 and 300 mg and PBO was 24%, 28%, and 4% at Week 26, and 28%, 33%, and 11% at Week 104. The proportion of patients with weight loss $\geq 10\%$ was low across groups in both studies, but higher with CANA versus GLIM or PBO.

Conclusion: CANA 100 and 300 mg provided body weight reductions in a greater proportion of patients with T2DM compared with GLIM and PBO over 104 weeks; most patients experienced body weight reductions with CANA, and a greater proportion achieved $\geq 5\%$ and $\geq 10\%$ weight loss.

Dapagliflozin added to metformin is effective in achieving combined improvements in HbA_{1c} and weight without hypoglycaemia over 4 years

P. Fenici¹, C. Sternhufvud², V. Cain³, J. Mukherjee⁴, K. Rohwedder⁵;
¹AstraZeneca, Melbourn, UK, ²AstraZeneca, Mölndal, Sweden, ³AstraZeneca, Wilmington, ⁴Bristol-Myers Squibb, Wallingford, USA, ⁵AstraZeneca, Wedel, Germany.

Background and aims: The goal of type 2 diabetes (T2D) management is to achieve optimal glycaemic control whilst avoiding side effects, including hypoglycaemia and weight gain. Dapagliflozin (DAPA) increases glucosuria in a glucose-dependent and insulin-independent manner, resulting in reductions in hyperglycaemia and weight, with a low risk of hypoglycaemia. Key 4-year results (1 × 52 week double-blind treatment period; 2 × double-blind extension periods of 52 and 104 weeks) from a study comparing DAPA with the sulfonylurea, glipizide (GLIP), as add-on to metformin (MET) in patients with inadequately controlled T2D

(HbA_{1c} >6.5 - ≤10%) have been reported previously. The aim of this post-hoc analysis was to investigate the proportion of patients achieving composite outcomes including reductions in HbA_{1c} and weight and no hypoglycaemic episodes with DAPA compared with GLIP over 4 years.

Materials and methods: HbA_{1c} reduction was considered to be a decrease ≥0.5%. Weight reduction was considered to be any decrease in weight ≥3% or ≥5%. HbA_{1c} and weight reductions were defined as change from baseline and percent change from baseline, respectively, to Week 208. Major (symptomatic episodes requiring third-party assistance and prompt recovery after glucose or glucagon administration, and capillary or plasma glucose <3.0 mmol/L [<54 mg/dL]) and minor (symptomatic or asymptomatic episode, with capillary or plasma glucose <3.5 mmol/L [<63 mg/dL] regardless of need for external assistance, that does not qualify as a major episode) hypoglycaemic events were considered when defining “no hypoglycaemic events”. Binomial exact P-values and 95% CI for the difference in proportions between treatment groups were calculated using StatXact (r) PROCs (v9.0, Cytel Inc., USA).

Results: The proportion of patients achieving the composite outcomes of interest over 4 years (Table) was consistently higher in those receiving DAPA + MET (24.5-56.0%) compared with those receiving GLIP + MET (2.1-12.9%). This difference was significant for all endpoints explored, but was largest when the proportion of patients experiencing no hypoglycaemia was included in the analysis.

Conclusion: This post-hoc analysis demonstrates that over 4 years DAPA is more effective than GLIP, when added to MET, at achieving combined improvements of HbA_{1c} and weight without hypoglycaemia. 27.1% of DAPA-treated patients still benefited from both HbA_{1c} and weight reduction (≥0.5% and ≥3%, respectively) with no hypoglycaemic events after 208 weeks compared with 2.9% of GLIP-treated patients. This suggests that DAPA can positively impact long-term disease management in patients with T2D.

Proportion (%) and risk difference (%) of patients achieving composite outcomes including reduction in HbA_{1c} and weight and no hypoglycaemic episodes at 208 weeks with dapagliflozin compared with glipizide, each in addition to metformin.

Composite outcome	DAPA + MET (N=400) n/N# (%)	GLIP + MET (N=401) n/N# (%)	Risk difference vs GLIP + MET % (95% CI)
HbA _{1c} reduction ≥0.5% AND Weight reduction ≥3% AND No major/minor hypoglycaemia	42/155 (27.1)	4/140 (2.9)	24.2 (16.9, 32.2)*
HbA _{1c} reduction ≥0.5% AND Weight reduction ≥3%	48/155 (31.0)	18/140 (12.9)	18.1 (8.7, 27.4)†

Triple therapy with saxagliptin and dapagliflozin add-on to metformin: safety of dual add-on versus sequential add-on

R. Garcia-Sanchez¹, S. Del Prato², S. Matthaei³, N. Iqbal⁴, L. Hansen⁴, E. Johnsson⁵, H. Chen¹, A.J. Chin¹, C. Mathieu⁶;
¹AstraZeneca, Gaithersburg, USA, ²School of Medicine, University of Pisa, Italy, ³Diabetes-Center, Quakenbrück, Germany, ⁴Bristol-Myers Squibb, Princeton, USA, ⁵AstraZeneca, Mölndal, Sweden, ⁶Katholieke Universiteit Leuven, Belgium.

Background and aims: Triple oral therapy with dual add-on of saxagliptin (SAXA) plus dapagliflozin (DAPA) to metformin (MET) was previously shown to reduce HbA1c to a greater extent than dual therapy with either SAXA or DAPA add-on to MET and was an effective treatment option in patients with high baseline HbA1c poorly controlled with MET. We assessed the safety and tolerability of triple therapy with concomitant dual add-on of SAXA and DAPA to MET versus the sequential single add-on of SAXA to dual therapy of DAPA plus MET and the single add-on of DAPA to dual therapy of SAXA plus MET in 3 randomized trials of adults with type 2 diabetes (T2D).

Materials and methods: In the dual add-on trial, patients on stable MET (baseline HbA1c 8.0%–12.0%) received SAXA 5 mg/d plus DAPA 10 mg/d for 24 weeks. In the sequential add-on trials, patients (baseline HbA1c 7%–10.5%) on stable MET+SAXA 5 mg/d or stable MET+DAPA 10 mg/d received add-on DAPA 10 mg/d or SAXA 5 mg/d, respectively for 24 weeks. Safety results from the sequential add-on trials were pooled and compared with the dual add-on trial.

Results: Events of hypoglycemia were uncommon and similar in the 2 groups. Overall adverse events (AEs) and serious AEs (SAEs) were similar between treatment regimens (Table). The most common AE was nasopharyngitis (3.9% vs 3.5% for dual vs sequential add-on, respectively). Urinary tract infections were more frequent in patients receiving sequential add-on therapy; genital infections were reported only with the sequential single add-on of DAPA to dual therapy of SAXA plus MET. There were no events of hypotension/dehydration/hypovolemia. There was 1 event of hepatic cancer that was subsequently identified as pancreatic cancer that had metastasized to the liver and was considered unrelated to drug treatment.

Conclusion: In a cross-study comparison, dual add-on of SAXA and DAPA to MET had a similar safety and tolerability profile compared with single add-on of either SAXA or DAPA to existing dual therapy in patients poorly controlled on MET.

A randomised, double-blind phase 3 trial of dapagliflozin add-on to saxagliptin + metformin in type 2 diabetes

C. Mathieu¹, A.E. Ranetti², D. Li³, E. Ekholm⁴, W. Cook⁵, B. Hirshberg⁵, L. Hansen³, N. Iqbal³;
¹Katholieke Universiteit Leuven, Belgium, ²Carol Davila University of Medicine and Pharmacy and “Dr. Carol Davila” Central University Emergency Military Hospital, Bucharest, Romania, ³Bristol-Myers Squibb, Princeton, USA, ⁴AstraZeneca, Mölndal, Sweden, ⁵AstraZeneca, Gaithersburg, MD, USA.

Background and aims: SGLT2 and DPP-4 inhibitors have complementary mechanisms of action. We compared the efficacy and safety of dapagliflozin (DAPA) versus placebo (PBO) as add-on to saxagliptin (SAXA)+metformin IR (MET) in adults with type 2 diabetes (T2D).

Materials and methods: Patients on stable MET (stratum A; baseline A1C 8.0%–11.5%) or stable MET+DPP-4 inhibitor (stratum B; A1C 7.5%–10.5%) for ≥8 weeks received open-label SAXA 5 mg/d+MET for 16 (stratum A) or 8 weeks (stratum B, any DPP-4 inhibitor was replaced with SAXA). At the end of the open-label period, patients with inadequate glycemic control (A1C 7%–10.5%) were randomized to PBO or DAPA 10 mg/d plus open-label SAXA+MET. Primary end point was change in A1C from baseline to week 24. Secondary end points included fasting plasma glucose (FPG), 2-hour postprandial glucose (PPG), body weight, and the proportion of patients achieving A1C<7%.

Results: DAPA+SAXA+MET resulted in a greater A1C reduction than PBO+SAXA+MET (−0.82% vs −0.10%) (Table). More patients achieved A1C<7% and greater reductions in FPG, PPG, and weight were observed with DAPA+SAXA+MET vs PBO+SAXA+MET. AEs were similar across treatment groups with a low overall risk of hypoglycemia (~1%). More patients developed genital infections with DAPA (5%) vs PBO (0.6%).

Conclusion: Addition of DAPA to SAXA+MET improves glycemic control and is well tolerated in patients with T2D inadequately controlled with SAXA+MET.

Impact of canagliflozin added-on to insulin and metformin in type 2 diabetes: a substudy of the CANVAS trial

D. Matthews¹, J. Rosenstock², M. Desai³, G. Capuano³, G. Meininger³, W. Canovatchel³;

¹University of Oxford, UK, ²Dallas Diabetes and Endocrine Center at Medical City, Dallas, ³Janssen Research & Development, LLC, Raritan, USA.

Background and aims: Canagliflozin (CANA) is a sodium glucose co-transporter 2 (SGLT2) inhibitor developed for the treatment of adults with type 2 diabetes mellitus (T2DM). The CANagliflozin cardioVascular Assessment Study (CANVAS) is a cardiovascular (CV) outcomes trial in patients with T2DM and a history or high risk of CV disease. The efficacy and safety of CANA vs. placebo (PBO) were evaluated in a subset of patients from CANVAS who were on ≥ 30 IU/d of insulin and $\geq 2,000$ mg/d of metformin.

Materials and methods: Patients on ≥ 30 IU/d of insulin and $\geq 2,000$ mg/d of metformin (N=432; mean age, 61 yrs; HbA1c, 8.2%; fasting plasma glucose [FPG], 9.2 mmol/L; body mass index [BMI], 34.9 kg/m²; insulin dose, 93 IU/d) were randomised to receive CANA 100 or 300 mg or PBO once daily for 18 weeks. Efficacy endpoints were evaluated at 18 weeks; safety was assessed by adverse event (AE) reports.

Results: Relative to PBO, CANA 100 and 300 mg provided significant least squares (LS) mean reductions in HbA1c (-0.7% and -0.8%; P < 0.001), FPG (-0.9 and -1.4 mmol/L; P < 0.001), and body weight (-1.7% and -2.7%; P < 0.001) at Week 18 (Table). PBO-subtracted LS mean reductions in systolic blood pressure were -3.5 and -6.1 mmHg (P < 0.001) with CANA 100 and 300 mg. The overall incidence of AEs was 66%, 67%, and 61% with CANA 100 and 300 mg and PBO, respectively, with low rates of AE-related discontinuations across groups. The incidence of hypoglycaemia (≤ 3.9 mmol/L) was similar with CANA 100 and 300 mg and PBO (42%, 47%, and 46%), with low rates of severe episodes (1%, 2%, and 3%). Genitourinary AEs were consistent with the reported frequency in the SGLT2 inhibitor class.

Conclusion: Short-term CANA treatment improved glycaemic control, reduced body weight, and was generally well tolerated as add-on to insulin and metformin in patients with T2DM.

Efficacy and safety of dapagliflozin in patients with type 2 diabetes on insulin ± metformin regimens

H. Yeh, A. Katz;
AstraZeneca, Fort Washington, USA.

Background and aims: This analysis evaluated the efficacy and safety of dapagliflozin (DAPA) in patients with type 2 diabetes (T2D) inadequately controlled with high doses of insulin (INS)±up to 2 oral antidiabetes agents.

Materials and methods: In this post hoc analysis of a 24-week, placebo (PBO)-controlled trial of DAPA in patients with T2D inadequately controlled with INS±up to 2 oral antidiabetes agents, 587 patients were stratified by INS regimen (basal, sliding scale, or basal/sliding scale) and metformin (MET) use.

Results: Mean T2D duration was >10 years and baseline HbA1c was 8.4%–8.8% across groups. With each of the 3 INS regimens, DAPA 5 and 10 mg/d significantly reduced HbA1c (all P < 0.001 vs PBO) and body weight (BW, all P < 0.01, except DAPA 5 mg/d + basal INS) from baseline at week 24. DAPA reduced HbA1c and BW with MET (all P < 0.0001 vs PBO) or without MET (HbA1c, all P < 0.0001; BW, P = 0.0439 and < 0.0001 for DAPA 5 and 10 mg/d, respectively), but reductions were numerically larger with MET and significantly more patients receiving MET had HbA1c < 7% at 24 weeks (P < 0.01 vs PBO). Genital and urinary tract infections were more frequent with DAPA than PBO. Hypoglycemia was more common with DAPA (45%, 48%) than PBO (42%); 1 major hypoglycemia event occurred in each DAPA dose group and 2 in the PBO group. **Conclusion:** In patients with T2D, including those with progressive disease (inadequately controlled on INS, T2D duration > 10 years), DAPA was effective and well tolerated with each INS regimen, with no increase in major hypoglycemia. The effects of DAPA appeared greater in patients receiving MET in addition to INS.

Efficacy and safety of canagliflozin added to background insulin in patients with type 2 diabetes mellitus in subgroups by baseline insulin dose

L. Van Gaal¹, R. Dumas², D. Matthews³, M. Desai⁴, G. Capuano⁴, G. Meininger⁴;

¹Department of Endocrinology, Diabetology and Metabolism, Antwerp University Hospital, Belgium, ²Laval Clinic Research Center, Montreal, Canada, ³University of Oxford, UK, ⁴Janssen Research & Development, LLC, Raritan, USA.

Background and aims: Across Phase 3 studies, canagliflozin (CANA), an SGLT2 inhibitor, was associated with improvements in glycaemic control and reductions in body weight and blood pressure (BP) in patients

with type 2 diabetes mellitus (T2DM) on a range of background antihyperglycaemic agents, including insulin. This analysis evaluated the efficacy and safety of CANA in patients with T2DM who were on background insulin with or without other antihyperglycaemic agents in subgroups by baseline insulin dose.

Materials and methods: This post hoc analysis assessed efficacy and safety in the subset of patients enrolled in the CANagliflozin cardioVascular Assessment Study (CANVAS); patients with T2DM who had a history or high risk of cardiovascular disease) who were on insulin ≥ 30 IU/d by tertiles based on baseline insulin dose (<54, 54–<90, and ≥ 90 IU/d). Patients (N=1,718; mean age, 63 y; HbA1c, 8.3%; body weight, 97.0 kg; eGFR, 74.9 mL/min/1.73 m²; T2DM duration, 16.6 y; insulin dose, 83 IU/d) received CANA 100 or 300 mg or placebo (PBO) once daily over 18 weeks. Patient characteristics across tertiles were generally similar, except for baseline body weight, which increased as insulin dose increased.

Results: During the study, 6%, 10%, and 9% of patients across treatment groups in the <54, 54–<90, and ≥ 90 IU/d tertiles decreased their insulin dose; 2%, 1%, and 2% increased their insulin dose. In general, more patients decreased their insulin dose with CANA than PBO; the proportion with increases in insulin was similar across groups. Relative to PBO, CANA 100 and 300 mg provided reductions in HbA1c, body weight, and fasting plasma glucose (FPG) over 18 weeks that were similar across tertiles (Table). PBO-subtracted reductions in systolic BP (SBP) were also observed with CANA 100 and 300 mg across tertiles. The incidence of overall adverse events (AEs) with CANA 100 and 300 mg and PBO was 62.8%, 54.6%, and 53.5% in the <54 IU/d tertile; 57.9%, 64.7%, and 58.0% in the 54–<90 IU/d tertile; and 70.3%, 76.8%, and 65.0% in the ≥ 90 IU/d tertile; rates of serious AEs and AEs leading to discontinuation were low across groups. Increased incidence of male and female genital mycotic infections and osmotic diuresis-related AEs was seen with CANA versus PBO across tertiles. The incidence of documented hypoglycaemia episodes was higher with CANA 100 and 300 mg compared with PBO across tertiles. The incidence of severe hypoglycaemia episodes was low across groups in all tertiles.

Conclusion: Consistent with its insulin-independent mechanism of action, CANA provided improvements in glycaemic control, as well as body weight and SBP reductions, and was generally well tolerated compared with PBO across tertiles by baseline insulin dose in patients with T2DM over 18 weeks.

Table. Summary of Efficacy Outcomes and Hypoglycaemia Incidence by Baseline Insulin Tertile at Week 18 (mITT, LOCF^a)

	Baseline insulin dose <54 IU/d			Baseline insulin dose 54–<90 IU/d			Baseline insulin dose ≥ 90 IU/d

PS 064 SGLT-2 inhibitors: cardio-renal implications

746

Cystatin C and creatinine-based estimates of glomerular filtration rates in dapagliflozin phase 3 clinical trials

C. Mende¹, A. Katz²;

¹Department of Medicine, University of California at San Diego, La Jolla, ²AstraZeneca, Fort Washington, USA.

Background and aims: Sodium-glucose cotransporter 2 (SGLT2) inhibitor efficacy depends on the kidneys' ability to filter glucose and declines with lower glomerular filtration rate (GFR). Estimates of GFR based on creatinine (eGFR_{cr}) are routinely used but are affected by factors, such as muscle mass and diet, and may be inaccurate under certain conditions. Estimates based on cystatin C (eGFR_{cys}) appear to correlate better with morbidity and mortality than eGFR_{cr}. KDIGO guidelines suggest measuring eGFR_{cys} when eGFR_{cr} is 45–59 mL/min/1.73 m² with no evidence of kidney damage and/or when eGFR_{cr} may be unreliable. This analysis compared the proportion of patients with type 2 diabetes (T2D) with eGFR <60 and ≥ 60 mL/min/1.73 m² in 9 dapagliflozin (DAPA) clinical trials when GFR was estimated using creatinine versus cystatin C.

Materials and methods: Using pooled data from 9 DAPA phase 3 trials, the proportion of patients with T2D with eGFR 30–<60 and ≥ 60 mL/min/1.73 m² was determined using both eGFR_{cr} and eGFR_{cys}.

Results: The correlation between eGFR_{cr} and eGFR_{cys} was poor; r²=0.25. At least 60% of patients who had moderate renal impairment (eGFR 30–<60) at baseline based on eGFR_{cr} had an eGFR_{cys} ≥ 60 . Among patients with eGFR_{cr} ≥ 60 , $\geq 95\%$ remained ≥ 60 with eGFR_{cys}. Decreases in HbA1c, body weight, and systolic blood pressure with DAPA were similar in patient subgroups defined by either eGFR estimate, and statistically significant and clinically meaningful with DAPA 10 mg in most subgroups.

Conclusion: The data suggest that in patients with T2D, renal function as assessed by eGFR_{cr} may be underestimated, rendering such patients ineligible to receive medications limited by renal function (eg, metformin, SGLT2 inhibitors).

Effect of longer-term canagliflozin treatment on eGFR in patients with type 2 diabetes mellitus and various degrees of baseline renal function

P. Fioretto¹, M. Weir², R. Gilbert³, M.J. Davies⁴, G. Meininger⁵;

¹Department of Medicine, University of Padova, Italy, ²University of Maryland School of Medicine, Baltimore, USA, ³University of Toronto, Canada, ⁴Janssen Scientific Affairs, LLC, ⁵Janssen Research & Development, LLC, Raritan, USA.

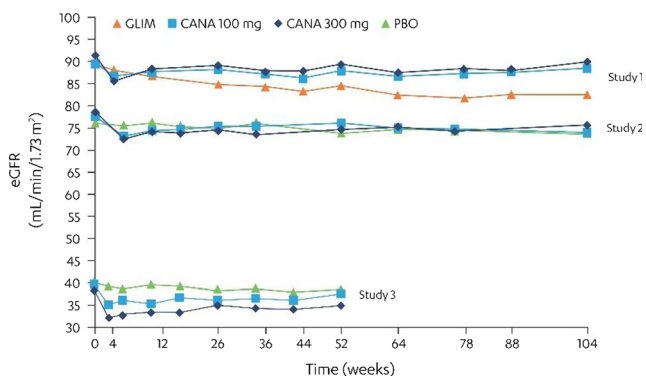

Background and aims: Canagliflozin (CANA), a sodium glucose cotransporter 2 inhibitor, is associated with a small, transient reduction in estimated glomerular filtration rate (eGFR) after treatment initiation,

which stabilizes or attenuates towards baseline levels with continued treatment in short-term studies (i.e. 26 weeks). This analysis evaluated the effect of CANA on renal function in patients with type 2 diabetes mellitus (T2DM) for up to 2 years.

Materials and methods: eGFR over time was compared between CANA and glimepiride (GLIM) or placebo (PBO) using data from 3 clinical studies: Study 1, patients aged 18–80 years (mean eGFR 90.2 mL/min/1.73 m²) received CANA 100 mg or 300 mg, or GLIM for 2 years; Study 2, patients aged 55–80 years (eGFR 77.5 mL/min/1.73 m²) received CANA 100 mg or 300 mg, or PBO for 2 years; and Study 3, patients aged ≥ 25 years with Stage 3 chronic kidney disease (eGFR 39.4 mL/min/1.73 m²) received CANA 100 mg or 300 mg, or PBO for 1 year.

Results: Following an initial decrease with CANA, eGFR stabilized or attenuated toward baseline within the first 3–6 weeks and remained unchanged for up to 2 years; eGFR progressively declined with GLIM but not with PBO (Figure). Consistent absolute effects of CANA on eGFR were observed in all patients across study groups, regardless of baseline renal function. Reductions in the urine albumin to creatinine ratio were also seen with CANA 100 mg and 300 mg, versus increases with GLIM and PBO.

Conclusion: In summary, changes in eGFR with CANA were transient and attenuated over time.

The effect of renal impairment on the pharmacokinetics and pharmacodynamics of ertugliflozin in subjects with type 2 diabetes mellitus

V. Sahasrabudhe¹, S.G. Terra², R.J. Fontaine¹, A. Hickman¹, D. Saur³, K. Matschke⁴, H. Shi¹, M. O’Gorman¹, M.V. Chakravarthy⁵, D.L. Cutler⁶;

¹Pfizer Inc., Groton, ²Pfizer Inc., Andover, USA, ³Pfizer Inc., Paris, France, ⁴Pfizer Inc., Collegenille, ⁵Merck & Co., Kenilworth, ⁶Merck & Co., North Wales, USA.

Background and aims: Ertugliflozin is a highly selective and potent inhibitor of Sodium Glucose co-Transporter 2 (SGLT2) that is under development for the treatment of T2DM. Ertugliflozin inhibits renal glucose reabsorption resulting in urinary glucose excretion (UGE), thereby reducing elevated plasma glucose and HbA1c. The glycemic efficacy of SGLT2 inhibitors depends on the amount of glucose filtered through the kidney. As renal impairment (RI) is a co-morbidity of T2DM, this study evaluated the effect of RI on the pharmacokinetics, pharmacodynamics (as measured by 0 to 24 hour urinary glucose excretion [UGE24]), safety, and tolerability of ertugliflozin in subjects with T2DM.

Materials and methods: In this Phase 1, multi-centre, open-label study, a single 15 mg oral dose of ertugliflozin was administered in the fasted state to healthy and T2DM subjects with normal renal function (estimated

glomerular filtration rate not normalized for body surface area [eGFR] ≥90 mL/min) and in T2DM subjects with mild RI (eGFR 60–89 mL/min), moderate RI (eGFR 30–59 mL/min) and severe RI (eGFR <30 mL/min). Serial blood samples and urine samples at specified intervals were collected predose and for 96 hours post-dose for pharmacokinetic evaluation and for measurement of UGE24.

Results: Geometric mean (CV%) values for ertugliflozin exposure parameters (area under the concentration-time curve [AUC_{0-inf}] and peak concentration [C_{max}]) are presented in the table below. Ertugliflozin exposures were similar in healthy subjects and T2DM subjects with normal renal function. Based on an analysis of variance, the geometric mean ratio (GMR) [90% confidence interval (CI)] for AUC_{0-inf} in T2DM subjects with mild, moderate, and severe RI compared to healthy and T2DM subjects with normal renal function (pooled) was 1.56 [1.28, 1.91], 1.70 [1.39, 2.08], and 1.55 [1.24, 1.94], respectively. Regression analysis of the change from baseline in UGE24 versus eGFR showed a decrease in urinary glucose excretion with declining renal function.

Conclusion: Systemic exposure of ertugliflozin was increased by less than 2-fold in subjects with varying degrees of renal impairment compared to subjects with normal renal function. The observed increase in exposure in renal impairment is not anticipated to be clinically meaningful. As expected for this mechanism, UGE24 decreased with declining renal function due to a decrease in the filtered glucose load. A single 15 mg dose of ertugliflozin was well tolerated in subjects with normal renal function and in T2DM subjects with renal impairment.

Renal Function	C _{max} (ng/mL)	AUC _{0-inf} (ng-hour/mL)
Healthy Normal (n=8)	219 (26)	1236 (27)
T2DM Normal (n=6)	216 (35)	1199 (42)
T2DM Mild RI (n=8)	313 (30)	1908 (28)
T2DM Moderate RI (n=8)	306 (23)	2075 (19)
T2DM Severe RI (n=6)	196 (28)	1895 (23)

Empagliflozin moderately increases LDL-cholesterol levels through reduced LDL catabolism while it increases slightly the reverse cholesterol in hamsters

F. Briand¹, N. Burr¹, I. Urbain¹, E. Mayoux², T. Sulpice¹; ¹Physiogenex S.A.S, Labège, France, ²Boehringer-Ingelheim, Biberach, Germany.

Background and aims: The slight increase of LDL-cholesterol (LDL-C) level described with SGLT2 inhibitors could result of the haem-concentration associated with glucosuria and osmotic diuresis. Because chronic treatment with SGLT2 inhibitors shifts substrate utilization from carbohydrate to lipid with a moderate increase of ketone bodies, we investigated in hamster, a preclinical model with a human-like cholesterol metabolism, whether other mechanisms could contribute to this increase in LDL-C levels.

Materials and methods: Diet-induced dyslipidemic hamsters were treated orally (2 weeks) with vehicle or empagliflozin 30 mg/kg/day.

Results: Empagliflozin increased urinary glucose excretion (1200-fold, $p < 0.001$), reduced fasting glycemia and insulin ($p < 0.05$), and moderately but significantly increased ketone bodies and LDL-C levels. In the liver, empagliflozin increased HMG-CoA reductase activity and cholesterol levels and reduced LDL-receptor protein levels by 20% ($p < 0.05$). In line with lower LDL-receptors in response to higher hepatic cholesterol level, empagliflozin reduced LDL-3H-C catabolism by 20% ($p < 0.05$), indicating that the raise in LDL-C may be due to lower LDL-C catabolism. Interestingly, empagliflozin increased LDL-derived 3H-C fecal excretion by 26% ($p < 0.05$). This effect was related to a 40% reduction in intestinal cholesterol absorption determined after oral gavage of 14C-cholesterol-oil. We next evaluated whether the reverse cholesterol transport was affected by injecting hamsters (i.p.) with 3H-cholesterol labeled macrophages. Empagliflozin increased macrophage-derived 3H-tracer fecal excretion by 29% ($p < 0.05$).

Conclusion: In conclusion, empagliflozin promotes LDL-derived cholesterol fecal excretion and reverse cholesterol transport despite a moderate increase in LDL-C levels possibly through lower LDL-C catabolism in response to a moderate increase in ketone bodies and a switch in substrate utilization.

Potential relevance of changes in haematocrit to changes in lipid parameters with empagliflozin in patients with type 2 diabetes

S.S. Lund¹, N. Sattar², A. Salsali³, S. Crowe¹, U.C. Broedl¹, H.N. Ginsberg⁴;

¹Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany,

²University of Glasgow, Glasgow, UK, ³Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, ⁴College of Physicians and Surgeons of Columbia University, New York, USA.

Background and aims: Empagliflozin (EMPA), when given as monotherapy or as add-on therapy, has consistently reduced HbA_{1c} in patients with type 2 diabetes (T2DM). Changes in lipid parameters have also been observed following treatment with EMPA. To test our hypothesis that these changes in lipids could be partly due to haemoconcentration as a result of increased urinary volume and subsequent volume contraction during EMPA treatment, we used pooled data from four 24-week, Phase III, randomised trials to analyse the contributions of haematocrit (HCT) changes, a marker of changes in plasma volume, to changes in LDL-cholesterol (LDL-C), HDL-cholesterol (HDL-C), triglycerides (TG) and apolipoprotein B (Apo B).

Materials and methods: Patients with T2DM received placebo (PBO), EMPA 10 mg or EMPA 25 mg for 24 weeks as monotherapy or add-on therapy (N=2477; mean [SD] age 55.6 [10.2] years, HbA_{1c} 7.99 [0.85] %, BMI 28.7 [5.5] kg/m²). Total changes in LDL-C, HDL-C, TG and Apo B, and changes associated with (i.e., potentially contributed to by) and independent of changes in HCT were assessed using baseline-adjusted ANCOVA models.

Results: Increases in LDL-C, HDL-C and Apo B, and decreases in TG were observed with EMPA 10 mg and 25 mg; although changes from baseline in Apo B and TG at week 24 did not reach statistical significance with both doses of EMPA and EMPA 25 mg, respectively (table). At baseline, mean (SE) HCT was 41.9 (0.1) % in the EMPA groups and 41.5 (0.2) % in the PBO group. At week 24, the PBO-corrected adjusted mean (SE) percentage changes from baseline in HCT were 5.2 (0.3) % and 5.5 (0.3) % with EMPA 10 mg and EMPA 25 mg, respectively (both $p < 0.001$). Changes in HCT were significantly associated with changes in LDL-C, HDL-C, TG and Apo B (table). The contribution of changes independent of changes in HCT varied among the lipid parameters; these were only significant for changes in HDL-C and TG.

Conclusion: Changes in HCT were associated with changes in LDL-C, HDL-C, TG and Apo B. As the observed increase in HCT may reflect haemoconcentration, the changes seen in these lipid parameters following 24 weeks' treatment with EMPA in patients with T2DM may be partly due to haemoconcentration. Changes in HDL-C and TG that were independent of changes in HCT were more pronounced than for the other lipid parameters; it may be hypothesised that improvements in metabolic control following treatment with EMPA in patients in T2DM may drive HCT-independent changes in HDL-C and TG.

Contrasting influences of renal function on blood pressure, body weight and HbA_{1c} reductions with empagliflozin: pooled analysis of phase III trials

M.E. Cooper¹, D. Cherney², S. Crowe³, O. Johansen⁴, S.S. Lund³, H.J. Woerle³, U.C. Broedl³, T. Hach³;

¹Baker IDI Heart and Diabetes Institute, Melbourne, Australia, ²Toronto General Hospital, University of Toronto, Canada, ³Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany, ⁴Boehringer Ingelheim Norway K.S., Asker, Norway.

Background and aims: The SGLT2 inhibitor empagliflozin (EMPA) reduces HbA_{1c}, weight and blood pressure (BP) in patients with type 2 diabetes (T2DM). While glucose lowering with EMPA is dependent on renal function, it is less well understood how chronic kidney disease (CKD) influences BP modulation and weight loss with EMPA.

Materials and methods: In five randomised Phase III trials, 2286 patients with T2DM received EMPA 25 mg or placebo (PBO) for 24 weeks as monotherapy or add-on therapy. Using pooled data from these trials, we assessed changes from baseline in systolic BP (SBP), HbA_{1c} and body weight with EMPA 25 mg vs PBO in subgroups by baseline eGFR (MDRD equation), adjusting for differences in baseline SBP (SBP analyses only), baseline body weight (body weight analyses only), baseline HbA_{1c}, region, treatment, study, baseline eGFR and treatment by baseline eGFR interaction between groups.

Results: In patients with normal renal function, or stage 2 or 3 CKD, EMPA significantly reduced HbA_{1c}, SBP and body weight vs PBO (Table). As expected, PBO-corrected HbA_{1c} reductions with EMPA decreased with decreasing baseline eGFR and PBO-corrected reductions in body weight tended to decrease, with decreasing baseline eGFR. In contrast, PBO-corrected reductions in SBP with EMPA appeared to be maintained with decreasing baseline eGFR (Table).

Conclusion: Unlike HbA_{1c} and possibly body weight, reductions in SBP with EMPA in patients with T2DM appeared to be maintained in patients with lower baseline eGFR, indicating that SBP modulation with EMPA may involve pathways other than urinary glucose excretion such as diuretic effects, weight loss, reduced arterial stiffness or direct vascular effects.

Blood-pressure lowering effects of canagliflozin across a range of background antihyperglycaemic treatment regimens used in patients with type 2 diabetes mellitus

J. Ren¹, M.R. Weir², J. Yee³, U. Vijapurkar³, G. Meiningers³; ¹Janssen Scientific Affairs, LLC, Raritan, ²Division of Nephrology, University of Maryland School of Medicine, Baltimore, ³Janssen Research & Development, LLC, Raritan, USA.

Background and aims: Hypertension is a common comorbidity in patients with type 2 diabetes mellitus (T2DM) and is an important risk factor for cardiovascular disease. Therefore, lowering blood pressure in patients with T2DM without meaningfully increasing heart rate is of benefit in reducing the risk of cardiovascular complications. In this analysis, the effect of the sodium glucose co-transporter 2 inhibitor canagliflozin (CANA) on blood pressure and heart rate was studied in patients with T2DM across a broad range of antihyperglycaemic treatment regimens.

Materials and methods: In four Phase 3 clinical trials (26 weeks) and two substudies (18 weeks), CANA 100 mg and 300 mg were compared with: placebo (PBO) as monotherapy; dual therapy (add-on to metformin [MET] or a sulfonylurea [SU]); triple therapy (add-on to MET + SU or MET + pioglitazone [PIO]); and add-on to insulin (± other antihyperglycaemic agents). In three active-controlled, Phase 3 clinical trials (52 weeks), CANA was compared with sitagliptin (SITA) 100 mg as dual therapy (add-on to MET; CANA 100 mg and 300 mg) or triple therapy (add-on to MET + SU; CANA 300 mg only); and to glimepiride (GLIM) as dual therapy (add-on to MET; CANA 100 mg and 300 mg). Efficacy and safety endpoints reported here include change from baseline in systolic blood pressure (SBP), diastolic blood pressure (DBP), and heart rate. The last observation carried forward imputation method was employed.

Results: Treatment with CANA 100 mg and 300 mg was associated with reductions in SBP and DBP compared with PBO, with generally no increase in mean heart rate across the range of treatment regimens evaluated. PBO-subtracted changes (least square [LS] mean change from baseline and 95% CIs) are reported for each endpoint (Table). When added to MET, CANA 100 mg and 300 mg provided greater reductions in SBP and DBP compared with SITA (differences in LS mean change from baseline [95% CI] with CANA 100 mg and 300 mg, respectively, vs. SITA: SBP -2.9 mmHg [-4.5, -1.3] and -4.0 mmHg [-5.6, -2.4]; and DBP -1.4 mmHg [-2.4, -0.5] and -1.5 mmHg [-2.5, -0.5]). When added to MET, CANA 100 mg and 300 mg provided greater reductions in SBP and DBP compared with GLIM (differences in LS mean change from baseline [95% CI] with CANA 100 mg and 300 mg, respectively,

vs. GLIM: SBP -3.5 mmHg [-4.9, -2.1] and -4.8 mmHg [-6.2, -3.4]; and DBP -1.7 mmHg [-2.6, -0.8] and -2.4 mmHg [-3.3, -1.5]). As addition to MET + SU, CANA 300 mg lowered SBP (-5.9 mmHg [-7.6, -4.2]) and DBP (-2.7 mmHg [-3.8, -1.7]) compared with SITA. No clinically meaningful differences in heart rate were observed with CANA across the studies.

Conclusion: Compared with placebo and commonly used antihyperglycaemic agents, CANA reduced SBP and DBP without changing heart rate in patients with T2DM whether used alone, in combination with oral antihyperglycaemic agents, or with insulin.

The effects of empagliflozin on blood pressure and markers of arterial stiffness and vascular resistance by subgroups of age, sex and degree of hypertension in type 2 diabetes

O. Johansen¹, I. Tikkanen², C.P. Cannon³, S. Crowe⁴, H.-J. Woerle⁵, U.C. Broedl⁵, R.J. Chilton⁶;

¹Medical Department, Boehringer-Ingelheim, Asker, Norway, ²Medical Department, Helsinki University Central Hospital and Minerva Institute for Medical Research, Finland, ³Harvard Clinical Research Institute, Boston, USA, ⁴Boehringer-Ingelheim, ⁵Therapeutic Area Metabolism, Boehringer-Ingelheim, Ingelheim, Germany, ⁶University of Texas Health Science Center, San Antonio, USA.

Background and aims: Empagliflozin improves glycemia and reduces weight, blood pressure as well as central and peripheral hemodynamic parameters. Differential effects of empagliflozin on this by age, sex and degree of hypertension are unknown. We assessed the hypothesis that empagliflozin would reduce blood pressure (BP), pulse pressure (PP), a validated surrogate marker of arterial stiffness being determined by the cardiac output and the stiffness of elastic central arteries like the aorta and wave reflection (PP=systolic BP - diastolic BP), and mean arterial pressure (MAP), a measure reflecting the cardiac cycle and is determined by the cardiac output, systemic vascular resistance, and central venous pressure (MAP = [(2 × diastolic BP) + systolic BP]/3) across these subgroups. It was also postulated that greater reductions would be seen in those with highest baseline systolic BP and advanced age.

Materials and methods: Overall 2477 patients were analyzed from four 24-week phase III randomized trials (on no, one or two background glucose lowering drugs) of empagliflozin 10 mg or 25 mg (n=1652) versus placebo (n=825). At screening, patients in these trials had type 2 diabetes, HbA1c ≥7% and ≤10%, a body mass index (BMI) ≤45 kg/m² and were on a diet and exercise regimen.

Results: Mean ± SD age was 55.6±10.2 years, HbA1c 7.99±0.85%, systolic BP/diastolic BP 129.1±15.0/78.3±8.8 mmHg, heart rate 74.2±9.6 bpm and BMI 28.7±5.5 m/kg² for the overall population and demographics and baseline characteristics were generally balanced between treatment groups. HbA1c was significantly reduced with empagliflozin (pooled) compared to placebo at week 24 (adjusted mean [SE]):-0.65% (0.03), p<0.001). The overall adjusted mean difference vs placebo in change from baseline in systolic BP at week 24 was -3.6 mmHg (95% CI -4.5, -2.7; p<0.001) and in DBP was -1.3 mmHg (95% CI -1.9, -0.8; p<0.001) and change from baseline in heart rate vs placebo was -0.8 bpm(95% CI -1.4, -0.2; p=0.012). Systolic BP, diastolic BP, PP and MAP were reduced in all subgroups. For systolic BP and MAP, greater reductions were observed in those with highest systolic BP whereas PP was reduced most in those with advanced age (Table).

Conclusion: Reductions in BP and arterial stiffness are two of the effects of SGLT2 inhibitors that might ameliorate cardiovascular risk in patients with type 2 diabetes. EMPA-REG OUTCOME™, reporting 2015, will evaluate if these benefits will translate into CV risk reduction.

Table. Adjusted mean changes from baseline in systolic and diastolic BP, pulse pressure and mean arterial pressure for empagliflozin relative to placebo after 24 weeks of treatment.

No increased risk of cardiovascular events with dapagliflozin in elderly patients with type 2 diabetes mellitus, cardiovascular disease and hypertension

I. Gause-Nilsson, C. Sonesson, P.A. Johansson, E. Johnsson; AstraZeneca, Mölndal, Sweden.

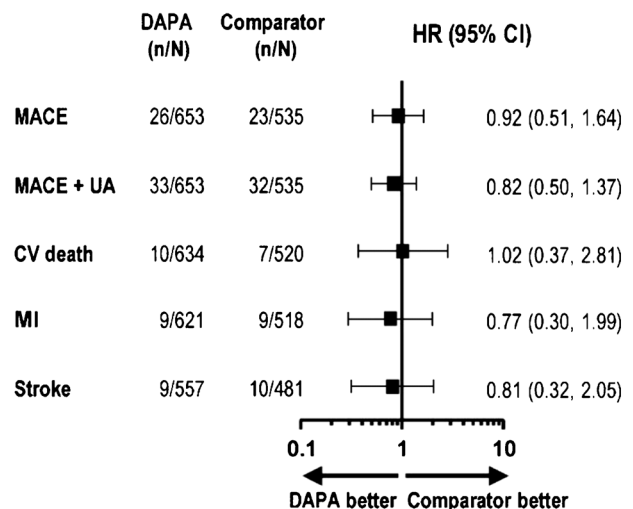

Background and aims: Dapagliflozin (DAPA) reduces plasma glucose in patients with type 2 diabetes mellitus (T2DM) by inhibiting renal glucose reabsorption, leading to increased glucosuria. DAPA is also associated with blood pressure and weight reduction. In a previous pooled analysis of 21 phase 2b/3 trials in T2DM (≤4 years), the hazard ratio (HR) for the pre-specified primary endpoint of major adverse cardiac events (MACE: cardiovascular [CV] death, myocardial infarction, and stroke) plus unstable angina for DAPA (all doses [2.5, 5, 10, 20 and 50 mg]; N=5936) versus comparator (N=3403) was 0.79 (95% CI: 0.58, 1.07). The HR for MACE was 0.77 (95% CI: 0.54, 1.10).

Materials and methods: This *post hoc* pooled analysis of the data assessed CV safety in a high-risk subgroup of elderly (≥65 years) patients with a history of CV disease and hypertension (n=707 for DAPA; n=556 for comparator).

Results: Baseline characteristics were similar between treatment groups. For MACE, the HR was 0.92 (95% CI: 0.51, 1.64). For MACE plus unstable angina, the HR was 0.82 (0.50, 1.37). Additional HRs are shown in the figure. The overall adverse events profile was similar between treatment groups.

Conclusion: These analyses suggest that DAPA is not associated with increased CV risk in elderly patients with T2DM, comorbid CV disease and hypertension. The impact of DAPA on CV events is being prospectively tested in the ongoing DECLARE-TIMI58 study.

Safety and tolerability of combinations of empagliflozin/linagliptin for 52 weeks in subjects with type 2 diabetes

S. Kohler¹, S. Patel², R.A. DeFronzo³, A. Lewin⁴, D. Liu⁵, R. Kaste⁵, H.-J. Woerle⁶, U. Broedl⁶;

¹Boehringer Ingelheim Ltd., Ingelheim, Germany, ²Boehringer Ingelheim Ltd., Bracknell, UK, ³University of Texas Health Sciences, San Antonio, ⁴National Research Institute, Los Angeles, ⁵Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, USA, ⁶Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany.

Background and aims: Two 52-week Phase III studies evaluated the efficacy and safety of once daily combinations of empagliflozin/linagliptin (EMPA/LINA) as monotherapy or add-on to metformin in subjects with type 2 diabetes (T2DM). Using pooled data from these trials, we assessed the safety and tolerability of EMPA/LINA.

Materials and methods: A total of 1363 subjects were treated with EMPA 25 mg/LINA 5 mg (n=273), EMPA 10 mg/LINA 5 mg (n=272), EMPA 25 mg (n=276), EMPA 10 mg (n=275), or LINA 5 mg (n=267). Adverse events (AEs) were assessed descriptively in subjects who took ≥1 dose of study drug.

Results: Total exposure was 251, 255, 256, 249, and 243 patient-years in the EMPA 25 mg/LINA 5 mg, EMPA 10 mg/LINA 5 mg, EMPA 25 mg, EMPA 10 mg, and LINA 5 mg groups, respectively. The percentage of subjects with any AE(s) was similar across groups (Table). The percentage of subjects with confirmed hypoglycaemic AEs (plasma glucose ≤70 mg/dL and/or requiring assistance) was low in all groups (1.1%–2.2%); none required assistance. Events consistent with urinary tract infection were reported in similar percentages of subjects in all groups. Events consistent with genital infection were reported in higher percentages of subjects on EMPA/LINA or EMPA than LINA 5 mg, and in a greater proportion of female than male subjects.

Conclusion: EMPA/LINA as monotherapy or add-on to metformin for 52 weeks was well tolerated in subjects with T2DM, with safety profiles similar to individual components, including a low risk of hypoglycaemia.

Efficacy and safety of canagliflozin in patients with type 2 diabetes mellitus living in hot climates

M. John¹, R. Violante², C. Deerochanawong³, U. Vijapurkar⁴, W. Canovatchel⁴, G. Hamilton⁵;

¹Health and Research Centre, Trivandrum, Kerala, India, ²Centro de Estudios de Investigación Metabólicos y Cardiovasculares S.C., Tampico, Mexico, ³Rajavithi Hospital, Bangkok, Thailand, ⁴Janssen Research & Development, LLC, Raritan, USA, ⁵Janssen-Cilag Ltd, High Wycombe, UK.

Background and aims: In hot climates, patients with type 2 diabetes mellitus (T2DM) treated with canagliflozin (CANA), an SGLT2 inhibitor, may be at increased risk for adverse events (AEs; eg, dehydration). This post hoc analysis assessed the efficacy and safety of CANA in a pooled population of patients living in hot climates (ie, countries between the Tropics of Cancer and Capricorn: Colombia, Costa Rica, Guatemala, Hong Kong, India, Malaysia, Mexico, Peru, Philippines, Singapore, and Thailand).

Materials and methods: This analysis pooled data from 4 randomised, placebo (PBO)-controlled, Phase 3 studies. Patients (N=611; mean age, 53.3 y; HbA1c, 8.0%; BMI, 28.9 kg/m²) received CANA 100 or 300 mg or PBO once daily for 26 weeks.

Results: Relative to PBO, CANA 100 and 300 mg lowered HbA1c (-0.88% and -0.98%), body weight (-2.2% and -3.0%), and systolic BP (-3.5 and -5.8 mmHg) over 26 weeks. Overall AE incidence was 58.6%, 61.1%, and 57.1% with CANA 100 and 300 mg and PBO, with a similar safety profile as the overall population (Table). The incidence of genital mycotic infections in men and women and osmotic diuresis-related AEs was higher with both CANA doses versus PBO. While 3.6% of patients in the hot climate dataset were at high risk for volume-related AEs (eGFR <60 mL/min/1.73 m², on loop diuretic, and/or aged ≥75 y), rates of these AEs were low across groups. Consistent with the overall population, documented hypoglycaemia rates were low but higher with CANA 100 and 300 mg versus PBO in patients not on sulphonylurea (SU; n=535; 6.5%, 4.0%, 1.5%), with a higher incidence across groups in those on SU (n=76; 39.1%, 18.5%, 19.2%).

Conclusion: In summary, CANA reduced HbA1c, body weight, and BP, and was generally well tolerated in patients with T2DM living in hot climates over 26 weeks.

Table. Summary of Overall Safety and Selected AEs at Week 26 (Regardless of Rescue Medication)

Assessment of dehydration parameters with dapagliflozin in patients with type 2 diabetes mellitus during Ramadan fasting month

N. Kamaruddin¹, W. Wan Seman², N. Kori¹, S. Rajoo², N. Mohd Noor², N. Mohd Noor², N. Mustafa¹;

¹Department of Medicine, University Kebangsaan Malaysia Medical Centre, Cheras, Kuala Lumpur, ²Department of Medicine, Putrajaya Hospital, Wilayah Persekutuan Putrajaya, Malaysia.

Background and aims: The population-based Epidemiology of Diabetes and Ramadan (EPIDIAR) study showed that 79% of the 12,243 people in their study fasts during Ramadan. There will be changes in glycaemic, metabolic profile and biochemistry parameters among patients who fasts during Ramadan. Dapagliflozin is a novel class of glucose-lowering medications which acts via blocking the sodium-glucose cotransporter (SGLT 2) in the proximal renal tubule and leads to urinary glucose excretion. We assessed the dehydration parameters in Type 2 diabetic patient on either Dapagliflozin or sulphonylurea during Ramadan fasting month.

Materials and methods: In this 12-weeks, randomized, open-label, two-arm parallel group study, 119 patients with T2DM on sulphonylurea (SU) and metformin therapy randomised to either switch to Dapagliflozin 10 mg od (n=58) or remain on pre-study therapy sulphonylurea (n=52). The primary endpoint was to assess the proportion of patient with dehydration, defined as loss of 1.8% of body weight within 13 hours period of fasting daily; which is weight difference between after sunrise ('sahur') and before sunset ('iftar'). Other assessment of dehydration included 4 parameters; medical history questions (feeling thirsty, recent fever, recent vomiting and diarrhoea, vigorous exercise and frequency of passing urine), physical examination parameters (dry mucus membrane, dry tongue, reduce skin turgor and altered mental status), blood biochemistry (blood urea, serum creatinine, serum sodium, plasma osmolarity, uric acid and blood ketone) and urine biochemistry analysis (urine osmolarity, urine sodium and urine specific gravity). Data analysed via IBM SPSS Statistics Version 22.

Results: There is no difference in the proportion of patient with dehydration 73.1% (n=38) vs 81.6% (n=38); p=0.258, defined as 1.8% weight loss within 13 hours of fasting in both Dapagliflozin and sulphonylurea group. More patients in the Dapagliflozin group, 43.1% (n=25) vs 23.1% (n=12); p=0.026 complained of thirst sensation. Other parameters such as BMI, postural hypotension, changes in standing heart rate, physical examinations were similar in both groups. There is higher mean blood ketone (0.2 (0.20) versus 0.1 (0.10) mmol/L; p=0.002) and mean haematocrit level (41.6 (3.60)% versus 40.0 (4.70)%; p=0.009) in Dapagliflozin group versus sulphonylurea group respectively. There is a significantly higher mean urine osmolarity (805 (116.23) vs 652 (220.19) mOsm/L; p=0.001) and a significantly lower mean urine sodium (85 (43.0) vs 120 (50) mmol/24 hr; p<0.005) in Dapagliflozin group compared to sulphonylurea group, at Week 6 and Week 12. Adjustment of 1.8% of weight loss to age, gender, HbA1c, urine osmolarity and blood ketone did not show any significant correlation via binary logistic regression analysis.

Conclusion: Clinical dehydration assessment of 1.8% loss of body weight within 13 hours of fasting, physical examination and blood biochemistry (except blood ketone and haematocrit) parameters were similar between both groups, postulating that Dapagliflozin does not pose a higher risk of dehydration in Ramadan fasting month. In conclusion, Dapagliflozin is well-tolerated in diabetic patients fasting during Ramadan month without an increase risk of dehydration.

Incidence of genital mycotic infections decrease over time in patients with type 2 diabetes mellitus treated with canagliflozin over 2 years

M. Davies¹, J.D. Sobel², R.M. Goldenberg³, K. Khunti⁴, U. Vijapurkar⁵, G. Meininger⁵;

¹Janssen Scientific Affairs, LLC, Raritan, ²Harper University Hospital, Detroit, USA, ³LMC Diabetes and Endocrinology, Thornhill, Canada, ⁴University of Leicester, UK, ⁵Janssen Research & Development, LLC, Raritan, USA.

Background and aims: Patients with type 2 diabetes mellitus (T2DM) are at increased risk of genital mycotic infections (GMIs), and those with poorly controlled diabetes have higher risks. Sodium glucose co-transporter 2 inhibitors, such as canagliflozin (CANa), improve glycaemic control by inhibiting renal glucose reabsorption and increasing urinary glucose excretion, a mechanism of action associated with an increased incidence of GMIs.

Materials and methods: The incidence of GMIs was evaluated over 2 years in a pooled analysis of 2 randomized clinical studies including 2,164 patients with T2DM; patients received CANa 100 mg or 300 mg, or glimepiride (GLIM) in Study 1 or placebo (PBO) in Study 2. The incidence of GMIs was monitored and evaluated overall, and at 3-month intervals.

Results: The cumulative incidence of GMIs was higher with CANa 100 mg and 300 mg versus GLIM/PBO in both females (17.2% and 16.5% vs 3.2%) and males (8.2% and 9.7% vs 1.7%). The highest incidence of GMIs occurred in the first 3 months of treatment in both females and males, and then declined with time (Figure). GMIs were characterized by the investigators as generally mild to moderate in intensity and responded to standard treatment. In both CANa-treated groups, around 1% of patients (a total of 4 men and 6 women) discontinued treatment due to GMIs.

Conclusion: In summary, in patients with T2DM, GMIs associated with CANa occurred early in treatment, were mild to moderate in intensity, and decreased over time.

Fig. Incidence of GIMs in female and male patients with T2DM treated with CANA or GLIM/PBO

Genital infections and relation to body mass index in patients with type 2 diabetes mellitus treated with dapagliflozin

G. Rudofsky¹, I. Baldycheva², E. Johnsson³, K. Rohwedder⁴;

¹Kantonsspital Olten, Olten, Switzerland, ²AstraZeneca, Gaithersburg, USA, ³AstraZeneca, Mölndal, Sweden, ⁴AstraZeneca, Wedel, Germany.

Background and aims: Treatment with dapagliflozin (DAPA), a highly selective sodium glucose co-transporter 2 (SGLT2) inhibitor, increases glucosuria and reduces hyperglycaemia in patients with type 2 diabetes mellitus (T2DM). Genital infections are a common side effect of treatment with SGLT2 inhibitors, likely resulting from this increase in glucosuria. Clinical trials have reported a greater frequency of vulvovaginitis, balanitis and related genital infections with DAPA versus placebo. In addition, patients with T2DM are generally at increased risk of genital infections. Because obesity is a potential risk factor for some infections, it could be speculated that patients with a higher body weight are at increased risk of genital infections. DAPA has been shown to promote modest weight loss and may therefore be a useful option when it is desirable to avoid weight gain or induce weight loss, particularly in overweight or obese patients. This pooled analysis investigated whether there was a relationship between baseline body mass index (BMI) and the frequency of genital infections in patients with T2DM treated with DAPA, in order to determine whether overweight or obese patients have a clinically important increased susceptibility to this adverse event (AE).

Materials and methods: Data were pooled from 13 studies of up to 24 weeks' duration comprising 2,360 patients treated with DAPA 10 mg and 2,295 patients treated with placebo. The frequency of genital

infections was compared between three BMI subgroups (<30, ≥30 to <35 and ≥35 kg/m²).

Results: Genital infection AEs were reported in 130 (5.5%) patients receiving DAPA and 14 (0.6%) patients receiving placebo; none of which were serious. Baseline HbA1c was similar in DAPA-treated patients with and without a genital infection (8.12 and 8.18%, respectively). AEs of genital infections were more common in females than males treated with DAPA (64.6 and 35.4%, respectively). The frequency of genital infection AEs in DAPA-treated patients was similar between the BMI subgroups (4.3% [38/882], 5.9% [47/796], 6.6% [45/682] in patients with BMI <30, ≥30 to <35 and ≥35 kg/m², respectively). Discontinuations due to genital infections were low in DAPA-treated patients (N=5) and were similar in all BMI subgroups (0.2% [2/882], 0.1% [1/796], 0.3% [2/682] in patients with BMI <30, ≥30 to <35 and ≥35 kg/m², respectively). There were several limitations to this *post hoc* pooled analysis, including the low numbers of cases of genital infection, the short duration of the analysis and the exclusion of patients with a BMI of >45 kg/m².

Conclusion: The frequency of genital infection was low in patients with T2DM treated with DAPA 10 mg. Although these findings were hypothesis-generating only, there was a trend towards a greater frequency of genital infections in patients with a higher baseline BMI. This observed trend is unlikely to be clinically relevant and there is currently no need to adjust advice about the risk of genital infections in overweight or obese patients versus lean patients.

Low carbohydrate diet and SGLT-2 inhibitors dissimilarly influenced on body weight and adiposity in normal mice

K.K. Atageldiyeva, Y. Fujita, T. Yanagimachi, J. Honjo, A. Abiko, Y. Takiyama, Y. Makino, M. Haneda;

Division of Metabolism and Biosystemic Science, Department of Medicine, Asahikawa Medical University, Japan.

Background and aims: Carbohydrate is one of major energy sources, but its excess intake can induce metabolic disorders including obesity and diabetes. Low-carbohydrate diet (LCHD) has been favourably indicated to prevent obesity, dyslipidaemia and hyperglycaemia mostly in the short-term studies. While, a new class of glucose lowering agents, sodium-glucose cotransporter-2 inhibitor (SGLT-2i), exerts its therapeutic activity independently on insulin secretion by facilitating glucose excretion through the kidneys. SGLT-2i improves glycaemic control and potentially promotes body weight reduction. However, it is still obscure whether dietary carbohydrate-restriction via LCHD functions similarly to urinary glucose disposal by SGLT-2 inhibitors. Moreover, it is not clear whether LCHD is still beneficial to long-term metabolism or not. In current study, we investigated how differently LCHD and SGLT-2i can influence on metabolic changes including body weight, adiposity and glycaemia using normal mice.

Materials and methods: We conducted an eight-week study using non-diabetic C57Bl/6 mice. Mice were fed either LCHD (carbohydrate : protein : fat (C:P:F)=16:40:44%cal) or normal diet (ND, C:P:F=68:20:12%cal) ad libitum and treated with either SGLT-2i (ipragliflozin 3 mg/kg) or saline by daily oral gavage. Mice were randomized into four groups (each n=5~10): LC group fed with LCHD, Ipra group treated with ipragliflozin, LC + Ipra group combined with LCHD and ipragliflozin and C group as controls. To evaluate metabolic changes, we monitored body weight and glycaemia. We also compared glucose excursions, glucose-stimulated insulin secretion and insulin sensitivity among the groups by 2 g/kg OGTT or intraperitoneal insulin tolerance

test (0.6 U/kg). Then, we conducted the calorie-adjusted pair-feeding (PF) study, where mice were similarly divided to four groups: LCPF, IpraPF, LC + IpraPF, controlPF, respectively.

Results: There was no significant difference in non-fasted glucose levels among the groups fed ad libitum. However, not LCHD but SGLT-2i treatment reduced glucose excursion after OGTT compared to controls (AUC glucose, LC: 1698±77.04, Ipra*: 1190±62 C: 1730±102 mmol/l x min, * p<0.0001 vs C). Both LCHD and SGLT-2i treatment enhanced calorie-intake compared to controls (p<0.03), whereas LCHD unexpectedly increased body weight (LC*, **: 27.0±0.9, Ipra: 23.9±0.5, LC+Ipra: 22.9±0.7, C: 23.6±0.4 g, *p<0.005 vs C, **p<0.005 vs Ipra) and epididymal fat mass (LC*, **: 0.90±0.09, Ipra: 0.34±0.01, LC+Ipra: 0.43±0.01, C: 0.38±0.02 g, *p<0.0001 vs C, **p<0.0001 vs Ipra). Furthermore, insulin tolerance test indicated that LCHD induced insulin resistance in mice treated with SGLT-2i. (LC+Ipra vs Ipra, p<0.05). In contrast, glucose-stimulated insulin secretion was increased in LC to compensate glucose excursions. Finally, pair-feeding ameliorates LCHD-induced body weight gain, fat deposition and insulin resistance by calorie-adjustment to ND

Conclusion: Collectively, our results suggest that LCHD without calorie restriction may unexpectedly induce insulin resistance and obesity in non-diabetic mice.

Hypersensitivity events with dapagliflozin: a pooled analysis

A. Mellander, M. Billger, K. Johnsson, E. Johnsson;
AstraZeneca Pharmaceuticals LP, Mölndal, Sweden.

Background and aims: In patients with type 2 diabetes mellitus dapagliflozin (DAPA) improves glycaemic control, is generally well tolerated, and has an adverse event (AE) profile typically related to its mechanism of action. Hypersensitivity events have been reported in some patients with sodium-glucose co-transporter 2 inhibitors, including a report of dermatological AEs in Japan.

Materials and methods: We therefore investigated the frequency and characteristics of hypersensitivity AEs pooled across 21 phase 2/3 comparator-controlled DAPA trials, including a subanalysis of Asian patients.

Results: In the total population, AEs and serious AEs (SAEs) of hypersensitivity were infrequent and reported in a similar proportion of patients with DAPA or comparator (Table); the most common events were rash, eczema, dermatitis, and urticaria. Few patients discontinued as a result of hypersensitivity AEs. In patients of Asian descent, a lower frequency of hypersensitivity AEs was observed with DAPA vs comparator. In the placebo (PBO)-controlled pools hypersensitivity AEs were slightly more frequent with DAPA vs PBO across the overall population and less frequent with DAPA vs PBO in Asian patients.

Conclusion: In conclusion, hypersensitivity events with DAPA were infrequent across the clinical programme and were similar between PBO and comparator. These events rarely led to discontinuation of DAPA and were not more frequent in Asian patients.

PS 066 SGLT-2 inhibitors: new insights, new uses

762

Urinary glucose excretion and insulin to carbohydrate ratio to assess insulin dose adjustments in type 1 diabetes mellitus patients treated with dapagliflozin

L. Hansen¹, C. Sonesson², F. Thoren², A. Ptaszynska¹, N. Iqbal¹, E. Johnsson²;
¹Bristol-Myers Squibb, Princeton, USA, ²AstraZeneca, Mölndal, Sweden.

Background and aims: Dapagliflozin is a selective sodium-glucose co-transporter 2 inhibitor that lowers HbA1c, body weight and systolic blood pressure in patients with type 2 diabetes mellitus (T2DM). Dapagliflozin has previously been shown to be safe and well tolerated in a 14-day Phase 2 study in patients with type 1 diabetes mellitus (T1DM).

Materials and methods: We hypothesised that carbohydrate (CHO) loss, counted as 24 hour urinary glucose excretion (UGE), after 7 days of dapagliflozin treatment in patients with T1DM (Phase 2 data) or as UGE estimated from a dapagliflozin dose-response model, could be used with the calculated insulin to CHO ratio (I/C) to assess insulin dose adjustments needed upon initiation of dapagliflozin treatment. Data on total daily insulin dose (TDD) were obtained from the Phase 2 study, or arbitrarily chosen to represent “low” or “high” insulin dose. The ‘450 rule’ i.e. I/C (for adults on short acting insulin)=450 / TDD was applied to derive I/C. TDD adjustment was calculated as UGE:I/C.

Results: Empirically, there was agreement between observed mean TDD adjustments (Phase 2 data) and I/C-calculated mean TDD adjustments using either observed mean UGE (Phase 2 data) or estimated mean UGE from the dapagliflozin dose-response model (Table).

Conclusion: UGE and I/C can be used to assess mean reductions in TDD upon initiation of dapagliflozin. Further assessments are needed to evaluate the impact of patient characteristics such as eGFR and average plasma glucose on individual TDD adjustments.

Method of assessment	Mean 24 hr UGE (g) after DAPA T/t	Mean BL TDD (IU)	I/C = 450/TDD (g/IU)	Mean daily INS dose reduction (%)
Phase 2 study – observed*				Observed
DAPA 5 mg (n=14)	71.25	39.36		19
DAPA 10 mg (n=13)	88.02	55.14		17
Phase 2 study – calculated from UGE*				Calculated
DAPA 5 mg (n=14)	71.25	39.36	11.43	16
DAPA 10 mg (n=13)	88.02	55.14	8.16	20
Model estimated UGE				Modelled
DAPA 10 mg	80.00	18 (low)	25.00	18
DAPA 10 mg	80.00	63 (high)	7.14	18

*From a Phase 2 study of DAPA in patients with type 1 diabetes; BL=baseline; DAPA=dapagliflozin; I/C=insulin to carbohydrate ratio; TDD=total daily insulin dose; T/t=treatment; UGE=urinary glucose excretion.

Empagliflozin decreases glucose exposure and variability in patients with type 1 diabetes: continuous glucose monitoring data (EASE-1) S. Kaspers¹, S. Famulla², T.R. Pieber³, J. Eilbrach⁴, D. Neubacher⁵, N. Soleymanlou¹, U.C. Broedl⁵;

¹Boehringer Ingelheim Canada Ltd./Ltee, Burlington, Canada, ²Profil, Neuss, Germany, ³Medical University of Graz, Austria, ⁴Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, ⁵Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany.

Background and aims: Empagliflozin (EMPA) lowers blood glucose by reducing renal glucose reabsorption via a mechanism independent of the action of insulin. In the EASE-1 study, we characterised the effects of EMPA as adjunct to insulin on glucose exposure in patients with type 1 diabetes, by analysing glucose patterns via continuous glucose monitoring (CGM).

Materials and methods: In this Phase II, double-blind trial, patients with type 1 diabetes were randomised to placebo (PBO; n=19), EMPA 2.5 mg (n=19), EMPA 10 mg(n=19) or EMPA 25 mg (n=18) as adjunct to insulin for 4 weeks. Insulin dose was to be kept as stable as possible for the first 7 days and was freely adjustable thereafter. Markers of glucose exposure and variability were assessed from 7-day blinded CGM periods.

Results: At week 1, all EMPA doses decreased total glucose exposure (AUC) and increased time in the glucose range of >70 mg/dL to ≤180 mg/dL vs PBO; results were sustained to week 4 with EMPA 25 mg (Table). A similar pattern was observed in nocturnal glucose exposure (00:00-05:59 h). Hours/day with glucose ≤70 mg/dL increased with EMPA 10 mg and 25 mg vs PBO at week 1 but there were no significant differences with EMPA vs PBO at week 4. Hours/day with glucose ≤54 mg/dL were not increased with EMPA vs PBO. All EMPA doses significantly reduced glucose variability, as measured by interquartile range (IQR [Table]; ambulatory glucose profiling) and mean amplitude of glucose excursions (MAGE), vs PBO at weeks 1 and 4. **Conclusion:** These CGM data show that EMPA as adjunct to insulin therapy decreased glucose exposure and variability and increased time in glucose target range over 4 weeks in patients with type 1 diabetes. EMPA is not yet approved for use in patients with type 1 diabetes.

		PBO	EMPA 2.5 mg	EMPA 10 mg	EMPA 25 mg

Sotagliflozin, a dual SGLT1 and SGLT2 inhibitor, reduces glucose variability in type 1 diabetes mellitus in a randomised, placebo-controlled, double-blind study

P.S. Strumph¹, A.T. Sands¹, J. Rosenstock², P. Lapuerta¹, B.W. Bode³, S.K. Garg⁴, J.B. Buse⁵, P. Banks¹, R. Heptulla⁶, M. Rendell⁷, W. Cefalu⁸, B. Zambrowicz¹;

¹Lexicon Pharmaceuticals, Inc., The Woodlands, ²Dallas Diabetes and Endocrine Center, ³Atlanta Diabetes Association, ⁴University of Colorado Denver/Barbara Davis Center for Childhood Diabetes, Aurora, ⁵University of North Carolina Diabetes Care Center, Chapel Hill, ⁶Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, ⁷Creighton Diabetes Center, Omaha, ⁸Pennington Biomedical Research Center, Baton Rouge, USA.

Background and aims: Sotagliflozin (LX4211) is a dual inhibitor of sodium-glucose cotransporters SGLT1 and SGLT2. Inhibition of SGLT1, the major intestinal glucose transporter, reduces glucose absorption in the gastrointestinal tract, and SGLT2 inhibition reduces renal glucose reabsorption. We hypothesized that sotagliflozin would increase “time in glucose range” by decreasing postprandial hyperglycemia and glycemic variability.

Materials and methods: This 29-day study evaluated 33 subjects with T1D (age 21–57 years, diabetes duration 3–42 years) with screening A1C 7.0%–9.0%, randomized to double-blind treatment with sotagliflozin 400 mg or placebo 1×/day. All subjects wore masked continuous glucose monitors (CGM).

Results: All 33 patients completed the study. Raw means are displayed; p-values for change from baseline and between group effects are based on least squares means.

Conclusion: Sotagliflozin, a next generation SGLT inhibitor, significantly improved time in glucose range as measured by the following CGM glucose indices: Mean daily glucose, % time spent between 70 and 180 mg/dL, >180 mg/dL, and >250 mg/dL, and glucose variability (mean standard deviation, MAGE, and HBGI). Sotagliflozin as an adjunctive treatment to insulin showed improved glucose control and glycemic variability. Larger studies of longer duration are needed to confirm these findings.

Efficacy and safety of dapagliflozin in patients with type 2 diabetes mellitus and concomitant heart failure

M. Kosiborod¹, I. Gause-Nilsson², C. Sonesson², E. Johnsson²;

¹Saint Luke's Mid America Heart Institute, Kansas City, USA, ²AstraZeneca, Mölndal, Sweden.

Background and aims: Over 40% of patients with heart failure (HF) have type 2 diabetes mellitus (T2DM); a number that is expected to increase due to rising prevalence of both conditions. Yet, remarkably little

is known about the optimal glycaemic management in this patient group. Dapagliflozin (DAPA), a sodium-glucose co-transporter 2 inhibitor, promotes renal glucose excretion, causing osmotic diuresis, weight loss and decreased blood pressure (BP). These effects may provide a unique benefit to patients with coexisting T2DM and HF, but have not been formally evaluated in this group.

Materials and methods: We pooled data from 5 clinical trials, selecting patients randomised to DAPA 10 mg or placebo that had a documented history of HF. Using longitudinal repeated-measures models, we examined the effects of DAPA vs placebo on HbA1c, weight and BP for up to 1 year in patients with T2DM and HF. Safety was also assessed.

Results: In total, 171 patients received DAPA 10 mg and 149 patients received placebo across the 5 studies (age 64 years, T2DM duration 13.2 years, HbA1c 8.18%, ~50% with New York Heart Association [NYHA] class ≥ 2 HF). Patients receiving DAPA experienced clinically meaningful placebo-adjusted declines in HbA1c (−0.55%; 95% CI −0.80, −0.30), weight (−2.67 kg; 95% CI −3.88, −1.47) and systolic BP (−2.1 mmHg; 95% CI −5.68, 1.57) over 52 weeks; there was no change in heart rate in either group. The rates of orthostatic hypotension, syncope and hypoglycaemia were similar between the two groups. More patients on DAPA vs placebo had a decrease in creatinine clearance (11 [6.4%] vs 2 [1.3%]) and an increase in creatinine (7 [4.1%] vs 2 [1.3%]); however, absolute difference in estimated GFR from baseline to 50 weeks was minimal (−2.6 vs −1.4 mL/min/1.73 m² with DAPA vs placebo).

Conclusion: Treatment with DAPA 10 mg vs placebo produced clinically meaningful reductions in HbA1c, weight and systolic BP in patients with T2DM and HF, and was well tolerated. The weight and BP effects of DAPA may lead to improvement in HF-related symptoms in this patient population, which should be further investigated in prospective studies. Consistent weight changes irrespective of baseline HbA1c with the combination of empagliflozin/linagliptin in subjects with type 2 diabetes

C. Lee¹, A.H. Barnett², R.A. DeFronzo³, A. Lewin⁴, S. Patel⁵, D. Liu⁶, R. Kaste⁶, U. Broedl¹;

¹Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany, ²Diabetes Centre, Heart of England NHS Foundation Trust and University of Birmingham, UK, ³University of Texas Health Sciences, San Antonio, ⁴National Research Institute, Los Angeles, USA, ⁵Boehringer Ingelheim Ltd., Berkshire, UK, ⁶Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, USA.

Background and aims: Two Phase III studies evaluated the efficacy and safety of once daily combinations of empagliflozin/linagliptin (EMPA/LINA) as initial therapy or add-on to metformin (MET) in subjects with type 2 diabetes (T2DM) for 52 weeks. Change from baseline in weight at week 24 was a key secondary endpoint in both studies. In both studies, EMPA/LINA led to significant reductions in weight vs LINA but not vs EMPA at week 24. In pre-specified subgroup analyses, we assessed the influence of baseline HbA1c on weight changes at week 24 with EMPA/LINA vs the individual components.

Materials and methods: Changes from baseline in weight at week 24 were analysed by subgroups of baseline HbA1c (<8.5% and $\geq 8.5\%$) in subjects randomised to EMPA 25 mg/LINA 5 mg, EMPA 10 mg/LINA 5 mg, EMPA 25 mg, EMPA 10 mg, or LINA 5 mg as initial therapy or as add-on to stable-dose MET.

Results: EMPA/LINA significantly reduced weight vs LINA in both HbA1c subgroups as add-on to MET but only in subjects with HbA1c <8.5% as initial therapy (Table). There were no significant differences in changes in weight with EMPA/LINA vs EMPA as initial therapy or add-

on to MET in either HbA1c subgroup. The treatment and baseline HbA1c interaction was not significant, suggesting no differential treatment effect across HbA1c subgroups ($p=0.308$ and $p=0.649$ for interaction when EMPA/LINA was given as initial therapy and add-on to MET, respectively).

Conclusion: The degree of glycemic control at baseline had no effect on weight changes with EMPA/LINA given as initial therapy or add-on to MET for 24 weeks in subjects with T2DM.

Efficacy of SGLT2 inhibitors on bone mineral density in Japanese patients with type 2 diabetes

M. Kusunoki¹, Y. Natsume¹, D. Sato², H. Tsutsui³, H. Sasaki², T. Nakamura², T. Miyata⁴, Y. Oshida¹;

¹Research Center of Health, Physical Fitness and Sports, Nagoya University, ²Department of Biomedical Information Engineering, Yamagata University, ³Department of Hygiene and Public Health, Teikyo University School of Medicine, ⁴Vascular Center, Sanno Medical Center, Tokyo, Japan.

Background and aims: Sodium-glucose co-transporter-2 (SGLT2) inhibitor enhances glucose excretion in urine, and reduces blood glucose in type 2 diabetic patients. In addition to glycemic control effects, it is reported that SGLT2 inhibitor lowers serum lipid profile and body weight. However, few studies have examined the effects of SGLT2 inhibitor on bone density. In the present study, we evaluated change of bone mineral density in Japanese patients with type 2 diabetes treated with SGLT2 inhibitors.

Materials and methods: The subjects were 115 type 2 diabetic outpatients, consisting of 77 men and 38 women (52 ± 9 and 54 ± 12 years old, respectively; mean \pm SD) who were orally treated with any one of three SGLT2 inhibitors (luseogliflozin 2.5 mg qd, dapagliflozin 5 mg qd or tofogliflozin 20 mg qd) for 6 months. We measured BMI, hemoglobin and HbA_{1c} levels, serum uric acid (UA) level, renal function parameter (serum creatinine and urine creatinine and albumin levels), and bone mineral density (BMD) before and after the drug treatment.

Results: After the 6-month treatment, SGLT2 inhibitors significantly reduced BMI and HbA_{1c} level in both male and female patients (BMI in male: from 29.2 ± 4.9 to 28.4 ± 4.8 kg/m², $p<0.01$; in female: from 28.4 ± 5.1 to 27.6 ± 5.0 kg/m², $p<0.01$; HbA_{1c} in male: from 7.1 ± 1.2 to $6.9 \pm 0.9\%$, $p<0.05$; in female: from 6.8 ± 0.9 to $6.7 \pm 0.7\%$, $p<0.05$). Hemoglobin level was significantly elevated (in male: from 14.6 ± 1.1 to 15.6 ± 1.2 g/dL, $p<0.01$; in female: from 12.8 ± 1.1 to 13.8 ± 1.1 g/dL, $p<0.01$). Although significant changes were not detected in serum creatinine and urine creatinine and albumin levels, UA level was lowered (in male: from 5.6 ± 1.3 to 5.0 ± 1.3 mg/dL, $p<0.01$; in female: from 5.0 ± 1.4 to 4.1 ± 1.2 mg/dL, $p<0.01$). BMD compared to that of a young adult mean

was raised (in male: from 87 ± 15 to $90 \pm 15\%$, $p<0.01$; in female: from 94 ± 15 to $97 \pm 14\%$, $p<0.01$).

Conclusion: The treatment of SGLT2 inhibitors reduced BMI and HbA_{1c} level. Interestingly, SGLT2 inhibitors raised BMD compared to that of a young adult mean. Since it was reported that SGLT2 inhibitor preserves renal function in diabetic patients, the improvement of BMD seen in this study may be attributed to alteration of the renal function including production of active vitamin D. In addition, SGLT2 inhibitors decreased UA level although the detailed mechanisms were not cleared in this study. Some of antihypertensive agents elevate UA level and reduce BMD. Thus, SGLT2 inhibitors could also prevent such adverse effects. On the other hand, SGLT2 inhibitors increased hemoglobin level. These changes may derived from diuretic effects of SGLT2 inhibitors and consequent body fluid reduction. In the present study, it is suggested that SGLT2 inhibitors are potentially useful to reduce fracture risk while the treatment require attention to dehydration in type 2 diabetic patients.

Comparative persistency with newer agents to treat type 2 diabetes in the US: canagliflozin vs dipeptidyl peptidase-4 inhibitors and glucagon-like peptide-1 agonists

J. Diels¹, C. Neslusan²;
¹Janssen Research & Development, Beerse, Belgium, ²Janssen Global Services, LLC, Raritan, USA.

Background and aims: Canagliflozin is an agent approved for the treatment of type 2 diabetes mellitus (T2DM) that inhibits sodium glucose co-transporter 2 (SGLT2), and as such, has been shown to reduce not only HbA_{1c}, but also weight and blood pressure with an acceptable tolerability profile. In contrast, dipeptidyl peptidase-4 (DPP-4) inhibitors do not impact weight and blood pressure, and tolerability issues have been documented with glucagon-like peptide-1 (GLP-1) agonists. As these different treatment profiles may impact treatment persistency in the real world, retrospective claims data were used to estimate the time to discontinuation of canagliflozin versus these alternatives.

Materials and methods: Patients with T2DM who received a first prescription for a DPP-4 inhibitor (sitagliptin, saxagliptin, linagliptin), GLP-1 agonist (liraglutide, exenatide, exenatide long-acting), or canagliflozin in 2013 were extracted from two United States claims databases of commercially insured patients (Truven, Optum). The analytical sample included only patients with ≥ 6 months of retrospective data prior to their first paid claim. Discontinuation was defined as an observed refill gap ≥ 90 days (sensitivity analysis for 30/60 days) between two subsequent prescriptions. Time to discontinuation was analysed using Kaplan-Meier and Cox proportional hazards regression, including demographics, treatment background, and diabetes-related complications/comorbidities as covariates.

Results: 66,206 patients (mean age, 52.6 years; 50% male; median/maximum follow-up, 10.1/19.0 months) were identified in the Truven database. After one year, the percentage of patients still on treatment was significantly higher with canagliflozin 100 mg ($n=7,445$; 64.0%) and 300 mg ($n=4,486$; 65.0%) versus DPP-4 inhibitors (30.2% [linagliptin] to 50.1% [sitagliptin]) and GLP-1 agonists (24.3% [exenatide] to 43.0% [liraglutide]) ($P<0.0001$ for all comparisons). The adjusted hazard ratio (HR) for time to discontinuation for canagliflozin 100 mg (reference) and 300 mg (HR=0.92 [0.86; 0.99]) was significantly lower versus DPP-4 inhibitors and GLP-1 agonists: sitagliptin ($n=29$, 426; HR=1.28 [1.22; 1.34]); saxagliptin ($n=1,566$; HR=2.01 [1.86; 2.16]); linagliptin ($n=1,432$; HR=2.08 [1.92; 2.24]); exenatide ($n=2$, 376; HR=2.59 [2.41; 2.77]); exenatide long-acting ($n=5,922$; HR=1.46 [1.40; 1.52]); liraglutide ($n=17,690$; HR=1.23 [1.20; 1.27]). Being younger, male, and being on monotherapy were associated with higher discontinuation risk. HRs were stable across sensitivity analyses using

alternative discontinuation definitions. Analyses from Optum were generally consistent with these results.

Conclusion: These analyses indicate that patients who received canagliflozin versus DPP-4 inhibitors or GLP-1 agonists remained on their therapy longer, which may reflect better effectiveness and/or tolerability.

Sodium-glucose cotransporter 2 inhibitor increases circulating zinc- α 2-glycoprotein levels in patients with type 2 diabetes

Y. Chen^{1,2}, L. Li^{1,2}, G. Yang³,

¹Key Laboratory of Diagnostic Medicine (Ministry of Education) & Department of Clinical Biochemistry, ²College of Laboratory Medicine, ³Department of Endocrinology, the Second Affiliated Hospital, Chongqing medical University, China.

Background and aims: Zinc- α 2-Glycoprotein (ZAG) has recently been characterized as a potent metabolic regulator, but the effect of anti-diabetic agents on circulating ZAG in humans remains unknown. Our aim was to study the effects of Sodium-glucose cotransporter 2 inhibitors (SGLT2) inhibitors on circulating ZAG and adiponectin (ADI) in newly diagnosed type 2 diabetes mellitus (nT2DM).

Materials and methods: 171 subjects with nT2DM were assigned to receive placebo or SGLT2 inhibitors for 3 months. Before and after treatment, ZAG and ADI concentrations were measured by ELISA.

Results: Circulating ZAG and ADI levels in nT2DM patients were significantly lower than in the controls ($P < 0.01$). After 3-months of SGLT2 inhibitors therapy, HbA1c, fasting blood glucose (FBG), postprandial glucose (2 h-PBG), free fatty acids (FFA), triglyceride (TG), blood pressure, body mass index (BMI), waist-to-hip ratio (WHR), body weight, the percentage of fat in vivo (FAT%), fasting insulin (FINS), and homeostasis model assessment of insulin resistance (HOMA-IR) in T2DM patients decreased significantly ($P < 0.05$ or $P < 0.01$), whereas high-density lipoprotein cholesterol (HDL-C) was significantly increased ($P < 0.05$). Importantly, circulating ZAG and ADI levels in nT2DM patients were also significantly increased after SGLT2 inhibitors therapy (both $P < 0.01$). The change of circulating ZAG (Δ ZAG) was associated with Δ TG, Δ total cholesterol (TC), Δ HDL-C and Δ FFA, whereas Δ ADI associated Δ HDL-C, Δ 2-h insulin after glucose load (2 h-INS) and Δ LDL-C.

Conclusion: These findings suggest that ZAG and ADI can be regulated by SGLT2 inhibitors, and SGLT2 inhibitors may play a physiologic role in enhancing insulin sensitivity.

Three-year efficacy and safety of exenatide once weekly: a pooled analysis of three trials

M.E. Trautmann¹, L. Van Gaal², J. Han³, E. Hardy⁴;

¹Diabetes Research, Hamburg, Germany, ²Antwerp University Hospital, Edegem, Belgium, ³Pharmapace, San Diego, ⁴AstraZeneca, Gaithersburg, USA.

Background and aims: Long-term data for glucose-lowering therapies (eg, glucagon-like peptide-1 receptor agonists) help to inform drug selection for treatment strategies.

Materials and methods: This *post hoc* analysis examined the efficacy and safety of exenatide once weekly (QW) in pooled completer data (N=329) from extensions (2.5-3 years) of three trials (DURATION-1, -2, -3); 3 year data for insulin glargine (IG) was included for reference (N=158), as IG was a long-term comparator in one trial (DURATION-3).

Results: Baseline mean age, weight, and HbA1c were 56/58 years, 93.7/90.3 kg, and 8.3/ 8.3%, in the exenatide QW/IG groups, respectively. After 3 years, patients receiving exenatide QW had improvements from baseline in HbA1c, fasting glucose, body weight, and some cardiovascular risk markers (Table). A total of 101 (30.7%) exenatide-treated patients and 26 (16.5%) IG-treated patients achieved the stringent goal of HbA1c $\leq 6.5\%$, and 95 (28.9%) and 11 (7.0%), respectively, achieved the Composite goal of HbA1c $< 7\%$, no hypoglycaemia, and no weight gain. Diarrhoea, nausea, vomiting, and injection-site pruritus occurred in 24.0%, 22.2%, 10.6%, and 8.2% of patients, respectively, receiving exenatide QW and in 8.2%, 2.5%, 3.2%, and 0% of patients, respectively, receiving IG. Major and minor hypoglycaemia were more frequent with sulphonylurea than without (exenatide QW: 32.6% vs 10.0%; IG: 70.2% vs 45.9%, respectively).

Conclusion: Long-term exenatide QW treatment improved multiple outcomes in a large, pooled cohort of patients. Exenatide QW was associated with weight loss and a lower risk of hypoglycaemia than the reference IG treatment, but had a higher incidence of gastrointestinal and injection-site events.

Table. Changes from Baseline in Outcomes at 156 Weeks

Parameter	Exenatide QW (N=329)	Insulin Glargine (N=158)
HbA1c (%), mean \pm SEM	-1.06 \pm 0.07*	-0.82 \pm 0.08*
HbA1c goal $< 7\%$, n (%)	159 (48.3)	59 (37.3)

Treatment of patients with type 2 diabetes mellitus and baseline HbA_{1c} ≥10% with exenatide twice daily, exenatide once weekly, or basal insulin: a pooled analysis of 20 randomised controlled trialsR.S. Busch¹, L. Ferri², J. Ruggles³, E. Hardy², J. Han⁴;¹The Endocrine Group, Albany, ²AstraZeneca, Gaithersburg, ³AstraZeneca, Fort Washington, ⁴Pharmapace, San Diego, USA.

Background and aims: Guidelines recommend insulin-based injectable therapy for type 2 diabetes mellitus (T2DM) patients presenting with HbA_{1c} ≥10%–12%, to rapidly minimise glucotoxicity. We explored the effects of a glucagon-like peptide-1 receptor agonist, exenatide, on glycaemic control in patients with very high HbA_{1c}, to determine whether options other than basal insulin may be shown to be appropriate for such patients. In individual randomised controlled trials (RCTs) with a mean baseline HbA_{1c} of 8.1%–8.5%, HbA_{1c} reduction with exenatide twice daily (BID) was noninferior to basal insulin and with exenatide once weekly (QW) was superior to basal insulin; however, no previous assessment of these agents has been conducted in the subset of patients with HbA_{1c} ≥10%.

Materials and methods: Using pooled intention-to-treat (ITT) data from 4,340 patients treated for ≥24 weeks in 20 RCTs, we evaluated glycaemic parameters for exenatide BID, exenatide QW and basal insulin, in a subpopulation of patients with baseline HbA_{1c} ≥10%. Most patients in this subgroup (>80%) also used metformin-and/or sulfonylurea (SU) as background therapy.

Results: Reductions from baseline in HbA_{1c} were significant from Week 2 (earliest timepoint; $P<0.001$) with exenatide BID, Week 4 ($P<0.001$) with exenatide QW, and Weeks 12 and 10 (earliest timepoints with available patient data; both $P<0.001$) for the corresponding basal insulin groups. Endpoint reductions in HbA_{1c} (Table) were comparable between exenatide BID and basal insulin, and numerically greater with exenatide QW than basal insulin. Significant reductions from baseline in fasting glucose were observed at endpoint (Table) that were greater with basal insulin. A higher proportion of patients achieved an HbA_{1c} of <7% or ≤6.5% with exenatide QW than with basal insulin. Weight significantly decreased with exenatide and increased with basal insulin. Major and minor hypoglycaemia incidence was numerically higher in SU vs non-SU users and with basal insulin.

Conclusion: In this post-hoc analysis, exenatide BID and QW achieved marked reductions in HbA_{1c} in patients with T2DM and baseline HbA_{1c} ≥10%. Exenatide BID and QW may be appropriate treatment alternatives to basal insulin for patients with HbA_{1c} ≥10%.

Table. Endpoint parameters in patients with baseline HbA_{1c} ≥10%.

Responses to exenatide twice daily, basal insulin or placebo with oral medications over different durations of type 2 diabetes mellitus: Does diabetes duration matter?S.L. Aronoff¹, L. Ferri², J.A. Ruggles³, J. Han⁴;¹Endocrine Associates of Dallas, ²AstraZeneca, Gaithersburg, ³AstraZeneca, Fort Washington, ⁴Pharmapace, San Diego, USA.

Background and aims: Type 2 diabetes is a progressive disease; thus, patients with longer disease durations are usually more difficult to treat. Using the exenatide clinical development database, we investigated whether patients with longer durations of type 2 diabetes had lesser responses to therapy, and whether certain therapy combinations appeared more effective at certain type 2 diabetes durations.

Materials and methods: We compared the efficacy of exenatide twice daily (BID) with basal insulin therapy or placebo in patients with longer type 2 diabetes durations, and examined whether use of concomitant metformin, sulfonylurea, or both, affected response after 16–30 weeks of treatment, based on the duration of type 2 diabetes. We analysed intention-to-treat data from 14 studies of ≥16 weeks' duration with exenatide BID (N=2792) compared with basal insulin (N=935) or placebo (N=1092) in patients with type 2 diabetes treated with diet and exercise with or without ≥1 oral drug(s) (mean HbA_{1c} 8.3%, type 2 diabetes duration 7.7 years). Patients continued existing treatment (metformin, n=1020; sulfonylurea, n=464; metformin + sulfonylurea, n=2433).

Results: Overall results from the metformin population showed that baseline HbA_{1c} increased with type 2 diabetes duration (≤2 years, 7.83%; >2–≤5 years, 8.05%; >5–≤10 years, 8.14%; >10–≤15 years, 8.45%; >15 years, insufficient sample size), supporting concerns for loss of efficacy of metformin. However, correlations between improvement in efficacy variables (HbA_{1c}, fasting glucose and weight) and type 2 diabetes duration were weak for all drug combinations studied. The table shows HbA_{1c} changes and goal achievement by type 2 diabetes duration categories and concomitant oral drug(s). Responses with exenatide BID and basal insulin were similar within each type 2 diabetes duration category, which was particularly evident among patients on concomitant metformin + sulfonylurea (the largest concomitant treatment subgroup).

Conclusion: Our analysis indicated that a longer type 2 diabetes duration was not associated with a reduced response to exenatide BID compared with basal insulin; however, the majority of patients with longer durations of type 2 diabetes needed multiple therapies to achieve an HbA_{1c} of 7%.

The effect of added exenatide twice daily or bolus insulin on insulin glargine and total insulin dose with improved HbA1c: subgroup analysis of the 4B study

E. Hardy¹, K. Brismar², M. Davies³, J. Han⁴, B.H.R. Wolfenbittel⁵; ¹AstraZeneca, Gaithersburg, USA, ²Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, ³University of Leicester, Diabetes Research Centre, UK, ⁴Pharmapace, San Diego, USA, ⁵University of Groningen, University Medical Center Groningen, Netherlands.

Background and aims: Persistent hyperglycaemia after insulin glargine (IG) up-titration necessitates treatment intensification. With multiple intensification options available for patients failing basal insulin, individualization of therapy becomes possible. A subgroup of particular interest is patients on high IG doses, who may respond less to additional therapies.

Materials and methods: This *post hoc* analysis examined responses to exenatide twice daily (BID) or insulin lispro (IL) added to IG + metformin in patients with type 2 diabetes mellitus (T2DM) according to IG dose tertile at randomisation. Baseline values in the exenatide BID/IL arms for total insulin were 33/33 U for tertile 1, 53/52 U for tertile 2 and 94/96 U for tertile 3. Postrandomisation, the daily IG dose was reduced by 33-50% and converted to IL in the IL arm, and reduced by ≥10% in patients with HbA1c ≤8.0% in the exenatide BID arm.

Results: The analysis included 627 patients. Baseline body weight with exenatide BID and IL was 81/82 kg for tertile 1, 90/87 kg for tertile 2 and 99/98 kg for tertile 3; baseline HbA1c was 8.2/8.0% for tertile 1, 8.2/8.1% for tertile 2 and 8.4/8.5% for tertile 3. At Week 30, HbA1c reductions with exenatide BID and IL were similar across tertiles (Table); fasting glucose decreased with exenatide BID in tertiles 1 and 3. Exenatide BID reduced body weight, while IL increased body weight. Proportions of patients achieving HbA1c <7.0% with exenatide BID and IL were generally similar across tertiles. In each tertile, greater proportions of patients treated with exenatide BID compared with IL achieved the composite goal of HbA1c <7.0%, no weight gain, and no major or minor hypoglycaemia. Tertile 3 had the numerically greatest IG dose reductions, but still had the highest total insulin dose at endpoint. Adverse events

(AEs) were generally similar across tertiles within treatment groups. Gastrointestinal AEs were more common with exenatide BID compared with IL (tertile 1: 46% vs 17%; tertile 2: 48% vs 13%; tertile 3: 46% vs 9%). The major and minor hypoglycaemia event rate/patient-year was lower with exenatide BID than with IL (tertile 1: 1.7 vs 5.2; tertile 2: 2.3 vs 6.0; tertile 3: 2.6 vs 4.8).

Conclusion: Patients with the highest baseline IG doses were able to sustain the largest reductions in the IG dose in both treatment groups, but only those treated with exenatide BID used less total insulin, with similar improvement in HbA1c. Adding exenatide BID or IL to patients on low or high insulin doses improved glycaemic control to a similar extent, with weight loss and less hypoglycaemia in the exenatide BID group, regardless of baseline IG dose. There was a higher incidence of gastrointestinal AEs with exenatide BID compared with IL.

Table. Outcomes Across IG Dose Tertiles After 30 Weeks*

Treatment With Exenatide BID or IL Added to IG + Metformin

Safety and tolerability of liraglutide versus sulphonylurea in people with type 2 diabetes before, during and after Ramadan fasting: a randomised trial (LIRA-Ramadan)

N. Shehadeh¹, A. Echtay², D.D. Ørsted³, M.S. Kalsoff⁴, S.T. Azar⁵;
¹Pediatric Diabetes Unit, Rambam Medical Center, Haifa, Israel, ²Lebanese University Medical School, Rafik Hariri University Hospital, Beirut, Lebanon, ³Novo Nordisk, Søborg, France, ⁴Novo Nordisk, Søborg, Denmark, ⁵American University of Beirut Medical Centre, Lebanon.

Background and aims: Fasting during Ramadan is challenging for people with diabetes due to 5- and 7.5-fold increased risks of severe hyper- and hypoglycaemia, respectively. Data are needed to guide planning and treatment. We report safety and tolerability data from the LIRA-Ramadan trial, which compared liraglutide (lira) with sulphonylurea (SU) in people with T2D during Ramadan.

Materials and methods: In this open-label trial, adults (HbA1c 7-10%; BMI >20 kg/m²; stable SU + metformin [Met]) intending to fast during Ramadan were randomised to switch to once daily lira 1.8 mg (N=172) or continue pretrial SU (N=171), both + Met, then followed for ≤32 weeks. Lira was dose-escalated for 3-4-weeks then administered at ≤1.8 mg for 6-19-weeks before Ramadan (4 weeks). Changes in SU dose and/or timing using ADA recommendations were allowed during Ramadan. Primary endpoint was change in fructosamine (FA) from start to end of Ramadan (lira, N=151; SU, N=165). Treatment continued for 4 weeks post Ramadan.

Results: There was a significantly greater reduction in FA from baseline to end of Ramadan with lira vs SU (estimated treatment difference [ETD] [95% CI]: -10.3 [-18.7, -1.89] μmol/L; p=0.0165). Despite lower FA and HbA1c at start of Ramadan in the lira arm, similar FA reductions occurred with lira and SU during Ramadan (ETD: 3.51 [-5.26, 12.28] μmol/L; p=0.4311). Results were similar for HbA1c (data not shown). Nonetheless, significantly fewer confirmed hypoglycaemic events (ADA defined) occurred with lira vs SU over the study period (estimated rate ratio for lira/SU: 0.2 [0.1, 0.5]; p=0.0027). No nocturnal hypoglycaemic events occurred with lira (vs 3 with SU [42 events/1000 subject years of exposure]). During the trial, 77% of people switching to lira and 57% continuing on SU experienced adverse events (AEs). Few serious AEs were observed (lira, 2.9%; SU, 1.2%). More people had GI AEs with lira than SU, commonly nausea (generally transient; 33% vs 0%), diarrhoea (22% vs 4%) and vomiting (21% vs 1%). There were no cases of acute pancreatitis. The proportion of withdrawals was similar for lira and SU (15.1% and 14.0%, respectively). With lira, 20/26 withdrawals occurred before Ramadan. The most common reason for withdrawal with lira was an AE: 11 participants in the lira arm (6%) withdrew due to an AE (n=10 before Ramadan) vs 0 in the SU arm. With SU, 11/24 withdrawals occurred during Ramadan, and the most common withdrawal reasons were fasting plasma glucose exceeding the protocol limit (n=7), or not fasting in Ramadan (n=3). No withdrawals during Ramadan were due to AEs. No significant differences between lira and SU were observed for change in overall treatment satisfaction (Diabetes Treatment Satisfaction Questionnaire [DTSQ]) or Short Form-36 Health status questionnaire scores during Ramadan. A non-significant difference in perceived frequency of hypoglycaemia was observed for lira vs SU (DTSQ ETD -0.297 [-0.701, 0.106]; p=0.1480).

Conclusion: A significantly lower risk of hypoglycaemic events was seen with lira vs SU, despite lower levels of FA and HbA1c. No new safety concerns were identified with lira during the trial, which included a physiologically challenging fasting period during Ramadan.

The addition of liraglutide 1.8 mg to insulin in type 1 diabetes does not improve patient-reported outcome measures

R. Hirsch¹, T.F. Dejgaard¹, M.W. Pedersen¹, B.J. von Scholten¹, C.S. Frandsen², S. Madsbad², H.U. Andersen¹;
¹Steno Diabetes Center, Gentofte, ²Hvidovre Hospital, University of Copenhagen, Denmark.

Background and aims: In insulin treated type 2 diabetes (T2D) the addition of a glucagon-like peptide-1 receptor agonist (GLP-1RA) has improved both metabolic control, and patient satisfaction with treatment. In patients with type 1 diabetes (T1D) studies have reported positive effects on weight and glycaemic control by adding a GLP-1 RA to insulin treatment. However, as a potential future treatment of T1D it is important to evaluate the patient-reported outcomes.

Materials and methods: A total of 100 patients with T1D, poor glycaemic control, and overweight, were randomised to liraglutide 1.8 mg once daily or placebo as an add-on to intensive insulin therapy in a double-blind, parallel design (The Lira-1 Study). To evaluate patient-reported outcomes, we used the Diabetes Treatment and Satisfaction (DTSQs) and Problem Areas in Diabetes (PAID) questionnaires at baseline, after 3 weeks of treatment, and at the end of treatment (26 weeks). The DTSQs was divided into a treatment satisfaction section and a hypoglycaemia section.

Results: Mean baseline characteristics were similar between the liraglutide and placebo groups (liraglutide;placebo, mean ± SD) age 46 ±13;50±13 years, HbA1c 73±8;73±7 mmol/mol, total daily insulin dose 60±23;61±21 IU/day and bodyweight 93.0±14.3;93.7±13.2 kg except diabetes duration 20±12;27±12 years (p=0.009). Patient-reported outcomes were assessed in 73 patients (38 and 35 patients in the liraglutide and placebo groups, respectively). The overall satisfaction score for the DTSQs in the liraglutide group did not differ significantly from baseline 23.0±3.5 to 23.7±3.2 (p=0.18) after 3 weeks or at the end of treatment 24.1±3.4 (p=0.051). In the placebo group, the mean baseline score 23.7±4.1 showed no significant change after 3 weeks of treatment 24.3±3.1 (p=0.31), but increased to 25.5±3.3 (p=0.013) at the end of treatment. No significant differences were observed between the groups in changes or the overall satisfaction score at any time point (p>0.46). For the DTSQs hypoglycaemia section, the score in the liraglutide group increased from 4.7±1.4 to 5.4±1.0 (p=0.004) after 3 weeks of treatment, but showed no significant change 5.3±1.3 (p=0.055) at the end of treatment compared with baseline. In the placebo group, baseline 4.5±1.6, and 3 weeks score did not differ significantly 5.1±1.2 (p=0.075), but increased significantly to 5.3±0.9 (p=0.003) at the end of treatment compared with baseline. No significant differences were observed in the changes in the hypoglycaemia score between the groups at any time point (p>0.59). In the PAID questionnaire, the mean score in the liraglutide group decreased from 24.9±15.9 to 18.8±15.4 (p<0.0001) after 3 weeks, and was 20.4±17.2 (p=0.029) at the end of treatment. In the placebo group, the mean baseline score of 22.6±14.4 showed no significant change at 3 weeks 19.3±13.3 (p=0.074) or at 26 weeks 20.7±15.8 (p=0.21). No significant differences were observed between the groups at any time point (p>0.21).

Conclusion: The addition of 1.8 mg liraglutide once-daily to insulin in overweight and poorly regulated patients with T1D did not improve the patient reported outcome measures DTSQs and PAID, during or after 26 weeks of treatment. These findings are in contrast to the improved treatment satisfaction reported in obese insulin treated T2D patients after add-on of the GLP-1 RA liraglutide to insulin.

Liraglutide as add-on to insulin in normal-weight and poorly controlled patients with type 1 diabetes: the T1DMLIRA studyC.S. Frandsen¹, T.F. Dejgaard², J.J. Holst³, H.U. Andersen², B. Thorsteinsson⁴, S. Madsbad¹;¹Department of Endocrinology, Hvidovre University Hospital, ²Steno Diabetes Center, Gentofte, ³Novo Nordisk Foundation Center for Basic Metabolic Research, Copenhagen, ⁴Department of Cardiology, Nephrology and Endocrinology, Nordsjællands Hospital, Hillerød, Denmark.**Background and aims:** Combination of a GLP-1 receptor agonist (GLP-1RA) with insulin is a novel, potential treatment strategy in patients with type 1 diabetes (T1D). Open-label and mechanistic studies indicate that GLP-1RA treatment induces weight loss, improves PPG excursions and reduces insulin requirements with improved or unaltered glycemic control in patients with T1D. This is the first randomized, double-blinded, placebo-controlled study to evaluate efficacy and safety of liraglutide as add-on to insulin treatment in normal-weight T1D patients without residual β -cell function**Materials and methods:** In total 40 patients with T1D were randomized to once-daily liraglutide 1.2 mg or placebo adjunct to pre-existing insulin treatment for 12 weeks. Baseline characteristics were similar between groups (liraglutide; placebo): HbA1c 73 \pm 2; 72 \pm 2 mmol/mol, BMI 24.2 \pm 0.6; 22.8 \pm 0.4 kg/m², diabetes duration 18 \pm 2 20 \pm 2 years, basal insulin 34 \pm 2; 34 \pm 4 IU/day, bolus insulin 28 \pm 3; 24 \pm 2 IU/day. Insulin dose was adjusted according to a treat-to-target algorithm. Primary endpoint was mean change in HbA1c from baseline to week 12**Results:** After 12 weeks, changes in HbA1c from baseline were similar with liraglutide and placebo (table). Patients taking liraglutide had greater reductions in body weight and bolus insulin requirements compared with placebo (table). Changes in glycemic variability and frequency of hypoglycemia were similar between groups (table). Heart rate (HR) increased with liraglutide compared with placebo (between-group difference 2.44 beats/min (CI: -1.92 to 6.81), $p=0.04$). Simultaneously, systolic blood pressure (SBP) decreased with liraglutide compared with placebo-treated patients (between-group difference 3.21 mmHg (CI: -8.31 to 1.90), $p=0.04$). Gastrointestinal (GI) AEs were significantly more frequent with liraglutide than placebo (% pts): nausea 33; 23, dyspepsia 15; 5**Conclusion:** In conclusion, liraglutide added to insulin significantly reduces body weight and bolus insulin requirements, but has no additional effect on HbA1c in T1D patients inadequately controlled on insulin alone. Frequency of hypoglycemia did not differ between groups. GI AEs were more frequent with liraglutide than placebo. HR increases and SBP decreases significantly with liraglutide compared with placebo

Effects of liraglutide vs lifestyle changes on subcutaneous and visceral fat, liver steatosis, insulin sensitivity and beta cell function after comparable weight lossF. Santilli¹, M. Guagnano¹, A. Tartaro², P.G. Simeone¹, R. Liani¹, R. Tripaldi¹, M. Maccarone², E. Zecca¹, E. Angelucci³, V. Federico⁴, A. Quirino³, L. Pansa⁴, M. Golato⁴, G. Davi¹, A. Consoli¹;¹Department of Medicine and Aging and Center of Excellence on Aging, ²Department of Neuroscience & Imaging, University of Chieti, ³Department of Clinica Medica, Chieti Hospital, ⁴Department of Clinical Pathology, Chieti Hospital, Italy.**Background and aims:** Obesity, insulin resistance and beta cell deterioration are key issues in the development and progression of type 2 diabetes (T2DM). Given the concurrent effects acknowledged for GLP-1 agonists on body weight, fat mass, insulin resistance and beta cell preservation, we hypothesized that this class of drugs may exert additional actions on top of those anticipated for lifestyle intervention-mediated weight loss.**Materials and methods:** Twenty-nine metformin-treated obese subjects with impaired glucose tolerance (IGT), impaired fasting glucose (IFG) or newly diagnosed T2DM, were randomized to liraglutide treatment (1.8 mg/d) or lifestyle counseling to assess whether changes in subcutaneous (SAT) and visceral (VAT) adipose tissue distribution and in degree of non-alcoholic fatty liver disease (NAFLD) (all assessed by MRI) after a modest and comparable weight loss (7% of initial body weight), might affect insulin sensitivity (Matsuda Index) and β -cell performance (by Insulin Secretion-Sensitivity Index-2 (ISSI-2)) during multiple sampling oral glucose tolerance test.**Results:** At baseline, VAT was correlated directly with HbA1c (Rho=0.374, $p=0.045$) and ISSI-2 (Rho=-0.378, $p=0.043$), and inversely with adiponectin (Rho=-0.470, $p=0.010$), whereas SAT was significantly and directly correlated with C-reactive protein (Rho=0.466, $p=0.013$), leptin (Rho=0.811, $p<0.0001$) and NAFLD degree (Rho=0.379, $p=0.042$). VAT, SAT and NAFLD grade were significantly and comparably reduced in both treatment groups, whereas insulin sensitivity was not significantly affected by any intervention. In contrast, the liraglutide group showed a significantly greater reduction in median VAT ($p=0.001$), as compared to the lifestyle group (-15.3% vs. -7.3% median decrease) and a greater improvement in beta cell function (ISSI-2) (96.3% vs. 29.8%, $p=0.006$), which translated into a significantly more pronounced reduction in both fasting, 1-hour and 2-hour postprandial plasma glucose, despite comparably reduced HbA1c in both groups (by 7.0%). In the liraglutide arm, but not in the lifestyle arm, VAT percent decrease throughout the intervention period was significantly related to improvement in beta-cell function (ISSI-2, Rho=-0.60, $p=0.023$) and increase in adiponectin levels (Rho=-0.589, $p=0.021$). SAT and leptin percent changes were instead associated with improvement in insulin sensitivity, as reflected by Matsuda index (Rho=-0.722, $p=0.002$, and Rho=-0.708, $p=0.003$).**Conclusion:** This pilot study may help establishing a cause-and-effect relationship between VAT inflammation, adipokine secretion, beta cell performance and development or progression of T2DM, unraveling as well potential mechanisms by which liraglutide may favorably impact T2DM pathogenesis.

The efficacy and safety of once-weekly, subcutaneous dulaglutide monotherapy compared to glimepiride in Asian patients with type 2 diabetes mellitus

W. Wang¹, C.-N. Huang², M.-C. Young³, P. Li⁴, L. Gu⁴, J. Yang⁴,
¹Ruijin Hospital, Shanghai Jiao Tong University, Shanghai, China, ²Chung Shan Medical University Hospital, Taichung City, Taiwan, ³Seoul National University Hospital, Republic of Korea, ⁴Lilly Suzhou Pharmaceutical Co., Ltd, Shanghai, China.

Background and aims: This Phase 3, randomized, double-blind, parallel-arm 26-week (wk) monotherapy study compared the efficacy and safety of once weekly dulaglutide (DU), a long-acting glucagon-like peptide-1 (GLP-1) receptor agonist, with glimepiride in Asian patients with type 2 diabetes mellitus who had discontinued oral antihyperglycemic medication (OAM) monotherapy or were OAM-naïve.

Materials and methods: A total of 807 patients (all Asian; mean baseline age, 52.8 years; mean duration of T2DM, 3.7 years; HbA1c, 7.94%; weight, 70.0 kg) were randomly assigned to once-weekly DU 1.5 mg, DU 0.75 mg or glimepiride (1-3 mg/day) in a 1:1:1 ratio. The primary and key secondary objectives were to test the noninferiority (margin 0.4%) and superiority of DU 1.5 and 0.75 mg versus glimepiride using a prespecified gatekeeping method, as measured by A1C change from baseline at Week 26.

Results: Both DU 1.5 mg and DU 0.75 mg demonstrated superiority to glimepiride (Least-squares [LS] mean difference [%][95% CI]: -0.60% [-0.78%, -0.41%] and -0.31% [-0.49%, -0.13%], respectively). More patients achieved HbA1c target <7.0% in both DU 1.5 mg and DU 0.75 mg than glimepiride. LS mean decrease from baseline in fasting blood glucose was significantly greater for both DU 1.5 mg and DU 0.75 mg compared with glimepiride. Total hypoglycemia incidence was significantly lower in both DU 1.5 mg and DU 0.75 mg than glimepiride. No severe hypoglycemic events were reported. Weight decreased with DU and increased with glimepiride. The most common treatment-emergent gastrointestinal adverse events for DU 1.5 mg, DU 0.75 mg were diarrhea (14.9%, 6.3%), nausea (8.6%, 4.1%), abdominal distension (6.0%, 2.6%) and vomiting (6.3%, 1.1%).

Conclusion: Superiority in change from baseline HbA1c of both dulaglutide 1.5 mg versus glimepiride and dulaglutide 0.75 mg versus glimepiride were statistically demonstrated in this study. These results, combined with the overall efficacy, safety, and tolerability data, support the use of dulaglutide as one of monotherapy options in Asian patients with T2DM.

Efficacy Measures (26wk, mITT)	Dula 1.5 mg (N=263)	Dula 0.75 mg (N=259)	Glimepiride (N=268)

Relationship between weight change and glycaemic control with once weekly dulaglutide treatment in patients with type 2 diabetes

L. Fernandez Lando¹, G. Umpierrez², K.M. Pantalone³, A. Kwan¹, A.G. Zimmermann⁴,
¹Lilly USA, LLC., Indianapolis, ²Division of Endocrinology, Emory University, Atlanta, ³Department of Endocrinology, Cleveland Clinic, Cleveland, ⁴Eli Lilly and Company, Indianapolis, USA.

Background and aims: Dulaglutide, a once weekly GLP-1 receptor agonist, was studied in the AWARD clinical trial program in adult patients with type 2 diabetes. In 6 head-to-head phase 3 trials, dulaglutide demonstrated significant HbA1c reduction and weight control effects. To assess the relationship between weight change and glycaemic control in dulaglutide-treated patients, HbA1c and body weight data from the 6 trials were analysed.

Materials and methods: Due to differences in design, background therapy, and baseline characteristics, analyses on HbA1c and body weight data at 26 weeks were conducted by trial rather than by pooling.

Results: Across the studies 87%-97% and 83%-95% of patients treated with dulaglutide 1.5 mg and 0.75 mg, respectively, demonstrated HbA1c reduction. Among the patients with HbA1c reduction, the majority of patients receiving dulaglutide 1.5 mg experienced weight loss (55%-83%) while 41%-79% in the dulaglutide 0.75 mg arm lost weight. Minimal correlation was observed between the changes in HbA1c and weight (IRI <0.3, all). Baseline characteristics of gender, age, duration of diabetes, HbA1c, body weight and BMI did not correlate with different weight responses.

Conclusion: In summary, dulaglutide demonstrated a dose-dependent effect on both weight loss and HbA1c reduction. Dulaglutide is an effective treatment option with both HbA1c reduction and weight loss observed across the type 2 diabetes treatment spectrum.

780

Baseline factors associated with the glycaemic response to treatment with once weekly dulaglutide in patients with type 2 diabetes

C. Wysham¹, B. Guerci², D. D'Alessio³, N. Jia⁴, F.T. Botros⁴,
¹Rockwood Center for Diabetes and Endocrinology, Spokane, USA, ²University of Lorraine and Brabois Hospital & Center of Clinical Investigation, Nancy, France, ³Duke University Medical Center, Durham, ⁴Eli Lilly and Company, Indianapolis, USA.

Background and aims: Dulaglutide (DU) is a once weekly glucagon-like peptide-1 (GLP-1) receptor agonist that has been recently approved

in the US and EU for the treatment of type 2 diabetes. Glycaemic efficacy of DU has been demonstrated in six Phase 3 studies. The objective of this analysis is to determine major baseline factors that are associated with the reduction in glycosylated haemoglobin A_{1c} (HbA_{1c}) in response to treatment with DU.

Materials and methods: DU patient (pt) covariates from across the 6 DU Phase 3 clinical trials were analysed using gradient boosting analysis to assess their relative contribution to the change in HbA_{1c} at 26 weeks of treatment. Baseline variables which were associated with the greatest amount of influence on HbA_{1c} change were further evaluated in univariate and multivariable modeling to assess the magnitude and direction of impact. Analysed baseline factors included age, race, ethnicity, gender, duration of diabetes, serum glucose measures, fasting serum C-peptide and insulin (FSI), weight, BMI, cardiovascular disease history, estimated glomerular filtration rate (eGFR), and albuminuria.

Results: This analysis included 2806 DU treated pt with mean age 56.3±9.8 years, duration of diabetes 7.8±6.0 years, baseline HbA_{1c} 8.0±1.0% (64±11 mmol/mol), BMI 32.4±5.2 kg/m², and eGFR 89.5±16.9 mL/min/1.73 m². Based on gradient boosting, the top 5 baseline factors associated with reduction in HbA_{1c} (and their relative influence) are baseline HbA_{1c} (48.8%), age (9.1%), fasting serum glucose (FSG) (8.2%), FSI (6.7%), and eGFR (5.4%). The role of baseline glycaemic factors (HbA_{1c}, FSG, FSI) was evaluated. Univariate regression demonstrated that higher baseline HbA_{1c} and FSG values and lower FSI values were associated with greater reduction in HbA_{1c} (coefficient estimates of HbA_{1c} change: -0.598%, -0.101%, and 0.002%, respectively, p<0.0001 for all). Multivariable linear regression showed similar results for baseline HbA_{1c} (-0.594±0.027%) and FSI (-0.197±0.045% for FSI ≤55 pmol/L), but greater baseline FSG was associated with smaller decrease in HbA_{1c} when adjusted for the other 4 factors (0.047±0.010%, p<0.0001), indicating that pts with smaller baseline FSG, while having similar baseline HbA_{1c} and other variables, are likely to have a greater decrease in HbA_{1c} in response to dulaglutide. Subgroup analysis by baseline HbA_{1c} (9 quantiles) confirmed that higher FSG is associated with smaller decreases in HbA_{1c} for pts within the same category of baseline HbA_{1c}. Multivariable linear regression also showed that greater reduction in HbA_{1c} was observed in associated pts with baseline eGFR ≤100 mL/min/1.73 m² (coefficient estimate of HbA_{1c} change: -0.143±0.047%, p=0.002) and age ≤65 years (coefficient estimates of HbA_{1c} change: -0.175±0.058%, p=0.003).

Conclusion: These data indicate that higher baseline HbA_{1c}, reflecting poor glycaemic status, is the major factor associated with greater reduction in HbA_{1c} in response to treatment with DU. Other baseline factors associated with greater decrease in HbA_{1c} in response to dulaglutide, albeit to a limited extent, include baseline FSG, FSI, age, and eGFR.

Improvement in HbA_{1c} in patients with type 2 diabetes mellitus treated with once weekly dulaglutide across baseline body mass index (BMI) subgroups at 26 or 52 weeks

L.A. Vázquez¹, E. Jódar², C. Trescoli³, C. Nicolay⁴, J. Reviriego¹, R. Gentilella⁵;

¹Eli Lilly, Alcobendas, ²Hospital Universitario Quirón, Madrid, ³Hospital Universitario de la Ribera, Alzira, Valenzia, Spain, ⁴Lilly Deutschland GmbH, Bad Homburg, Germany, ⁵Lilly Diabetes, Sesto Fiorentino, Italy.

Background and aims: This post-hoc analysis investigated the efficacy of dulaglutide and active comparators across baseline BMI categories (BMI <30, ≥30-<35 or ≥35 kg/m²) in patients with T2DM using data from the phase 3 randomised trials AWARD-1 to -6.

Materials and methods: Patients with T2DM received dulaglutide [1.5 mg, n=1719 (AWARD-1 to -6); 0.75 mg, n=1417 (AWARD-1 to -5)], or exenatide (n=276), insulin glargine (n=558), metformin (n=268),

sitagliptin (n=315) or liraglutide (n=300), in addition to other concomitant background treatments (Table). Analysis of covariance models (AWARD-1 to -5) or mixed-effects model for repeat measures (AWARD-6), including treatment-by-BMI subgroup interaction terms, were applied by study to estimate the effect of each treatment on HbA_{1c} at 52 weeks (AWARD-1 to -5) or 26 weeks (AWARD-6) and to compare dulaglutide and corresponding active comparators for patients with baseline BMI <30, ≥30-<35 or ≥35 kg/m² (intention-to-treat population).

Results: Baseline mean BMI in each study ranged from 31.2–33.6 kg/m². HbA_{1c} reductions from baseline according to BMI subgroup are shown for each study (Table). In all studies, dulaglutide 1.5 mg, dulaglutide 0.75 mg and all active comparators achieved statistically significant HbA_{1c} reductions from baseline overall and in all BMI subgroups. No statistically significant treatment-by-BMI subgroup interactions were found for reductions in HbA_{1c} (Table).

Conclusion: Dulaglutide (1.5 mg or 0.75 mg) is an effective treatment for patients with T2DM, regardless of baseline BMI. There was no evidence of any treatment-by-BMI subgroup interaction for HbA_{1c} change, suggesting that baseline BMI had no effect on the relative antihyperglycaemic efficacy associated with dulaglutide versus comparator antidiabetes agents.

Achieving the composite endpoint of HbA_{1c} <7.0% (53 mmol/mol), no hypoglycaemia, and no weight gain in the once weekly dulaglutide AWARD programme

J.L. Fahrbach¹, K.M. Dungan², I. Raz³, Z. Skrivanek¹, W. Sealls¹;

¹Eli Lilly and company, Indianapolis, ²The Ohio State University, Columbus, USA, ³Hadassah Hebrew University Hospital, Jerusalem, Israel.

Background and aims: The 6 completed Phase 3 trials from the dulaglutide AWARD program, a once weekly glucagon-like peptide-1 receptor agonist, demonstrated significant improvements in HbA_{1c} and weight, with a low risk for hypoglycaemia. Post-hoc analyses from these data compare dulaglutide 1.5 mg and 0.75 mg with active comparator therapies and placebo on the composite endpoint of HbA_{1c} <7% (53 mmol/mol), and no weight gain or hypoglycaemia.

Materials and methods: A logistic regression analysis was performed on the intent-to-treat population, last observation carried forward patient data on the composite endpoint of glycated haemoglobin HbA_{1c} <7.0% (53 mmol/mol), no weight gain (≤0 kg) and no hypoglycaemia (glucose <3.0 mmol/L or any report of severe hypoglycaemia) after 26 weeks of treatment.

Results: At 26 weeks, within each study, 37 to 58% of patients on DU 1.5 mg, 27 to 49% of patients on DU 0.75 mg, and 9 to 61% on AC

achieved the composite endpoint. Significantly more patients reached the composite endpoint with DU 1.5 mg than with metformin, sitagliptin, exenatide BID, and insulin glargine (odds ratio [95% CI]: 1.5 [1.0, 2.2; $p < .05$], 4.5 [3.0, 6.6; $p < .001$], 2.6 [1.8, 3.7; $p < .001$], 7.4 [4.4, 12.6; $p < .001$], respectively); with no difference between dulaglutide 1.5 mg and liraglutide 1.8 mg (Figure). In addition, significantly more patients reached the composite endpoint with DU 0.75 mg compared to sitagliptin and insulin glargine (3.3 [2.2, 4.8; $p < .001$], 4.5 [2.7, 7.8; $p < .001$], respectively).

Conclusion: Dulaglutide is an effective treatment option, resulting in a similar or greater proportion of patients who reached the HbA1c target of $<7.0\%$ (53 mmol/mol), without weight gain or hypoglycaemia compared to active comparators.

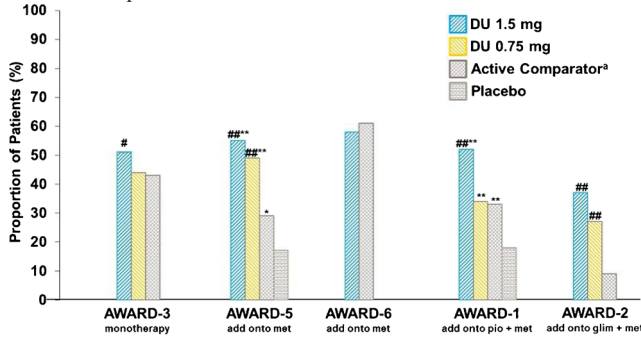

Figure. Proportion of patients achieving the composite outcome of A1C $<7.0\%$, no hypoglycemia, and no weight gain at Week 26. * $p < .05$ and ** $p < .001$ vs active comparator; $^{\#}p < .05$ and $^{\#\#}p < .001$ vs PL. *AWARD-3, -5, -6, -1, and -2 active comparators: metformin (1500–2000 mg), sitagliptin 100 mg, liraglutide 1.8 mg, exenatide 10 µg twice daily, titrated insulin glargine, respectively.

Effects of once weekly dulaglutide on kidney function in clinical trials
K.R. Tuttle¹, T.D. McKinney², G. Anglin³, K.D. Harper², F.T. Botros²;
¹Providence Health Care, University of Washington, Spokane, ²Eli Lilly and Company, Indianapolis, USA, ³Eli Lilly Canada Inc, Toronto, Canada.

Background and aims: Dulaglutide is a once weekly glucagon-like peptide 1 receptor agonist approved for the treatment of type 2 diabetes (T2D). Postmarketing cases of acute decreases in kidney function related to other incretin-based therapies have been reported. However, experimental models of diabetes have not suggested harm to the kidney from these therapies. The aim of this study was to determine effects of dulaglutide (1.5 mg and 0.75 mg) on kidney function and adverse events (AEs) in post hoc analyses of clinical trials with placebo (PL) and active comparators.

Materials and methods: Serum creatinine (sCr), estimated glomerular filtration rate (eGFR), and urine albumin-to-creatinine ratio (UACR) were evaluated using integrated data from 9 completed Phase 2 and 3 trials. Dulaglutide was compared to PL in 3 studies (treatment duration 16–26 weeks) and to a combined active comparator group (sitagliptin, exenatide [twice daily], insulin glargine, and metformin) in 5 studies (Treatment duration 52–104 weeks). Dulaglutide was also compared to insulin glargine alone in 2 studies (at 52 weeks).

Results: Treatment durations were comparable between dulaglutide and comparator arms for all studies included in this analysis. No significant differences in sCr or eGFR were observed at baseline or during treatment between dulaglutide and PL, the combined active comparator group, or insulin glargine alone. UACR values were slightly but significantly lower for dulaglutide than for PL, the combined active comparators, and insulin glargine alone during the treatment period. AE terms reflecting potential acute kidney injury were reported at rates of 3.4, 1.7, and 7.0 events per 1000 patient years of exposure for dulaglutide (n=12; N=4006), all active comparators (n=3; N=1541), and PL (n=2; N=703), respectively.

Conclusion: Treatment of T2D patients with dulaglutide in clinical trials did not appear to alter kidney function when compared to PL, a group of active comparators, or insulin glargine alone. Rates of reported AEs related to kidney disease were comparable for all groups.

Measures of kidney function and albuminuria during treatment with dulaglutide (DU) versus placebo (PL), combined active comparators^a (AC), or insulin glargine (IG) alone

Low incidence of anti-drug antibody in type 2 diabetes patients treated with once weekly dulaglutide

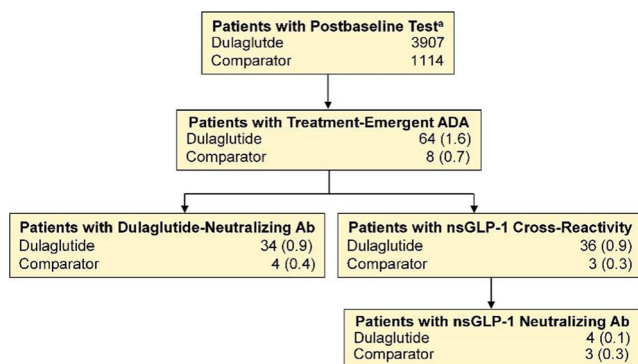

Z. Milicevic¹, G. Anglin², K. Harper³, R. Konrad³, Z. Skrivaneck³, W. Glaesner⁴, K. Mace³;
¹Eli Lilly and Company, Vienna, Austria, ²Eli Lilly Canada Inc., Toronto, Canada, ³Eli Lilly and Company, Indianapolis, ⁴Eli Lilly and Company, San Diego, USA.

Background and aims: Dulaglutide, a once weekly glucagon-like peptide-1 (GLP-1) IgG4-Fc fusion protein for type 2 diabetes treatment, was structurally modified to reduce immunogenic potential by eliminating T-cell epitopes based on the results of the EpiVax algorithm. Immunogenicity of dulaglutide was assessed in 9 clinical studies.

Materials and methods: Blood samples collected serially were assayed for dulaglutide anti-drug antibody (ADA) using validated ELISAs. Samples with treatment-emergent ADA were tested for dulaglutide - neutralizing antibody and native sequence GLP-1 (nsGLP-1) cross-reactivity, and then neutralization of nsGLP-1. Associations between ADA and hypersensitivity adverse events, injection site reactions, and HbA_{1c} changes were assessed.

Results: A total of 3907 dulaglutide and 1114 non-GLP-1 receptor agonist comparator patients were tested. The incidence of treatment-emergent ADA with dulaglutide was 1.6% vs 0.7% with non-GLP-1 receptor agonist comparator. Dulaglutide-neutralizing antibody, nsGLP-1 cross-reactivity, and nsGLP-1 neutralizing antibody were observed in 0.9%, 0.9%, and 0.1% of dulaglutide patients, respectively. There was no evidence of an effect of ADA on HbA_{1c} change after 26 or 52 weeks of treatment. Only 19 (0.5%) of dulaglutide patients had a hypersensitivity adverse event, none had treatment-emergent ADA. There were 20 (0.5%) dulaglutide-exposed patients with potentially immune-mediated injection site reactions; 2 of them (0.05% of 3907) had treatment-emergent ADA.

Conclusion: Incidence of ADA in patients exposed to dulaglutide was low. No association between dulaglutide ADA and hypersensitivity adverse events, injection site reactions, or HbA_{1c} changes was observed.

Data presented as n (%) unless otherwise noted
 Abbreviations: Ab = antibody; ADA = anti-drug antibody; n = number of patients in specified category; nsGLP-1 = native sequence glucagon-like peptide-1

Albiglutide provides effective glycaemic lowering across diabetes duration subgroups

P. Home¹, D. Miller², M.C. Carr²;

¹Newcastle University, Newcastle upon Tyne, UK, ²GlaxoSmithKline, King of Prussia, USA.

Background and aims: Incretin therapies work in part by stimulating insulin secretion, so it is important to characterize their efficacy in people with longer-standing diabetes and less residual β -cell function. Here we test the hypothesis that albiglutide will have a similar efficacy and safety profile independent of diabetes duration.

Materials and methods: Pooled phase-3 data were from 1391 participants in placebo comparator studies, randomized 923 to albiglutide and 468 to placebo, \pm oral agents. Efficacy analyses use the primary outcome variable (HbA1c) and other measures pooling data 6 months from randomization

Results: Baseline characteristics were generally well balanced vs placebo and typical of people with T2DM (age 54 yr, HbA1c 8.1% (65.02 mmol/mol), BMI 33.1 kg/m²). Change in HbA1c for albiglutide vs placebo varied from a difference of -0.93 (-1.08,-0.79) %-units (-10.17 [-11.81, -8.64] mmol/mol) in the <5-yr group to -0.70 (-0.90, -0.50) %-units (-7.65 [-9.84, -5.47] mmol/mol) in the \geq 10-yr group (Table). The fasting plasma glucose difference was -1.65 (-2.03, -1.27) mmol/L at short duration, -1.30 (-1.75, -0.86) mmol/L in the middle group, and -1.44 (-1.97, -0.92) mmol/L at \geq 10-yr duration. Adverse events did not differ between albiglutide groups except for injection site reactions (fewer at longer duration). Serious adverse events were similar by duration of diabetes for the albiglutide group.

Conclusion: Albiglutide had good efficacy independent of diabetes duration with no deterioration of adverse event profile.

PS 069 GLP-1 receptor agonists: approaching approvability

786

Efficacy and tolerability of ITCA 650 (continuous subcutaneous exenatide) for 39 weeks in patients with poorly controlled type 2 diabetes mellitus and high baseline HbA_{1c} (>10%)

R.R. Henry¹, J. Rosenstock², D. Denham³, P. Prabhakar⁴, L. Kjems⁴, M. Baron⁴;

¹University of California San Diego School of Medicine, Veterans Affairs San Diego Healthcare System, ²Dallas Diabetes and Endocrine Center at Medical City, ³Clinical Trials of Texas, San Antonio, ⁴Intarcia Therapeutics, Inc., Boston, USA.

Background and aims: ITCA 650 is an injection-free glucagon-like peptide-1 (GLP-1) receptor agonist that provides continuous subcutaneous (SC) exenatide for up to 12 months from a single sub-dermal placement. Open-label treatment with ITCA 650 was offered to type 2 diabetes (T2DM) patients ineligible for a double-blind, placebo-controlled trial because of HbA1c >10%.

Materials and methods: Patients were 18-80 years with HbA1c >10% to \leq 12%, BMI 25-45 kg/m², on stable (\geq 3 months) diet and exercise or oral antidiabetics (OADs). ITCA 650 was initiated at 20 mcg/d for 13 weeks, then 60 mcg/d for 26 weeks. Baseline (BL) OADs were continued; sulfonylureas (SUs) were adjusted if medically necessary. Endpoints were change from BL for HbA1c and body weight (BW) and % achieving HbA1c <7% at 39 weeks.

Results: Sixty patients were enrolled. Six (10.0%) patients discontinued for adverse events (AEs). At BL, HbA1c was 10.8%, age 51.9 years, BMI 32.0 kg/m², diabetes duration 9 years, OAD use 69%. At Week 39, mean reduction of HbA1c from BL to Week 39 (last observation carried forward) was -2.8% (p<0.001), and 22% achieved HbA1c <7%. Significant A1C reductions were seen by Week 6 (Figure). The most common AEs were nausea, vomiting, diarrhea, headache, and urinary tract infection. Nausea, vomiting, and diarrhea rapidly decreased after Week 1. There were no reports of pancreatitis or major hypoglycemic events; 6.7% reported minor hypoglycemia, and all serious AEs were considered unrelated to ITCA 650.

Conclusion: ITCA 650 for 39 weeks produced significant reductions in HbA1c, improved BW and goal attainment and was well tolerated in these poorly controlled T2DM patients with high HbA1c.

787

Absorption, metabolism and excretion of [³H]-semaglutide following a single, subcutaneous dose in healthy male subjects

A.F. Roffel¹, L. Jensen², J.J. van Lier¹, E. Rowe³, J. Derving Karsbøl², M.L. Pedersen²;

¹PRA Health Sciences Early Development Services, Zuidlaren, Netherlands, ²Novo Nordisk, Søborg, Denmark, ³Novo Nordisk Inc., Princeton, USA.

Background and aims: Semaglutide is a human GLP-1 analogue in clinical development for once-weekly treatment of T2D. Semaglutide has minor modifications versus native human GLP-1 that aim to reduce renal clearance and protect against dipeptidyl peptidase-4 degradation, resulting in a prolonged half-life. This open-label study investigated the absorption, metabolism and excretion of radiolabelled semaglutide in humans.

Materials and methods: Healthy male subjects (n=7; aged 48-64 years; body mass index 21.7-29.7 kg/m²) received a single subcutaneous dose of

radioactively labelled semaglutide (0.5 mg/450 μ Ci/16.5 MBq [3 H]-semaglutide). The [3 H] label, used previously in non-clinical semaglutide studies, was attached to the semaglutide fatty acid side chain. Radioactivity was determined in the blood, plasma, urine, faeces and expired air up to 56 days after administration. Metabolites were quantified in plasma, urine and faeces using HPLC followed by radio detection. In addition, routes and rates of excretion, blood-to-plasma ratio, pharmacokinetics (PK) of [3 H]-semaglutide-related material and standard PK were assessed.

Results: Total recovery of [3 H]-semaglutide-related material was 75.1% (coefficient of variation in percentage [CV%] 5.2) of the administered dose: urine 53.0% (8.2); faeces 18.6% (19.9); and expired air 3.2% (9.0) (Figure). Intact [3 H]-semaglutide was the major component in plasma at all time points analysed, accounting for 83% of the total radioactivity, based on the area under the concentration-time curve (AUC). A total of 6 metabolites were detected in plasma, each accounting for between 0.4% and 7.7% of the total amount of radioactivity. Intact semaglutide accounted for ~3% of the administered dose in urine. In addition, 21 metabolites were detected in urine; the 2 most abundant each comprised ~14% of the administered dose (all other metabolites each \leq 1.8%). Intact semaglutide was not detected in faeces. In total, 7 metabolites were detected in faeces, each \leq 1.5% of the administered dose. The blood-to-plasma ratio of radioactivity showed that [3 H]-semaglutide-related material was primarily distributed in the plasma compartment, and was relatively constant over time. The PK properties of [3 H]-semaglutide in this study were comparable with results from previous trials with unlabelled semaglutide. No new or unexpected safety or tolerability issues were identified.

Conclusion: This study shows that, following treatment with [3 H]-semaglutide, intact semaglutide is the main component in plasma. Semaglutide is extensively metabolised prior to elimination, and semaglutide-related material is primarily excreted in the urine. Semaglutide has limited renal excretion in its intact form. This supports that semaglutide may be used without dose adjustment in subjects with renal impairment.

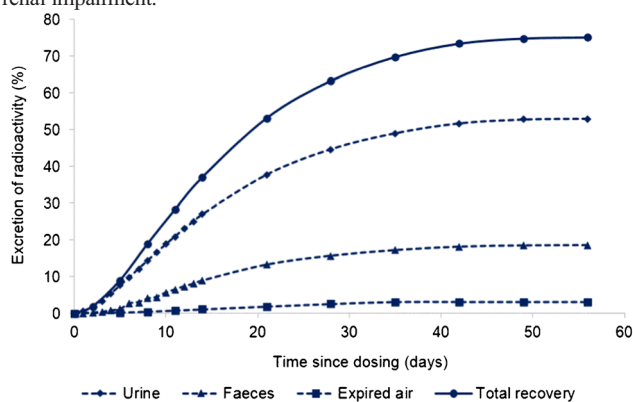

Figure. Cumulative excretion of radioactivity in urine, faeces and expired air (mean for all subjects; $n=7$) after a single, subcutaneous dose of 0.5 mg/450 μ Ci/16.5 MBq [3 H]-semaglutide. Subjects who met the end criterion prior to Day 56 had their missing cumulative values imputed with the last available cumulative value.

Superagonistic mechanism of increased glucodynamic and weight loss effects of ^{LAPSO}CA-exendin-4 (efpeglenatide)

I. Choi¹, S. Park¹, M. Trautmann², J. Kim¹, J. Kim¹, Y. Lee¹, J. Kang¹, M. Hompesch², S. Kwon¹;

¹Hanmi Pharm. Co., Ltd., Hwasung, Republic of Korea, ²Profil Institute for Clinical Research, Inc., Chula Vista, USA.

Background and aims: The novel long-acting GLP-1 receptor agonist, efpeglenatide, was developed for the treatment of type 2 diabetes and is currently in phase II clinical trials as a weekly or monthly GLP-1 receptor agonist (GLP-1RA). It consists of an exendin-4 analog (CA-Exendin-4) conjugated via non-peptidyl linker to a non-glycosylated human Fc fragment. Previously, CA-Exendin-4 showed greater blood glucose lowering efficacy in *db/db* mice compared to native exendin-4 and it was hypothesized that such a superagonistic action of CA-Exendin-4 is due to its fast dissociation from human GLP-1 receptor. In this study, we investigated further the mechanism using CA-Exendin-4 and efpeglenatide.

Materials and methods: Affinity to GLP-1 receptor (GLP-1R) was measured by Surface Plasmon resonance (SPR) analysis. Internalization of GLP-1R was assessed in GLP-1R/U2OS cells using the PathHunter™ eXpress Kit (DiscoverRx Corp. Ltd., UK). Surface GLP-1R level was determined by [125 I]GLP-1 binding after acid-wash of the cells. *In vitro* activity after chronic treatment of GLP-1RAs was determined by measuring intracellular cyclic AMP in GLP-1R/CHO and insulin release in RINm5F cells. The cells were pre-treated with 10 nM of GLP-1RAs for 4 to 24 hours and followed by cAMP or insulinotropic induction by re-treatment with 0-5,000 nM of GLP-1RAs. In order to compare *in vivo* efficacy between efpeglenatide and other GLP-1RAs, change of blood glucose and HbA1c in *db/db* mice by subcutaneous injection was monitored during 4 weeks and body weight loss was compared in DIO rats for 4 weeks.

Results: CA-Exendin-4 elicited less internalization of GLP-1 receptors compared to exendin-4 in human GLP-1R overexpressed U2OS, and this was also confirmed in hGLP-1R/CHO cells by measuring the residual surface receptors. Further, GLP-1R internalization was compared between efpeglenatide and other long-acting GLP-1RAs. Efpeglenatide led to less GLP-1R internalization (e.g. 50% or less) than liraglutide and dulaglutide in both hGLP-1R/U2OS and hGLP-1R/CHO cells. Efpeglenatide also led to less receptor desensitization under chronic treatment conditions in cAMP accumulation and insulinotropic assays. Finally, in *db/db* mice, efpeglenatide showed a greater HbA1c decrease (-3.8% in 4 weeks) than liraglutide and dulaglutide (-2.6% and -2.8%, respectively) at doses to corresponding to human use. In addition, efpeglenatide revealed greater efficacy in body weight loss of -20.9% in DIO mice for 4 weeks, compared with -18.6% by liraglutide and -7.1% by dulaglutide.

Conclusion: Following conjugation to Fc the fast receptor dissociation kinetics of CA-Exendin-4 were maintained in efpeglenatide (k_d $4.2 \times 10^{-3} \text{ s}^{-1}$ vs. $1.0 \times 10^{-3} \text{ s}^{-1}$ for efpeglenatide). We also demonstrated that efpeglenatide lead to significantly less GLP-1R internalization than liraglutide and dulaglutide in human GLP-1R transformed U2OS cells. This translated into more potent glucose lowering in *db/db* mice and greater body weight loss in DIO mice in comparison to liraglutide and dulaglutide. Taken together, CA-Exendin-4 even after conjugation to the human Fc-fragment seems to achieve more pronounced GLP-1R activation due to reduced receptor internalization and consequently leads to more potent effects. These findings may explain the observed efficacy of efpeglenatide in clinical trials relative to liraglutide.

789

CCK and GLP-1 receptor agonist co-administration ameliorates diabetes in mice

S. Ali¹, S. Hawkins², S. Will³, M. Feigh⁴, D. Hornigold³, A. Konkar³, J.L. Trevasakis³;

¹Cardiovascular and metabolic disease, Medimmune, ²Laboratory Animal Resources, Medimmune, ³Cardiovascular Metabolic Disease, Medimmune, Gaithersburg, USA, ⁴Gubra, Hørsholm, Denmark.

Background and aims: GLP-1 and CCK are hormones secreted from gut endocrine cells in response to meals that regulate metabolism. Co-administration of CCK and GLP-1 analogs induce synergistic weight loss in diet-induced obese rats.

Materials and methods: We investigated the impact of selective CCK1R (A1) or CCK2R (A2) agonists alone or in combination with a GLP-1R agonist (AC3174) on acute inhibition of food intake in lean mice, insulin secretion from a rat beta cell line (Ins-1 cells), and on body weight and glycemia in obese and diabetic *db/db* mice.

Results: Combined AC3174 (0.3 nmol/kg, sc) and A1 (300 nmol/kg, ip) administration had greater impact on inhibiting food intake vs. monotherapy, whereas addition of A2 to AC3174 had no further impact on food intake. In Ins-1 cells, glucose-dependent insulin secretion was enhanced by incubation with AC3174, and to a lesser extent A1. Incubating Ins-1 cells with AC3174 and A1, but not A2, resulted in additive effects on insulin secretion. These findings suggest synergy between CCK and GLP-1 requires activation of CCK1R and not CCK2R. Diabetic *db/db* mice administered AC3174 (0.3 nmol/kg, sc, qd) and A1 (300 nmol/kg, ip, qd) for 14 days exhibited a robust reduction in body weight (-25.8%) compared to vehicle (+8%), AC3174 alone (-4.9%) or A1 alone (-13.4%). Weight loss was associated with reduced food intake, and combination treatment was associated with lower glucose and a trend towards lower HbA_{1c} levels vs. monotherapy- or vehicle-treated groups. AC3174 did not affect liver weight, however a significant reduction in liver weight was observed with A1 alone and in combination with AC3174, and was associated with reduced plasma alanine aminotransferase and triglyceride levels.

Conclusion: In summary, our results demonstrate that co-administration of CCK1R and GLP-1R agonists elicits synergistic weight loss and improvement in glucose control, potentially via improved liver function and/or co-operative actions on pancreatic function.

790

Potent weight loss mechanism and improvement of NASH by the long-acting GLP-1/glucagon receptor dual agonist HM12525A

S. Jung¹, J. Lee¹, J. Kim¹, Y. Lee¹, Y. Kim¹, J. Kang¹, M. Trautmann², M. Hompesch², S. Kwon¹;

¹Hanmi Pharmaceutical, Seoul, Republic of Korea, ²Profil institute, Chula Vista, USA.

Background and aims: Dual agonists activating the GLP-1 receptor (GLP-1R) and the glucagon receptor (GCG-R) may represent a new therapeutic approach for obesity with the potential for enhanced weight loss beyond those of GLP-1R agonists. Oxyntomodulin, a human gut hormone with agonism to the GLP-1R and the GCG-R, causes a significant reduction in weight by regulating both, appetite and energy expenditure, however its clinical application is limited due to a short half-life. HM12525A is a long-acting GLP-1/glucagon receptor dual agonist for once-weekly administration. It consists of a GLP-1/glucagon receptor dual agonist conjugated via non-peptidyl linker to a non-glycosylated human Fc fragment. The aim of this development was to achieve increased body weight loss (BWL) compared to GLP-1R agonists while extending the half-life. This study investigated the mechanism responsible for increased BWL and the effect on nonalcoholic steatohepatitis (NASH) by HM12525A by assessing energy expenditure (EE) and lipid metabolism.

Materials and methods: To evaluate the effect on FGF21 related EE increase, firstly, the secretion of FGF21 was investigated in primary hepatocytes and DIO (diet induced obesity) rats after HM12525A treatment. Next, the expression of UCP-1, a well known mediator of EE, was investigated in differentiated 3 T3-L1 adipocytes by co-treatment with FGF21. In vivo energy intake and expenditure as well as locomotor activity were assessed by using a combined indirect calorimetry system in DIO mice. To evaluate the effect on lipid metabolism in the liver, liver histology and CPT-1 expression, a marker of β -oxidation, were investigated in DIO rats following chronic administration of HM12525A. To evaluate the effect on NASH, hepatic levels of inflammation, fibrosis marker, and histological scoring were investigated in ALIOS- (American lifestyle induced obesity syndrome) and methionine-choline deficient (MCD) diet-mice as NASH models.

Results: The secretion of FGF21 was significantly increased in primary hepatocytes (2-fold vs. vehicle) as well as in DIO rats after HM12525A treatment. HM12525A treatment induced the expression of UCP-1 (4.5-fold vs. vehicle) which was further enhanced by co-treatment with FGF21 (13.4-fold vs. vehicle). Consistent with these in vitro results, HM12525A increased EE without affecting locomotor activity in DIO mice. These results suggest that the HM12525A-FGF21 axis plays an essential role in BWL by enhancing EE. In DIO rats, the chronically administered HM12525A ameliorated fatty livers together with the increase of CPT-1 expression (1.8-fold vs. vehicle). In ALIOS mice, HM12525A resulted in greater effects on body weight and hepatic TG reduction compared to liraglutide. Hepatic levels of inflammation, fibrosis marker, and histological scoring for NASH were decreased consistently after HM12525A administration in MCD mice.

Conclusion: Taken together, our results demonstrate that the novel GLP-1/glucagon receptor dual agonist HM12525A may have clinical potential for the treatment of obesity and obesity-related liver disease.

791

The ultra-long acting ^{LAPS}GLP/GCG dual agonist, HM12525A, demonstrated safety and prolonged pharmacokinetics in healthy volunteers: a phase 1 first-in-human study

J. Kang¹, J.-H. Kim¹, J. Yi¹, O. Han¹, Y. Kim¹, E. Baek¹, S. Jung¹, S. Kwon¹, M.E. Trautmann², M. Hompesch²;

¹Hanmi Pharmaceuticals Co., Ltd, Seoul, Republic of Korea, ²Profil Institute for Clinical Research, Inc., Chula Vista, USA.

Background and aims: Glucagon-like peptide-1 (GLP-1) /glucagon (GCG) dual agonists have potential to treat obesity and diabetes by activating both GLP-1 and GCG receptors. Once-weekly ^{LAPS}GLP/GCG dual agonist, HM12525A, is site-specifically conjugated by LAPSCOVERY technology for sustained duration. Combining the synergistic effects with this long-acting platform, HM12525A may improve patient compliance and thereby treatment outcomes further. This First-in-Human, Phase I, randomized, double-blinded, placebo-controlled single ascending dose study evaluated the safety, tolerability, PK and PD of HM12525A in healthy volunteers.

Materials and methods: Forty subjects (age: 48.3±10.4 years; male: 70%; BMI: 29.7±3.3 kg/m²) were randomly assigned to 5 cohorts (0.25, 0.5, 1.0, 2.0, and 4.0 nmol/kg), and received a single subcutaneous injection of either HM12525A or placebo (ratio, 3:1). The total duration of the study was 56 days, including follow up.

Results: HM12525A demonstrated prolonged PK profiles with tolerance. The observed C_{max} in each cohort was ranged from 0.759 to 18.5 nmol/L at 113.1±55.3 hr post-dose. AUC_{0-last} (120 to 6560 hr·nmol/L) and T_{1/2} (112.5 to 276.2 hr) was also observed. Among the 5 cohorts, the maximum tolerated single dose was determined at a dose level of 2.0 nmol/kg. Overall, none of the subjects exhibited any clinically significant alterations in vital signs, laboratory values, and 24 hr ambulatory ECG. During 24 hr ambulatory blood pressure assessments, no significant change

in heart rate (HR) was observed up to 1.0 nmol/kg dose. At 2.0 and 4.0 nmol/kg doses, mean HR was elevated by 5.77 ± 2.30 and 8.06 ± 2.56 (p -value: 0.017 and 0.004) compared to the placebo, while mean systolic and diastolic BPs had no significant changes. Anti-drug antibodies were detected in 7 subjects; 3 subjects already had ADA at baseline, while the other 4 were newly detected during the study. None of these 7 subjects had neutralizing antibodies. The most frequent treatment emergent adverse events (TEAEs) were gastrointestinal disorders, such as nausea and vomiting. No serious TEAEs were occurred.

Conclusion: In summation, this single ascending dose study demonstrates that HM12525A was well tolerated with prolonged PK profile, which may confirm the potential for once-weekly injections. Further investigation in T2DM patients is expected to explore further synergetic potential of this ^{LAPS}GLP/GCG dual agonist to provide beneficial and effective therapeutic regimens.

792

LAPS-Exendin-4 (HM11260C) enhances insulin secretion and beta cell responsiveness in subjects with type 2 diabetes

E. Watkins¹, J. Kang², M. Trautmann¹, L. Morrow¹, S. Choi², O. Han², M. Hompesch¹;

¹Profil Institute for Clinical Research, Inc, Chula Vista, USA, ²Hanmi Pharmaceutical Co., Ltd, Seoul, Republic of Korea.

Background and aims: LAPSExendin-4 (HM11260C) is a glucagon like peptide -1 (GLP-1) receptor agonist being developed for the treatment of type 2 diabetes mellitus (T2DM). In this phase 1B study the effects of different HM11260C regimens on insulin secretion rate (ISR), β -cell responsiveness, and gastric emptying (GE) compared to placebo and to liraglutide were investigated.

Materials and methods: Subjects with T2DM received 6 mg HM11260C weekly (cohort A; age: 52.8 years, HbA1c: 8.4, n=13), 16 mg HM11260C monthly (cohort B; age: 50.1 yr, HbA1c: 8.1, n=13), 1.8 mg liraglutide daily (cohort C; age: 54.9 yr, HbA1c: 8.02 n=13), or placebo (age: 54.1 yr, HbA1c: 8.6, n=8). Subjects in cohorts A and C were evaluated at baseline and steady state, and cohort B was evaluated at trough (day [d] 82) and peak (d89) drug concentration. Islet β -cell function was assessed during a graded IV glucose infusion (GGI); infusion steps: 2, 4, 6, 8, 12 mg/kg/min of 20% IV glucose for 30 min each. Insulin C-peptide levels, and plasma glucose response to each GGI step were measured. ISR were determined using a population based C-peptide de-convolution model. AUC(insulin) and AUC(C-peptide) as measures of ISR were determined for each treatment. β -cell responsiveness was assessed as the ratio of ISR/ blood glucose (BG) over the duration of the GGI, and the slope of the ISR/BG was compared between the treatments. The rate of GE was determined for 1 g of liquid acetaminophen following a mixed meal and a mixed meal tolerance test (MMTT) was performed. For GE, non-inferiority to liraglutide was tested using a margin of 0.8 for the least squares (LS) mean ratio.

Results: Insulin secretion for all active treatments was increased compared to placebo and for HM11260C 6 mg and 16 mg was greater than for liraglutide (point estimates LS mean ratio: 1.765 mU/L, 90% CI: 1.331, 2.342 mU/L, one-sided $p=0.0008$, and LS mean ratio: 1.440 mU/L, 90% CI: 1.080, 1.920 mU/L, one-sided $p=0.0196$). Comparisons of the relationship between ISR and plasma glucose using mixed effects modelling showed an improvement in beta cell responsiveness relative to placebo/baseline which was not different among treatments. In the monthly treatment group, there was a diminution of effect at PK trough (d82). For postprandial glucose following the MMTT the LS means of the Cmax, AUC0-180, and AUC0-360 parameters were significantly (two-sided $p < 0.8$) to liraglutide in terms of acetaminophen Cmax, AUC0-120 min, and AUC0-180 min. While for Cohort B the effect on gastric emptying appeared to be similar

or even less when compared to liraglutide, formal non-inferiority could not be established for all parameters. GE was delayed in cohorts A and B compared to placebo.

Conclusion: HM11260C improved measures of β -cell function significantly compared to placebo, and for the weekly treatment regimen (cohort A), significantly compared to liraglutide. The results of this trial suggest that HM11260C is a safe and efficacious GLP-1 receptor agonist and that with regard to gastric emptying it inhibited less or similarly compared to other known GLP-1 receptor agonists.

793

Dose-response improvements in glycaemic control and body weight reduction with HM11260C, a once weekly GLP-1 receptor agonist with liraglutide as reference, in type 2 diabetes

K.-H. Yoon¹, J. Kang², S. Choi², O. Han², S. Kil², K. Gee², I. Choi², S. Kwon², M. Trautmann³, M. Hompesch³;

¹Department of Endocrinology and Metabolism, Seoul St. Mary's Hospital, The Catholic University of Korea, ²Hanmi Pharmaceutical Co., Ltd., Seoul, Republic of Korea, ³Profil Institute for Clinical Research, Inc., Chula Vista, USA.

Background and aims: HM11260C (HM) is a novel long acting GLP-1R agonist with a $T_{1/2}$ of ~158 hrs resulting in a flat PK profile. This 12-week, randomized, placebo (PBO) controlled, double-blind parallel group study with an open label active control liraglutide (LIRA) arm, was designed to investigate the dose ranging efficacy, safety, and tolerability of once weekly (QW) doses of HM in subjects with Type 2 Diabetes (T2DM).

Materials and methods: Stratified by metformin use 254 patients (mean age 55.3 yrs, BMI 31.76 kg/m², diabetes duration 73.08 months) were randomized to one of five HM QW doses, PBO or to LIRA QD up-titrated to 1.8 mg. All HM doses were not titrated.

Results: HM 0.3 to 4 mg produced dose-dependent reduction in HbA1c, fasting plasma glucose, and 7-point daily glucose (Table 1). In addition, HM 4 mg reached statistical significance in demonstration for non-inferiority to LIRA by mean % change of HbA1c from baseline (Difference = -0.23, 95.1% CI = [-0.56, 0.10]). Attainment of target HbA1c < 7% with HM was 89.7% (3 mg, $p < 0.0001$) and 89.3% (4 mg, $p < 0.0001$) vs 26.5% (PBO), and 73.3% (LIRA). The reduction in body weight with HM 3 mg (2.732 kg) and 4 mg (3.309 kg) was significantly greater than that with PBO (1.290 kg, $p < 0.049$, both). The most frequent AEs were gastrointestinal side effects of mild or moderate severity: nausea and vomit that subsided over time.

Conclusion: In summary, all doses of HM demonstrated clinically meaningful improvements in blood glucose and body weight, with higher doses being more effective. Safety profiles were comparable to LIRA. The current results warrant further studies to assess the long-term efficacy and safety of HM11260C in T2DM.

Table 1. Summary of efficacy and safety measures after 12 weeks (Final analysis)

	Placebo (n=37)	HM11260C 0.3 mg/wk (n=37)	HM11260C 1 mg/wk (n=37)	HM11260C 2 mg/wk (n=35)	HM11260C 3 mg/wk (n=36)	HM11260C 4 mg/wk (n=36)	Liraglutide 1.8 mg/day (n=36)

Once weekly glucagon-like peptide 1 receptor agonists for type 2 diabetes: systematic review and meta-analysis

A. Liakos¹, T. Karagiannis¹, E. Bekiari¹, E. Athanasiadou¹, P. Paschos¹, D. Vasilakou¹, M. Mainou¹, M. Rika¹, P. Boura², D.R. Matthews³, A. Tsapas^{1,3},

¹Clinical Research and Evidence-Based Medicine Unit, Second Medical Department, Aristotle University Thessaloniki, ²Second Medical Department, Aristotle University Thessaloniki, Greece, ³Harris Manchester College, University of Oxford, UK.

Background and aims: Albiglutide, dulaglutide and exenatide extended release are injectable glucagon-like peptide 1 receptor agonists (GLP-1 RAs) administered once weekly that have recently been approved for type 2 diabetes. We performed a systematic review and meta-analysis to assess their efficacy and safety.

Materials and methods: We searched for randomised controlled trials with at least 12 weeks duration of treatment in Medline, Embase, the Cochrane Library, ClinicalTrials.gov, and abstracts of major scientific meetings through December 2014. We synthesised results regarding change in HbA_{1c} and body weight, and incidence of hypoglycemia, injection site reactions, nausea, vomiting, serious adverse events (SAEs) and all cause mortality. We conducted separate analyses for studies against placebo or active comparator. We quantified heterogeneity with the I² statistic.

Results: We included 33 trials (16,003 participants) with a duration between 12 and 156 weeks in our systematic review. Participants' mean age ranged from 52 to 63 years and baseline HbA_{1c} from 7.1% to 8.7%. The majority of albiglutide and dulaglutide trials utilised a double blind design, whilst most exenatide extended release studies were open label. Compared with placebo, change in HbA_{1c} was -0.66% (six studies; 95% CI -1.14 to -0.19; I²=88%) with albiglutide, -1.18% (seven studies; 95% CI -1.34 to -1.02; I²=65%) with dulaglutide, and -1.48% (two studies; 95% CI -2.61 to -0.36; I²=80%) with exenatide extended release. Once weekly GLP-1 RAs outperformed sitagliptin, daily exenatide and basal insulin in terms of HbA_{1c} lowering, and were equally effective with liraglutide (Table). Based on placebo controlled trials, treatment with once weekly GLP-1 RAs did not result in significant body weight reduction (weighted mean difference -0.61 kg; 95% CI -1.31 to 0.09; I²=84%), although weight sparing benefits were evident relative to sitagliptin and basal insulin, but not versus liraglutide (Table). Risk for any hypoglycaemia was higher compared to sitagliptin, similar to daily GLP-1 RAs, and lower in comparison with basal insulin (Table). Main adverse effects included gastrointestinal and injection site reactions (Table). Incidence of SAEs and all cause mortality did not differ between once weekly GLP-1 RAs and across all comparator arms (ORs 0.93; 95% CI 0.82 to 1.04; I²=13% and 0.67; 95% CI 0.40 to 1.11; I²=0% respectively).

Conclusion: Given their overall efficacy and safety profile and convenient dosing scheme, once weekly GLP-1 RAs are an attractive therapeutic alternative to oral antidiabetic agents, basal insulin, or twice daily exenatide in patients inadequately controlled with metformin alone.

Adherence with GLP-1RA therapy in Germany: exenatide once weekly vs liraglutide once daily

Q. Qiao¹, S. Grandy², K. Kostev³;

¹Medical Evidence and Observational Research Center, Global Medical Affairs, AstraZeneca Pharmaceuticals, Mölndal, Sweden, ²Global Medicines Development, AstraZeneca, Wilmington, USA, ³Epidemiology, IMS Health, Frankfurt am Main, Germany.

Background and aims: The aim was to estimate the adherence of primary care patients initiating therapy with GLP-1 receptor agonist (GLP-1 RA) once weekly (exenatide) or once daily (liraglutide).

Materials and methods: Initiation of GLP-1 RA therapy documented in statutory health insurance patients in Germany between January 1, 2011 and September 30, 2014 (date of initiation=index) were studied. The database covers 60% of all prescriptions nationwide. A minimum 6-month prior to and at least 6-month post-index pharmacy benefits enrollment was required for eligibility of inclusion. Adherence was measured using the ‘proportion of days covered’ (PDC) with index GLP-1RA during the 6-month post-index period. PDC was calculated by taking the total number of days supply per patient during the post-index 6-month period and dividing that by 180 days. Days supplied was calculated as follows: pack size * pack count * 7 for exenatide; and strength * pack size * pack count / 1.3 (median dose) for liraglutide.

Results: Overall, 5,449 patients (mean (sd) age: 59.7 (11.8) years, men 51.4%) initiating exenatide, and 24,648 patients (mean (SD) age: 59.4 (11.4) years, men 49.7%) initiating liraglutide therapy were included in the data analysis. The median PDC was 0.88 for exenatide and 0.77 for liraglutide (p<0.001). 53.4% of the patients receiving exenatide, and 47.7% of those receiving liraglutide had an adherence of at least 80% (p<0.001) during the 6 months after initiating the drugs. There was no significant gender difference in the median PDC (exenatide: male 0.85 and female 0.86; liraglutide: male 0.77 and female 0.77). The medians of the PDC in age groups of ≤50, 51-60, 61-70 and >70 years were 0.78, 0.92, 0.92 and 0.81 for exenatide, and 0.77, 0.79, 0.79 and 0.77 for liraglutide, respectively.

Conclusion: Over a 6-month period after initiation of GLP-1RA therapy, patients treated with exenatide once weekly had significantly better adherence compared with patients on liraglutide once daily, particularly among patients aged 50 years or older.

Achieving postprandial glucose control with lixisenatide improves glycaemic control in patients with type 2 diabetes mellitus on basal insulin

S. Paranjape¹, W. Stager¹, R. Berria², L.A. Leiter³;

¹ProUnlimited@Sanofi, ²Sanofi US, Inc., Bridgewater, USA, ³Li Ka Shing Knowledge Institute and Keenan Research Centre for Biomedical Science, St Michael’s Hospital, University of Toronto, Canada.

Background and aims: Lixisenatide is a prandial glucagon-like peptide-1 receptor agonist. Given the rationale for combining complementary therapies to improve glycaemic control, we examined the impact of lixisenatide on postprandial plasma glucose (PPG) target achievement (measured 2 hours after a standard liquid breakfast), and subsequent efficacy and safety in patients with type 2 diabetes mellitus (T2DM) on basal insulin. The hypothesis was that achieving PPG targets with lixisenatide increases the likelihood of reaching HbA_{1c} goals.

Materials and methods: Data were analysed from the GetGoal-L, GetGoal-Duo1, and GetGoal-L Asia studies in which patients with T2DM were treated with lixisenatide plus basal insulin. Patients (lixisenatide: n=587, 47% male, mean weight 82 kg, mean HbA_{1c} 8.1%; and placebo: n=484, 50% male, mean weight 81 kg, mean HbA_{1c} 8.1%) were categorized by baseline fasting plasma glucose (FPG) levels of <126 or ≥126 mg/dL (<7.0 or ≥7.0 mmol/L, respectively). Lixisenatide-treated patients were grouped as PPG responders (<180 mg/dL [<10.0 mmol/L]) or non-responders (≥180 mg/dL [≥10.0 mmol/L]). Data were derived from a fixed effect meta-analysis with inverse variance weights. Changes in HbA_{1c} and body weight were analysed using an analysis of variance using last observation carried forward at Week 24.

Results: In both FPG categories, more lixisenatide-treated patients with T2DM reached target PPG versus placebo (<126 mg/dL [<7.0 mmol/L]: 55% vs 18%; and ≥126 mg/dL [≥10.0 mmol/L]: 48% vs 10%). Greater reductions in HbA_{1c} and weight were seen in lixisenatide-treated patients; efficacy was superior in patients meeting the PPG targets for both FPG categories (Table). Lixisenatide-treated patients were more likely to achieve HbA_{1c}<7.0% and had no increased risk of symptomatic hypoglycaemia (Table).

Conclusion: These results support the hypothesis that achieving PPG targets with lixisenatide increases HbA_{1c} goal achievement in patients with T2DM and uncontrolled HbA_{1c} on basal insulin, and highlights the importance of PPG control.

Table. Efficacy and safety outcomes in patients with T2DM treated with lixisenatide.

Glucagon-like peptide 1 receptor agonist or rapid-acting insulin as add-on to basal insulin therapy in patients with type 2 diabetes mellitus: a meta-analysis

L. Kuritzky¹, J. Lin², C.H. Wysham³;

¹Department of Community Health and Family Medicine, University of Florida, Gainesville, ²Novosys Health, Flemington, ³Rockwood Clinic, Spokane, USA.

Background and aims: When patients with type 2 diabetes mellitus (T2DM) are suboptimally controlled on oral antidiabetes agents plus basal insulin, clinicians must choose from a variety of next-step treatments. Glucagon-like peptide 1 receptor agonists (GLP) have been used as add-on to basal insulin (BI) in patients with T2DM due to their advantage in improving glycaemic control, with a lower risk of hypoglycaemia and less weight gain compared with intensified insulin regimens. This meta-analysis was conducted to compare add-on GLP (BI+GLP) with add-on rapid-acting insulin (BI+RAI) in patients with T2DM whose glycaemic control remained unoptimised with basal insulin therapy alone.

Materials and methods: Peer-reviewed literature was searched using PubMed and EMBASE, as well as abstracts presented at the American Diabetes Association and European Association for the Study of Diabetes meetings from 2009-2013. Endpoints included HbA_{1c} levels and symptomatic hypoglycaemia (defined as blood glucose level <56 mg/dL); and change in body weight and fasting plasma glucose (FPG). Three randomised clinical trials (duration 26-44 weeks) involving 1,370 patients with T2DM (28.4-54.0% of which were female) were included. Patients were aged 54.8-61.1 years, had baseline HbA_{1c} levels of 7.7-8.5%, and a BMI of 32.0-32.7 kg/m².

Results: Compared with patients treated with BI+RAI, patients treated with BI+GLP had significantly greater reductions in HbA_{1c} and body weight, and a significantly lower risk of symptomatic hypoglycaemia. Furthermore, these patients had numerically greater FPG reductions and, although not significant, higher odds of achieving HbA_{1c} <7.0% than patients treated with BI+RAI (Table).

Conclusion: GLP-1 RA therapy is a viable option to complement insulin therapy as the addition of a GLP-1 RA to basal insulin therapy improved glycaemic control with a lower risk of symptomatic hypoglycaemia, and without weight gain compared with the addition of RAI to basal insulin therapy. Therefore, this combined approach can be particularly valuable for patients with T2DM who are treated with basal insulin and have poor glycaemic control or issues with weight gain.

Table. Summary of meta-analysis outcomes.

Real world glucose and weight control in patients treated with GLP-1 receptor agonists, with addition or treatment change to insulin

K. Klein¹, A. Shaunik², S. Paul¹;

¹Clinical Trials & Biostatistics Unit, QIMR Berghofer Medical Research Institute, Brisbane, Australia, ²AstraZeneca, Washington DC, USA.

Background and aims: Glucose control and weight change in patients (pts) treated with GLP-1 receptor agonists (GLP-1 RA), and the patterns of addition or change to insulin from GLP-1 RA are not well studied in a real world setting. The aims were to (1) evaluate the change in HbA_{1c} and weight over 6 months, 1- and 2-years post initiation of GLP-1 RA and (2) evaluate the time and possible benefits of adding or change to insulin treatment post GLP-1 RA.

Materials and methods: A cohort of 75964 T2DM pts, who initiated GLP-1 RA treatment from May 2005, were selected for this longitudinal cohort study from the Centricity EMR Database of USA, with follow-up data available till September 2014. Longitudinal data on demographics, HbA_{1c}, weight and anti-diabetes medication before/after the GLP-1 RA initiation were available. These pts did not receive insulin before GLP-1 RA initiation.

Results: At baseline, the 75964 pts were mean (SD) 61 (11) yrs old, 43% male, with mean(SD) HbA_{1c}, weight and BMI of 8.2 (1.5)%, 109 (26) kg and 38 (8) kg/m² respectively. Of these, 46353 and 29611 initiated Exenatide and Liraglutide respectively with concomitant medications of 86% / 59% metformin/sulfonylurea (SU), while 13%/12% stopped metformin/SU. The proportions of pts with HbA_{1c}>7.5% and 8% at GLP-1 RA initiation were 69% and 51% respectively. Mean (min, max) and median (IQR) duration of treatment with GLP-1 RA were 11 (1, 121) months and 5 (1, 14) months respectively. After GLP-1 RA treatment for at least 6-months (n=35267), 1-year (n=23414) and 2-years (n=10834), 30%, 32% and 33% pts reduced their HbA_{1c} below 7% respectively. The adjusted changes in body weight at these time intervals were -2.3 (-2.4, -2.2) kg, -3.0 (-3.1, -2.9) kg and -3.7 (-3.9, -3.5) kg respectively. In the cohort, 44% (n=33341) and 22% (n=16726) pts added and changed to insulin, with mean (min, max) 3 (0, 106) months and 16 (0, 111) months to adding and changing to insulin respectively. The mean / median HbA_{1c} levels at the time of adding and changing to insulin were 8.3/7.9% and 8.8/8.5% respectively. Pts who added insulin within 1 year of GLP-1 RA initiation reduced the HbA_{1c} by an additional 0.60% at 1 year, starting with a baseline HbA_{1c} of 8.3% (Fig 1). Compared to pts who changed to insulin within a year, those who added insulin showed an additional HbA_{1c} reduction by 0.34%. Compared to pts who moved to insulin, those who added insulin within 1 year were 2.4 times (95% CI of odds ratio: 2.2, 2.6) more likely to reduce HbA_{1c} below 7% within 1 year.

Conclusion: Among pts with HbA_{1c} above 8%, more than a third were likely to achieve a guideline recommended glucose control within one year of initiation of GLP-1 RA treatment with accompanying weight loss during this period. In poorly controlled pts, early addition of insulin treatment with GLP-1 RA, rather than changing to insulin, offers clinically significant glycaemic benefits, while maintaining the statistically significant weight loss.

Non-adherence and non-persistence related to GLP-1 therapy in patients with type 2 diabetes mellitus: analysis of a large UK CPRD datasetT. Wilke¹, B. Berg¹, A. Groth¹, A. Martin², J. Logie², M. Sikirica³;¹Institut für Pharmakoökonomie und Arzneimittellogistik, University of Wismar, Wismar, Germany, ²GlaxoSmithKline, Uxbridge, Middlesex, UK, ³GlaxoSmithKline, King of Prussia, USA.**Background and aims:** This study describes the extent of non-adherence (NA) and non-persistence (NP) with Glucagon-like peptide 1 agonists (GLP-1) and oral anti-diabetic (OAD) therapy in T2DM patients in clinical practice in the UK.**Materials and methods:** Electronic primary health care data collected in the CPRD (Clinical Practice Research Datalink) database from 2010–2012 were used to identify patients with ≥ 1 diagnosis code for T2DM and also at least one antidiabetic medication prescription. NA and NP were measured for patients initiating new T2DM medication (no prescription of respective medication in prior 6 months). A patient was classified as NP when a medication gap ≥ 90 days was observed. Patient-specific estimates of adherence were calculated via medication possession ratios (MPR) for those patients maintaining their therapy (without gaps ≥ 90 days) during a one-year observational period. The maximum adherence possible was based on the assumption that adherence to therapy is equivalent to the drug-specific DDD (defined daily dosage). NA was defined as MPR $< 80\%$. Descriptive analyses with percentage of patients classified as NP and/or NA were conducted.**Results:** The persistence analysis included 1,905 and 13,387 T2DM patients initiating GLP-1 and OAD-therapy, respectively. Among GLP-1 patients, 1,083 received once-daily (OD) and 545 received twice daily (BID) therapies, the remaining patients switched between regimens. Mean age for GLP-1 users was 55.5 (SD 10.6) and 60.6 (SD 13.2) years in the OAD cohort. After 12 months, the percentage of patients with NP was 29.6% (all GLP-1 s), 27.2% (OD-GLP-1), 36.0% (BID-GLP-1), and 23.2% (OAD). The NA analysis included 1,744 GLP-1 and 11,722 OAD patients initiating therapy with ≥ 1 follow-up prescription. Mean age was 55.2 (SD 10.4) and 60.2 (SD 12.9) years for the GLP and OAD cohorts, respectively. Mean MPR was 88.6% (all GLP-1 s), 88.2% (OD-GLP-1), 89.3% (BID-GLP-1) and 64.7% (OAD). Percentage of patients affected by NA was 20.2% (all GLP-1 s), 20.0% (OD-GLP-1), 20.5% (BID-GLP-1) and 68.4% (OAD).**Conclusion:** In this UK dataset, we observed several patterns of patient behaviour. Persistence with OAD therapy was numerically higher than with GLP-1 therapy. Adherence to therapy within the GLP-1 cohort was high, and appears to be similar between dosing frequency regimens, while persistence rates may be higher with less frequently dosed GLP-1 s and should be investigated further.

Co-administration of a lipidated GIPR agonist with a GLP1 analogue provides no additional benefit on HbA_{1c}% over GLP1 analogue in db/db miceA. Seth¹, A. Suckow², B. Clayton¹, N. Burmeister¹, I. Sermadiras¹, J. Metcalfe¹, J. Naylor¹, A. Collinson¹, D. Hornigold¹, D. Baker¹;¹CVMD, MedImmune, Cambridge, UK, ²CVMD, MedImmune, Gaitherburg, USA.**Background and aims:** The incretin hormone glucose-dependent insulinotropic polypeptide (GIP) has well established actions in the β cell to enhance insulin secretion in humans. In addition, variants at the *GIP receptor (GIPR)* gene locus are associated with elevated glucose and decreased insulin secretion. However, there has been controversy regarding the anti-diabetic potential for GIPR agonists as many patients withdiabetes exhibit greatly reduced insulin responses to GIP. Further studies have suggested that normalisation of glycemia in diabetics can restore GIP sensitivity. In this study we set out to examine the anti-diabetic potential for GIPR agonism alone, or in combination with a GLP1R agonist in *db/db* mice.**Materials and methods:** A total of 56 male *db/db* mice 9 weeks of age were randomised into seven groups based on baseline HbA_{1c}%. Mice received either vehicle, low dose (LD) GLP1R agonist alone, LD GIPR agonist alone, combination of LD GLP1R agonist plus LD GIPR agonist, high dose (HD) GLP1R agonist alone, HD GIPR agonist alone or combination of HD GLP1R agonist plus HD GIPR agonist. LD and HD were determined by acute dose response glucose tolerance tests carried out in lean C57BL/6J mice. The GLP1 analogue was dosed at 10 nmol/Kg and 30 nmol/Kg for LD and HD respectively. The GIPR agonist was a lipidated GIP molecule dosed at 1 nmol/Kg and 10 nmol/Kg for LD and HD respectively. Mice received daily s.c. injections ≈ 3 hours before the dark cycle for three weeks. HbA_{1c}% was measured at the beginning and end of the study, 6 hour fasted blood glucose was measured at weekly intervals. Data was analysed by a one way ANOVA with a Fisher's LSD post hoc test.**Results:** Over the duration of the study the HbA_{1c}% in vehicle group increased by 2.49%, treatment with a GLP1 analogue significantly attenuated the increase in HbA_{1c}% by 1.2% in HD group and by 0.79% in the LD group. (vehicle vs HD GLP1R $p < 0.0001$, vehicle vs LD GLP1R $p < 0.001$). Treatment with lipidated GIP attenuated the increase in HbA_{1c}% in the HD group by 0.52% (vehicle vs HD GIP1R $p < 0.05$) and had no significant effect in the LD group. In combination with a GLP1 analogue the addition of GIPR agonism provided no additional benefit over GLP1R agonism to lower HbA_{1c}% at either dose. Initially, weekly fasted glucose readings suggested dual GLP1R/GIPR agonism did improve glucose control to a greater extent than either single agent alone in the HD groups (Δ fasted glucose 7 days: HD combination -11.96 ± 0.91 vs HD GLP1R -4.10 ± 3.44 $p = 0.046$, 14 days: HD combination -8.71 ± 1.46 vs HD GLP1R 0.03 ± 3.64 $p = 0.054$). Any differential effect between GLP1 single agent HD and the combination with GIP was lost by the end of the study (21 days: -0.40 ± 3.72 vs -0.53 ± 2.24 $p = n.s.$). These results are consistent with a parallel study in which an Fc conjugated GIP molecule had only modest effects on HbA_{1c}% as a single agent and provided no additional benefit in combination with GLP1R agonism in *db/db* mice.**Conclusion:** The glucose lowering actions of GIP are greatly blunted in the diabetic *db/db* mouse model. In combination with a GLP1 analogue, GIPR agonism did provide an initial additional benefit in glucose control; however, these effects were not sustained and did not translate to an overall improvement in HbA_{1c}%. In summary, these data do not support the hypothesis that combinations of GIPR/GLP1R agonists would provide a useful strategy to treat T2D.

Do we need another consideration during incretin based therapy? Aberrant expression of glucagon-like peptide-1 receptor in papillary thyroid carcinomasS. Kwon¹, M. Jung², J. Heo³, S. Kim³, S. Ock¹, B. Kim¹, Y. Choi¹, J. Kim⁴;¹Department of Internal Medicine, Kosin University College of Medicine, ²Department of Pathology, Kosin University College of Medicine, ³Department of Molecular Biology and Immunology, Kosin University College of Medicine, ⁴Department of Surgery, Kosin University College of Medicine, Busan, Republic of Korea.**Background and aims:** Incretin-based therapies are rapidly becoming one of the main glucose lowering agents in diabetes. Considering the large numbers of papillary thyroid carcinomas (PTC) and possible effects of Glucagon-like peptide-1 (GLP-1) on cell proliferation, the expression of GLP-1 receptor (GLP-1R) in PTC is likely to have clinical

significance. We performed this study to evaluate the expression of GLP-1R in PTC.

Materials and methods: Eighty-three cases of PTC and fifty-five cases of normal thyroid tissue were selected for immunostaining for GLP-1R by polyclonal antibody. Twenty-eight cases of PTC and twelve cases of normal thyroid tissue were selected for immunostaining for GLP-1R by monoclonal antibody. Total RNA was isolated from twenty-one cases of PTC and twelve cases of normal thyroid tissue for evaluation of GLP-1R mRNA RT-PCR.

Results: Immunohistochemical staining for GLP-1R by polyclonal antibody exhibited immunoreactivity in thirty-seven of eighty-three cases (44.6%) in PTC but, none of fifty-five cases of normal thyroid follicular cells. Eight of twenty-one cases (38.1%) of PTC and none of twelve normal thyroid tissues expressed GLP-1R mRNA.

Conclusion: Some of PTC tissues express GLP-1R, although normal thyroid follicular tissues do not express GLP-1R. The clinical significance of GLP-1R expression in PTC and long-term influence of pharmacologically increased GLP-1 to development and progression of GLP-1R expressed PTC associated with incretin based therapy should be evaluated.

PS 071 DPP-4 inhibitors: antihyperglycaemic efficacy

A randomised, double-blind trial of saxagliptin add-on to dapagliflozin + metformin

D. Catrinoiu¹, S. Matthaei², A. Celiński³, E. Ekholm⁴, W. Cook⁵, B. Hirshberg⁵, N. Iqbal⁶, L. Hansen⁶;

¹Spitalul Clinic Judetean de Urgenta Constanta, Romania, ²Diabetes-Center, Quakenbrück, Germany, ³CenterMed - Centrum Badań Klinicznych, Kraków, Poland, ⁴AstraZeneca, Molndal, Sweden, ⁵AstraZeneca, Gaithersburg, ⁶Bristol-Myers Squibb, Princeton, USA.

Background and aims: DPP-4 and SGLT2 inhibitors have complementary mechanisms of action that can potentially improve glucose control with a low risk of hypoglycemia. We compared the efficacy and safety of saxagliptin (SAXA) vs placebo (PBO) add on to dapagliflozin (DAPA) + metformin IR (MET) in adults with type 2 diabetes (T2D).

Materials and methods: Patients on stable MET (≥ 1500 mg/d) for ≥ 8 weeks with baseline A1C 8.0%-11.5% (mean A1C at screening 9.3%) received open-label DAPA 10 mg/d + MET for 16 weeks. At the end of the open-label period, patients with inadequate glycemic control (A1C 7%-10.5%) were randomized to PBO (n=153) or SAXA 5 mg/d (n=162) in addition to background DAPA+MET. Primary end point was change in A1C from baseline to week 24. Secondary end points included fasting plasma glucose (FPG), 2-hour postprandial glucose (PPG), and the proportion of patients achieving A1C <7%.

Results: There was a significantly greater reduction in A1C at 24 weeks with SAXA+DAPA+MET vs PBO+DAPA+MET (**Table**). Reductions in FPG and PPG were similar between treatment arms. A greater proportion of patients achieved A1C <7% with SAXA+DAPA+MET vs PBO+DAPA+MET. AEs were similar across treatment groups, although urinary tract infections and nasopharyngitis were higher with SAXA+DAPA+MET. Episodes of hypoglycemia were rare.

Conclusion: Addition of SAXA to DAPA+MET is well tolerated and produces significant improvements in glycemic control in patients with T2D inadequately controlled with DAPA+MET.

Effects of gemigliptin versus sitagliptin or glimepiride on glycaemic variability as initial combination therapy with metformin in drug-naïve patients with type 2 diabetes

B.-W. Lee¹, J. Kim², S. Park³, C. Jung⁴, S.-H. Lee⁵, S. Suh⁶, W. Lee⁴, J.-H. Cho⁵, Y. Jang⁷, S.-H. Kim⁷, C.-Y. Park³, STABLE Study;

¹Severance Hospital, University of Yonsei University College of Medicine, ²Samsung Medical Center, Sungkyunkwan University School of Medicine, ³Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, ⁴Asan Medical Center, University of Ulsan College of Medicine, ⁵Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, ⁶Dong-A Medical Center, Dong-A University College of Medicine, Busan, ⁷LG Life Sciences, Seoul, Republic of Korea.

Background and aims: Glycemic variability and chronic sustained hyperglycemia are the main components of dysglycemia in diabetes. The purpose of this study was to assess whether there is a difference between- or within drug classes on glycemic variability and glucose control as initial combination therapy with metformin in drug-naïve patients with type 2 diabetes.

Materials and methods: A multi-center, randomized, active controlled, open-label, parallel design study was performed in 69 patients with HbA1c greater than 7.5%. Subjects were randomized (1:1:1) to receive gemigliptin 50 mg qd, sitagliptin 100 mg qd, or glimepiride 2 mg qd for 12 weeks. The mean amplitude of glycemic excursions (MAGE) and standard deviation (SD) were used for assessing glucose fluctuations at baseline and after 12 weeks. Glycosylated hemoglobin (HbA1c), glycated albumin (GA), fructosamine, C-reactive protein and other metabolic parameters were also measured. Safety and tolerability based on adverse events (AEs) were assessed. To strengthen the reliability of the study results, data from continuous glucose monitoring system (CGMS) was evaluated independently by a blinded central evaluator.

Results: A total of 69 subjects were randomized to receive gemigliptin 50 mg (n=24), sitagliptin 100 mg (n=23) or glimepiride 2 mg (n=22). Mean baseline characteristics were similar across the groups (age, 50.0 years; HbA1c, 9.4%; GA, 26.4%; fructosamine, 412.8 μmol/L). At 12 weeks, MAGE was significantly lower in the DPP-4 inhibitor groups, gemigliptin and sitagliptin, than in the glimepiride group (-43.1, -38.3, and -21.7 mg/dl, respectively). Furthermore, the SD of mean glucose was significantly lower in patients with gemigliptin (vs sitagliptin p=0.01; vs glimepiride p=0.007) when compared with sitagliptin and glimepiride. Mean HbA1c was reduced from baseline by 2.75%, 2.24% and 2.75% for gemigliptin, sitagliptin and glimepiride, respectively. A similar profile was also observed in other glycemic control parameters (FPG, glycated albumin, and fructosamine). A greater decrease in total- and LDL-cholesterol and nitrotyrosine was observed for DPP-4 inhibitor groups versus glimepiride, although there were no significant differences between the groups. In addition, only gemigliptin significantly decreased C-reactive protein levels from baseline. Drug-related AEs including symptomatic hypoglycemia were reported more frequently in glimepiride group than in other groups.

Conclusion: In summary, gemigliptin was more effective than glimepiride and sitagliptin in reducing glucose variability as initial combination therapy with metformin in drug-naïve patients with T2DM.

Efficacy and safety of gemigliptin in type 2 diabetes patients with moderate to severe renal impairment

S. Yoon¹, B. Han², S. Kim³, S. Han⁴, Y.-I. Jo⁵, K. Jeong⁶, K.-H. Oh⁷, H. Park⁸, S.-H. Park⁹, S.-W. Kang¹⁰, K.-R. Na¹¹, Y. Jang¹², S.-H. Kim¹², D. Cha¹³, GUARD Study;

¹Uijeongbu St. Mary's Hospital, ²Yonsei University Wonju College of Medicine, ³Hallym University Sacred Heart Hospital, Anyang, ⁴Ilsan Paik Hospital, Goyang, ⁵Konkuk University School of Medicine, ⁶Kyung Hee University School of Medicine, Seoul, ⁷Seoul National University College of Medicine, ⁸Gangnam Severance Hospital, Seoul, ⁹Kyungpook National University School of Medicine, Daegu, ¹⁰Yonsei University College of Medicine, Seoul, ¹¹Chungnam National University College of Medicine, Daejeon, ¹²LG Life Sciences, Seoul, ¹³Korea University Ansan-Hospital, Republic of Korea.

Background and aims: Renal impairment in type 2 diabetes mellitus limits the available glucose-lowering medication and requires frequent monitoring of renal function. Gemigliptin, a potent and selective DPP-4 inhibitor, can be used without dose reduction in renal impairment. This randomized, double blind, parallel group Phase 3b study comprised a 12-week, placebo-controlled phase followed by a 40-week, double blind active-controlled extension phase (placebo switched to linagliptin). This 12-week randomized trial investigated the efficacy and safety of gemigliptin in type 2 diabetic patients with moderate to severe renal impairment. It was also evaluated whether gemigliptin has renoprotective effects in these patients.

Materials and methods: A total of 132 patients were randomized to gemigliptin (n=66) or placebo (n=66). Primary endpoint was HbA1c change from baseline at Week 12. Baseline demographics were similar between treatment groups (mean HbA1c 8.4%; age 62.0 years; BMI 26.2 kg/m², duration of T2DM 16.3 years; eGFR 33.3 mL/min/1.73 m²). The predominant background therapy was insulin (63.1%).

Results: At Week 12, adjusted mean±SE change HbA1c with gemigliptin was -0.83±0.14%(change with placebo 0.38±0.14%; difference -1.21, 95% CI -1.54 to -0.89; p<0.0001). A similar profile was also observed in other glycemic control parameters (FPG, glycated albumin, and fructosamine). After 12 weeks of gemigliptin treatment, albuminuria (measured by urinary albumin creatinine ratio [UACR]) significantly decreased in the patients with micro- and macro-albuminuria. Furthermore, urinary nephrin and type IV collagen in the gemigliptin were also significantly reduced compared to placebo. Drug-related AEs including hypoglycemia for gemigliptin was similar to placebo (15.2% and 12.1%, respectively). There was no meaningful change from baseline in body weight (gemigliptin, -0.3 kg; placebo -0.2 kg).

Conclusion: Gemigliptin improved glycemic control and provided additional renoprotection in T2DM patients with moderate to severe renal impairment. There was no additional risk of hypoglycemia and no weight gain.

Reduced incidence of hypoglycaemia with sitagliptin used with intensively titrated insulin may be due to factors other than the difference in insulin dose

S.S. Engel¹, F. Wu², L. Xu¹, R. Shankar¹;

¹Merck & Co., Inc., Kenilworth, USA, ²MSD R&D (China) Ltd., Beijing, China.

Background and aims: Addition of sitagliptin (SITA) relative to placebo (PBO) in patients (pts) (N=658) with type 2 diabetes who intensively titrate insulin glargine±metformin has been shown to result in a lower incremental insulin dose requirement (mean Δ=-4.7 units), better

glycemic control (mean Δ A1C=-0.45%), and a lower incidence of adverse events of symptomatic hypoglycemia (HYPO) (mean Δ =-11.6%).
Materials and methods: To determine if the reduced insulin dose requirement with SITA accounted for the lower HYPO incidence, we conducted a post hoc analysis of the incidence of HYPO in subgroups based on quartiles (Q) of change in insulin dose from baseline for the entire study cohort (Table).

Results: PBO-adjusted Δ A1C in Q 1-4 were -0.33%, -0.62%, -0.47% and -0.47%, respectively. For pts with the lowest insulin dose increment (≤ 6 units), no difference in incidence of HYPO was seen. For pts in the remaining 3 Qs, the incidence of HYPO was lower with SITA. Additionally, an analysis of the incidence of asymptomatic hypoglycemia showed similar between-group results in Q1 and Q2 but lower incidences in the SITA group in Q3 and Q4 (7.7% vs 17.9% and 1.5% vs 12.5% for SITA and PBO, respectively).

Conclusion: These analyses suggest that the reduced incidence of hypoglycemia seen when sitagliptin is used in conjunction with intensively titrated insulin may be due to factors other than the difference in insulin dose.

	Within-quartile Change from baseline in Insulin Dose	Mean Δ Insulin Dose: Sitagliptin Group	Mean Δ Insulin Dose: Placebo Group	HYPO: Sitagliptin Group Incidence (n/N)	HYPO: Placebo Group Incidence (n/N)	Difference in % HYPO (95% CI)

Type 2 diabetes patients on metformin and well-controlled basal: Can supplementary vildagliptin control residual prandial hyperglycaemia? VIBE study results

S. Franc^{1,2}, A. Daoudi^{1,2}, I. Xhaard², C. De Moura², C. Randazzo², G. Charpentier^{1,2};

¹Centre Hospitalier Sud Francilien, Corbeil-Essonnes, ²CERITD, Evry, France.

Background and aims: In patients with type-2 diabetes (DT2) treated with metformin and well-titrated basal insulin whose HbA1c remains above 7%, failure to optimize glycemic control is mainly due to a persistent elevation in postprandial glycaemia (PPG). Can supplementary vildagliptin reduce HbA1c to target levels ($< 7.0\%$) vs. placebo?

Materials and methods: In the study, 34 DT2 patients receiving metformin at the maximum tolerated dose together with well-titrated insulin glargin (fasting blood glucose: < 1.20 g/l), but with HbA1c persistently between 7 and 9%, were randomised to double-blind cross-over treatment with either vildagliptin (50 mg b.i.d.) or placebo, with the 3-month treatment periods being separated by a 3-month wash-out period. Immediately prior to the end of these two periods, patients wore a continuous glucose monitoring device for 5 days. The amount of carbohydrates was collected at the same time for each of the 5-day meals.

Results: 31 patients were randomised (4 F/27H) and 3 dropped out. Baseline data were as follows: HbA1c: $7.65 \pm 0.5\%$; diabetes duration: 6.1 ± 7.9 years; age: 59.4 ± 7.6 years; BMI: 28.6 ± 4.3 ; insulin glargin dose: 39.3 ± 36.8 u/d; metformin dose: 2.8 ± 0.29 g/d. The proportion of patients achieving an HbA1c $< 7\%$ with vildagliptin was 4 times as high as that of patients treated with placebo (28.6% vs. 7.4%, $p=0.007$). Moreover, the addition of vildagliptin allowed a mean HbA1c reduction of 1% in the vildagliptin group vs placebo (vildagliptin: $-0.7 (\pm 0.9)\%$; placebo: $+0.3 (\pm 0.9)\%$; $p=0.002$). Glucose excursions on CGM curves at mealtime, estimated through AUCs, were significantly lower with vildagliptin vs. placebo. Significantly more time was spent in the range [70-180 mg/dl] with vildagliptin vs placebo [74.8 ($\pm 18.0\%$) vs. 61.1 ($\pm 22.9\%$)]. Conversely the time spent above 180 mg/dl was significantly lower for vildagliptin vs placebo (21.2 (± 17.9)) vs 37.4 (± 23.2). Predictors for patient response to treatment were also studied.

Conclusion: In patients treated with metformin and well-titrated basal insulin, uncontrolled postprandial glycemic excursions are significantly improved by the addition of vildagliptin. By that way, 4 times more patients achieved the HbA1c target below 7%. This improved response involved a better control of post-prandial glycaemia, as attested by CGM data.

Efficacy and safety of linagliptin/metformin fixed-dose combination as initial therapy in drug-naïve Asian patients with type 2 diabetes

Y. Gong¹, Y. Mu², B. Fan³, U. Hehnke¹, C. Pan²;

¹Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany, ²Chinese PLA General Hospital, Beijing, ³Boehringer Ingelheim (China) Investment Co., Ltd, Shanghai, China.

Background and aims: A 24-week study investigated the efficacy and safety of initial fixed-dose combination (FDC) therapy with linagliptin (L) and metformin (M) immediate release in drug-naïve patients from Asia (83.4% from China) with type 2 diabetes (T2D) and inadequate glycemic control.

Materials and methods: In total 733 patients (initial HbA1c [$\%$] ≥ 7.5 - < 11) were randomized to one of five regimens (L 5 mg QD, M 500 mg BID, M 1000 mg BID, L 2.5 mg/M 500 mg BID, L 2.5 mg/M 1000 mg BID). The primary endpoint was HbA1c change from baseline to week 24.

Results: Overall mean baseline (SD) age, body mass index, HbA1c and fasting plasma glucose (FPG) were 51.3 (10.0) years, 26.0 (3.6) kg/m², 8.7 (1.0) % and 169.0 (39.5) mg/dL, respectively. At week 24, the FDCs showed clinically meaningful reductions from baseline in HbA1c (Table) and FPG. The first test of the primary HbA1c analysis (L 2.5 mg /M 1000 mg BID vs M 1000 mg BID) was borderline non-significant; however, all but one pre-defined sensitivity analysis showed that the FDCs had significantly greater reductions in HbA1c from baseline vs their respective monotherapy components. This was also shown for a pre-defined subgroup analysis in Chinese patients. Target HbA1c ($< 7\%$, week 24) was reached in the following % of patients: L 5 mg QD (44%), M 500 mg BID (50%), M 1000 mg BID (69%), L 2.5 mg/M 500 mg BID (72%), L 2.5 mg/M 1000 mg BID (77%). Adverse event (AE) rates were similar across groups except for a small but expected increase in gastrointestinal AEs with M and FDCs particularly with M 1000 mg. Hypoglycemic AEs were low across groups.

Conclusion: FDCs significantly improved glycemic control and were well tolerated.

Table. Adjusted change from baseline (BL) to week (wk) 24 for HbA1c by treatment groups*

Use of the Japanese health insurance claims database to assess durability of DPP-4 inhibitors in patients with diabetes: comparison with other anti-diabetic drugs

D. Yabe¹, H. Kuwata¹, R. Nishikino², M. Kaneko², C. Ito², K. Murotani³, T. Kurose¹, Y. Seino¹;

¹Center for Diabetes, Endocrinology and Metabolism, Kansai Electric Power Hospital, Osaka, ²Japan Medical Data Center Co., Ltd, Tokyo, ³Center for Clinical Research, Aichi Medical University, Japan.

Background and aims: Dipeptidyl peptidase-4 inhibitors (DPP-4i) have been widely used to manage type 2 diabetes (T2DM), especially in Japanese who show greater HbA1c-lowering effects compared to other ethnicities. However, its long-term therapeutic durability remains to be shown in actual clinical practice. The current study was initiated to evaluate durability of DPP-4i, GLP-1 receptor agonists (GLP-1RA) and other oral anti-diabetic drugs (OADs) among Japanese T2DM patients.

Materials and methods: The Japan Medical Data Center Claims Database, a comprehensive medical and pharmacy claims database, was used to compare average days before prescription change (DBPC) of anti-diabetic drugs in 1) untreated patients who received DPP-4i, GLP-1RA or other OADs as monotherapy (n=1,918) and 2) patients who had been on one OAD or GLP-1RA and received DPP-4i, GLP-1RA or other OADs as either switch (n=662) or add-on therapy (n=1,113). Patients aged 30-74 years with pharmacy and medical claims data for a continuous period of at least 32 months were included. This allowed a 6-month period for baseline observations and 26 months of observation after initiation of the index medication. Patients with at least one ICD-10 code of E11 or E14 during the observational period were subjected to further analyses, while those with E10, E12 and E13 were excluded. Patients on insulin injection and/or those on more than 2 OADs were excluded. The index date was defined as the prescription date of the first claim for a new OAD during the target period from December 1, 2009 through May 31, 2012. An anti-diabetic drug was considered new if there were no claims for the medication during the prior 6 months. The observation period started on the index date and ended on the initiation of another new OAD, GLP-1RA or insulin. The same patients were included multiple times into different index drug groups if they met the criteria.

Results: Among untreated patients who received OAD as monotherapy, DPP-4i (n=795) showed significantly longer DBPC compared to other OADs (n=1,117) (DPP4i 546.9 days; and Others 433.9 days; p<0.0001). Kaplan Meier analysis confirmed that DPP-4i showed longer DBPC than other OADs (Log-rank test, p<0.0001). Among patients who had been on one OAD or GLP-1RA and received OAD as switch, DPP-4i (n=397) showed significantly longer DBPC compared to other OADs (n=261) (DPP4i 554.5 days; and Others 367.7 days; p=0.0002). Among patients who had been on one OAD or GLP-1RA and received OAD as add-on, DPP-4i (n=431) showed significantly longer DBPC compared to other OADs (n=682) (DPP4i 564.9 days; and Others 442.4 days; p<0.0001). Among various OADs, DPP-4i add-on showed longer DBPC with α -glycosidase inhibitors (AGI) (AGI 650.0 days; Others 555.7 days; p=0.0004). Cox proportional hazard models revealed lower chance for prescription change with DPP-4i compared to other OADs as monotherapy or dual therapies. Limited or no patients receiving GLP-1RA as monotherapy (n=10) or dual therapy (n=0) did not allow meaningful analysis.

Conclusion: Despite numerous limitations, our findings indicate that DPP-4i, as first-line or second-line therapy, has long-term therapeutic durability superior to other OADs for Japanese T2DM in clinical practice. Supported by: JSPS, JADEC

PS 072 DPP-4 inhibitors: non-glycaemic effects

Dipeptidyl peptide-4 (DPP-4) inhibitors did not increase the incidence of infection in immune-compromised patients under chemotherapy

M. Morita¹, M. Yamamoto¹, T. Takahashi², T. Sugimoto¹;

¹Internal Medicine 1, Shimane University Faculty of Medicine, ²Oncology and Hematology, Shimane University Hospital, Izumo, Japan.

Background and aims: It is still unknown whether suppression of DPP-4 activity, which is known as T-cell activation antigen CD26, increases risk of infection. To clarify this issue, we compared the infection rate between the patients with malignant lymphoma with and without administration of DPP-4 inhibitor (DPP-4I) under chemotherapy.

Materials and methods: We analyzed 815 exposure chemotherapies, performed in 162 patients from September 2006 to December 2014 [mean (\pm SD) age: 66.8 \pm 13.2 years, men: 43.1%, range: 1-8 times/person]. Infection was defined as a body temperature higher than 38 degrees C except for infusion reactions of anticancer drug, or diagnosed by physician within 28 days after chemotherapy. We compared incidence of infection between 2 groups, classified by user of DPP-4I or non-user.

Results: The numbers of infection case/total care were 11/54 (20.4%) in user of DPP-4I, 215/761 (28.3%) in non-user. No significant increased risk of infection was observed in DPP-4I user adjusting for age, sex, Ann Arbor staging, performance status and serum levels of albumin [OR: 1.62 (95%CI: 0.78 - 3.33), p=0.193]. In contrast, serum levels of albumin and hemoglobin were significant preventive factor for infection [OR: 0.37 (95%CI: 0.25 - 0.53) and OR: 0.88 (95%CI: 0.79 - 0.99), respectively].

Conclusion: This study suggested that DPP-4I treatment did not affect the immune system even in immune-compromised patients under chemotherapy.

810

Linagliptin acutely increases endothelial progenitor cells and anti-inflammatory monocytes in a randomised, placebo-controlled cross-over study

G.P. Fadini, B. Bonora, M. Albiero, R. Cappellari, M. Marescotti, M. Vedovato, A. Avogaro;

Department of Medicine, University of Padova, Italy.

Background and aims: Circulating cells, including endothelial progenitor cells (EPCs) and monocyte subtypes are likely involved in the pathogenesis of diabetic complications. We herein assessed whether the dipeptidyl peptidase-4 (DPP-4) inhibitor linagliptin acutely modifies EPCs and monocyte subsets in patients with type 2 diabetes.

Materials and methods: This was a randomized cross-over placebo-controlled trial in which 46 type 2 diabetic patients with (n=18) or without (n=28) chronic kidney disease (CKD) underwent a 4 day treatment with linagliptin or placebo in random order, in 2 periods separated by a washout of 2 weeks. Before and the day after each period of 4-day treatment with linagliptin or placebo, blood samples were collected for the determination of EPC phenotypes and monocyte subsets.

Results: Linagliptin reduced DPP-4 activity by about 70%. Compared to placebo, linagliptin increased CD34+CD133+ progenitor cells (placebo-subtracted effect +40.4 \pm 18.7/10⁶; p=0.036), CD34+KDR+ EPCs (placebo-subtracted effect +22.1 \pm 10.2/10⁶; p=0.036), and CX3CR1^{high} monocytes (placebo-subtracted effect +1.7 \pm 0.8%; p=0.027). No effect was seen on other EPC phenotypes, M1 and M2 monocyte-macrophages, as well as traditional monocyte subsets (classical, intermediate and non-classical). In patients with CKD, as compared to those without, CD133+ and CD34+CD133+ cells were significantly reduced, whereas CD34+

and CD34+KDR+ cells were reduced with borderline significance ($p=0.06$ for both).

Conclusion: DPP-4 inhibition with linagliptin acutely increases vasculoregenerative and anti-inflammatory cells. These results highlight the direct, glucose-independent, effect of DPP-4 inhibition and may be important to lower vascular risk in diabetic patients, especially in the presence of CKD.

Gemigliptin, a dipeptidyl peptidase-4 inhibitor, inhibits retinal neovascularisation in oxygen-induced ischaemic retinopathy and retinal vascular leakage in db/db mice

E. Jung¹, S.-H. Kim¹, J. Kim²;

¹LG Life Sciences Ltd., R&D Park, Daejeon, ²Korean Medicine Convergence Research Division, Korea Institute of Oriental Medicine, Daejeon, Republic of Korea.

Background and aims: Retinal vascular leakage and neovascularization are features of diabetic retinopathy. Gemigliptin, a dipeptidyl peptidase-4 (DPP-4) inhibitor, has shown robust blood-glucose lowering effect in type 2 diabetic patients, but its effects on diabetic retinopathy have not been reported. This study evaluated the efficacy of gemigliptin on retinal vascular leakage in db/db mice, an animal model for type 2 diabetes and neovascularization in oxygen-induced retinopathy (OIR) mice, an animal model for ischemic proliferative retinopathy.

Materials and methods: Gemigliptin (100 mg/kg/day) was orally administered to db/db mice for 12 weeks. In OIR models, neonatal mice at postnatal day 7 (P7) were exposed to 75% concentration of oxygen for 5 days (P7~P12), and then returned to room air from P12 to P17 to induce retinal neovascularization. Gemigliptin (50 mg/kg/day) was administered once per day for 5 consecutive days (P12~P16) by intraperitoneal injection. Retinal neovascularization was measured at P17.

Results: Oral administration of gemigliptin for 12 weeks significantly ameliorated retinal vascular leakage and tight junction protein loss in db/db mice. Gemigliptin also ameliorated retinal neovascularization in OIR mice. Gemigliptin also attenuated overexpression of plasminogen activator inhibitor-1 (PAI-1), monocyte chemoattractant protein-1 (MCP-1) and vascular endothelial growth factor (VEGF) in the retinas of diabetic and OIR mice.

Conclusion: These results suggest that gemigliptin has a potent anti-angiogenic activity via its ability to inhibit the pro-angiogenic PAI-1-related signaling pathway and support the direct retinoprotective action of gemigliptin.

DPP-IV inhibitor linagliptin restores insulin-mediated vasorelaxation and attenuates vascular remodeling in middle cerebral arteries from type 2 diabetic GK rats

A. Ergul^{1,2}, T. Hardigan¹, Y. Abdul¹, M. Abdelsaid^{1,2}, M. Coucha^{1,2};

¹Georgia Regents University, ²Charlie Norwood Veterans Affairs Medical Center, Augusta, USA.

Background and aims: Diabetes is associated with macrovascular and microvascular complications leading to cerebrovascular disease. Insulin resistance in type-2 diabetes leads to impaired endothelial cell function and vascular dysfunction characterized by decreased vasodilation and increased vascular remodeling. It has been shown that insulin signaling in middle cerebral arteries (MCAs) induces vasorelaxation through production of nitric oxide in a PI3K/Akt dependent manner. The enzyme dipeptidyl peptidase-IV (DPP-IV) degrades glucagon-like peptide 1

(GLP-1), thereby reducing insulin secretion. DPP-IV inhibitors such as linagliptin have been shown to improve insulin secretion and endothelium dependent vascular function through PI3K/Akt signaling in rat aorta and mesentery. We hypothesized that linagliptin reverses cerebrovascular remodeling and restores vascular function via its direct and glucose lowering properties in type-2 diabetic GK rats.

Materials and methods: Diabetic and non-diabetic male GK rats, aged 24 weeks were used in this study, and were fed either normal chow or linagliptin mixed with normal chow for 4 weeks at a concentration of 166 mg/kg of chow ($n=5-6$ /group). MCA segments were mounted in an arteriograph chamber and vascular relaxation was determined by performing concentration response to insulin (Ins, 10^{-13} - 10^{-6} M), and measurements of vascular structure were recorded. Statistical significance was determined for multiple comparisons by ANOVA with Tukey post hoc correction or 2-Way ANOVA with Bonferroni post hoc correction at $p<0.05$.

Results: Linagliptin treatment does not alter hyperglycemia levels (Hemoglobin A1C%, Non-diabetic Vehicle (NDV): 5.68 ± 0.086 , Diabetic Vehicle (DV): $8.02\pm 0.273^{***}$, Non-diabetic Linagliptin (NDL): 5.85 ± 0.077 , Diabetic Linagliptin (DL): $8.20\pm 0.327^{***}$, $^{***}=p<0.001$) or body weight (grams, NDV: 404.5 ± 13.35 , DV: 411.3 ± 16.12 , NDL: 421.9 ± 14.98 , 398.8 ± 8.656). Linagliptin restores insulin-mediated vascular relaxation in MCAs from diabetic rats (Maximum Relaxation RMax%: NDV: 46.04 ± 2.803 , DV: $12.69\pm 0.9657^{***}$, DL: $45.89\pm 2.632^{###}$, $^{***}=p<0.001$ vs. NDV, $^{###}=p<0.001$ vs. DV). Linagliptin ameliorates pathological vascular remodeling in MCAs from diabetic rats. Improvement was observed in cross-sectional area (μm at max intraluminal pressure 120 mmHg: NDV: 21673 ± 569.8 , DV: $25765\pm 1530^*$, DL: $21319\pm 664.8^{\#}$, $^*=p<0.05$ vs. NDV, $^{\#}=p<0.05$ vs. DV), media thickness (μm at max intraluminal pressure 120 mmHg: NDV: 40.00 ± 1.027 , DV: $51.43\pm 3.139^*$, DL: $40.50\pm 1.067^{\#}$, $^*=p<0.05$ vs. NDV, $^{\#}=p<0.05$ vs. DV) and wall:lumen ratio (at max intraluminal pressure 120 mmHg: NDV: 0.1217 ± 0.0062 , DV: $0.1750\pm 0.0184^*$, DL: $0.1244\pm 0.0070^{###}$, $^*=p<0.05$ vs. NDV, $^{###}=p<0.01$ vs. DV).

Conclusion: There was no reduction in hyperglycemia level in the diabetic rats. This allowed us to examine the glucose-independent effects of DPP-IV inhibition with linagliptin. Type-2 diabetic rats have impaired cerebrovascular response to insulin-mediated relaxation and pathological vascular remodeling, both of which were improved following linagliptin treatment. DPP-IV inhibition with linagliptin holds potential as a possible therapy for diabetic vascular disease in addition to its clinical anti-hyperglycemic use.

A randomised, active- and placebo-controlled, three-period cross-over trial to investigate short-term effects of linagliptin on endothelial function in type 2 diabetes

T. Jax¹, M. von Eynatten², A. Stirban¹, A. Terjung¹, H. Esmaeili³, A. Berk³, S. Thiemann², R. Chilton⁴, N. Marx⁵;

¹Profil, Neuss, Germany, ²Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany, ³Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany, ⁴University of Texas Health Science Center, San Antonio, USA, ⁵University of Aachen, Germany.

Background and aims: Studies of dipeptidyl peptidase (DPP)-4 inhibitors report heterogeneous effects on endothelial function in patients with type 2 diabetes. This study assessed the effects of the DPP-4 inhibitor linagliptin versus the sulphonylurea glimepiride and placebo on measures of macro- and microvascular function.

Materials and methods: This study randomised type 2 diabetes patients ($n=42$) with $\text{HbA}_{1c} \leq 7.5\%$, no micro- or macrovascular disease and on stable metformin background to linagliptin 5 mg qd, glimepiride 1-4 mg qd or placebo for 28 days. Fasting and postprandial macrovascular

endothelial function, measured by brachial flow-mediated vasodilation (FMD), and microvascular function, measured by laser-Doppler, were analysed after 28 days.

Results: Baseline mean (SD) age and body-mass index were 60.3 (6.0) years and 30.3 (3.0) kg/m², respectively. After 28 days, changes in fasting FMD were similar between the 3 study arms [treatment ratio, gmean (90% CI): linagliptin vs glimepiride, 0.884 (0.633, 1.235); linagliptin vs placebo, 0.884 (0.632, 1.235); glimepiride vs placebo, 1.000 (0.715, 1.397); all *p*=not significant]. Similarly, no differences were seen in postprandial FMD. Linagliptin significantly improved fasting, but not postprandial, microcirculation (figure). Linagliptin had no effect on heart rate or blood pressure. Rates of overall adverse events with linagliptin, glimepiride and placebo were 27.5%, 61.0% and 35.0%. Fewer hypoglycaemic events were seen with linagliptin (5.0%) than glimepiride (39.0%).

Conclusion: Linagliptin had no effect on macrocirculation in type 2 diabetes, but significantly improved microcirculatory function in the fasting state.

Figure. Change from baseline after 28 days in fasting microcirculatory function using laser-Doppler method

Safety and efficacy of linagliptin in patients with type 2 diabetes and coronary artery disease: analysis of pooled incident investigator-reported events from phase 3 trials

M. Lehrke¹, L.A. Leiter², U. Hehnke³, S. Thiemann³, O.E. Johansen⁴, A. Bhandari⁵, S. Patel⁶, H.-J. Woerle³;

¹University Hospital Aachen, Germany, ²Keenan Research Centre in the Li Ka Shing Research Institute, St. Michael's Hospital, University of Toronto, Canada, ³Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany, ⁴Boehringer Ingelheim Norway KS, Asker, Norway, ⁵Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, USA, ⁶Boehringer Ingelheim Ltd, Bracknell, UK.

Background and aims: Patients with type 2 diabetes (T2D) continue to have increased coronary artery disease (CAD) morbidity and mortality. This analysis evaluated safety and efficacy data of the dipeptidyl peptidase-4 inhibitor linagliptin in patients with CAD.

Materials and methods: Data from T2D patients with CAD (identified using standardised MedDRA query “embolic and thrombotic events”) were pooled from a large clinical trial programme that included randomised placebo-controlled trials of linagliptin 5 mg. The safety set included patients with ≥12 weeks of treatment (19 trials: linagliptin, *n*=451; placebo, *n*=272). The efficacy set included patients with ≥24 weeks of treatment (12 trials: linagliptin, *n*=328; placebo, *n*=198).

Results: In the safety set, baseline mean (SD) age, body-mass index, and HbA_{1c} were 64.7 (9.2) years, 30.6 (4.9) kg/m², and 8.1 (0.9)%, respectively. Approximately 50% of patients in each group received ≥2 additional background antidiabetes drugs. Use of cardiovascular (CV) non-study drugs was similar between the linagliptin vs placebo groups: aspirin, 74.9 vs 77.6%; beta-blockers, 60.1 vs 59.9%; angiotensin-converting enzyme inhibitors, 46.3 vs 44.5%; statins, 62.3 vs 67.6%. Baseline mean (SD) vital signs and lipid levels were as follows: systolic BP, 135.5 (16.1) mmHg; pulse, 70.1 (10.5) bpm; total cholesterol, 176.6 (46.5) mg/dl. Median (range) exposure to linagliptin and placebo was 169 (6-707) days and 170 (1-706) days, respectively. Baseline CV risk factors/history were well matched between the groups (Table). The overall incidence of adverse events (AEs) was numerically lower with linagliptin than with placebo (Table). Cardiac AEs were reported by 9.1% of linagliptin patients and 9.2% of placebo patients (Table). In the efficacy set [baseline mean (SD) HbA_{1c} was 8.2 (0.9%)], the placebo-adjusted mean HbA_{1c} change from baseline at week 24 with linagliptin was -0.57% (95% CI -0.70, -0.43; *p*<0.0001). Although patients were more likely to achieve HbA_{1c} <7% with linagliptin vs placebo (OR 3.70; *p*<0.0001), the incidence of hypoglycaemia was 20.8% with linagliptin and 24.6% with placebo.

Conclusion: Linagliptin was well tolerated and efficacious in T2D patients with known risk factors for CAD. Ongoing CV outcomes trials will provide further insights into the long-term safety and efficacy of linagliptin.

Hepatic fat deposition is improved more with SGLT2 inhibitor luseogliflozin compared with sitagliptin: a randomised, crossover, controlled study using computed tomography

N. Fushimi, T. Shibuya, S. Takeishi, S. Itou, H. Kawai, A. Mori; Diabetes and Endocrinology, Ichinomiyanishi Hospital, Japan.

Background and aims: There are few drug therapies approved for non-alcoholic fatty liver disease (NAFLD) based on evidence-based medicine. Recently, incretin-related drugs with multiple pharmacological effects are expected to improve NAFLD. In addition, sodium-glucose co-transporter 2 (SGLT2) inhibitors are a new class of oral hypoglycemic agents that improve hyperglycemia and reduce body weight due to increased urinary glucose excretion. We hypothesized that SGLT2 inhibitors have the potential to improve NAFLD owing to this new mechanism. We aimed to compare the effect of the SGLT2 inhibitor luseogliflozin with that of the dipeptidyl peptidase-4 inhibitor sitagliptin on hepatic fat deposition.

Materials and methods: This study was conducted in 16 Japanese type 2 diabetic outpatients (male: 9, female: 7) treated with only oral hypoglycemic agents, including sitagliptin (50 mg/day). Participants were randomly assigned to groups that either continued with sitagliptin (S) or switched to luseogliflozin (L). After 4 weeks, participants then switched to the other drug for another 4 weeks. Characteristics of participants were as follows: age, 62 (57.3–66.5) years; diabetes duration, 9.5 (5–13.5) years; BMI, 27.7 (24.3–29.7) kg/m²; and HbA1c, 7.6% (7.2–7.9%). Other oral agent(s) received by participants were glimepiride (4), biguanide (12), thiazolidine (2), α -glucosidase inhibitor (2), statin (11), and angiotensin receptor blocker (7). The dosages of oral agents did not change in this study. Outcomes were as follows: evaluation of liver attenuation, liver-to-spleen attenuation ratio (L/S), and visceral fat mass area (VFA) measured by computed tomography; body weight (BW); and fasting plasma levels of alanine aminotransferase, aspartate aminotransferase, γ -glutamyl transferase, glycosylated hemoglobin, glucose, glycoalbumin, ketone bodies, immunoreactive insulin, and immunoreactive C-peptide. These data were evaluated at the end of administration of each drug.

Results: Liver attenuation and L/S in the L group were significantly higher than in the S group (liver attenuation: 50.6 (40.6–57.8) Hounsfield units (HU) vs. 44.2 (36.5–58.1) HU, $P=0.034$; L/S: 0.98 (0.73–1.04) vs. 0.90 (0.82–1.14), $P=0.013$, respectively). Moreover, both VFA and BW in the L group were significant lower than in the S group (VFA: 123.0 (105.3–151.6) vs. 135.4 (104.7–156.6) cm², $P=0.007$; BW: 68.5 (58.8–76.2) vs. 69.3 (59.6–76.3) kg, $P=0.049$, respectively), although plasma levels of ketone bodies in the L group were significant higher ($P=0.0007$) than in the S group. There was no significant difference among other outcomes measures, including glycemic control.

Conclusion: Based on both the reduced liver attenuation as well as L/S, this study suggests that luseogliflozin decreased hepatic fat deposition compared with sitagliptin. It is conceivable that increasing urinary glucose excretion with luseogliflozin, independently of glycemic control improvement, induced consumption of visceral fat and hepatic fat deposition.

Background and aims: Dipeptidyl peptidase 4 (DPP-4) inhibitors limit glucagon-like peptide-1 (GLP-1) degradation and are widely used to treat type 2 diabetes. DPP-4 exists in soluble and membrane-bound forms. It is unclear if plasma DPP-4 activity levels reflect the full extent of DPP-4 inhibition in all compartments. We used the selective inhibitor sitagliptin to explore the relationship between DPP-4 activity and protection of GLP-1.

Materials and methods: On four separate days, eight patients with type 2 diabetes (BMI: 28.8±1.4 kg/m² [mean±SEM]; HbA1c: 43.1±2.4 mmol/mol) and eight matched healthy controls (BMI: 28.1±1.2 kg/m²; HbA1c: 34.4±1.2 mmol/mol) received continuous i.v. GLP-1 (1.0 pmol/kg/min) and oral sitagliptin (0 [placebo], 25, 100 or 200 mg) administered in a double-blinded randomised order. Plasma (soluble) DPP-4 activity was measured by chromogenic assay, and the degree of protection of GLP-1 (assessed with specific RIAs) was used as a surrogate index of inhibition of 'total' DPP-4 activity in all compartments of the body.

Results: At steady-state (180–360 minutes), plasma DPP-4 activity decreased dose-dependently (Table), but with differences between 'total' and plasma DPP-4 compartments. A difference between the groups was also explored, possibly due to differences in absorption (Table). Despite relatively high inhibition of plasma DPP-4 activity, intact GLP-1 levels (N-terminal RIA) remained lower than total GLP-1 levels (C-terminal RIA).

Conclusion: Our results suggest that membrane-bound DPP-4 was not fully inhibited by single-dose sitagliptin. Furthermore, other enzymes, not inhibitable by sitagliptin, may also have been responsible.

Sitagliptin dose (mg)	Type 2 diabetes (n=8)		Control (n=8)	
	Plasma DPP-4 activity (% of placebo) ±SEM	'Total' DPP-4 activity (% of placebo) ±SEM	Plasma DPP-4 activity (% of placebo) ±SEM	'Total' DPP-4 activity (% of placebo) ±SEM

Islet-independent mechanisms contribute to the glucose-lowering effect of acute DPP-4 inhibition in healthy non diabetic and type 2 diabetes subjects after mixed meal intake

W. Alsalim, B. Omar, B. Ahrén;

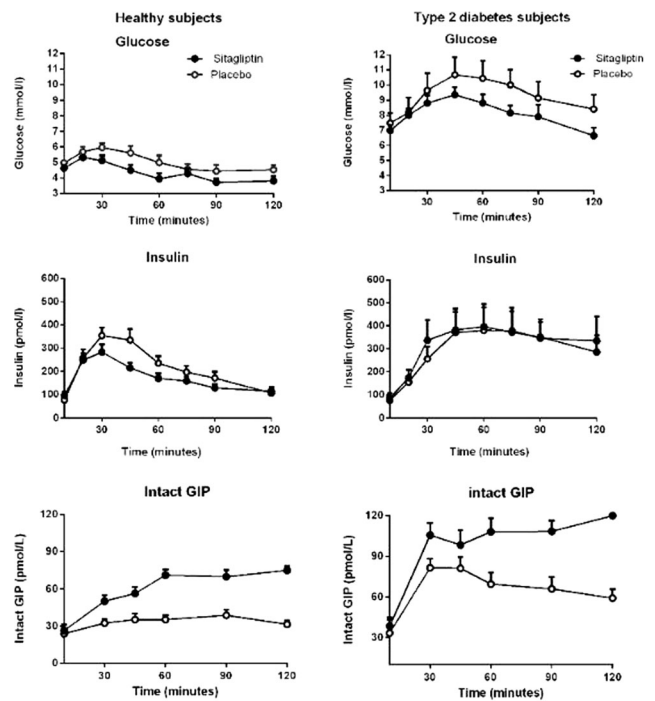

Dept of Clinical Sciences, Lund, Sweden.

Background and aims: Chronic use of DPP-4 inhibitors has been shown to improve glycemic control in type 2 diabetic subjects (T2D) by increasing levels of incretin hormones, glucagon-like peptide-1 (GLP-1) and glucose dependent insulinotropic polypeptide (GIP), resulting in stimulation of insulin secretion. It has been suggested that the insulinotropic effect of GIP is reduced in T2D subjects with insufficient glycemic control, and therefore, that GIP may be of less importance for the early glucose-lowering effect of DPP-4 inhibition. We therefore explored whether an increase in intact GIP by an acute single dose of the DPP-4 inhibitor sitagliptin is associated with effects on the islet hormones after intake of mixed meal in healthy and drug-naïve T2D subjects.

Materials and methods: After an overnight fast, twelve healthy male (mean age 22 yrs, BMI 22 kg/m²) and twelve well-controlled and drug-naïve T2D male subjects (mean age 64 yrs, BMI 27 kg/m², HbA1c 43 mmol/mol=6.0%, diabetes duration 4 yrs) underwent two tests in random order and ingested a standardized mixed meal with sitagliptin (SITA; 100 mg) or placebo (PBO). Blood samples were taken for analyses of glucose, insulin, glucagon and intact GIP and their suprabasal 120 min areas under the curve (AUC) were calculated. β -cell function was estimated as insulinogenic index [IGI=AUC insulin/ AUC glucose] calculated from the glucose and insulin levels.

Results: Plasma intact GIP levels increased after meal intake with augmented effects of sitagliptin in healthy subjects (SITA vs PBO AUC GIP 5835±409, 3059±294 pmol/l x min; $P<0.001$) and in T2D subjects (SITA vs PBO AUC GIP 9227±1157 vs 5891±553 pmol/l x min; $p=0.003$). Sitagliptin almost completely suppressed the rise in glucose in healthy (AUC 46±16 vs 70±15 mmol/l x min; $P=0.03$) and in T2D subjects (AUC 146±28 vs 239±49 mmol/l x min; $P=0.04$). This was associated with significant reduction in insulin levels in healthy (AUC 16±1 vs 21±2 nmol/l x min, $P=0.02$) but not in T2D subjects (AUC 29.2±7.1 vs 29.8±6.9 nmol/l x min; $P=0.3$). There were increases in IGI, however, sitagliptin treatment showed no significant increase in IGI compared to the placebo both in healthy (AUC 4.6±0.4 vs 4.8±0.4 nmol/mmol, $p=0.7$) and T2D subjects (AUC 3.7±1.1 vs 3.6±1.1 nmol/mmol; $P=0.4$). Sitagliptin did not suppress glucagon in healthy (AUC 382±102 vs 294±88 pmol/l x min; $p=0.2$) or T2D subjects (AUC 643±98 vs 569±143 pmol/l min, $P=0.2$).

Conclusion: The increased glycemia after meal ingestion is prevented by sitagliptin without preceding increase in insulin or reduction in glucagon in well controlled and drug-naïve type 2 diabetes and healthy non-diabetic subjects. Furthermore, the β -cell function is not increased by sitagliptin in spite of augmentation of intact GIP levels in T2D. Our results therefore suggest that extra-islet effects contribute to the glucose-lowering effect of a single dose of sitagliptin after standardized mixed meal ingestion in healthy and in T2D individuals but increases in intact GIP do not appear to contribute.

Levels of plasma glucose, insulin and intact GIP after ingestion of mixed meal in healthy non-diabetic and T2D subjects with concomitant administration of sitagliptin (●●) or placebo (○○). Mean±SEM are shown.

Sitagliptin effect on lipid and glucose metabolism (SLIM) study

S. Oikawa¹, M. Nagao², T. Harada², K. Tanimura-Inagaki², H. Sugihara², S. Moritani³, J. Sasaki⁴, S. Kono⁵, STREAM Study Investigators;

¹Fukujuji Hospital, ²Department of Endocrinology, Diabetes and Metabolism, Nippon Medical School, ³Moritani Clinic, Tokyo, ⁴International University of Health and Welfare, Fukuoka, ⁵National Institute of Health and Nutrition, Tokyo, Japan.

Background and aims: DPP4-inhibitors are expected to improve the post-prandial hyperlipidemia in addition to improving the glycemic control. This study was designed to investigate the “Sitagliptin Effect on Lipid and Glucose Metabolism” (SLIM Study) in the type 2 diabetic patients.

Materials and methods: The SLIM study was a multicenter, prospective, open-labeled, randomized study from April 2010 to September 2014. The type 2 diabetic outpatients treated with sulfonylureas (SU), who accepted the informed consent, were recruited. The inclusion criteria were HbA1c 6.9-8.5% and serum triglyceride (TG) concentration 120-400 mg/dl. They were randomized to the sitagliptin group (Sita, 50 mg/day of sitagliptin addition) and the non-sitagliptin group (non-Sita, SU multiplication), and the goal after 6 months treatment was HbA1c <6.9%. This study conformed to the principles out-lined in the Declaration of Helsinki, and was approved by the ethics committees of all participating hospitals. We monitored the fasting levels of blood glucose, HbA1c, glycated albumin (GA), lipids (TC, TG, HDL-C), and apolipoproteins (AI, AII, B, CII, CIII, E, and B48) before and after 3 and 6 months treatment.

Results: There were no significant differences in the sex and age distribution (n=81, 45 men, 62±13 years old and 36 women, 68±10 years old in the sitagliptin group, and n=83, 45 men, 62±11 years old, and 38

women, 66±9 years old in the non-sitagliptin group, mean ± SD), and HbA1c 7.5±0.8 vs. 7.5±0.7%, GA 20.2±4.0 vs. 20.5±3.6%, TC 5.4±1.0 vs. 5.4±0.9 mmol/L, TG 2.1±1.4 vs. 1.8±1.3 mmol/L, HDL-C 1.3±0.3 vs. 1.4±0.3 mmol/L, and Apo B48 6.6±5.2 vs. 5.7±4.0 µg/ml, sitagliptin group vs. non-sitagliptin group, respectively. There were no differences in the Apo CII (5.1±2.5 and 4.6±2.0) or CIII (11.8±4.7 and 10.4±3.6) levels between the sitagliptin and non-sitagliptin group. The reduction of HbA1c (-0.5±0.8%) and GA (-2±3.1%) in the sitagliptin group were significant, but not in the non-sitagliptin group (0.1±0.9 and -0.1±3.5%, respectively). The fasting lipids-profile was not significantly changed in the both groups, but TG levels slightly decreased in the sitagliptin group (-0.2±1.0 mmol/L). Apo B48, CII and CIII levels were significantly decreased in the sitagliptin group (-1.2±4.5 µg/ml, -0.4±1.3 mg/dl, and -1.1±2.7 mg/dl, respectively), but not in the non-sitagliptin group.

Conclusion: The SLIM Study demonstrated that the sitagliptin treatment effectively reduced the fasting levels of Apo B48, CII and CIII, which are related to the chylomicron and remnant metabolism, with the improved glucose metabolism. DPP4-inhibitor, sitagliptin, will effectuate the reduction of atherogenic lipoproteins in diabetes. The further study should elucidate the mechanism of DPP4-inhibitor effect on the lipid metabolism through the direct effect on lipid metabolism by this agent, the inhibitory effect on DPP4, or the improved glucose metabolism.

Incidence of microvascular outcomes in type 2 diabetes patients treated with vildagliptin vs sulphonylurea: a retrospective study using German electronic medical records

W.M. Kolaczynski¹, M. Hankins², S.-H. Ong¹, H. Richter³, A. Clemens¹, M. Toussi⁴;

¹Novartis Pharma AG, Basel, Switzerland, ²IMS Health, London, UK, ³IMS Health, Frankfurt, Germany, ⁴IMS Health, Paris, France.

Background and aims: Preliminary data suggest that dipeptidyl peptidase-4 (DPP-4) inhibitors may reduce microvascular events, but there is little evidence to support this from adequate real-world studies. This study aimed to compare the microvascular outcomes between patients prescribed vildagliptin and those prescribed sulphonylurea (SU).

Materials and methods: This retrospective cohort study was conducted on a large sample from the German electronic medical records database IMS Lifelink Disease Analyzer. We used propensity score matched samples of patients prescribed either vildagliptin or SU. Exposure was defined as therapy (SU or vildagliptin); primary outcomes were a diagnosis of retinopathy, nephropathy, neuropathy or diabetic foot ulcer over the observation period in patients with no previous record of these outcomes. Secondary outcome was a composite of any primary outcome occurring during the observation period.

Results: 16321 patients prescribed SU and 4481 prescribed vildagliptin met the inclusion criteria. After propensity score matching each sample comprised 3015 patients. Mean age was 63.7/64.6 years for SU/vildagliptin, respectively, with mean disease duration of 3.2/3.1 years and mean treatment duration of 2.5/2.3 years. Treatment with vildagliptin was associated with a significantly lower incidence of retinopathy (OR=0.55, $p=0.0004$), neuropathy (OR=0.71, $p=0.001$) and the composite outcome (OR=0.70, $p<0.0001$). Incidences of nephropathy and diabetic foot ulcer were lower for vildagliptin, but not significantly so (OR=0.90, $p=0.3920$; OR=0.76, $p=0.0742$, respectively). There were no significant differences in incident rate ratios (all $p>0.05$).

Conclusion: Treatment with vildagliptin was associated with a reduced incidence of microvascular complications, especially neuropathy and retinopathy, compared to treatment with SU.

Linagliptin, independently of blood glucose control, ameliorates cognitive impairment and brain atrophy induced by transient cerebral ischaemia in type 2 diabetic mice

S. Kim-Mitsuyama, M. Ma, N. Koibuchi, T. Nakagawa, B. Lin, Y. Hasegawa;

Department of Pharmacology and Molecular Therapeutics, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan.

Background and aims: It is well established that type 2 diabetes is significantly associated with cognitive decline and stroke. It remains to be clarified whether dipeptidylpeptidase-4 (DPP-4) inhibition can counteract the impairment of cognitive function and brain atrophy caused by transient cerebral ischemia in type 2 diabetes. The present study was performed to test our hypothesis that linagliptin, a DPP-4 inhibitor, administration following transient cerebral ischemia can ameliorate cognitive impairment and brain atrophy in diabetic mice.

Materials and methods: Eight-week-old male db/db mice, a model of obese type 2 diabetes, were subjected to transient cerebral ischemia by 17 minutes of bilateral common carotid artery occlusion (BCCAO), and were administered (1) vehicle or (2) linagliptin (0.083 g/kg in chow) for 8 weeks or 1 week.

Results: Linagliptin administration almost completely suppressed the blood DPP-4 activity in db/db mice ($P<0.01$). However, linagliptin did not significantly reduce blood glucose or not improve glucose tolerance in old db/db mice. Linagliptin administration following transient cerebral ischemia significantly counteracted cognitive impairment in diabetic mice subjected to BCCAO, as estimated by water maze test (Figure (A)) and passive avoidance test. Linagliptin administration ameliorated the decrease in brain weight (Figure (B)), and also alleviated the decrease in cerebral volume (Figure (C)) and neuron cell number (Figure (D)) in hippocampus and cortex of diabetic mice subjected to BCCAO. Linagliptin administration significantly reduced the increase in cerebral IgG extravasation (blood brain barrier disruption) and the increase in reactive microglia caused by BCCAO in diabetic mice. Linagliptin significantly suppressed the increase in cerebral oxidative stress in BCCAO-subjected diabetic mice. Furthermore, linagliptin significantly increased cerebral claudin-5, a main cerebral endothelial tight junction protein, and significantly decreased gp91phox, a major subunit of NADPH oxidase, in diabetic mice subjected to BCCAO.

Conclusion: DPP-4 inhibition with linagliptin counteracted cognitive impairment and brain atrophy induced by transient cerebral ischemia in type 2 diabetic mice, independently of blood glucose-lowering effect. This cerebroprotective effect of linagliptin was associated with the suppression of blood brain barrier disruption and the attenuation of cerebral oxidative stress. We propose that DPP-4 inhibition seems to be a promising therapeutic strategy for cognitive impairment and cerebral vascular complications in type 2 diabetes.

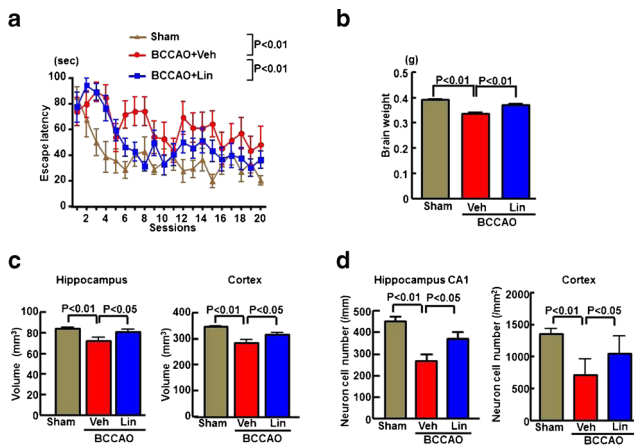

Figure legends: Effect of linagliptin administration following transient cerebral ischemia on cognitive function (escape latency on the water maze test) (A), brain weight (B), volume of hippocampus and cortex (C), and hippocampal or cortical neuron cell number (D) in type 2 diabetic mice. Abbreviations used: BCCAO, transient cerebral ischemia by 17 minutes of bilateral common carotid artery occlusion; Sham, sham-operated group; BCCAO+Veh, group subjected to transient BCCAO followed by vehicle administration; BCCAO+Lin, group subjected to transient BCCAO followed by linagliptin administration. Each value represents mean±SEM (n=10 in Sham, n=10 in BCCAO+Veh, n=11 in BCCAO+Lin, except for cortical neuron cell number; in cortical neuron cell number, n=7 in Sham, n=6 in BCCAO+Veh, n=7 in BCCAO+Lin). In (A), statistical analysis was performed by two-way ANOVA with repeated measurements. In (B)–(D), statistical analysis was performed by one-way ANOVA followed by the Tukey's multiple comparisons test.

Incidence of hypoglycaemia with the dipeptidyl peptidase-4 inhibitor linagliptin in type 2 diabetes patients with renal impairment

M. von Eynatten¹, U. Hehnke¹, H.-J. Woerle¹, M.C. Thomas²,
¹Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany,
²Baker IDI Heart and Diabetes Institute, Melbourne, Australia.

Background and aims: Patients with type 2 diabetes (T2D) and renal impairment (RI; eGFR <60 ml/min/1.73 m²) have a significantly increased risk for hypoglycaemia. This can lead to therapeutic inertia, a reluctance to intensify management and the compromise of less stringent targets for glycaemic control in patients with RI. In this context, the addition of a dipeptidyl peptidase (DPP)-4 inhibitor is a potentially attractive alternative. Therefore, we evaluated the incidence of hypoglycaemic events in placebo-controlled trials with the DPP-4 inhibitor linagliptin specifically in participants with RI.

Materials and methods: Participants with T2D and RI were identified from 20 randomised placebo-controlled trials (duration 12–52 weeks) of linagliptin 5 mg once daily as monotherapy or add-on to other glucose-lowering drugs. The incidence of pre-defined overall and confirmed hypoglycaemic events was determined.

Results: 1155 participants with T2D and RI were identified (linagliptin, n=669; placebo, n=486). 80% of participants had an eGFR between 30 and <60 ml/min/1.73 m² and 20% had an eGFR <30 ml/min/1.73 m². Overall, participants with T2D and RI were 66±9 years of age, had a prolonged duration of diabetes and frequent vascular comorbidities. 44% of participants were treated with insulin. Mean baseline HbA_{1c} was 8.2% and mean exposure was >6 months in both groups. In these participants, linagliptin significantly lowered HbA_{1c} versus placebo (–0.53%, –0.57% and –0.53% at 12, 24 and 52 weeks, respectively; all p<0.0001). Although the background incidence of hypoglycaemia was high (>30%), lowering of glucose levels with linagliptin was not associated with an increase in any of the pre-defined hypoglycaemic event categories (Figure). The incidence risk ratio of any confirmed hypoglycaemic event for linagliptin versus placebo was 0.99 (95% CI 0.79–1.24). Severe hypoglycaemia occurred in 1.3% of linagliptin participants and 1.0% of placebo participants (p=not significant).

Conclusion: These findings support the addition of linagliptin for improving glycaemic control in patients with T2D and RI without increasing the risk for hypoglycaemia.

Major cardiovascular outcomes in the EXAMINE trial according to ACE inhibitor use

W.B. White¹, C.A. Wilson², G.L. Bakris³, R.M. Bergenstal⁴, C.P. Cannon⁵, W.C. Cushman⁶, P.R. Fleck², S.R. Heller⁷, S. Kupfer², C.R. Mehta⁸, V. Menon⁹, S.E. Nissen⁹, A.T. Perez², F. Zannad¹⁰,

¹Calhoun Cardiology Center, University of Connecticut School of Medicine, Farmington, ²Takeda Development Center Americas, Inc, Deerfield, ³Pritzker School of Medicine, The University of Chicago, ⁴Park-Nicollet Clinic, International Diabetes Center, Minneapolis, ⁵Brigham and Women's Hospital, Harvard Medical School, Boston, ⁶University of Tennessee College of Medicine, Memphis Veterans Affairs Medical Center, USA, ⁷University of Sheffield, UK, ⁸Harvard School of Public Health, Boston, ⁹Cleveland Clinic Foundation, Cleveland, USA, ¹⁰Inserm 1143, Université de Lorraine and CHU, Nancy, France.

Background and aims: Activation of the sympathetic nervous system through substance P occurs when there is DPP-4 inhibition (DPP-4i) in the presence of high-dose ACE inhibition (ACEi). This has led to concerns of potential increases in cardiovascular (CV) events when the 2 classes of drugs are used together; hence, we evaluated CV outcomes from the large CV outcomes trial EXAMINE according to ACEi use.

Materials and methods: Patients with type 2 diabetes mellitus (T2DM) with a recent acute coronary syndrome (ACS) were randomly assigned to receive alogliptin or placebo added to existing antihyperglycemic and CV prophylactic therapies. Major CV events were adjudicated by a committee blinded to treatment assignment. Risks of CV death, nonfatal MI and stroke, and hospitalized HF (HHF) were analyzed using a Cox proportional hazards model in patients with and without baseline ACEi.

Results: There were 5380 patients randomized for a median follow-up of 18 months. At baseline, 3323 (62%) EXAMINE patients were using an ACE inhibitor (1681 on alogliptin; 1642 on placebo). The composite rates of CV mortality, nonfatal MI, and nonfatal stroke were similar for alogliptin vs placebo with ACEi (11.4% vs 11.8%; HR=0.97; 95% CI, 0.79-1.19) and without ACEi use at baseline (11.2% vs 11.9%; HR=0.94; 95% CI, 0.72-1.21). CV death or HHF in patients on ACEi use at baseline occurred in 6.8% of patients on alogliptin vs 7.2% on placebo (HR=0.93; 95% CI, 0.72-1.20). In addition, alogliptin showed no effect on HHF alone in ACEi-treated patients (3.3% vs 3.1%; HR=1.09; 95% CI, 0.81-1.48) for alogliptin vs placebo, respectively. There were also no significant differences for these endpoints in patients without ACEi use at baseline. Subgroup analyses according to any prerandomization history of HF and ACEi use at baseline showed the primary endpoint (CV death, MI, and stroke) occurring in 13.9% and 16.5% of patients on alogliptin vs placebo, respectively (HR=0.87; 95% CI, 0.63-1.19) and CV death or

HHF in 12% and 13.2% of patients on alogliptin vs placebo, respectively (HR=1.01; 95% CI, 0.69-1.49).

Conclusion: Cardiovascular outcomes were not different for alogliptin compared with placebo in patients with T2DM and coronary disease treated with ACE inhibitors.

RG-125 (AZD4076): clinical candidate with a novel modality to treat insulin resistance through inhibiting miR-103/107

B. Wagner¹, P. Tran¹, R. Pagarigan¹, S. Neben¹, J. Kim², B. Zarrouki³, P. Andersson³, E.-L. Lindstedt³, A. Turnbull³, D. MacKenna⁴;

¹Regulus Therapeutics Inc., San Diego, ²University of Massachusetts Medical School, Boston, USA, ³Cardiovascular & Metabolic Diseases Innovative Medicines, AstraZeneca, Mölndal, Sweden, ⁴Regulus Therapeutics, San Diego, USA.

Background and aims: Anti-miRs targeting the miR-103/107 family have been shown to improve insulin sensitivity and glucose homeostasis in diet induced obese (DIO) and db/db mice. In vitro and in vivo screening of anti-miR-103/107 oligonucleotides (anti-miRs) led to the identification of RG-125, a GalNAc conjugated anti-miR. The goal of these studies was to evaluate RG-125 potency and efficacy in insulin resistant DIO and db/db mice. In addition a hyperinsulinemic-euglycemic clamp was performed in DIO mice to examine the mechanism by which miR-103/107 inhibition improves insulin sensitivity. RG-125 was also evaluated in mouse and non-human primate (NHP) toxicology studies.

Materials and methods: DIO and db/db mice were dosed s.c. at dose levels noted, once weekly for 3-9 weeks. Oral glucose tolerance tests and weekly fasting glucose and insulin were performed after 6 hour fasting. Clamp studies were performed on conscious, overnight-fasted mice using an indwelling intravenous catheter with operator blinded to dosing group. Exploratory toxicology studies were performed in CD-1 mice and cynomolgus monkeys, dosed s.c. once weekly for 5-6 weeks.

Results: RG-125 induces dose-dependent reductions in weekly fasting blood glucose and plasma insulin in DIO mice, with significant improvements in the homeostatic assessment of insulin resistance (HOMA-IR) at doses as low as 5 mg/kg. There were no effects on body weight. RG-125 normalized glucose tolerance to that of lean controls. Clamp studies in DIO mice confirm the insulin sensitizing effects of miR-103/107 inhibition with RG-125 administration giving clear dose-responsive improvements in both glucose infusion rate and whole body glucose turnover. Decreases in clamped hepatic glucose production along with increased glucose uptake in brown adipose tissue and skeletal muscle indicates that RG-125 improves hepatic and peripheral insulin sensitivity. RG-125 also reversed the extreme hyperglycemia that develops with age in db/db mice. Exploratory toxicology studies in mice and NHP show RG-125 was well tolerated across multiple dose levels and provided insight into GLP study design.

Conclusion: RG-125 (AZD4076), via inhibition of miR-103/107, is a novel insulin sensitizer with proven efficacy across a number of mouse disease models, and good tolerability in both mouse and NHP. These data support clinical development of RG-125 for treatment of type 2 diabetes and associated metabolic disorders.

824

Preclinical pharmacokinetics-pharmacodynamics modelling to guide first-time-in-human studies with the anti-miR-103/107, RG-125 (AZD4076)

M. Sundqvist¹, M. Antonsson¹, B. Zarrouki¹, E.-L. Lindstedt¹, A. Turnbull¹, T. Owen², K. Liu², J. Grundy², B. Wagner²;

¹Cardiovascular & Metabolic Diseases Innovative Medicines, AstraZeneca, Mölndal, Sweden, ²Regulus Therapeutics, San Diego, USA.

Background and aims: MicroRNAs (miR) are short, non-coding RNA sequences controlling the expression of multiple genes by mRNA

degradation or post-transcriptional regulation. In humans, hepatic expression of miR-103/107 is increased in patients with fatty liver disease and correlates with insulin resistance. In rodent models of insulin resistance and diabetes, inhibition of miR-103/107 alleviates insulin resistance and reduces hyperglycemia. RG-125, a novel anti-miR-103/107 GalNAc-conjugated oligonucleotide, increases insulin sensitivity in the diet-induced obesity mouse model (DIO). By using pharmacokinetic-pharmacodynamic modelling to integrate all preclinical data we predicted human dose and time-course of response.

Materials and methods: RG-125 was administered s.c. once weekly at multiple dose levels to mouse (50–450 mg/kg) and non-human primate (NHP; 5–150 mg/kg) in combined pharmacokinetic and toxicology studies. A mathematical pharmacokinetic model was fitted, describing both plasma and liver exposure for parent drug and its metabolites in mouse and NHP. In a separate series of studies, RG-125 was dosed once weekly s.c. in DIO mice (1.7–45 mg/kg) and plasma glucose and insulin were measured over time to assess potency and efficacy. The homeostatic model assessment of insulin resistance (HOMA-IR) response in DIO mice was calculated from glucose and insulin, and fit to a turnover model, taking the animal disease progression into account.

Results: A pharmacokinetic model including saturated uptake into liver, predicted observed plasma and liver concentrations of the combined RG-125 active metabolites in the evaluated animal species well, justifying an allometric approach to predict human pharmacokinetic parameters. The pharmacodynamic model liver IC_{80} parameter estimate was 8.4 μ M (95% confidence interval: 6–12 μ M) in DIO mice and assumed applicable to humans. Allometric scaling was further implemented on the pharmacodynamic model to predict human response over time. The observed time to achieve 50% maximal inhibitory response in RG-125 treated DIO mice (~5 days) was extrapolated to humans (~30 days), based on reported glucose turnover half-life values in mouse (~3 days) and human (~19 days) studies with thiazolidinediones. The model predicted human therapeutic s.c. dose of RG-125 was predicted to be 70 mg once weekly and which will need to be confirmed in clinical testing.

Conclusion: RG-125 (AZD4076) causes robust insulin sensitization in DIO mice and is an attractive candidate to investigate effects on insulin sensitization in man. The human PKPD model, albeit assumption-rich, could be further used to guide the design of safety studies as well as early clinical trials, impacting both duration and dosing regimen.

GMC-252 Lysine Salt, a conjugate of the anti-inflammatory diflunisal and the antioxidant N-acetylcysteine, shows anti-diabetic effects in db/db mice

S. García Vicente¹, L. Martí¹, M. Serrano Muñoz¹, D. Pérez Cáceres², A. Zorzano^{3,4},

¹Genmedica Therapeutics S.L., Esplugues de Llobregat, ²Servei d'Experimentació Animal, Universitat de Barcelona. Facultat de Farmàcia, ³Departament de Bioquímica i Biologia Molecular, Universitat de Barcelona. Facultat de Biologia., Esplugues de Llobregat, ⁴Institute for Research in Biomedicine (IRB Barcelona), Spain.

Background and aims: Chronic inflammation is seen to be involved in the pathogenesis of insulin resistance and type 2 diabetes. Oxidative stress is the common factor underlying insulin resistance, type 2 diabetes and cardiovascular disease, which helps to explain the presence of inflammation in all these conditions. Here we investigate the anti-diabetic effects of GMC-252, a conjugate, which allows the sustained release of the anti-inflammatory Diflunisal and the antioxidant N-acetylcysteine, in db/db mice.

Materials and methods: 5-weeks old BKS(D)-Lepr^{db}/JOrlRj mice (db/db) were administered orally daily with GMC-252 Lysine Salt (0.5 mmol/kg/day) or vehicle (PBS-Tween 20 0.1%) for 28 days. Non-fasting glycemia, body weight, food and fluid intake were measured every 2–3 days.

GTT and ITT test were performed before the end of the treatment. C-Peptide, insulin, HbA1c, plasma lipids, pancreatic insulin content and pancreatic morphology were analyzed at the end of the treatment.

Results: After 4 weeks of treatment, db/db mice treated with GMC-252 Lysine Salt showed an increase in glycemic control (reduction in non-fasting glycemia and HbA1c). There was also an improvement in pancreatic function (increases of plasma insulin, plasma c-peptide and pancreatic insulin content). Pancreata morphology analysis revealed increased insulin immunostaining signal (1.75 fold; $P < 0.05$) and islet size (1.62 fold; $P < 0.05$) due to GMC-252 treatment. There was also a decrease in plasma Free Fatty Acids and plasma Triglycerides but plasma total cholesterol was not modified (see Table 1). Moreover, GMC-252 oral chronic treatment does not affect animal weight. We observed in GMC-252 treated mice an improvement in glucose tolerance in the glucose tolerance test ($P < 0.05$) and the action of insulin lasted longer during the insulin tolerance test ($P < 0.05$).

Conclusion: In conclusion, GMC-252, a conjugate formed by the anti-inflammatory Diflunisal and the antioxidant N-acetylcysteine, showed anti-diabetic effects in db/db mice. This indicates that co-targeting inflammation and oxidative stress could be a new therapeutic approach for the treatment of type 2 diabetes.

	db/db + vehicle (n = 10)	db/db + GMC-252 (n = 9)	P-Value

Metabolic effects of dietary supplementation with *Lactobacillus reuteri* DSM 17938: a randomised proof-of-concept study in type 2 diabetes

R. Mobini¹, P. Kovatcheva¹, V. Tremaroli¹, F. Karlsson², M. Levin³, M. Ljungberg⁴, M. Sohlin⁴, H. Bertéus Forslund⁵, M. Ståhlman¹, E. Connolly⁶, F. Bäckhed¹, P.-A. Jansson¹;

¹Department of Molecular and Clinical Medicine, University of Gothenburg, ²Department of Chemical and Biological Engineering, Chalmers University of Technology, ³Department of Oncology, University of Gothenburg, ⁴Department of Radiation Physics, University of Gothenburg, ⁵Department of Internal Medicine, University of Gothenburg, ⁶BioGai, Stockholm, Sweden.

Background and aims: Growing clinical evidence bridges composition of the human gut microbiota to metabolic diseases. However, very few randomised controlled trials (RCT) have addressed the effect of probiotics on metabolic outcomes in type 2 diabetes (T2D) patients. We conducted a RCT in T2D patients and evaluated metabolic effects after oral supplementation with *Lactobacillus reuteri* DSM 17938 (LR).

Materials and methods: Forty-six insulin treated T2D patients participated in a double-blind and placebo-controlled trial and were randomised to one of three parallel groups receiving daily either placebo (n=15, 11 M/4 F, Age: 65±5 years, BMI: 31.2±4.0 kg/m², HbA1c: 60.4±1.5 mmol/mol and total insulin dose: 67±52 U/day, Mean ± SD), a low dose of LR (10⁸ Colony Forming Unit (CFU), n=16, 12 M/4 F, Age: 65±6, BMI: 31.3±4.0, HbA1c: 61.5±1.5 and total insulin dose: 41±25) or a high dose of LR (10¹⁰ CFU, n=15, 12 M/3 F, Age: 64±6, BMI: 32.5±3.0, HbA1c: 66.4±2.2 and total insulin dose: 51±37). We assessed metabolic control by HbA1c, fat distribution by CT scan, liver steatosis by MRI, insulin sensitivity by a euglycemic hyperinsulinemic glucose clamp (120 mU/m²/min), fat cell size by subcutaneous needle biopsy, dietary

registration by a validated questionnaire and fecal microbiota composition by sequencing of the 16S rRNA gene at the baseline and 12 weeks after treatment in an intention to treat analysis.

Results: The study groups differed in HbA1c at baseline but showed similar anthropometry and pharmacological treatment (oral hypoglycemic agents in addition to insulin were metformin≈80% and sulfonylurea≈20%). We observed no difference in HbA1c, BMI, fat distribution, liver steatosis, calorie intake and microbiota composition when comparing baseline and follow-up after 12 weeks within or between the placebo (P), low dose (L) or high dose (H) LR groups. However, patients treated with the high dose LR increased the insulin sensitivity index (1.41 ± 0.16 vs $1.76 \pm 0.24 \times 100 \times \text{mg} \times \text{L} \times \text{kg}^{-1} \times \text{min}^{-1} \times \text{mU}^{-1}$, mean±SEM, $p < 0.05$, Wilcoxon signed rank test). While fat cell size increased in the placebo group (81 ± 2 vs $88 \pm 1 \mu\text{m}$, mean±SEM, $p < 0.05$, $n = 11$), we observed a tendency to decreased fat cell size in the high LR dose group (84 ± 3 vs $81 \pm 4 \mu\text{m}$, $p = 0.09$, $n = 9$). Finally, we observed a trend for an increased serum adiponectin at follow-up in the high LR dose group (7.6 ± 1.5 vs $8.4 \pm 1.6 \text{ mg/L}$, mean±SEM, $p = 0.06$, $n = 14$).

Conclusion: Dietary supplementation with *Lactobacillus reuteri* DSM 17938 for 12 weeks did not improve HbA1c in insulin treated T2D patients. However, insulin sensitivity in skeletal muscle and adipose tissue significantly increased in patients treated with the highest dose of *Lactobacillus reuteri*.

Effect of *Gymnema sylvestris* administration on metabolic syndrome, insulin sensitivity and insulin secretion

E. Martínez-Abundis, L.Y. Zuñiga, M. González-Ortiz;

Institute of Experimental and Clinical Therapeutics, University of Guadalajara, Mexico.

Background and aims: The metabolic syndrome (MetS) is a cluster of most dangerous heart attack risk factors: diabetes mellitus type 2 and prediabetes, abdominal obesity, high cholesterol and high blood pressure. A quarter of the world's adults have MetS in Mexico 49.8%. *Gymnema sylvestris* indigenous herb, belonging to the class dicotyledonous of Asclepiadaceae. Although the herb is widely used as a naturopathic treatment for diabetes, it also demonstrates promising effects in the treatment of obesity, dyslipidemia, hypertension, insulin secretion, among others. The above-mentioned findings show that *Gymnema sylvestris* has an excellent potential for the prevention and treatment of MetS. The aim of this study was to evaluate the effect of *Gymnema sylvestris* administration on MetS, insulin sensitivity, and insulin secretion.

Materials and methods: A randomized, double-blind, placebo-controlled clinical trial was carried out in 24 patients with a diagnosis of MetS in accordance with the modify International Diabetes Federation criteria. After simple random allocation using a random number list, 12 patients received *Gymnema sylvestris* capsules (300 mg), two times per day before breakfast and dinner for 90 days. The remaining 12 patients received placebo at the same dose and the same pharmacological presentation. Before and after intervention we evaluated: the components of MetS, body weight, body mass index, total cholesterol, low-density lipoprotein, very-low-density lipoprotein. We calculated: area under the curve of glucose and insulin, Insulinogenic index, Stumvoll index, and Matsuda index.

Results: The placebo group showed significant increase in body weight (78.8 ± 16.1 vs. $80.3 \pm 18.2 \text{ kg}$, $p = 0.01$), body mass index (30.3 ± 3.2 vs. $30.7 \pm 3.8 \text{ kg/m}^2$, $p = 0.03$), waist circumference (98.3 ± 13.6 vs. $100.5 \pm 14.7 \text{ cm}$, $p = 0.01$), low density lipoprotein (82 ± 23 vs. $107 \pm 21 \text{ mg/dl}$, $p = 0.01$), area under the curve of insulin (10719 ± 5819 vs. $15136 \pm 7556 \mu\text{U/min}$, $p = 0.01$), Insulinogenic index (0.61 ± 0.33 vs. 0.95 ± 0.66 $p = 0.01$), as well as an decrease in the Matsuda index (3.3 ± 1.9 vs. 2.5 ± 1.4 , $p = 0.02$).

After *Gymnema sylvestris* administration, there were significant decrease in body weight (81.3 ± 10.6 vs. $77.9 \pm 8.4 \text{ kg}$, $p = 0.02$), body mass index (31.24 ± 2.55 vs. $30.43 \pm 2.23 \text{ kg/m}^2$, $p = 0.02$) and very low density lipoprotein (40 ± 13 vs. $31 \pm 13 \text{ mg/dl}$, $p = 0.05$).

Conclusion: *Gymnema sylvestris* decreased body weight, body mass index and the low density lipoprotein in patients with MetS, likewise, in counterpart with placebo, *Gymnema sylvestris* prevented decrease in insulin sensitivity and compensatory hyperinsulinemia in this population.

Clinical Trial Registration Number: NCT02370121

Insulin-sensitising effects of methysulfonolymethane (MSM), an organosulfur compound, in insulin-resistant obese mice

I.S. Lima¹, S. Park², J. Seo¹, M. Chung¹, L. Moura¹, M. Macedo³, Y.-B. Kim¹;

¹Division of Endocrinology, Diabetes and Metabolism, Beth Israel Deaconess Medical Center, ²Boston Children's Hospital, Boston, USA, ³CEDOC Nova Medical School, Lisboa, Portugal.

Background and aims: Methysulfonolymethane (MSM) is an organosulfur compound present in plants. MSM has been used as a supplement to improve various metabolic-related diseases, including joint inflammation, osteoarthritis, rheumatoid arthritis, osteoporosis, musculoskeletal pain, and chronic pain. However, the effects of MSM treatment on obesity-linked metabolic disorders remains unclear. The aim of this work was to determine whether MSM therapy ameliorates glucose metabolism and insulin resistance.

Materials and methods: Male leptin receptor-deficient (db/db, 6 weeks of age) and control mice were treated with MSM (3-5% m/v) in drinking water for 4 weeks. Male C57 mice (5 weeks of age) fed a high-fat diet (HFD) were treated with MSM (2.5-5% m/v) for 10 weeks. Insulin sensitivity and glucose tolerance were assessed; body weight and glucose levels were monitored. Hepatic and serum content in triglycerides and cholesterol and gene expression of key molecules involved in lipid metabolism and inflammation were determined. Hematoxylin and eosin stain (H&E stain) of liver sections from control, db/db and HFD mice was performed.

Results: Four weeks of MSM treatment decreased blood glucose levels from $516 \pm 18.79 \text{ mg/dl}$ (before treatment) to $242.3 \pm 41.78 \text{ mg/dl}$ (after treatment) in db/db mice ($p < 0.001$), suggesting effects for glucose-lowering action. Interestingly, this effect occurred in the presence of hyperinsulinemia ($6.349 \pm 1.121 \text{ ng/mL}$ for untreated versus $12.59 \pm 1.204 \text{ ng/mL}$ for treated db/db mice, $p < 0.001$). Histological analysis indicated that hepatic steatosis was decreased in MSM-treated db/db mice. This was consistent with a reduction in hepatic triglyceride ($263.8 \pm 34.46 \text{ mg/dL}$ for untreated versus $137.6 \pm 10.96 \text{ mg/dL}$ for treated db/db mice, $p < 0.01$) and cholesterol ($231.2 \pm 29.45 \text{ mg/dL}$ for untreated versus $144.4 \pm 9.131 \text{ mg/dL}$ for treated db/db mice, $p < 0.01$) levels. MSM treatment also promoted a decrease in serum triglycerides ($171.1 \pm 12.84 \text{ mg/dL}$ for untreated versus $105.6 \pm 4.975 \text{ mg/dL}$ for treated db/db mice, $p < 0.01$) and cholesterol ($109.0 \pm 3.591 \text{ mg/dL}$ for untreated versus $79.97 \pm 15.89 \text{ mg/dL}$ for treated db/db mice, $p < 0.05$). In mice fed a high-fat diet (HFD), 10 weeks of MSM treatment led to a decrease in insulin ($10.40 \pm 1.183 \text{ ng/mL}$ for HFD versus $3.285 \pm 1.168 \text{ ng/mL}$ for treated HFD mice, $p < 0.01$) and glucose ($152.4 \pm 6.743 \text{ mg/dL}$ for HFD versus $128.2 \pm 3.364 \text{ mg/dL}$ for treated HFD mice, $p < 0.01$) levels. Importantly, MSM treated HFD-fed mice displayed hypersensitivity to insulin, indicating that MSM has insulin-sensitizing effect. In response to MSM, hepatic triglyceride ($21.19 \pm 0.9239 \text{ mg/g}$ of tissue for HFD versus $16.76 \pm 0.3724 \text{ mg/g}$ of tissue for treated HFD mice, $p < 0.01$) and cholesterol ($6.780 \pm 0.3642 \text{ mg/g}$ of tissue for HFD versus $4.906 \pm 0.5015 \text{ mg/g}$ of tissue for treated HFD mice, $p < 0.05$) contents were decreased in HFD fed mice. This was associated with a reduction in lipogenic gene expression of FAS and ACC. In addition, gene expression of key molecules

involved in inflammation, MCP1, TNF-alpha, and IL-6, were greatly suppressed by MSM.

Conclusion: These data suggest that MSM has beneficial metabolic effects on hyperglycemia, insulin resistance, and hepatic steatosis, all of which are often found in obesity and type 2 diabetes. Thus, MSM could be the therapeutic option for the treatment of metabolic disorders.

TAZ modulator, TM-25659-induced activation of FGF21 levels decreases insulin resistance

J. Jeon¹, S.-E. Choi², J. Jung³, S.-A. Lee³, Y. Kang², M. Bae⁴, J. Ahn⁴, H. Jeong⁵, E. Hwang⁵, S. Han⁵, H. Kim³, T. Kim⁶, S.-Y. An⁷, D. Kim³, K.-W. Lee³;

¹Endocrinology and Metabolism, Ajou University Hospital, ²Physiology, Ajou University Hospital, Suwon, ³Endocrinology and metabolism, Ajou University Hospital, Suwon, ⁴Korea Research Institute of Chemical Technology, University of Science & Technology, ⁵College of Pharmacy, Graduate School of Pharmaceutical Sciences, and Global Top5 Research Program, Ewha Womans University, Seoul, ⁶Division of Endocrine and Metabolism, Department of Internal Medicine, Seoul Medical Center, ⁷Endocrinology and Metabolism, Hongik Hospital, Seoul, Republic of Korea.

Background and aims: Transcriptional co-activator with PDZ binding motif (TAZ) plays a key role in regulating myogenic differentiation and muscle regeneration. In this study, we investigated the effects of TAZ on palmitate-induced insulin resistance.

Materials and methods: The effects of TAZ on palmitate-induced insulin resistance were investigated using TM-25659 to modulate TAZ, C2 myotubes, and C57BL/6J mice. And, we investigated the relationship between the expressions of FGF21 and TM-25659 using immunoblotting and quantitative real-time PCR. To elucidate the mechanism of action of TM-25659, we measured the levels of the pro-inflammatory cytokines TNF- α , IL-1- β , IL-6, and MCP-1, as well as FGF21. We also measured the secretion of FGF21 from cells into the cytosol after treatment with TM-25659. To determine whether TM-25659 exerted the same effects *in vivo*, C57BL/6J mice were injected intraperitoneally with either vehicle or TM-25659 every other day for 1 week. Finally skeletal muscle cells were transfected with FGF21 siRNA, and FGF21 levels and the effects of TM-25659 on palmitate-induced insulin resistance were measured.

Results: Palmitate reduced the phosphorylation of Akt, thereby impairing insulin signaling and eventually leading to reduced glucose uptake in C2 myotubes. However, treatment with TM-25659, which stimulates TAZ, blocked palmitate-inhibited glucose uptake and insulin signaling significantly. Different doses of TM-25659 inhibited the production of pro-inflammatory cytokines and induced FGF21 mRNA and protein levels. TM-25659 increased FGF21 RNA and protein levels significantly in the skeletal muscle. TM-25659 could not rescue cells from palmitate-induced insulin resistance when FGF21 had been knocked down. Therefore, the TAZ activator TM25659 protected palmitate-induced insulin resistance via FGF21.

Conclusion: The present study suggests that TM-25659 might have therapeutic potential as a treatment for insulin resistance and diabetes by inducing FGF21 expression.

Effect of lobeglitazone, a new PPAR-gamma agonist, on restenosis after balloon injury in diabetic rats

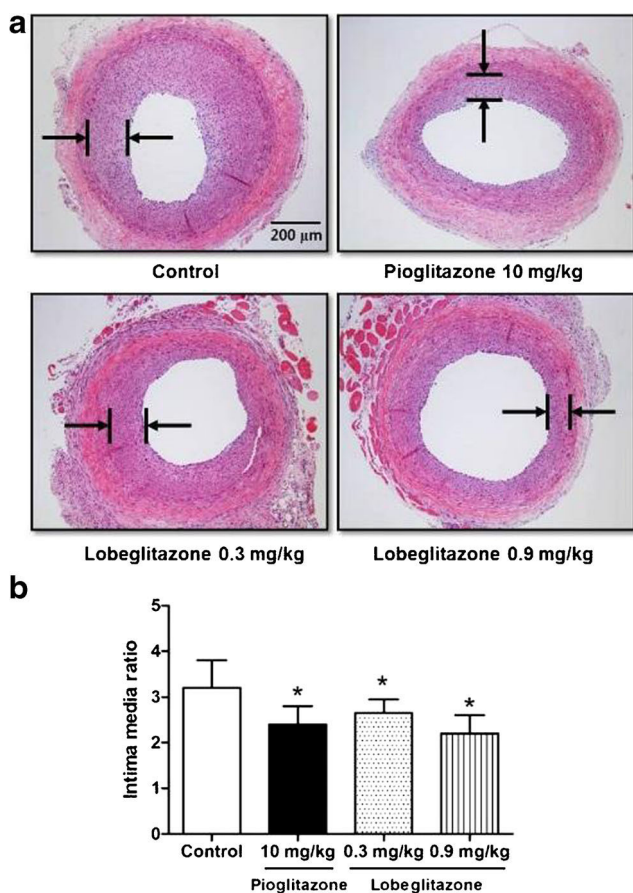

K. Kim, S. Lim, J. Lee, S. Choi, K. Park, H. Jang;
Internal Medicine, Seoul National University College of Medicine, Seongnam, Republic of Korea.

Background and aims: The ligand-activated transcription factor peroxisome proliferator-activated receptor gamma (PPAR γ) is a key factor in adipogenesis, insulin sensitivity, and cell cycle regulation. Activated PPAR γ might also have anti-inflammatory and antiatherogenic properties. We tested whether lobeglitazone, a PPAR γ agonist, might protect against atherosclerosis.

Materials and methods: A rat model of balloon injury to the carotid artery, and high-fat, high-cholesterol diet-fed apolipoprotein E gene double knockout (ApoE $^{-/-}$) mice were studied.

Results: After the balloon injury, lobeglitazone treatment (0.3 and 0.9 mg/kg) caused a significant decrease in the intima-media ratio compared with control rats (2.2 \pm 0.9, 1.8 \pm 0.8, vs. 3.3 \pm 1.2, P<.01) (figure 1). Consistent with this, in ApoE $^{-/-}$ mice fed a high-fat diet, lobeglitazone treatment (1, 3, and 10 mg/kg) for 8 weeks reduced atherosclerotic lesion sizes in the aorta compared with the control mice in a dose-dependent manner. Treatment of vascular smooth muscle cells with lobeglitazone inhibited proliferation and migration and blocked the cell cycle G0/G1 to S phase progression dose-dependently. In response to lobeglitazone, tumor necrosis factor alpha (TNF α)-induced monocyte-endothelial cell adhesion was decreased by downregulating the levels of adhesion molecules. TNF α -induced nuclear factor kappa-B (NF- κ B) p65 translocation into the nucleus was also blocked in endothelial cells. Insulin resistance was decreased by lobeglitazone treatment. Circulating levels of high sensitivity C-reactive protein and monocyte chemoattractant protein-1 were decreased while adiponectin levels were increased by lobeglitazone in the high-fat diet-fed ApoE $^{-/-}$ mice.

Conclusion: Lobeglitazone has antiatherosclerotic properties and has potential for treating patients with diabetes and cardiovascular risk.

Insulin degludec/liraglutide (IDegLira) improves patient-reported outcomes in subjects with type 2 diabetes uncontrolled on insulin glargine + metformin: DUAL V

I. Lingvay¹, F.C. Pérez Manghi², P.A. García-Hernández³, P. Norwood⁴, H. Jarlov⁵, J.H. Kongsø⁵, M. Brod⁶,
¹UT Southwestern Medical Center, Dallas, USA, ²CINME, Buenos Aires, Argentina, ³Hospital Universitario de Monterrey, Mexico, ⁴Valley Research, Fresno, USA, ⁵Novo Nordisk A/S, Søborg, Denmark, ⁶The Brod Group, Mill Valley, USA.

Background and aims: This 26-week, open-label trial compared the efficacy and safety of IDegLira vs insulin glargine (IGlar) in subjects with type 2 diabetes inadequately controlled on IGlar (20–50U).

Materials and methods: Adults (n=557, HbA_{1c} 7–10%) were randomised to either once-daily IDegLira or continued IGlar upitration, both + metformin. Initial doses were 16 dose steps (16U insulin degludec + 0.6 mg Liraglutide; maximum 50 dose steps) for IDegLira and pre-trial dose for IGlar (baseline mean 32U; no maximum). Fasting self-measured blood glucose titration target was 4.0–5.0 mmol/L for both arms. Patient-reported impact of treatment on functioning and well-being were assessed by TRIM-D and SF-36 v2. Scores were analysed using an ANCOVA method with treatment and region as fixed factors and baseline value as a covariate. Missing data were imputed using last observation carried forward.

Results: TRIM-D scores were summed from 5 subdomains and weighed together to give total score. Change from baseline was higher with IDegLira vs IGlar for total score (p=0.003) as well as the treatment burden (p=0.017) and diabetes management (p<0.001) subdomains (Table). The SF-36 validated multi-purpose questionnaire is grouped into 8 domains, including a physical component summary (PCS) score and mental component summary (MCS) score. The improvements in PCS (p<0.001) and 3 of the physical domain scores were significantly greater with IDegLira vs IGlar. The MCS and the mental domain scores were similar for both arms.

Conclusion: The statistical significant changes in the TRIM-D total score and SF-36 PCS score, indicate that patients with type 2 diabetes treated with IDegLira versus IGlar observed more improvement in their treatment-related impact as well as physical functioning.

	IDegLira Baseline (SD)	IGlar Baseline (SD)	IDegLira Change from baseline (SD)	IGlar Change from baseline (SD)	Treatment difference IDegLira – IGlar [95% CI]	p-value

Assessment of glycaemic control by continuous glucose monitoring in patients with type 2 diabetes treated with IDegLiraT. Vilsbøll¹, A. Philis-Tsimikas², E.S. Kilpatrick³, I.H. Langbakke⁴, K. Begtrup⁴, A.B. King⁵;¹Gentofte Hospital, Copenhagen, Denmark, ²Diabetes Care Center, San Diego, USA, ³Hull Royal Infirmary/Hull York Medical School, UK, ⁴Novo Nordisk A/S, Søborg, Denmark, ⁵Diabetes Care Center, Salinas, USA.**Background and aims:** This post-hoc analysis of the DUAL I trial examined glycaemic fluctuations and day-to-day variability with a novel, once-daily combination of insulin degludec (IDeg) and liraglutide (Lira) compared with IDeg or Lira alone.**Materials and methods:** Seventy-two hour continuous glucose monitoring (CGM) was performed in a subset of patients (type 2 diabetes [T2D] uncontrolled on metformin±pioglitazone; oral anti-diabetic drug use balanced across treatment groups; N=260) in DUAL I, a 52-week trial in which IDegLira reduced HbA1c (1.8%) more than IDeg (1.4%, $p < 0.0001$) or Lira alone (1.2%, $p < 0.0001$).**Results:** Mean interstitial glucose (IG) decreased more with IDegLira vs. Lira ($p < 0.0001$), while IDeg produced a similar reduction (Table). Significantly lower IG fluctuations (adjusted integrated absolute distance from the mean profile, i.e. flatness of IG profile, $p = 0.0018$) and postprandial IG increments across all meals ($p = 0.0288$) were observed with IDegLira vs. IDeg. Time outside the IG target range was lower with IDegLira vs. Lira ($p = 0.0072$). Day-to-day IG variability (SD of daily [24 h] mean) was similar with IDegLira vs. IDeg or Lira.**Conclusion:** IDegLira shifted the glucose profile downwards compared with Lira and flattened the profile compared with IDeg. Day-to-day glycaemic variability was low and similar between IDegLira, Lira and IDeg. These complementary actions on fasting and postprandial glucose narrow the overall range of glucose excursion and produce HbA1c levels lower than those routinely achieved in the management of T2D.

Table: Glycaemic fluctuation and variability in patients with type 2 diabetes treated for 52 weeks

CGM parameter		IDegLira (N=131)	IDeg (N=64)	Estimated treatment difference IDegLira vs IDeg	Lira (N=65)	Estimated treatment difference IDegLira vs Lira
Mean IG (mmol/l)	Mean at baseline (N) Mean Δ , w52 (N)	10.2 (104) -3.5 (72)	10.2 (53) -3.6 (34)	0.0 $p = \text{NS}$	10.0 (52) -2.5 (37)	-1.0 $p < 0.0001$
IG fluctuation (mmol/l)	Geometric mean at baseline (N)	1.5 (104)	1.6 (53)	Ratio: 0.8 $p = 0.0018$	1.5 (52)	Ratio: 1.0 $p = \text{NS}$
	Geometric mean at w52 (N)	1.0 (83)	1.3 (35)		1.1 (42)	
Postprandial IG increment (90 min, mmol/l)	Mean at baseline (N) Mean Δ , w52 (N)	1.4 (101) -0.5 (68)	1.4 (50) 0.2 (31)	-0.5 $p = 0.0288$	1.5 (50) -0.2 (34)	-0.2 $p = \text{NS}$
Time (hours/day) outside IG target range (<3.9 to ≥ 9.0 mmol/l)	Mean at baseline (N) Mean at w52 (N)	14.7 (104) 3.2 (83)	14.8 (53) 3.8 (35)	-0.7 $p = \text{NS}$	13.2 (52) 5.6 (42)	-2.2 $p = 0.0072$
Day-to-day IG variability (SD of daily [24 hours] mean, mmol/l)	Mean at baseline (N) Mean at w52 (N)	0.8 (104) 0.6 (83)	1.0 (53) 0.6 (35)	-0.1 $p = \text{NS}$	0.8 (52) 0.5 (42)	0.1 $p = \text{NS}$

CGM parameters are analysed based on observed data using an ANOVA method with treatment, region, baseline HbA_{1c}, stratum ($\leq 8.3\%$, $> 8.3\%$) and previous OAD treatment as fixed effects. Fluctuation is log-transformed before analysis. ANOVA, analysis of variance; CGM, continuous glucose monitoring; IDeg, insulin degludec; IDegLira, combination of insulin degludec and liraglutide; IG, interstitial glucose; Lira, liraglutide; OAD, oral anti-diabetic drug; SD, standard deviation; w, week.

Similar incidence of gastrointestinal side effects between IDegLira and non-glucagon-like peptide-1 receptor agonist comparatorsV. Aroda¹, E. Jaekel², H. Jarlov³, T.J. Abrahamson³, T. Vilsbøll⁴;¹MedStar Health Research Institute, Hyattsville, USA, ²Hannover Medical School, Germany, ³Novo Nordisk A/S, Søborg, Denmark, ⁴Gentofte Hospital, University of Copenhagen, Denmark.**Background and aims:** IDegLira is a novel, fixed-ratio combination of insulin degludec (IDeg), a basal insulin with an ultra-long duration of

action, and liraglutide (Lira), a glucagon-like peptide-1 (GLP-1) receptor agonist (GLP-1RA). This combination has previously demonstrated advantages in glycaemic control compared with basal insulin and GLP-1 therapy alone. In this post-hoc analysis, gastrointestinal side effects, often associated with GLP-1RAs during the first 12 weeks of treatment (Figure 1), were compared between IDegLira and non-GLP-1RA comparators.

Materials and methods: This is a post-hoc analysis of two double-blind, 26-week, phase 3 trials: (DUAL IV: IDegLira vs. placebo in patients inadequately controlled on oral antidiabetic drugs [OADs]; and DUAL II: IDegLira vs. IDeg in patients inadequately controlled on basal insulin and OADs) in which IDegLira was initiated at 10 and 16 dose steps, respectively (1 dose step=1 unit of IDeg and 0.036 mg Lira). We compared the proportion of patients experiencing gastrointestinal (GI) side effects.**Results:** The GI side effects are presented in Figure 1. There was no statistically significant difference in the odds of experiencing GI side effects for subjects on IDegLira vs. pooled comparators at weeks 4, 8, 12 or during the entire trial period (odds ratios, DUAL II: 2.0, 1.1, 1.1, 2.0; DUAL IV: 1.0, 2.0, 0.4, 0.9, respectively).**Conclusion:** In double-blinded studies, a similar proportion of patients treated with IDegLira experienced GI side effects compared with IDeg or placebo. This may be explained by the slow and steady titration of IDegLira which appears to improve tolerability vs. GLP-1RA therapy, while also improving glycaemic control.**Figure 1.** Incidence of nausea, vomiting or diarrhoea in DUAL II and IV. Lira arm from DUAL I (unblinded 26 wk trial of IDegLira vs IDeg and Lira) included for comparison only.

Efficacy and safety of IDegLira (combination of insulin degludec + liraglutide), in insulin-naïve patients with type 2 diabetes uncontrolled on GLP-1 receptor agonist (GLP-1RA) therapyS. Linjawi¹, B.W. Bode², L.B. Chaykin³, J.-P. Courreges⁴, Y. Handelsman⁵, L.M. Lehmann⁶, A. Mishra⁷, R.W. Simpson⁸;¹Coffs Endocrine & Diabetes Services, Coffs Harbour, Australia, ²Atlanta Diabetes Associates, Atlanta, USA, ³Meridian Research, Bradenton, USA, ⁴Diabetology and Vascular Disease Unit, General Hospital, Narbonne, France, ⁵Metabolic Institute of America, Tarzana, USA, ⁶Novo Nordisk A/S, Søborg, Denmark, ⁷Novo Nordisk A/S, Bangalore, India, ⁸Monash University and Eastern Health, Box Hill, Australia.**Background and aims:** Due to the progressive nature of type 2 diabetes (T2D) most patients will require treatment intensification. This phase 3 trial aimed to investigate the efficacy of IDegLira (a combination of insulin degludec and liraglutide) in controlling glycaemia in adults with T2D who were inadequately controlled on a glucagon-like peptide-1 receptor agonist (GLP-1RA) and oral anti-diabetic drugs (OADs).

Materials and methods: In this 26-week open-label trial, adults with T2D uncontrolled on maximum dose GLP-1RA therapy (liraglutide once daily [OD] or exenatide twice daily) + metformin ± pioglitazone ± sulphonylurea were randomised 2:1 to IDegLira OD (n=292) or continue unchanged GLP-1RA therapy (n=146); previous OADs were continued. **Results:** Mean HbA_{1c} decreased from baseline (7.8%/7.7%) to 6.4% (IDegLira) and 7.4% (unchanged GLP-1RA) (estimated treatment difference -0.94%, p<0.001). 75% of patients on IDegLira achieved HbA_{1c} <7% vs. 36% on unchanged GLP-1RA (p<0.001); 63% on IDegLira vs. 23% on unchanged GLP-1RA attained HbA_{1c} ≤6.5% (p<0.001). Fasting plasma glucose and 9-point self-measured blood glucose profiles improved significantly more with IDegLira than unchanged GLP-1RA (Table). Weight change was +2.0 kg with IDegLira and -0.8 kg with unchanged GLP-1RA. Confirmed hypoglycaemia rates were low (Table) but higher with IDegLira vs. unchanged GLP-1RA. Mean IDegLira dose at 26 weeks was 43 dose steps (i.e. 43 U insulin degludec, 1.55 mg liraglutide). Safety profile of IDegLira was consistent with previous findings; both treatments were well tolerated.

Conclusion: Consistent with previous findings on GLP-1RA intensification with insulin-containing therapy, IDegLira provided superior glycaemic control vs. unchanged GLP-1RA and represents an efficacious approach to intensifying therapy in patients with T2D uncontrolled on GLP-1RAs.

IDegLira in insulin-naïve patients with type 2 diabetes (T2D) inadequately controlled on sulphonylureas (SU) alone or combined with metformin: The DUAL IV Study

H.W. Rodbard¹, B.W. Bode², S. Harris³, L. Rose⁴, L.M. Lehmann⁵, H. Jarlov⁵, J. Thurman⁶;

¹Endocrine and Metabolic Consultants, Rockville, ²Atlanta Diabetes Associates, USA, ³Centre for Studies in Family Medicine, University of Western Ontario, London, Canada, ⁴Institut für Diabetesforschung Münster GmbH, Münster, Germany, ⁵Novo Nordisk A/S, Søborg, Denmark, ⁶SSM Medical Group, Saint Charles, USA.

Background and aims: This 26-week, multinational, double-blind study assessed the efficacy and safety of an insulin degludec/liraglutide combination (IDegLira) in adults (n=435) with T2D (HbA_{1c} 7.0–9.0%).

Materials and methods: Patients were randomised 2:1 to receive once-daily IDegLira or placebo added to SU±metformin, and started at 10 dose

steps (10 units IDeg/0.36 mg Lira), with titration to a fasting glycaemic target of 4.0–6.0 mmol/L.

Results: Mean HbA_{1c} decreased from 7.9% (both groups) to 6.4% with IDegLira and to 7.4% with placebo, (estimated difference -1.02%, p<0.001). HbA_{1c} <7% was achieved by 79.2% of IDegLira patients vs. 28.8% receiving placebo, odds ratio 11.95, p<0.001 (for HbA_{1c} ≤6.5%: 64.0% vs. 12.3%, odds ratio 16.36, p<0.001). Mean fasting plasma glucose decreased from 9.1 mmol/L (both groups) to 6.5 mmol/L with IDegLira and to 8.8 mmol/L with placebo, (estimated difference -2.3 mmol/L, p<0.001). At 26 weeks, a self-monitored 9-point blood glucose profile showed reductions in the profile mean of 2.2 vs. 0.7 mmol/L with IDegLira and placebo, respectively (estimated difference in mean glucose of -1.6 mmol/L, p<0.001). Blood glucose was significantly lower with IDegLira at all 9 time-points (post-hoc analysis). Mean IDegLira dose at 26 weeks was 28 dose steps (28 units IDeg/1.0 mg Lira). Confirmed hypoglycaemia (severe or plasma glucose <3.1 mmol/L) occurred in 41.7% and 17.1% of IDegLira- and placebo-treated patients, respectively, with rates of 3.5 vs. 1.4 events/patient year (estimated rate ratio: 3.74, p<0.001). Mean weight change was +0.5 kg with IDegLira vs. -1.0 kg with placebo (estimated difference 1.48 kg, p<0.001). The rate of serious adverse events was higher in the IDegLira group than in the placebo group (20.3 vs. 8.0 per 100 patient-years of exposure) without any obvious patterns in the type of events.

Conclusion: IDegLira significantly improved glycaemic control in combination with SU. Hypoglycaemia rates were low, but given the use of SUs, more common than in previous trials where IDegLira was used in combination with other oral anti-diabetic agents. Treatment was well tolerated, with overall adverse event rates comparable to previous IDegLira trials.

Insulin degludec/liraglutide (IDegLira) is superior to insulin glargine (IGlar) in HbA_{1c} reduction, risk of hypoglycaemia and weight change: DUAL V study

J.B. Buse¹, F.C. Pérez Manghi², P.A. García-Hernández³, P. Norwood⁴, L.M. Lehmann⁵, M.J. Tarp-Johansen⁵, I. Lingvay⁶;

¹Endocrinology and Metabolism, University of North Carolina School of Medicine, Chapel Hill, USA, ²CINME, Buenos Aires, Argentina, ³Hospital Universitario de Monterrey, Mexico, ⁴Valley Research, Fresno, USA, ⁵Novo Nordisk A/S, Søborg, Denmark, ⁶UT Southwestern Medical Center, Dallas, USA.

Background and aims: This 26-week, open-label trial compared the efficacy and safety of IDegLira vs IGLar in subjects with type 2 diabetes uncontrolled on IGLar (20–50U) and metformin.

Materials and methods: Adults (n=557, HbA_{1c} 7–10%) were randomised to either once-daily IDegLira or continued IGLar uptitration, both plus metformin. Initial doses were 16 dose steps (16U IDeg + 0.6 mg Lira; maximum 50 dose steps) for IDegLira and pre-trial dose for IGLar (mean 32U; no maximum). Fasting self-measured blood glucose titration target was 4.0–5.0 mmol/L for both arms.

Results: Mean HbA_{1c} decreased from 8.4 to 6.6% with IDegLira (change from baseline [SD] -1.81% [1.08]) and from 8.2 to 7.1% with IGLar (change from baseline [SD] -1.13% [0.98]); estimated treatment difference (ETD) IDegLira-IGlar [95% CI] -0.59 [-0.74; -0.45], p<0.001 (Figure). Mean fasting plasma glucose decreased similarly in both arms from 8.9 to 6.1 mmol/L with a change from baseline [SD] of -2.83 mmol/L [2.80] with IDegLira and -2.77 mmol/L [3.02] with IGLar; ETD [95% CI] -0.01 mmol/L [-0.35; 0.33], NS. Weight decreased from 88.3 to 86.9 kg with IDegLira (change from baseline [SD] -1.4 kg [3.5]) and increased from 87.3 to 89.1 kg with IGLar (change from baseline [SD] 1.8 kg [3.6]); ETD [95% CI] for weight change -3.20 kg [-3.77; -2.64], p

<0.001. Significantly more subjects achieved the ADA HbA_{1c} target and pre-specified composite endpoints with IDegLira vs IGlir: HbA_{1c} <7%, 71.6 vs 47.0%, estimated odds ratio (EOR) [95% CI] 3.45 [2.36; 5.05]; HbA_{1c} <7% without hypoglycaemia, 54.3 vs 29.4%, EOR [95% CI] 3.24 [2.24; 4.70]; HbA_{1c} <7% without hypoglycaemia and no weight gain, 38.8 vs 12.2%, EOR [95% CI] 5.53 [3.49; 8.77], respectively, all p<0.001. IDegLira was insulin sparing; mean 26-week dose was 41 dose steps (IDegLira) and 66U (IGlar), p<0.001.

Conclusion: IDegLira was superior to IGlir in terms of HbA_{1c} reduction, risk of hypoglycaemia and weight change and decreased insulin dose requirements. Through a greater reduction in HbA_{1c} combined with a lower rate of hypoglycaemia, IDegLira offers meaningful clinical advantages over IGlir in intensifying therapy, in subjects with type 2 diabetes uncontrolled on IGlir.

Higher early insulin exposure and greater early glucose-lowering effect with faster-acting insulin aspart vs insulin aspart in Japanese patients with type 1 diabetes

M. Shiramoto¹, T. Nishida², A. Hansen³, H. Haahr³; ¹SOUSEIKAI Global Clinical Research Center, ²Novo Nordisk Pharma Ltd., Tokyo, Japan, ³Novo Nordisk A/S, Søborg, Denmark.

Background and aims: Faster-acting insulin aspart (faster aspart) is a new formulation of insulin aspart (IAsp), with faster initial absorption following subcutaneous (s.c.) injection. This trial aimed to investigate the pharmacokinetic (PK) and pharmacodynamic (PD) properties of faster aspart vs IAsp following s.c. injection in Japanese patients with type 1 diabetes.

Materials and methods: Patients (N=43; mean age±SD: 39.4±9.4 yrs) received a single dose (0.2 U/kg s.c.) of faster aspart or IAsp under glucose-clamp conditions (STG-22; blood glucose target 100 mg/dL; duration 12 h post-dose) in a double-blind, randomised, crossover design.

Results: Onset of appearance and t_{50%C_{max}} with faster aspart occurred 58% and 35% earlier than with IAsp, and faster aspart had greater early insulin exposure during the first 2 h (2-fold greater exposure than IAsp in the first 30 min post-dose); total exposure was similar (Table). Faster aspart had a greater glucose-lowering effect within 2 h post-dose vs IAsp (greatest difference in the first 30 min), and earlier onset of glucose-lowering effect (Table). Earlier onset of action with faster aspart vs IAsp was supported by ~10 min shorter t_{50%GIR_{max}} (37.5 vs 47.4 min; treatment diff. [95% CI]: -9.97 min [-12.78; -7.15]). Both treatments were well tolerated.

Conclusion: Earlier onset and greater early insulin exposure with faster aspart led to a greater early glucose-lowering effect vs IAsp in Japanese patients with type 1 diabetes.

Table: PK and PD results for faster aspart vs IAsp

A novel GIP receptor agonist enhances the body weight lowering effect of liraglutide in diet-induced obese mice and has the potential for once-weekly administration in humans

P. Noerregaard, M.A. Deryabina, J.U. Fog, P.T. Shelton, L. Giehm, J.R. Daugaard; Zealand Pharma A/S, Copenhagen, Denmark.

Background and aims: Analogs of the incretin hormone glucagon-like peptide-1 (GLP-1) are used for the management of type 2 diabetes and are often accompanied by modest weight loss. One approach to enhance the efficacy of GLP-1 receptor (GLP-1R) agonists includes co-administration with other endogenous hormones e.g. glucagon. Recently, it has been demonstrated in animals that the incretin hormone glucose-dependent insulinotropic peptide (GIP) enhances the weight loss induced by GLP-1. Here we report the characterization of a novel long-acting GIP receptor (GIP-R) incretin (I) agonist, ZP-I-98.

Materials and methods: In vitro receptor activation by ZP-I-98 was measured as cAMP formation in HEK293 cells stably expressing human or mouse GIP receptors or human GLP-1 or glucagon receptors. Pharmacokinetic (PK) characterization of ZP-I-98 was performed in mice and monkeys and the acute pharmacodynamic effect of ZP-I-98 was investigated in mice by measuring blood glucose levels during an oral glucose tolerance test (OGTT). Sub-chronic effects of ZP-I-98, with or without liraglutide (GLP-1 analog) co-administration, on body weight and food intake were investigated in diet-induced obese (DIO) mice.

Results: ZP-I-98 activated the human and mouse GIP-R with EC₅₀ values of 9 and 52 pM, respectively, while it displayed selectivity >300 fold over the GLP-1 and glucagon receptors. The terminal half-life of ZP-I-98 in mice and monkeys, following i.v. administration, was estimated to approximately 15 h and 57 h, respectively. Simple two species allometric scaling of the PK indicated that the compound is suitable for once-weekly dosing in humans.

Compared to vehicle treatment, ZP-I-98 dosed s.c. 4 h prior to an OGTT, dose-dependently (3 and 30 nmol/kg) and significantly reduced blood glucose levels in lean mice (p<0.001 at 30 nmol/kg, 0-180 min after glucose administration), thus indirectly confirming the incretin effect of the compound. Administration with liraglutide (20 nmol/kg, once-daily) induced a transient reduction in food intake in DIO mice and 3 weeks of treatment resulted in a mean weight loss ± SEM of 3.0±1.3%. DIO mice treated with vehicle gained 4.3±0.95% body weight during the study. In contrast, co-administration of liraglutide (20 nmol/kg, once-daily) and ZP-I-98 (30 nmol/kg, once every third day) resulted in a weight loss of 9.0±1.9% over the three weeks of treatment. This weight loss was significantly greater than the liraglutide-induced weight loss (p<0.05). Co-treatment of liraglutide and ZP-I-98 transiently suppressed food intake to

a similar extent as liraglutide alone. Finally, ZP-I-98 (30 nmol/kg, once every third day) did not significantly affect the body weights of the mice compared to vehicle.

Conclusion: Our results suggest that a combination therapy consisting of ZP-I-98 and a GLP-1R agonist can improve the management of type 2 diabetes by inducing body weight loss superior to GLP-1R agonist alone. The in vivo profile of ZP-I-98 further suggests that ZP-I-98 can be used as a convenient once-weekly treatment in humans.

Patient characteristics and predictors of a future termination of basal insulin supported oral therapy in the DIVE registry

T. Danne¹, T. Bluhmki², M. Kaltheuner³, W. Rathmann⁴, J. Beyersmann², P. Bramlage⁵;

¹Kinder- und Jugendkrankenhaus “Auf der Bult”, Hannover, ²Institute of Statistics, Ulm, ³Gemeinschaftspraxis Kaltheuner – v. Boxberg, Leverkusen, ⁴Leibniz Center for Diabetes Research at the Heinrich Heine University, Institute for Biometrics and Epidemiology, Düsseldorf, ⁵Institut für Pharmakologie und Präventive Medizin, Mahlow, Germany.

Background and aims: The addition of a single daily injection of long-acting insulin to oral therapy is a well-established method for treating type-2 diabetes patients. Termed basal supported oral therapy (BOT), this approach can greatly improve glycaemic control. However, it is not an efficacious long term solution for every individual. The identification of patient-related characteristics that may predict failure of BOT would be beneficial in a clinical setting when assessing potential treatment regimens.

Materials and methods: Data taken from the Diabetes Versorgungs-Evaluation (DIVE) registry was analysed for patients who were younger than 90 years and had been treated with BOT for at least 3 months. Time origin was set to BOT-initiation. The event of interest ‘BOT failure’ was defined as the cessation of oral therapy, the cessation of insulin therapy, or the addition of short-acting insulin to the treatment regimen during the observational period. Risk quantification for demographic, glycaemic, and pharmacotherapeutic characteristics of patients was based on univariate and multivariate Cox proportional hazards regression.

Results: BOT failure occurred in 2,021 patients (35.7%) of the 5,663 that fulfilled the inclusion criteria for the study. Of these, 46.7% discontinued oral therapy, 32.7% discontinued insulin, and 20.6% had short-acting insulin added to their treatment. Multivariate analysis revealed that body mass index (BMI; HR: 1.012; 95% CI: 1.001, 1.023), diabetes duration (HR: 0.982; 95% CI: 0.976, 0.989), and HbA_{1c} level (HR: 1.102; 95% CI: 1.022, 1.188) were associated with BOT failure. Age, gender, fasting plasma glucose (FPG), presence of micro- or macrovascular disease, number of oral antidiabetic drugs (OADs), and number of concomitant drugs were not found to be predictive of BOT failure.

Conclusion: The identification of factors that may be predictive of the failure of BOT could be highly useful in a clinical setting when assessing the most appropriate treatment strategy for type-2 diabetes patients.

Predictors for a termination of BOT	Univariate HR (95%CI)	Multivariate HR (95%CI)
Age (years)	0.996 (0.991,1.000)	1.003 (0.999,1.008)
BMI (kg/m ²)	1.014 (1.005,1.023)	1.012 (1.001,1.023)
Diabetes duration (years)	0.984 (0.978,0.989)	0.982 (0.976,0.989)
HbA _{1c} (%)	1.111 (1.047,1.178)	1.102 (1.022,1.188)
FPG (mmol/l)	1.033 (0.999,1.068)	1.006 (0.963,1.051)
Gender (female)	1.006 (0.922,1.098)	0.990 (0.904,1.084)
Anamnestic microvascular diseases (yes vs. no)	0.978 (0.850,1.013)	0.940 (0.858,1.030)
Anamnestic macrovascular diseases (yes vs. no)	0.998 (0.911,1.094)	1.051 (0.955,1.159)
No. OADs at baseline 2 vs. 1	0.928 (0.839,1.028)	0.918 (0.828,1.019)

A composite measure to define insulin responders: HbA_{1c} <7% and ≥1% absolute decrease in HbA_{1c} from baseline

J. Reviriego¹, I. Conget², M.S. Kirkman³, D. Cao⁴, M. Wong⁴, D.M. Kendall⁴;

¹Medical Research, Lilly Spain, ²Hospital Clinic i Universitari, Barcelona, Spain, ³Medical Research, University of North Carolina School of Medicine, Durham, ⁴Eli Lilly and Company, Indianapolis, USA.

Background and aims: A majority of patients with type 2 diabetes (T2D) treated with insulin do not reach the hemoglobin A_{1c} (HbA_{1c}) goal of <7% suggested by guidelines, yet they can have clinically relevant HbA_{1c} reductions with insulin use. Using an integrated database of 53 insulin lispro clinical trials, we propose a composite HbA_{1c} measure to define patients with T2D responding to therapy and report their baseline (BL) characteristics.

Materials and methods: The analysis population included 9869 patients with T2D treated with any insulin regimen with a BL and ≥1 post-BL HbA_{1c} value. Responders were defined as patients with an endpoint HbA_{1c} <7% and/or a ≥1% absolute (AA) decrease from BL in HbA_{1c}. The percentage of responders was assessed at 12 and 24 weeks, along with the BL demographics of responders versus non-responders.

Results: Overall, only 29.6% and 40.6% of patients reached HbA_{1c} <7% at 12 and 24 weeks respectively, whereas the AA model identified greater proportions of patients as responders (62.3% at 12 weeks and 72.6% at 24 weeks). Responders at both 12 and 24 weeks had a significantly lower duration of diabetes and higher BL HbA_{1c} compared to non-responders. Compared to whites, significantly higher proportions of Hispanic patients were responders at 12 weeks (odds ratio [OR]: 1.81; 95% confidence interval [CI]: 1.45, 2.25) and 24 weeks (OR: 1.45; 95% CI: 1.11, 1.90). Conversely, significantly lower proportions of Asians compared to whites were responders at 12 (OR: 0.81; 95% CI: 0.71, 0.92) and 24 weeks (OR: 0.70; 95% CI: 0.60, 0.82). A limitation of this integrated database was that the clinical trial population is different from a real-world treatment population.

Conclusion: The composite HbA_{1c} measure (AA model), which has a ≥1% absolute decrease in HbA_{1c} from BL added to HbA_{1c} <7%, identified more patients with clinically meaningful responses to insulin therapy than an HbA_{1c} target alone. Characteristics of responders by the AA model (higher BL HbA_{1c}, fewer years of diabetes duration) were consistent with other reports. Proportions of responders by the AA model may be significantly higher among Hispanics and lower among Asians compared with Whites. Although additional validation analyses in real-world populations are necessary, this composite model of defining insulin therapy response may be useful in population management and quality measures.

Characteristics	12 Weeks			24 Weeks		
	N	HbA _{1c} <7%	AA	N	HbA _{1c} <7%	AA
Responders, n (%) in overall population	6506	1923 (29.6%)	4050 (62.3%)	4908	1991 (40.6%)	3561 (72.6%)

Patient characteristics are associated with treatment response to second line glucose lowering therapy: a MASTERMIND study

B.M. Shields¹, M. Lonergan², J. Dennis¹, A. Jones¹, L. Rogers¹, M. Weedon¹, L. Donnelly², R. Holman³, W. Henley¹, E. Pearson², A. Hattersley¹, The MASTERMIND Consortium;
¹University of Exeter Medical School, ²University of Dundee, ³University of Oxford, UK.

Background and aims: The most common second-line glucose-lowering agent in type 2 diabetes is a sulfonylurea (SU). Draft NICE (UK) guidelines, currently out for consultation, propose using a thiazolidinedione (TZD), pioglitazone, as second-line. There is no guidance regarding which treatment is most effective in which patients. We assessed whether patient clinical characteristics could be used to predict response and aid treatment decisions.

Materials and methods: 12-month glycaemic response (HbA_{1c} change from baseline) was calculated for patients in the CPRD (UK primary care) dataset treated with SUs (n=8748) or TZDs (n=8876). Relationships between clinical phenotype and glycaemic response were assessed using linear regression, with adjustment for baseline HbA_{1c}. This analysis was repeated for the ADOPT randomised controlled trial (SUs n=1441; TZDs n=1456).

Results: In CPRD, patients diagnosed younger had a smaller glycaemic response to both SUs and TZDs (~2 mmol/mol greater response per 10-year increase in age at diagnosis, p<0.0001). Female patients responded better to TZDs (1.9 mmol/mol greater HbA_{1c} reduction compared with males, p<0.0001), but worse to SUs (2.4 mmol/mol smaller response, p<0.0001). Obese patients (BMI≥30 kg/m²) responded better to TZDs (2.1 mmol/mol greater HbA_{1c} reduction compared with non-obese patients, p<0.0001), but non-obese patients responded better to SUs (1.9 mmol/mol greater HbA_{1c} response, p<0.0001). Combining categories led to greater differences (obese females: 4.4 mmol/mol greater response to TZDs; non-obese males: 3.3 mmol/mol greater response to SUs). Effect sizes were similar in ADOPT.

Conclusion: Clinical phenotype helps determine likely initial response to second-line glucose lowering therapies, and could influence therapeutic choices. Obese females have the greatest HbA_{1c} reduction with TZDs, and non-obese males with SUs.

Factors associated with type 2 diabetes mellitus treatment choice across Europe

E.M. Heintjes¹, J.A. Overbeek¹, G.C. Hall², F. Lapi³, D. Prieto-Alhambra⁴, I.D. Bezemer¹;

¹PHARMO Institute for Drug Outcomes Research, Utrecht, Netherlands, ²Grimsdyke House, Barnet, UK, ³Health Search, Italian College of General Practitioners and Primary Care, Florence, Italy, ⁴Idiap Jordi Gol Primary Care Research Institute, Universitat Autònoma de Barcelona, Spain.

Background and aims: Demographic and clinical factors associated with choice of type 2 diabetes mellitus (T2DM) treatment at treatment intensifications were explored using electronic health care databases in four European countries.

Materials and methods: Antidiabetic drug prescription records were obtained from electronic health care record databases for a 5-year study period (2007-2011/2008-2012) in The Netherlands (NL), Italy (IT), Spain (ES) and the United Kingdom (UK). A standardized analytical tool assessed treatment patterns in each database. Oral monotherapy was defined as first line, oral dual therapy as second line, >2 oral treatments or oral combined with an injectable as third line and injectables only as fourth line therapy. Treatment intensification was defined as starting a higher line of treatment, including start of treatment. Factors associated with the choice of treatment were identified using multivariate logistic regression. Potential associated factors included general characteristics, comedication, comorbidities and clinical parameters. Missing values were categorized as a separate category in order to avoid major loss of data.

Results: A total of 617,346 T2DM patients were included; 48,479 from NL, 67,751 from IT, 348,572 from ES and 152,544 from UK. Prescription of a sulfonylurea (SU) as a first line treatment was associated with age >75 years (RR ranged from 2.05 in ES to 3.66 in IT) and renal comorbidity (RR ranged from 1.36 in NL to 2.65 in UK) in all countries, while there was an inverse association with BMI≥30 kg/m² (RR 0.22 and 0.46, respectively) in UK and ES. For second line treatment, across all countries, age >75 years was associated with receiving metformin + SU (RR ranged from 1.05 in ES to 1.34 in IT) and renal comorbidity with receiving SU + dipeptidyl peptidase-4 inhibitors (DPP4) (RR ranged from 1.26 in UK to 2.31 in NL). In UK and ES, BMI≥30 kg/m² increased the probability of receiving metformin + thiazolidinedione (TZD) (RR 1.44 and 1.25, respectively) and, in UK only, also the probability of receiving metformin + DPP4 (RR 2.38). For third line treatment, age >75 years (RR ranged from 2.49 in ES to 3.56 in UK) and renal comorbidity (RR ranged from 1.61 in ES to 3.45 in UK) were associated with SU + insulin. BMI≥30 kg/m² decreased the probability of receiving metformin + SU + TZD as third line treatment in UK (RR 0.90), but increased the risk in ES (RR 1.51). Furthermore, a BMI≥25 kg/m² decreased the probability to receive any third line treatment including insulin in these two countries. Analyses of associations with fourth line treatments were not performed for all countries because there were few treatment options. Year of index or intensification date and prior treatment class also played a significant role in choosing treatment when intensifying.

Conclusion: The results from this study in four different EU countries suggest that age and renal comorbidity were the predominant factors significantly associated with T2DM treatment choice across treatment intensifications. Our findings might be used to investigate on appropriateness of diabetes pharmacotherapy in Europe.

Real-life intensification of pharmacotherapy in type 2 diabetes. ARETAEUS2 Study results

E. Placzkiewicz-Jankowska¹, W. Lesniak¹, M.M. Bala¹, R. Topor-Madry¹, E. Szymanska-Garbacz², P. Bijos³, J. Loba², L. Czupryniak²; ¹Jagiellonian University School of Medicine, Cracow, Poland, ²Medical University of Lodz, Poland, ³TEVA Pharmaceuticals, Kutno, Poland.

Background and aims: Type 2 diabetes (DM2) is a progressive disease, subsequently its pharmacotherapy requires constant intensification. Patients are also often treated for hypertension or dyslipidaemia, and these therapies are not seen as requiring a step up approach over time. In 2012 a cross-sectional nationwide study assessing DM2 treatment efficacy was conducted.

Materials and methods: Patients with DM2 (n=15,643) were enrolled at primary care (68%) and specialist (32%) outpatient clinics, and were analysed in three groups according to diabetes duration: up to 2, 2-10, more than 10 years.

Results: The patients with longer DM2 duration received more intensified treatment, with almost 50% taking insulin after 10 years of diabetes (Table). In the whole group HbA1c less than 7% was achieved in 30% of those treated with oral monotherapy, in 46% - dual oral therapy, in 62% - insulin only and in 69% - metformin + insulin. Among cardiovascular risk related therapies only statins and ACE inhibitors were used with increased frequency over time. Less than 10% of the patients achieved all main therapeutic targets (HbA1c lower than 7%, total cholesterol less than 175 mg/dl, HDL cholesterol over 40 (men) or 50 mg/dl (women), LDL cholesterol less than 100 mg or 70 mg/dl in patients with CVD, triglycerides less than 150 mg/dl, blood pressure less than 140/90 mmHg), while 20-25% failed to achieve any of them.

Conclusion: Despite widely accepted need for progressive and multifactorial treatment of DM2, still many patients are not treated intensively enough, even with older and inexpensive therapies.

	Total	Diabetes duration (years)

Quality of diabetes care and gender differences in the Netherlands (ZODIAC-45)

S.H. Hendriks¹, K.J.J. van Hateren¹, K.H. Groenier², S.T. Houweling¹, A.H.E. Maas³, N. Kleefstra^{1,4}, H.J.G. Bilo^{1,4};

¹Diabetes Centre, Isala Clinics, Zwolle, ²Department of General Practice, University of Groningen and University Medical Center Groningen, ³Department of Cardiology, Radboud University Medical Center, Nijmegen, ⁴Department of Internal Medicine, University of Groningen and University Medical Center Groningen, Netherlands.

Background and aims: The risk of cardiovascular disease and mortality increases by about two times in men and about four times in women with type 2 diabetes mellitus (T2DM) compared to men and women without T2DM. Poorer control of cardiovascular risk factors in women has been described as a possible explanation for this difference. Aim of the current study was to investigate whether trends in quality of diabetes care differ between sexes in the Netherlands from 1998 till 2013.

Materials and methods: This is a prospective observational cohort study (ZODIAC) using data from patients with T2DM treated in primary care. Information about HbA1c, blood pressure, BMI, lipid profile, renal function, foot and eye examination and medication use was collected annually. Target values for clinical parameters were defined according to national guidelines. Linear time trends from 1998 to 2013 were estimated using linear mixed models, adjusted for gender and age. Differences in trends between genders were investigated by adding sex as an interaction term to the model and by performing stratified analyses. Absolute differences between gender were visually investigated and by adding gender as a confounder to the model for the whole study group.

Results: The number of participating patients increased in the period 1998 to 2013 from 2644 to 62,230. Trend differences between sexes over time were observed for systolic blood pressure and smoking (figure 1). Throughout the whole study period the target value for systolic blood pressure was achieved more often in men and the cut-off value for cholesterol-HDL ratio was achieved more often in women. The difference between sexes concerning the percentage of smokers decreased to a 5% difference, still in favor of women. The prevalence of albuminuria decreased from 48% to 24% in men and from 38% to 16% in women. In the group of patients with a BMI >25 kg/m², men were more overweight and women were more obese. Antihypertensive drugs and insulin were prescribed more often in women and lipid lowering drugs more often in men. No relevant absolute gender differences were found for HbA1c, neuropathy and diabetic retinopathy.

Conclusion: The quality of care for patients with T2DM has improved considerably in the period 1998-2013 in both sexes. In all years, absolute gender differences were observed for systolic blood pressure, cholesterol-HDL ratio, smoking and BMI. Relevant trends differences in the improvement of the quality of care between sexes were only observed for systolic blood pressure and smoking, with women reaching target values of blood pressure almost as much as men and with men smoking less every year while smoking in women has plateaued.

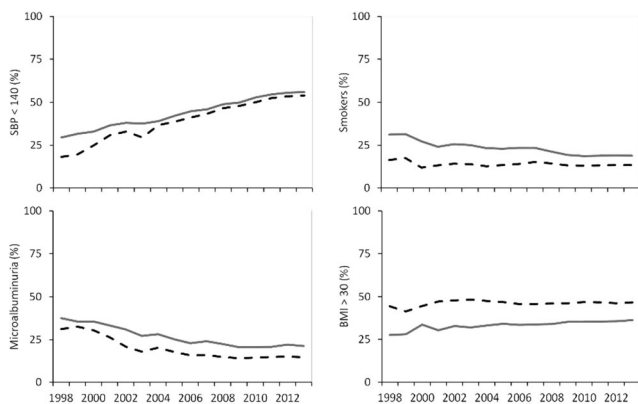

Figure 1: Trends in achieving target values stratified according to gender (Men: gray line, Women: black striped line). SBP: Systolic blood pressure; BMI: Body Mass Index.

845

Treatment of patients with type 2 diabetes mellitus with HbA_{1c} levels above target: the follow up of the Diabetes Care System (DCS) cohort

R. Mast¹, A.A. van der Heijden², P.J.M. Elders², R.J. Heine³, J.M. Dekker², J.G. Hugtenburg¹, G. Nijpels²;

¹Department of Clinical Pharmacology and Pharmacy, EMGO Institute for Health and Care Research, ²Department of General Practice and Elderly Care Medicine, EMGO Institute for Health and Care Research, Amsterdam, Netherlands, ³Eli Lilly and Company, Indianapolis, USA.

Background and aims: Because of the progressive nature of the type 2 diabetes (T2DM), many patients show a pattern of so-called ‘serial failure’ as a result of sequential addition of glucose lowering drugs including insulin as the final step. The determinants and the sustainability of good glycemic control following the initiation of insulin therapy have not been described. The aim of this study was to assess the patient characteristics and the treatment responses to the initiation of insulin therapy in a large cohort of T2DM patients.

Materials and methods: The study was performed in the population based diabetes cohort of the Diabetes Care System (DCS) responsible for the quality of T2DM care and uses a managed care plan for almost all T2DM patients in the region, in collaboration with contracted general practices (GP’s). The managed care plan encompasses the care provided by patient’s GP, according to the Dutch College of GPs’ treatment guidelines for T2DM and a standardised annual assessment organised centrally since 1998 by the DCS in the Netherlands. Of a total of 9849 type 2 diabetes patients, 1203 T2DM patients initiated insulin. ‘Serial failure’, compared to ‘good response’, was defined as HbA_{1c} levels of 53 mmol/mol or higher (7%) at more than 1/3 of the time points during the mean 5.6 year (SD 2.8) follow-up. Differences of the demographic characteristics, HbA_{1c}, BMI, and diabetes duration at baseline between the ‘serial failure’ group and ‘good response’ group were tested with ANOVA and post hoc Bonferroni tests for mean levels, with Chi-square tests for proportions and Kruskal - Wallis test for median levels.

Results: Of the 1203 patients initiating insulin therapy 294 patients (24.4%) showed a ‘good response’, whereas 909 patients (75.6%) showed a ‘serial failure’ response with an equal follow-up of 5.5 year. Patients in the ‘serial failure’ group were significantly younger, and had higher HbA_{1c} and glucose levels at the initiation of insulin. More patients in the ‘serial failure’ group were using a combination of metformin and sulfonylureas (SU) (table 1). There was no difference in total mortality between serial failure (14.0%) and good response (16.0%).

Conclusion: Less than a quarter of the patients showed sustained glucose control after the start of insulin treatment. Those with ‘good response’ were characterised by lower HbA_{1c} level and higher age at the start of insulin therapy. The ‘good responders’ may represent a subgroup of patients with a less progressive disease. Alternatively, it may be speculated

that initiating insulin earlier, increases the likelihood of achieving and sustaining glycemic control by preserving beta-cell function.

Table 1. Baseline characteristics of the ‘good response’ and ‘serial failure’ patients.

	Good response	Serial failure
N (%)	294 (24.4)	909 (75.6)
Baseline characteristics		
Age (yr)	67.3 ± 9.9*	64.8 ± 10.1*
Male (%)	52.4	50.8
Diabetes duration (yr)	8.2 (4.8 – 12.9)	8.4 (5.3 – 12.4)
HbA _{1c} (mmol/mol)	50 ± 0.8*	63 ± 1.2*
BMI (kg m ⁻²)	31.0 ± 6.2	30.8 ± 5.6

Identification of key success factors in type 2 diabetes care in Sweden

S. Ekeblad Lien¹, L. Odevall¹, T. Holm², M. Bojestig³, S. Gudbjörnsdóttir^{4,5}, C.-G. Östenson⁶;

¹Health Navigator, ²Swedish Association of Local Authorities and Regions, Stockholm, ³Region Jönköping county, ⁴Institute of Medicine, Sahlgrenska University Hospital, University of Gothenburg, ⁵National Diabetes Register, Centre of Registers, Gothenburg, ⁶Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and aims: In Sweden, the National Diabetes Register (NDR) has shown differences in treatment outcomes for diabetes patients in primary care, both between and within the 21 county counties (CCs). This study of the structure and provision of diabetes care was conducted to identify factors associated with high performance in type 2 diabetes (T2D) primary care, based on glycemic (HbA_{1c}) and blood pressure control, and use of lipid-lowering medication.

Materials and methods: 4 CCs with high performance, and 4 with low performance, as well as 4 high performing and 6 low performing primary care centers (PCCs) were selected based on 2011 NDR outcome data. Differences in the provision of T2D care were explored using a combination of quantitative and qualitative analysis. Semi-structured in-depth interviews were conducted with 66 selected individuals with professional key roles in diabetes care, either as PCC managers, members of the commissioning organisation or political leadership, including 22 in-depth interviews with PCC clinical staff. In addition, steering documents, guidelines, staffing levels and diabetic medication use were analysed.

Results: Comparing high and low performing CCs no systematic differences were identified in tender documents or reimbursement models. Different reimbursement models and care requirements were used, but no apparent pattern distinguishing high and low performing CCs could be identified. The number of listed patients per full-time specialist ranged from 1955 to 2275 (median=2048) and 1755 to 2181 (median=1840), in high and low performing CCs respectively. No clear differences were seen regarding insulin use. The average number of defined daily doses of insulin per diabetes patient ranged from 212 to 281 (median=227) and 209 to 244 (median=219), and the proportion of the total number of diabetes patients using insulin ranged from 45 to 53% (median=47%) and 45 to 51% (median=46%) in high and low performing CCs respectively. The interview analysis did however show large differences in the structure and provision of diabetes care between high and low performing CCs and PCCs. Systematic differences, where CCs and PCCs with better outcomes stand out, were described in terms of seven success factors relating to PCC design and delivery of healthcare (1. Focus on quickly achieving target values for each patient; 2. Systematic targeted efforts to help patients with suboptimal outcomes; 3. Own results always on the agenda of both clinical staff and management), CC leadership and

management of care (4. Easily accessible evidence-based guidelines, and expectation of adherence to recommendations; 5. Follow-up and feedback on results; 6. Continuous improvement efforts in diabetes care), and the culture that permeates the organisation as a whole (7. Ownership of results and focus on secondary prevention).

Conclusion: Comparison of high and low performers, based on national register data from Sweden, yielded insight into key success factors in T2D care. The factors can serve as a basis for discussion and improvement initiatives striving toward evidence-based and equal care.

Real-life practice glycaemic control in patients with latent autoimmune diabetes of the adult and type 2 diabetes

C. Lopez¹, L. Gutierrez¹, J. Valls², E. Rubinat², M. Granado², M.D. Santos¹, F. Rius¹, A. Betriu³, D. Mauricio⁴, A. Lecube¹, M. Hernandez¹; ¹Endocrinology and Nutrition, Hospital Universitari Arnau Vilanova, lerida, ²Institut de recerca biomedica, Hospital Universitari Arnau Vilanova, lerida, ³Nephrology, Hospital Universitari Arnau Vilanova, lerida, ⁴Endocrinology and Nutrition, Hospital Universitari Germans Trias i Pujol, Barcelona, Spain.

Background and aims: The objective of our study was to compare the glycemic control before and after initiation of insulin therapy between type 2 diabetes patients and patients with latent autoimmune diabetes in adults (LADA).

Materials and methods: We retrospectively assessed previous glycaemic control in a case-control study on cardiovascular risk in 189 patients with type 2 diabetes and 66 patients with LADA. All the HbA1c determinations from primary and specialized care during the period 2004-2014 and time of insulin initiation were recorded. Differences in raw Area Under the Curve (AUC) of HbA1c and HbA1c-weighted by the follow-up time were assessed with a Mann-Whitney test. All analyses were obtained using R, setting a threshold for significance at 5% ($\alpha=0.05$)

Results: Patients with type 2 diabetes and LADA were similar in age (58.4 ± 10.1 vs. 58.3 ± 12.1 yr), gender distribution (55% vs. 48% male participants), prevalence of retinopathy (19% vs. 18%) and albumin-to-creatinine ratio (14.5 ± 32.9 vs. 19.7 ± 71.6 mg/g) respectively. Type 2 diabetic patients exhibited higher body mass index (31.2 ± 5 vs. 27.5 ± 5.6 Kg/m²) and waist circumference (104.5 ± 11.7 vs. 95.5 ± 14.9 cm), and shorter diabetes duration (8.8 ± 7.9 vs. 12 ± 8.8 years), respectively ($P\leq 0.01$ for all comparisons). Frequency of insulin treatment was 19% in type 2 diabetes and 86% in LADA ($P < 0.001$). Mean day-weighted HbA1c AUC was higher in LADA than in patients with type 2 diabetes (7.9 ± 1 vs 7.3 ± 1 , $P < 0.001$). Patients with type 2 diabetes were exposed for a longer period to values of HbA1c $\geq 7.5\%$ than LADA patients before insulin initiation (527.9 ± 699.6 vs 197.7 ± 361 , $P < 0.001$). However, LADA patients were exposed to HbA1c $\geq 7.5\%$ for an overall longer period than type 2 diabetic patients (1232 ± 834 vs 735 ± 821 days, days, $p < 0.001$)

Conclusion: Despite earlier initiation of insulin therapy for poor glycaemic in patients with LADA, they were exposed to higher burden of hyperglycemia than type 2 diabetes patients.

PS 077 Burden of diabetes: economic and otherwise

848

Humanistic and economic outcomes of people with type 1 diabetes in Europe with various degrees of complications

C. Sternhufvud¹, E. Sörstadius¹, K. Bergenheim¹, A. Romanovschi², F. Thorén¹, E.A. Witt³, A. Rydén¹; ¹AstraZeneca, Mölndal, Sweden, ²AstraZeneca, London, UK, ³Kantar Health, Princeton, USA.

Background and aims: Following the limited research on Type 1 diabetes (T1DM) regarding burden of the disease, aim of this study was to estimate the impact of complications on health-related quality of life, work productivity, and healthcare resource use.

Materials and methods: The 5EU NHWS is a proprietary survey of adults (≥ 18 years) where respondents complete a suite of demographic, clinical and healthcare utilization questions, as well as standardized PROs to assess health-related quality of life (SF-36) and work impairment (WPAI) approximately every 18 months. Data from the SF-36, WPAI and healthcare resource use items from the 2013 survey were evaluated for patients indicating a diagnosis of T1DM. Within this sample, data was compared between those with no diabetes-related micro or macrovascular complications, 1 complication or 2 or more complications using one-way ANOVAs with a significance level of $p < 0.05$.

Results: The T1DM sample comprised 402 people. Mean time since T1DM diagnosis was 21.7 years. 67.2% of patients had no complications, 18.9% had one complication, and 13.9% had 2 or more complications. Groups were similar in terms of age, gender, marital status, working status, education, smoking status and income. Significant differences were observed in BMI, such that the proportion of those who were obese was higher in the ≥ 2 complications group relative to the other two groups, 19.6% vs. 5.6% and 5.3%, respectively. This group was also less likely to report that they had exercised in the past month, 42.9% vs. 65.6% and 61.8%. In general, as the number of complications increased (0, 1, ≥ 2) overall health-related quality of life and health utility scores, as reported by the SF-36 decreased; see Table. On the WPAI, there were significant differences such that those with 1 complication and those with ≥ 2 complications were significantly more likely to report impairment in the form of Presenteeism, Work Productivity, and Activity Impairment than those with no complications. Those with 1 complication did not differ significantly from those with ≥ 2 complications on all work productivity and activity impairment measures; see Table. Patients with ≥ 2 complications reported significantly more ER Visits, number of hospitalizations, and visits to healthcare providers than those patients with no complications. Those with 1 complication did not differ significantly from either those with no complications or those with ≥ 2 complications.

Conclusion: Diabetes-related complications can have a significant humanistic burden on patients with T1DM, and a significant economic impact on the healthcare system. Patients should be educated beyond the incidence of complications to understand the humanistic and economic burden.

	Type 1 Diabetes by Complications					
	None (n = 270)		1 (n = 76)		≥2 (n = 56)	
<i>Health-related Quality of Life (mean, sd)</i>						
Mental Component Summary	44.57 _a	11.28	42.93 _{ab}	9.79	40.51 _b	12.10

<i>Healthcare Resource Use (mean, sd)</i>						
ER Visits (number in last 6 months)	.29 _a	.79	.42 _{ab}	.93	.73 _b	1.52
Hospitalizations (number in last 6 months)	.24 _a	1.07	.25 _{ab}	.52	.66 _b	1.64
HCP Visits (number in last 6 months)	6.28 _a	7.45	7.96 _a	7.65	15.20 _b	14.87

Note: P value represents significance of overall ANOVA. Subscripts represent pairwise comparisons. Values in the same row not sharing the same subscript (e.g., "a" and "b") are significantly different from each other at p<.05. Those that are not (e.g., "a" and "a", "b" and "b") are not significantly different from each other at p<.05. Cells with no subscript are not included in the test. Tests assume equal variances.¹

1. Tests are adjusted for all pairwise comparisons within a row of each innermost subtable using the Bonferroni correction.

*Absenteeism, presenteeism, and work productivity loss were only assessed for those respondents who were employed at the time of the survey.

The humanistic and economic burden of type 1 diabetes in Europe
 A. Rydén¹, E. Sörstadius¹, K. Bergenheim¹, A. Romanovsch², F. Thorén¹, E.A. Witt³, C. Sternhufvud¹;
¹AstraZeneca, Mölndal, Sweden, ²AstraZeneca, London, UK, ³Health Outcomes Research, Kantar Health, Princeton, USA.

Background and aims: Following the limited research on Type 1 diabetes mellitus (T1DM) regarding burden of the disease, aim of this study was to estimate the humanistic and economic burden of T1DM regarding health-related quality of life, work productivity, and healthcare resource use.

Materials and methods: The 5EU NHWS is a proprietary survey of adults (≥18 years) where respondents complete a suite of demographic, clinical and healthcare utilization questions, as well as standardized PROs to assess health-related quality of life (SF-36) and work impairment (WPAI) approximately every 18 months. Data from the SF-36, WPAI and healthcare resource use items from the 2013 survey were compared between patients indicating a diagnosis of Type 1 diabetes and those who indicated no diabetes diagnosis (thereby excluding type 2 diabetes from the comparator group) via one-way ANOVAs with a significance level of p<0.05.

Results: The sample comprised 402 patients with T1DM and 57,912 people without diabetes (non-diabetes). Mean time since T1DM diagnosis was 21.7 years. Two thirds of the T1DM respondents had no diabetes-related micro or macro-vascular complications. T1DM respondents reported lower income, lower BMI scores, and higher Charlson comorbidity index scores relative to non-diabetes respondents. With regard to demographics, a higher proportion of T1DM patients were male and a higher proportion were current smokers when compared with non-diabetes respondents. Age, marital status, working status, education and exercise frequency was similar between the cohorts. 83.1% of T1DM respondents reported experiencing hypoglycaemia; 62.7% in the past month. T1DM respondents reported significantly worse health-related quality of life, with lower SF-36 scores on all domains as well as mental component and physical component scores compared to non-diabetes respondents; see Table. The utility values were also lower for the T1DM patients and they reported significantly more Presenteeism (27.94 vs. 16.35, p<.001), work productivity loss (30.91 vs. 19.74, p<.001), and activity impairment (36.29 vs. 23.95, p<.001) on the WPAI compared to non-diabetes respondents, but no more absenteeism (7.22 vs. 5.45, p .154). Furthermore, T1DM patients reported significantly more healthcare resource use than non-diabetes respondents: ER Visits 0.38 vs.

0.19 (p<.001); Days of hospitalization 0.30 vs. 0.12 (p .001); HCP visits 7.86 vs. 4.43 (p<.001).

Conclusion: There is a significant humanistic and economic burden of T1DM. Treatment strategies for T1DM should seek to balance the clinical, humanistic and economic outcomes to achieve the greatest value to the healthcare system and to individual patients.

Post-prandial hyperglycaemic episodes (PPH): impact on healthcare resource use among people with type 1 and type 2 diabetes in the US, UK and Germany

K.M. Pfeiffer¹, A. Nikolajsen², J. Weatherall³, M. Brod¹;
¹The Brod Group, Mill Valley, USA, ²Novo Nordisk A/S, Søborg, Denmark, ³Novo Nordisk, Inc., Plainsboro, USA.

Background and aims: Post-prandial hyperglycaemic episodes (PPH) among people with diabetes are a well-known clinical challenge to diabetes management. While the impact of post-prandial hypoglycaemia on healthcare resource use has been well studied, little is known about the impacts of PPH episodes on healthcare resource use. The purpose of this study was to assess the impact of respondent-reported PPH on healthcare resource use among people with type 1 (T1DM) and type 2 (T2DM) diabetes treated with meal-time bolus insulin.

Materials and methods: Data were collected in a web-survey of 906 adults diagnosed with T1DM (39%) and T2DM (61%) and treated with self-administered bolus insulin therapy, but not using pre-mixed insulin or GLP-1 analogues (with or without OADs), in the US (40%), UK (26%), and Germany (34%). Respondent experience of PPH was self-reported.

Results: Analyses demonstrated that inadequate post-prandial glucose control was prevalent among people with diabetes. Sixty-six percent of respondents reported difficulty getting blood glucose (BG) stable after eating during the past week. Thirty-six percent of respondents indicated that they experienced post-prandial hypoglycaemia in the past week, and 62% reported experiencing PPH in the past week. A total of 11% of respondents experienced post-prandial hypoglycaemia 3 or more times in the previous week, and 30% experienced PPH episodes 3 or more times in the previous week. Further, respondents who experienced PPH episodes in the past week called or emailed their physicians or other healthcare professionals about their diabetes an average of 2.7 times in the previous year compared to an average of 1.4 times for those who did not experience PPH episodes in the previous week (p<.001). Respondents who experienced PPH in the past week made an average of 5.5 diabetes-related visits to their physicians or healthcare professionals in the past year, compared to an average of 4.4 visits for those who did not experience PPH episodes (p<.001). The associations between PPH and contact with healthcare professionals were significant among those with T2DM, but not for those with T1DM. Of those who experienced PPH episodes during the past week, 72% reported at least one medical complication related to diabetes, compared to 55% of those who did not experience PPH episodes (p<.001). More specifically, compared to those

without PPH in the past week, respondents who experienced PPH in the previous week were significantly more likely to report being diagnosed with high blood pressure (41% vs. 29%, $p < .001$), eye problems (33% vs. 21%, $p < .001$), and nerve damage (neuropathy) (28% vs. 21%, $p < .05$) related to their diabetes. Respondents who experienced PPH episodes during the previous week reported measuring their BG 1.9 additional times on days they experienced symptoms of PPH compared to their usual BG measurement on an average day.

Conclusion: These results indicate that PPH episodes among adults with diabetes are common and are significantly associated with greater use of healthcare resources, including increased communication and contact with physicians and other healthcare professionals and greater incidence of one or more medical complications related to diabetes, as well as more frequent BG measurement. The additional use of healthcare resources associated with PPH may increase the costs of diabetes management for both T1DM and T2DM.

Economic impact and associations of recurrent diabetic ketoacidosis in type 1 diabetes

M.L. Byrne¹, C. Garrett², J. Collins³, S.A. Amiel¹, K. Ismail², S. Thomas³, D. Hopkins¹;

¹Diabetes Research Group, ²Diabetes and Psychiatry Research Group, King's College London, ³Dept of Diabetes & Endocrinology, Guy's and St Thomas' Hospital, London, UK.

Background and aims: For a small, but high risk sub-population of type 1 diabetes (T1D) patients, self-management is extremely difficult and characterised by recurrent admissions with diabetic ketoacidosis (rDKA). Economic studies demonstrate T1D patients experiencing DKA incur 1.4–2.2 times the cost of a non-DKA T1D patient, with further increases with rDKA. There are currently no UK studies that have analysed the healthcare cost burden of patients with rDKA admissions. To understand the reasons for rDKA and its economic impact we have reviewed data on all individuals with rDKA admissions over 8-years at two inner-city teaching hospitals.

Materials and methods: Retrospective analysis of combined biochemical (HbA1c), demographic (age, sex, ethnicity and socio-economic status) and health resource utilisation data (outpatient and inpatient activity) collected between 2006–2014 for T1D patients with rDKA in a defined geographical catchment area of London, UK. rDKA patients were identified by ≥ 3 DKA admissions and compared with the local T1D population. Costs were calculated using the UK National Schedule of Reference costs (2010–2011) and NHS best practice tariffs for DKA episodes post April 2013.

Results: 68 patients, mean age 27.8 (± 12.5) years, had a total of 407 DKA admissions (mean 6.0 admissions/patient, range 3–24) with total bed day occupancy for DKA of 1,373 days (mean 3.4 days/admission). rDKA admission tended to 'cluster' with 43.2% occurring ≤ 3 months from the previous episode. The total cost of DKA admissions was £360,093 [€493,829] (£5,295/patient [€7,262]). Additionally, other diabetes-related and non-diabetes related inpatient visits cost £227,640 [€312,184] and £171,581 [€235,305] respectively for this group. These patients were also high users of diabetes outpatient services (mean 5.4 diabetes clinic appointments/year) but were poor attenders, with 34.8% of appointments being missed. Total annualised cost of 'routine' diabetes care was £317,565 [€435,507] (£584/patient/year [€801]). Use of non-diabetes appointments was too high totaling £264,595 [€362,864]. Compared to the local T1D cohort, rDKA was associated with greater socio-economic deprivation (mean index of multiple deprivation score 32.9 ± 10.5 vs. 29.5 ± 9.8 ; $p = 0.01$) and ethnic minority status (62% vs. 27% non-white ethnicity, $p < 0.01$). For those with complete medical history data ($n = 37$) glycaemic control was consistently poor, with mean HbA1c 101

(± 30.6) mmol/mol and 92 (± 20.7) mmol/mol ($p = 0.10$) at the start and end of the 8-year period. Only 16.7% had attended structured diabetes education, 88.9% had noted issues with compliance and 30.6% had a clinical diagnosis of depression.

Conclusion: These data demonstrate that rDKA patients incur extremely high healthcare costs. DKA episodes have a tendency to 'cluster' but occur on a background of long-term non-compliance and outpatient non-attendance. This behaviour suggests a long-term relational psychological difficulty and would fit with acute admissions related to affect regulation. Therefore, specific psychological and social interventions capable of even a modest decrease in DKA frequency would have a significant economic impact.

852

Risk factor and economic burden of hypoglycaemia in elderly patients with type 2 diabetes mellitus initiating Basal Insulin (BI) in a US medicare advantage population

L. Liao¹, H. Wang¹, C. Pan², M. Bala³, J. Escalada⁴;

¹Sanofi, Bridgewater, ²ProUnlimited, Boca Raton, ³Sanofi, Cambridge, ⁴Department of Endocrinology and Nutrition, Clinica Universidad de Navarra, Pamplona, Spain.

Background and aims: Insulin treatment is an essential tool in diabetes management and hypoglycaemic (HG) remains a barrier for optimal glycaemic control. Older patients are at increased risk of experiencing severe HG events compared with other age groups with Type 2 diabetes. We present a retrospective US health insurance claims database study to assess risk factors for HG and its cost burden in elderly patients with T2DM who initiated BI on top of OADs/GLP-1s (2007–2013).

Materials and methods: The Clinformatics® Data Mart Medicare Advantage database was used to identify patients with T2DM who initiated Basal insulin (BI) between January 2007 and December 2013. All patients had a minimum of one year continuous medical and pharmacy coverage prior to (baseline period) and after (follow-up period) BI initialization. Logistic regression was used to identify risk factors of HG occurred during 1-year follow-up, adjusting baseline patient characteristics that include age, gender, comorbidities, prescriptions, HG and healthcare utilization. The economic burden of HG was evaluated accounting for baseline patient characteristics with a generalized linear model assuming gamma distribution with log link for healthcare costs to accommodate its skewed distribution.

Results: There were 31,035 patients included in the study (mean age: 72 years). Of these patients, during the one year follow up period, 3,066 (9.9%) patients experienced one or more episodes of medically attended HG (HG group) and 27,969 patients did not experience HG (non-HG group). At baseline, the HG group were more likely to have general comorbid conditions (Charlson Comorbidity Index excluding diabetes 2.6 vs 1.7 , $p < 0.001$) and incurred higher total annual healthcare costs (\$54,057 vs \$30,249, $p < 0.001$) than the non HG group. The HG group were also more strongly associated with baseline macrovascular (OR = 1.23, 95%CI: 1.12–1.34) and microvascular (OR = 1.50, 95%CI: 1.38–1.63) complications, mental illness (OR = 1.24, 95%CI: 1.15–1.35) and foot disease (OR = 2.32, 95%CI: 2.08–2.59). In the one year follow up period, percentage of patients with such conditions increased from baseline by 8.0–9.3% for HG group and was lower or stable in the non-HG group. After BI initiation, average annual healthcare costs slightly fell, from \$32,601 at baseline to \$32,460. However, there was a 8.3% decrease in non-HG while 39% increase in HG group. After adjusting for baseline characteristics, the HG group was associated with substantially higher annual healthcare expenditure (\$53,375 vs \$25,881) and diabetes-related costs (\$19,938 vs \$8539) compared with non-HG group, mainly driven by inpatient and outpatient services. The HG group also incurred \$5337 HG-related annual costs.

Conclusion: Elderly T2DM patients with comorbidities are at increased risk of HG after BI initiation and patients experiencing HG are associated with substantially higher healthcare utilization and costs, highlighting the need for a BI with a reduced risk of HG that can further improve glycaemic control.

Investigating sickness absence as a pathway behind labor market consequences of childhood onset type 1 diabetes mellitus

S. Persson¹, G. Dahlquist², U. Gerdtham^{1,3}, K. Steen Carlsson¹;

¹Health Economics Unit, Department of Clinical Sciences, Lund, ²Pediatrics Unit, Department of Clinical Sciences, Umeå, ³Department of Economics, Lund University, Sweden.

Background and aims: Earlier studies from our research group show that childhood onset of type 1 diabetes mellitus (T1DM) negatively impacts employment and earnings from labor market entrance and onwards. Less is however known to what extent these differences are directly related to indicators of adult health and what is explained by other factors. This study analyzed sickness absence as a mediator explaining the negative impact on employment and earnings in adults with childhood onset of T1DM.

Materials and methods: We selected all individuals born 1962-1977 ($n=3,507$) with onset of T1DM before age 15 and registered in the national Swedish Childhood Diabetes Register (SCDR) which covers incident cases of T1DM since 1977. The impact of T1DM was investigated using a matched case-control design where Statistics Sweden identified controls matched for year of birth and residency ($n=14,029$). The SCDR has been linked to national health and labour market registers and we used information on sickness absence including sickness benefits (shorter duration) and sickness compensation (long duration or permanent; full or part time) as indicators of health in ages 30-33 and 40-43 years old, respectively. First, we investigated the absolute and relative risks of sickness absence in people with T1DM compared to controls. Secondly, we added the sickness absence as a control variable in regression analyses of employment and earnings to explore the robustness of the basic T1DM effect shown in previous work. The analyses used logistic and panel data regression methods, controlling for calendar year, demographic and socioeconomic background.

Results: Men and women with childhood onset of T1DM were more likely to have been on sickness benefits at least once in ages 30-33 years (men 31% vs 19% (OR 1.94, 1.71-2.19); women 64% vs 46% (OR 2.09, 95% CI 1.85-2.35)) and in ages 40-43 years (men 33% vs 22% (OR 1.80, 1.30-2.50); women 53% vs 33% (OR 2.40, 1.71-3.36)). Additionally, the length of the sickness period was longer, statistically significantly for women with T1DM (men 14 days more ($p=0.209$); women 21 days more ($p=0.007$) in age 33). The likelihood of long-term/permanent sickness compensation was also higher (\leq age 33; men 5% vs 3% (OR 1.98, 1.49-2.64), women 10% vs 4% (OR 2.84, 2.27-3.55) and \leq age 43; men 12% vs 5% (OR 2.64, 1.53-4.56), women 28% vs 8% (OR 4.20, 2.71-6.50)). In ages 30-33 years, T1DM had a negative effect on employment (men OR 0.63, 0.51-0.77; women OR 0.56, 0.44-0.70) and earnings if employed (men -9.4%, $p<0.001$; women -7.3%, $p=0.004$) and remained or slightly increased in age 40-43 years. Adding sickness absence to the regression analyses slightly decreased the estimated effect of T1DM on employment and earnings but T1DM in itself remained negative and significant.

Conclusion: While childhood onset of T1DM significantly increased the risk of sickness absence early in adulthood, particularly among women, it accounted for only a small part of the diabetes related difference in employment and earnings we have shown earlier.

Type 1 diabetes with early onset and educational field at upper secondary and university level: Is own experience an asset for a health care carrier?

K. Steen Carlsson, I. Lovén, for the Swedish Childhood Diabetes Register StudyGroup; Lund University, Sweden.

Background and aims: Earlier work from our group on long-term consequences of type 1 diabetes with early onset has shown small but significant negative impact on school grades, final educational level and earnings. Less is known about other aspects of consequences, such as choices of educational field. We analyzed the probability of having a health-related education at upper secondary and university level, comparing people with type 1 diabetes onset before age 15 and matched population controls.

Materials and methods: From the Swedish Childhood Diabetes Register we retrieved all incident cases of childhood-onset type 1-diabetes from 1977-1990 for people born 1962-1975 and their four population controls matched for year of birth and municipality of residence at the time of diabetes onset. The main outcome variable, health-oriented education was defined using the SUN-classification in the Swedish National Educational Register for vocational and theoretical programmes at the upper secondary level and at university level using the last available registration up to year 2010. These educations thus ranged from nursing assistant exam from the vocational programmes at upper secondary level to physician exam at the university level. The hypothesis of no systematic differences between people with diabetes and population controls was tested using regression analyses (multinomial and standard logit regression) for women and men separately, and controlling for demographic and socioeconomic background obtained from the Longitudinal Integration Database for Health Insurance and Labour Market Studies (LISA) at Statistics Sweden.

Results: From the selected years, 2,756 people had onset of diabetes in ages 2-15 years (mean age at diagnosis 10.9 (SD 2.9); 53% boys) and there were 11,020 population controls (51% boys). The majority of the included subjects completed upper secondary school (girls/ boys: 90.5/88.1%, with no significant differences between people with diabetes and population controls. Women with type 1 diabetes were more likely to complete health-oriented education at the upper secondary level (+5.3%, $p<0.01$ vocational health; +1.4%, $p=0.08$ theoretical health) compared to vocational non-health programme (reference category), but less likely to complete a theoretical non-health oriented programme (-6.4%, $p<0.01$). Men were more likely to complete a vocational health programme (+3.2%, $p<0.01$) but less likely to complete both types of theoretical programmes (health -0.7%, $p=0.01$; non-health -4.1%, $p<0.01$). People with type 1 diabetes were less likely to have a university exam (women 40% vs 46%; -6.4% $p<0.01$; men 30% vs 35%; -5.7% $p<0.01$), but among people with a university exam, women were more likely to have a health orientated exam (+7.4%, $p<0.01$), while no significant difference was found for men. The effect was consistent at all levels for women with diabetes, adding to the population based differences between men and women as regards field of education. The significant pro-health orientation was robust in sub-group analysis and remained when controlling for school grades at previous level.

Conclusion: We rejected the hypothesis of no systematic differences in choice of educational field between people with type 1 diabetes onset up to age 15 and population controls. People with diabetes were more likely to complete health-oriented educational programmes, both at upper secondary and university levels.

Education level, occupational status and quality of life in adults with type 1 diabetes and in the general population: a comparative study

L.L. Ovesen¹, H.B. Nielsen¹, L.H. Mortensen², C.J. Lau³, L.E. Joensen¹; ¹Patient Education Research, Health Promotion Research, Steno Diabetes Center A/S, Gentofte, ²University of Copenhagen, ³Research Center for Prevention and Health, Glostrup, Denmark.

Background and aims: Type 1 diabetes is a complex disease, demanding a high degree of self-care throughout life. Few studies have examined how adults with type 1 diabetes differ from the general population regarding education level, occupational status and self-rated quality of life. Research in this field has shown inconsistent results and is characterized by small samples and poor classification of type 1 diabetes. Furthermore most studies are published before 2005. The aim of this study is to compare adults with type 1 diabetes and the general population in terms of education level, occupational status and self-rated quality of life.

Materials and methods: This study compared 2,415 adults with type 1 diabetes and 48,511 adults from the general population. Data were collected in 2010 and 2011 from two cross-sectional surveys of Danish adults living in the capital region. One survey from a specialist diabetes clinic targeting type 1 diabetes patients and one from the capital region of Denmark representing the general population. Validated questions measured education level, occupational status, working hours, sick leave per year and self-rated quality of life. Self-rated quality of life was assessed with eight domains of health scored with SF-12. Data were sex- and age standardized. Mean difference and risk difference (RD) were calculated as outcome measures. For each outcome we used stepwise addition of covariates in a multivariable linear regression model to identify potential confounding (partner, children living at home, education, occupational status and self-rated quality of life). Further, we analysed the difference between education level, occupational status and self-rated quality of life in subgroups by age and sex. A sensitivity analysis excluding individuals participating in both surveys from the general population was conducted. **Results:** Compared to the general population, a larger proportion of the diabetes population were male (52% vs. 44%) and between 30-59 years old (58% vs. 52%). After taking age and sex into account, adults with type 1 diabetes, on average, reported a higher education level (RD between 0.2 - 1.6, $p < .0001$), lower level of employment (RD=7.69, $p < .0001$), more sick leave per year (mean difference=0.71 days, $P = 0.0027$) and lower scores on all domains of self-rated quality of life (RD between 3 - 8, $p < .0001$) compared to the general population. No difference was found in working hours per week (mean difference=0.06 hours, $p = 0.6$). Yet, after adjusting for education, the results suggested that adults with type 1 diabetes worked fewer hours a week (0.28 hours, $P = 0.0119$) compared to the general population. Covariates explained only a small proportion of the overall difference. Results remained the same in the sensitivity analysis.

Conclusion: Our findings indicate differences between adults with type 1 diabetes and the general population in relation to education level, occupational status and self-rated quality of life. Further research into the mechanisms is needed in order to develop interventions supporting adults with type 1 diabetes.

PS 078 Double trouble: depression and diabetes

856

A trial to decrease diabetes distress in diabetic persons with depression

B. Potter van Loon¹, C. Schmidt¹, I. de Vlioger², E. Kilibic¹, F.J. Snoek³, A. Honig^{4,5};

¹Internal Medicine, OLVG-Sint Lucas Andreas, ²Psychology, OLVG-Sint Lucas Andreas, ³Psychology, VU Medical Centre, ⁴Psychiatry, OLVG-Sint Lucas Andreas, ⁵Psychiatry, VU Medical Centre, Amsterdam, Netherlands.

Background and aims: Screening for depression is recommended annually. We set up a programme to screen for diabetes distress (DD), depressive symptoms (Depr), and hypoglycaemia fear burden (Hypo). If Depr was detected in combination with DD, DD was discussed with the patient in 2 structured meetings in order to reduce the burden and influence both DD and Depr.

Materials and methods: DD was measured by PAID-5; cutoff value 8 for distress; Depr was measured by Extended Kessler -10 (EK-10); cutoff value 20; Hypo was determined by both Dutch 33-item Hypoglycaemia Fear Survey (HFS-AHV) and 3-item questionnaire (3I-S); non-parametric statistics (Wilcoxon, Spearman correlation and chi square).

Results: Out of 810 patients screened 73 (9%) had both Depr and DD. 61 patients were invited for structured discussing; 20 completed the intervention, 30 started the intervention but failed to complete. No show was 50% in the total group. In Completers PAID-5 score decreased from 11, 2 (SD 2,5) to 8,9 (3,8) ($p < 0.05$) and EK-10 score decreased from 24,2 (8,6) to 20,8 (6,9) ($p < 0.05$). In a subset of 410 insulin treated patients DD was present in 52% of those with Hypo ($n = 95$) and in 9% without Hypo ($P < 0.001$). Also, HbA1c was higher (71 mmol/mol) in those with Hypo than without (62 mmol/mol; $P < 0.001$). HFS-AHV score correlated with 3I-S ($r = 0.65$, $p < 0.001$); Sensitivity of 3I-S in detecting fear of hypoglycaemia was 90% and specificity was 98%. PPV was 57% and NPV was 95%

Conclusion: In patients with Depression and Diabetes Distress a structured intervention aimed at reducing Diabetes Distress reduces both. Hypoglycaemia fear burden is an important determinant of diabetes distress and can be measured by a 3-item questionnaire. Longer duration follow up is warranted.

Association of anxiety, stress and depression with demographic, anthropometric, socioeconomic glycaemic and cardiometabolic risk factors in patients with type 2 diabetes

A. Sereti, A. Angelidi, C. Verras, S. Vrakas, A. Papazafropoulou, A. Foutris, K. Charpidis, V. Liosi, V. Gkizlis, A. Melidonis; Diabetes Center, Tzanio General Hospital, Piraeus, Greece.

Background and aims: Depression is a serious mental disease quite prevalent. Surveys have shown a strong association between depression, anxiety and stress with diabetes mellitus. These disorders can negatively affect disease control. The purpose of this study is to explore possible correlations between demographic, anthropometric, socioeconomic and cardiometabolic parameters with the presence and severity of depression, anxiety and stress in people with type 2 diabetes.

Materials and methods: 391 patients (193 males, aged 64.9 ± 10.3 years) with type 2 diabetes were included in the study. Information regarding demographic characteristics, socioeconomic status, anthropometric and metabolic parameters, glycemic control, type of antidiabetic treatment

and the presence of complications of diabetes were collected from all patients. The questionnaire DASS-21 is widely used and it is a set of three self-report scales designed to measure the emotional states of depression, anxiety and stress. It consists of 21 questions each answer being scored on a scale value of 0 to 3. The higher total scores indicate more severe symptoms. Statistical analysis was performed using STATA 9.0 software.

Results: Severity of stress showed a statistically significant association with the following parameters: sex($p=0.020$), age($p=0.002$), marital status($p=0.045$) and insulin treatment($p=0.032$), regarding anxiety: sex($p=0.002$), age($p=0.022$) and insulin treatment ($p<0.001$) while depression was associated with: sex($p=0.004$), age($p=0.007$), educational level($p=0.043$), marital status($p=0.004$), BMI ($p=0.012$) and insulin treatment ($p=0.01$). On multivariate analysis, insulin treatment showed significant positive association with stress and anxiety (Coefficient=4.56, 95%CI:0.61–8.52, $p=0.024$ and Coefficient=6.46, 95%CI:3.02–9.9, $p<0.001$, respectively), while BMI showed significant positive association with the severity of depression (Coefficient=0.27, 95%CI:0.03–0.51, $p=0.028$). Moreover, further analysis regarding insulin treatment revealed that when the number of insulin injections per day was increased from two injections to three or four per day, a strong association with the severity of stress was observed ($p=0.007$ and $p=0.019$, respectively).

Conclusion: Obesity appears to act adversely to the presence and severity of depression, giving further emphasis on the importance of adopting a healthy lifestyle of living and weight loss in people with type 2 diabetes. Insulin treatment (especially when more than two injections per day are performed) is accompanied by increased stress and anxiety levels in people with type 2 diabetes.

858

Glycaemic control and diabetes mellitus duration are associated with geriatric depressive scale in elderly male people with type 2 diabetes mellitus

S.-Y. An¹, H. Kim², S. Han², Y. Kim³, D. Shin³, N. Kim⁴, J. Seo⁴, Y. Ahn⁵, S. Ko⁵, Y. Cho⁶, S. Park⁶, S. Kim⁶, K. Kim⁷, C. Kim⁸, K.-W. Lee²; ¹Endocrinology and metabolism, Hongik Hospital, Seoul, ²Endocrinology and metabolism, Ajou University School of Medicine, Suwon, ³Internal Medicine, Bundang Jesaeng Hospital, Seongnam, ⁴Internal Medicine, Korea University Ansan Hospital, College of Medicine, ⁵Internal Medicine, St. Vincent's Hospital, The Catholic University of Korea College of Medicine, Suwon, ⁶Internal Medicine, CHA Bundang Medical Center, CHA University, Seongnam, ⁷Internal Medicine, Dongtan jeil Women's Hospital, Hwaseong, ⁸Internal Medicine, Hallym University Sacred Heart Hospital, Hallym University College of Medicine, Anyang, Republic of Korea.

Background and aims: The prevalence of depression and Type 2 Diabetes Mellitus (T2DM) are increasing in the elderly population of Korea and these are known to be related with each other. We evaluated the relationship between T2DM related factors and the degree of depression using the Korean Geriatric Depressive Scale (K-GDS) in elderly Type 2 DM subjects.

Materials and methods: This study was based on data from seven hospitals in Korea. To assess the status of depressive symptoms, the K-GDS was used. High GDS meant high probability of depression. DM related factors were the duration of T2DM, HbA1c, and the existence of T2DM complications.

Results: A total of 154 subjects (55 male and 99 female) with a mean age of 71.3 years, and a mean HbA1c of 7.6% were included. In males, the well-controlled (HbA1c<7%) T2DM group showed low GDS compared to the less-controlled T2DM group (1.94 ± 2.59 vs. 4.54 ± 3.57 , $p=0.016$). The mean GDS of well/less controlled T2DM groups did not show any significant difference in females. The mean GDS was higher in the group with a longer duration (10 years and more) of T2DM in both gender

groups, but this trend showed significance only in the male group. Compared to the subjects with no complications or micro-vascular complications, the subjects with micro- and macro-vascular complications showed high GDS in males ($p=0.029$). In a multiple linear regression analysis, DM duration and HbA1c were independently associated with GDS in the male group.

Conclusion: Greater depression was associated with poorer glycemic control and longer diabetic duration in elderly male subjects with T2DM.

859

The temporal relationship between diagnosis of diabetes and depression

B. Cleal¹, U.H. Nielsen², I. Willaing¹, R.I.G. Holt³;

¹Health Promotion Research, Steno Diabetes Center, Copenhagen, ²Incentive A/S, Holte, Denmark, ³Human Development and Health Academic Unit, Faculty of Medicine, University of Southampton, UK.

Background and aims: The purpose of this study was to investigate the temporal relationship between diagnosis with diabetes (Source: Danish National Diabetes Register) and first purchase of prescribed antidepressants (Source: Register Medicinal Product Statistics) in a working-age population.

Materials and methods: We included all Danish adults aged 18–59 who were diagnosed with diabetes in the study period (01/01/96 - 31/12/10) We ceased inclusion after 31/12/05 in order to ensure all subjects could be followed for five years after diagnosis. We excluded individuals who purchased antidepressants at any time within, and up to, a year prior to their inclusion in the data-set. Subjects were stratified according to the highest occupational category they attained in study period. For those who purchased antidepressants in the study period, we calculated the time elapsed from their diabetes diagnosis to the point at which they first purchased antidepressants. We calculated the percentage of people with diabetes who purchased antidepressants within one and five years post-diagnosis. Furthermore, we calculated the proportion who purchased antidepressants within one year post-diagnosis among all those who purchased antidepressants within five years. P-values for between-group differences were calculated using two sided Fisher's exact tests.

Results: Of those who develop depression within five years, 25.3% do so in the first year. Thus, more develop depression within the first year than if the likelihood was the same in all five years of follow-up. Of the individuals who go on to purchase antidepressants within five years of diagnosis, a greater proportion from the higher occupational groups did so within the first year (e.g. Employee at highest level 29.7%: Employee at basic level 24.2%). In contrast, overall incidence after five years is significantly greater in the lower occupational groups (e.g. Employee at highest level 9.7%: Employee at basic level 11.9%). Likewise, men as a whole were more liable to purchase antidepressants within one year of their diagnosis (Men: 27.1%: Women: 23.5%), whereas the incidence among men after five years is significantly lower than that of women (Men: 9.7%: Women: 13.5%).

Conclusion: The data indicate that diagnosis of diabetes precipitates depression across the workforce. Of those who purchase antidepressants within five years of diagnosis, both men and individuals with higher occupational status are more likely to do so within the first year. With previous research indicating purchase of antidepressants is more prevalent among women and lower occupational groups in the general population, our results suggest that it is in the period immediately after diagnosis that people with diabetes least resemble the general population in terms of their propensity to purchase antidepressants, with the impact dissipating over time.

	Depression within 1 year, %	Depression within 5 years, %	Share with depression within 1 year, % (1)/(2)	Different from employee at highest level, p-value	N	N with depression within 1 year	N with depression within 5 years

Depression and anxiety among young adults with type 1 diabetes

K.-M. Roelver¹, S. Matthaer¹, A. Lueg², B. Lutze³, K. Lange³;

¹Diabetes-Zentrum, Christliches Krankenhaus Quakenbrück, ²Diabetologische Schwerpunktpraxis, Hameln, ³Medical Psychology, Hannover Medical School, Germany.

Background and aims: Data on prevalence of depression and anxiety among young adults with type 1 diabetes are heterogeneous. Most studies report a high rate of comorbidity. In a representative sample of young adults with type 1 diabetes in Lower-Saxony (Germany) the prevalence of both mental disorders and the association with critical life events and quality of metabolic control were assessed.

Materials and methods: In 26 specialized diabetes out-patient units all patients (19–30 yrs.) diagnosed with type 1 diabetes in childhood or adolescence were invited to complete a questionnaire on their psychosocial and diabetes status, diabetes specific distress (PAID), critical life-events, and depression and anxiety (HADS-D).

Results: 306 patients (47% female, mean age 24.1±3.5 yrs., mean diabetes duration 11.7±5.8 yrs.; 43% CSII; HbA_{1c}: 8.3±1.6% (67.2±6.0 mmol/mol)) participated (additional 12 patients refused). HADS-score >10 indicating clinical relevant anxiety was seen in 6.1% of the participants, symptoms of depression in 4.0% (HADS-D score >10). These prevalence data correspond to published prevalence data of the background population. On the other hand 25% of the participants reported a high level of diabetes specific distress (PAID score >39; mean score: 26.8±19.8). Diabetes distress was mainly connected to the items “worrying about future” and “feeling guilty”. Sum scores of HADS-D and PAID were both associated with HbA_{1c} (r=-0.14; r=0.23; each p<0.01). Critical life events during the last 12 months were reported by 33.2% of the patients with negative impact on metabolic control (HbA_{1c} 8.8±1.8% vs. 8.0±1.5%; p<0.001)

Conclusion: Despite several challenges of diabetes the majority of young adults were able to cope successfully with age specific developmental tasks without suffering from mental disorder (anxiety and depression). In contrast they report of a high level of diabetes specific distress, mainly associated with fear of late complication and feelings of guilt. A regular assessment of diabetes specific burden and critical life events is recommended to suggest a personalized insulin therapy regimen and psychosocial support.

Undiagnosed cognitive impairment, health status and depressive symptoms in patients with type 2 diabetes

P.S. Koekkoek¹, G. Biessels², M. Kooistra¹, J. Janssen¹, L. Kappelle², G.E.H. Rutten¹;

¹Julius Center for Health Sciences and Primary Care, ²Neurology, University Medical Center Utrecht, Netherlands.

Background and aims: Type 2 diabetes is associated with cognitive impairment. We aimed to examine whether undiagnosed cognitive impairment in patients with type 2 diabetes is associated with a reduced health status and depressive symptoms.

Materials and methods: 225 primary care patients aged ≥70 years with type 2 diabetes were examined, both at their homes and at a memory clinic, for undiagnosed cognitive impairment (dementia or mild cognitive impairment [MCI]). Dementia and MCI were defined according to internationally accepted criteria. Questionnaires assessing health status (SF-36, EQ-5D and EQ-VAS) and depressive symptoms (CES-D) were filled out. Health status and depressive symptoms were compared between patients with and without cognitive impairment.

Results: Patients with cognitive impairment (n=57) showed significantly lower scores on the SF-36 on six out of the eight domains, on the physical and mental summary scores, and on both the EQ-5D and the EQ-VAS scores. CES-D scores were significantly higher in patients with cognitive impairment (9.2±7.1 versus 12.7±8.5; p=0.009). Depression (CES-D≥16) occurred almost twice as often in patients with cognitive impairment (RR 1.8; 95%-CI: 1.1–3.0).

Conclusion: Undiagnosed cognitive impairment in patients with type 2 diabetes is associated with a reduced health status and more depressive symptoms. Detection of cognitive impairment in type 2 diabetes patients identifies a vulnerable group of patients that could benefit from integrated and tailored treatment.

Female sex, age (<50 and ≥70 years), northern German residency, high HbA_{1c} and insulin use predict depressed mood in 35,691 type 2 diabetes patients

N. Scheuing¹, S. Ebner², A. Grünerbel³, U. Henkelüdecke⁴, N. Hermanns⁵, M. Hummel⁶, C. Schäfer⁷, C. Wagner⁸, J. Weiland⁹, R. Welp¹⁰, R.W. Holl¹, for the DPV initiative;

¹ZIBMT, University of Ulm and German Center for Diabetes Research (DZD), Germany, ²2nd Medical Department, General Hospital Linz, Austria, ³Specialized practice for diabetes and nutritional medicine, Munich, ⁴Internal Medicine, Hospital Malteser St. Johannes-Stift, Duisburg, ⁵Diabetes Centre Mergentheim, Bad Mergentheim, ⁶Specialized diabetes practice, Rosenheim, ⁷Internal Medicine, Hospital Neumarkt, ⁸Specialized diabetes practice, Saaldorf-Surheim, ⁹Internal Medicine, Hospital Bad Reichenhall, ¹⁰Internal Medicine, Knappschafts-Krankenhaus, Bottrop, Germany.

Background and aims: A bidirectional relationship between type 2 diabetes (T2D) and depressive symptoms has been reported. The primary aim was to analyze predictors of depressed mood in T2D. Secondly, the odds ratio of developing a clinically recognized depression in patients with conspicuous screening result was evaluated.

Materials and methods: 35,691 T2D patients aged ≥18 years (median [IQR]: 68.9 [59.2–76.5] years) from the German/Austrian multicenter prospective diabetes follow-up registry (DPV) were analyzed. All patients had completed the WHO-5 questionnaire, a reliable and validated 5-item screening tool for depression (score ≤7: likely depression). Logistic regression modeling (SAS 9.4) was applied to study potential predictors (e.g. demographics, regional aspect, diabetes therapy, glycemic

control) for depressed mood as well as the risk of developing clinically recognized depression.

Results: Depressed mood was present in 11.2% (n=4,000) of patients screened and thereby significantly more prevalent compared to the adult German population (DEGS study: 8.1%, $p < 0.001$). Patients with likely depression had a later diabetes onset (60.5 [49.6–70.2] vs. 58.3 [49.1–67.7] years, $p < 0.001$) and were more often female (54.0 vs. 48.0%, $p < 0.001$) compared to patients with inconspicuous results. Duration of diabetes did not differ significantly between groups (7.6 [2.4–12.9] vs. 7.0 [2.1–13.5] years, $p = 0.76$). Young and very old age as well as female sex were associated with depressed mood (table 1, model 1). Moreover, living in northern federal states of Germany, poor glycemic control ($HbA_{1c} \geq 58$ mmol/mol) and insulin treatment were significantly related to depressed mood in T2D (table 1). Overall, the odds of developing a clinical diagnosis of depression was 1.95 (95%CI: 1.66–2.29) times higher in patients scored ≤ 7 in the WHO-5 questionnaire.

Conclusion: Depressed mood is a frequent psychological comorbidity in adult T2D patients. In clinical care, routinely screening for psychological problems as recommended by guidelines is absolutely advisable, especially in high-risk patients.

Table 1. Sequential multiple logistic regression models for predicting depressed mood (WHO-5 score ≤ 7) in 35,691 T2D patients

The synergistic effect of depression and diabetes on cognitive function in a community sample of older adults

A. Nouwen¹, P. Demakakos²;

¹Department of Psychology, Middlesex University, ²Department of Epidemiology and Public Health, University College London, London, UK.

Background and aims: Diabetes and depression are independently associated with increased risk of cognitive decline. But the synergistic effect of depression and diabetes on cognitive function has yet to be studied in the general population. We used a nationally representative sample of community-dwelling individuals aged ≥ 50 years to investigate whether patients with diabetes and depression are at greater risk of cognitive decline compared with patients with either depression or diabetes.

Materials and methods: Our sample comprised 10,812 individuals (45.5% male) from the English Longitudinal Study of Ageing (mean age 65.0 years; $SD \pm 10.1$). Diabetes was defined by self-reported diagnosis and depression by a score of ≥ 4 symptoms on the 8-item Centre for Epidemiological Studies-Depression scale. We measured two domains of cognitive function, memory and verbal fluency. We estimated OLS regression models of change in the summary score of immediate and delayed recall (range 0–20 words) over a 10-year follow-up (2002–2012) and change in the animal naming score (range at baseline 0–50) over an 8-year follow-up (2002–10). Age, sex, marital status, education, occupational class, BMI, physical activity levels, smoking, and alcohol use were assessed at baseline and used as covariates. We also used six repeated measurements of the word recall score and five of the animal naming score to estimate lagged GEE models of the average 2-year change in these two cognitive function domains.

Results: At baseline, 616 individuals had T2DM, 1,574 had depression, and 188 individuals both. In OLS regression models adjusted for baseline cognition, age, sex, and marital status, individuals with diabetes, depression, or both experienced a significant decline in both memory and verbal fluency compared with individuals free of both conditions. In the fully adjusted model, individuals with diabetes but without depression no longer scored significantly lower on the word recall score compared with individuals free of both diabetes and depression (β coeff -0.31; -0.70 to 0.85), but those with depression (-0.42; -0.68 to -0.14) or with depression and diabetes (-1.25; -2.1 to -0.46) did. Similarly, in the fully adjusted model, individuals with depression (β coeff -0.64; -1.11 to -1.81) and those with both diabetes and depression (-1.87; -3.27 to -0.46) scored significantly lower on the animal naming test compared with individuals free of both conditions; this did not apply to individuals with diabetes (-0.54; -1.27 to 0.18). The GEE models indicated that, on average, compared with individuals without diabetes and depression, those with either condition or both conditions experienced a significant decline on both domains of cognitive function on a 2-year basis.

Conclusion: Depression and diabetes are associated with an increased risk of cognitive decline in a large community cohort of older adults. The effect of diabetes and depression on cognitive function appears to be multiplicative. The effects are seen over a 10-year period, but are evident also over repeated 2-year assessments. In most cases, the risk of cognitive decline was independent of sociodemographic, lifestyle, and clinical risk factors. Cognitive decline was more pronounced in depressed individuals than in diabetes patients. The consequences of depression, especially in individuals with diabetes, are serious; regular monitoring of depression in clinical practice is required.

PS 079 Recognising and treating hypoglycaemia

864

Nocturnal hypoglycaemia can be predicted by retrospective analysis of glucose variability in elderly type 2 diabetic patients treated by insulin

N.E. Myakina, V.V. Klimontov;

Laboratory of Endocrinology, Institute of Clinical and Experimental Lymphology, Novosibirsk, Russian Federation.

Background and aims: Nocturnal hypoglycemia (NH) is underestimated complication of insulin therapy, especially in elderly subjects. We aimed to determine the applicability of glucose variability (GV) indices, calculated from continuous glucose monitoring (CGM) data, for prediction of NH in elderly type 2 diabetic patients treated with insulin.

Materials and methods: We analyzed blinded CGM data for 176 nights generated by 83 in-patients, aged 65–80 years, HbA1c 7.8, 6.9–8.2% (median, 25th–75th percentile). Patients were treated with basal insulin (n=17), premixed insulin (n=24), or basal-bolus insulin therapy (n=42). The values of standard deviation (SD), continuous overlapping net glycaemic action (CONGA), lability index (LI), M-value, J-index, mean absolute glucose (MAG), high blood glucose index (HBGI), low blood glucose index (LBGI), mean amplitude of glucose excursions (MAGE) and average daily risk range (ADRR) were estimated. Most of GV parameters were computed for nocturnal hours, daytime hours and one-hour pre-midnight interval. The values of MAGE and ADRR were calculated for the whole recordings, in accordance with computational algorithms for these indices. Bedtime glucose trend was evaluated as difference between glucose values at 11 p.m. and at midnight (deltaG). Hypoglycemia was defined as glucose level ≤ 3.9 mmol/L.

Results: At least one episode of non-severe CGM-defined NH was recorded in 39 (47%) patients. The NH was present in 68 out of 176 analyzed nights (39%). Subjects with detected NH did not differ significantly from those without by age, body mass index, diabetes duration, total and basal insulin dose and HbA1c levels (all $p > 0.05$). None of these parameters was significant predictor for NH in univariate logistic regression model. Lower daytime mean glucose, CONGA, J-index (all $p < 0.02$) and higher MAG and LBGI (both $p < 0.0001$) values were found in patients with NH as compared to those without. Bedtime mean glucose and J-index was lower ($p < 0.0001$), while bedtime M-value, deltaG and LBGI was higher (all $p < 0.01$) in patients with NH. The value of ADRR was higher in patients with NH as compared to those without ($p = 0.003$), meanwhile the differences in MAGE did not reach statistical significance ($p = 0.07$). Antecedent daytime hypoglycemia increased the risk of NH ($p < 0.0001$). In multivariate logistic regression analysis the combination of three bedtime parameters (mean glucose, LBGI and deltaG) was the most reliable predictor of subsequent NH (accuracy 93.5%, $p < 0.0001$).

Conclusion: The retrospective analysis of CGM-derived GV indices could improve prediction of NH in elderly type 2 diabetic patients treated with insulin.

Prevention of hypoglycaemia by the predictive low glucose management feature in a user evaluation study

I. Conget¹, P. Choudhary², B.S. Olsen³, L. Vorrink⁴, J. Shin⁵, S. Liabat⁴;

¹Endocrinology Unit, Hospital Clinic i Universitari, Barcelona, Spain, ²King's College London, UK, ³Herlev Hospital, Denmark, ⁴Medtronic plc, Tolothenaz, Switzerland, ⁵Medtronic plc, Northridge, USA.

Background and aims: Automated suspension of insulin delivery in response to hypoglycaemia detected by continuous glucose monitoring (CGM) sensors has been shown to reduce severity and duration of hypoglycemic events. Suspending insulin delivery earlier, in response to predicted hypoglycaemia, may allow patients with type 1 diabetes to further reduce or avoid hypoglycaemia entirely. Performance of a predictive low glucose management feature in a commercially-available sensor-augmented pump system was evaluated in a user evaluation study.

Materials and methods: Three study sites in Europe enrolled 40 subjects (18 female, ages 9–65 years) with type 1 diabetes whose mean (\pm SD) A1C was $7.6 \pm 0.87\%$. The pumps were programmed to suspend insulin delivery if the sensor glucose (SG) value was predicted to be at or below the programmed threshold with a +20 mg/dL offset within 30 min and to restart when the SG value was at least 20 mg/dL above the threshold value and predicted to be at least 40 mg/dL above it within 30 min. Subjects wore the pumps and sensors for 4 weeks, after which data were downloaded and questionnaires were completed.

Results: The pump suspension feature was activated 2417 times, or 2.1 times per subject-day. The median duration of pump suspensions was 57.8 (interquartile range [IQR], 49.2–63.3) min. The median minimum SG value during the suspensions was 3.85 (IQR, 3.67–4.15) mmol/l (69.3 mg/dL), and the median SG value was 8.95 (IQR, 8.04–9.27) mmol/l (161.1 mg/dL) 2 h after restart. Most (70.5%) pump suspensions were terminated automatically; 29.5% were terminated manually. The Figure shows median and IQR of SG values surrounding the activations; the dotted line at 3 mmol/l represents the most-commonly chosen threshold value. The mean and median absolute relative differences (ARDs) between 5195 pairs of SG and contemporaneous blood glucose values were 9.5% and 5.6%, respectively. Of the 2401 evaluable activations, 2327 (96.9%) were not followed by any SG value(s) below the pre-specified threshold value. Based on mean questionnaire responses, subjects found the system's low glucose management features easy to set up and beneficial with respect to managing hypoglycaemia, and almost all (97%) expressed a preference for it compared to the system they had been using before the study.

Conclusion: Insulin pump suspension in advance of predicted hypoglycaemia helped subjects with type 1 diabetes avoid hypoglycaemia in 97% of the occasions when it was predicted. These data show that predictive low glucose management was effective in preventing hypoglycaemia and well accepted by patients.

Sensor glucose values surrounding N=2401 evaluable activations of the predictive low glucose management feature. Time 0 represents the time of pump suspension. The dotted line at 3 mmol/l represents the most commonly used threshold value.

Clinical Trial Registration Number: NCT01726621

Detecting hypoglycaemia in breath-exhaled isoprene and acetone as biomarkers of blood glucose

S. Neupane¹, G. Richmond², T. Blaikie², R. Peverall², D. Taylor², I. Campbell², G. Hancock^{2,3}, M.L. Evans¹;

¹Wellcome Trust-MRC Institute of Metabolic Science, University of Cambridge, ²Oxford Medical Diagnostics (OMD), ³Department of Chemistry, University of Oxford, UK.

Background and aims: Despite decades of research, no viable non-invasive alternatives to capillary blood glucose testing currently exist. Given reports of rescue dogs responding to changes in glycaemia, particularly alerting of hypoglycaemia, we hypothesized that volatile compounds (VOCs) in exhaled breath might change with blood glucose offering biomarkers for non-invasively monitoring glycaemia

Materials and methods: 8 female non-smoking patients with type 1 diabetes (age 46±14, duration of diabetes 23±20 years) attended on 2 occasions. After an overnight fast, we used a 220 min stepped insulin clamp technique (actrapid 0.3 mU/kg/min for 2 h then increased to 1.5 mU/kg min) with variable 20% dextrose. On one occasion, arterialised plasma glucose was adjusted stepwise to 7.1±0.8, 8.7±0.4, 10.7±0.1, 4.3±0.3 and 2.8±0.1 mM (40 min steps). On the other day, glucose was maintained throughout at 6.2±0.1 mM (CON) with STEP and CON studies performed in random order at least 1 week apart (single blinded). Thus, the study design allowed us to examine the relationship between VOCs and glucose independent of insulin which was infused identically on both study days. At 20 minute intervals, 1.1 L of exhaled breath samples were collected in Fischer Analysen Instrumente GmbH bags and analysed using V&F Airsense Compact Ion-Molecule-Reaction Mass Spectrometer. VOCs (acetone, isoprene, methyl nitrate, ethyl benzene, ethanol and propane) were standardised for exhaled CO₂. We subtracted CON from STEP values for VOCs and glucose and examined using Pearson Correlation with IBM SPSS Statistics 21. Looking specifically for a biomarker of hypoglycaemia, we also compared VOC values during final 2.8 mM step with those from non-hypoglycaemia range.

Results: (1) Exhaled breath isoprene increased significantly at glucose of 2.8 mM compared to non hypoglycaemia range (85±15 vs 34±13 parts per billion (ppb), $p<0.05$ - see figure). (2) We found a linear correlation across study glucose values between exhaled acetone and plasma glucose with higher acetone at higher glucose values ($r=0.25$, $p<0.05$). (3) There was no obvious correlation for other measured VOCs.

Conclusion: Our data suggest that exhaled breath VOCs might offer an alternative non-invasive method for monitoring changes in blood glucose, including detecting hypoglycaemia, in diabetes.

Breath Isoprene and Plasma Glucose

Needle-free nasal delivery of glucagon is superior to injectable delivery in simulated hypoglycaemia rescue

J. Yale¹, C. Piche², M. Lafontaine², R. Margolies³, E. Dissinger³, A. Shames³, N. Fink³, M. Egeth³, H. Dulude²;

¹McGill University, ²Locemia Solutions, Montreal, Canada, ³CORE Human Factors, Philadelphia, USA.

Background and aims: Injecting glucagon to treat severe hypoglycemia (SH) can be difficult for caregivers of persons with diabetes (PWDs). This study evaluated the ability of people to use injectable glucagon (Glucagon Emergency Kit - GEK) and needle-free Glucagon Nasal Powder (GNP) devices to treat a simulated episode of SH.

Materials and methods: The Caregiver arm included 16 pairs each composed of an adult with diabetes (PWD) and their caregiver. PWDs, who were taught how to use 1 of the devices in random order, then instructed their caregivers on device use. Approx. 1 wk later, caregivers treated a manikin during a simulated episode of SH. The procedure was repeated with the other product. The Acquaintance arm had 15 adults, not associated with any particular PWD, who said they were willing to assist someone in distress. Acquaintances were not trained on device use but were shown the device prior to the simulation. Acquaintances treated 2 episodes of SH, in random order, with a delay of about 10 min between each. A fully clothed adult manikin represented a PWD in the simulation. Participants were told the manikin was in SH and that they had to administer the rescue glucagon as quickly as possible. They were told to find the PWD's glucagon rescue kit in the PWD's backpack. The backpack contained the glucagon rescue kit being evaluated in that episode and the PWD's diabetes supply pouch (glucometer and strips, alcohol swabs, lancing device, insulin syringe and a vial of insulin). Sound effects and distractions created a sense of urgency.

Results: Fifteen of 16 caregivers and 14 of 15 acquaintances administered a full dose of GNP (avg. time 0.27 and 0.44 min, respectively; see table below). The 2 participants who failed to fully depress the plunger on the GNP device also failed to inject GEK. With GEK, only 8 of 16 caregivers injected glucagon (avg. time 1.89 min) of which 2 gave a full dose. Failures included injection of diluent only (n=4) and bent needle (n=1). Three caregivers administered insulin instead of glucagon; when then prompted to use GEK, 2 injected only diluent. Only 3 of 15 acquaintances injected glucagon (avg. time 2.4 min); none gave a full dose. Failures included injection of diluent only (n=9), refusal to attempt to inject (n=1) and injection with an empty syringe (n=1). One acquaintance injected insulin instead of glucagon; when then prompted to use GEK, only diluent was injected.

Conclusion: Under conditions that simulate some of the stress associated with real episodes of SH, Caregivers and Acquaintances injected glucagon with a very low success rate and numerous errors; however, the same people used GNP successfully in less time. The data indicate that delivery of GNP is easier for non-medical third parties to administer successfully and suggest administering glucagon using a different route and dosage form than those used for insulin may also reduce the risk of accidental delivery of insulin.

Arm	Parameter	GNP	GEK
Caregivers	Number	16	
	Age - median (min, max)	53.5 yrs (20, 69)	
	Male:Female	6:10	
	Full dose delivered - number (%) ¹	15 (94)	2 (12.5)
	Partial dose delivered - number (%) ¹ (% min, max)	0 (0)	6 (37.5) (3, 85)
	No dose delivered - number (%)	1 (6)	8 (50)
	Minutes to deliver dose - mean ² (min,max)	0.27 (0.03, 0.93)	1.89 (1.27, 2.75)
Acquaintances	Number	15	
	Age - median (min, max)	40.0 yrs (22, 78)	
	Male:Female	6:9	
	Full dose delivered - number (%) ¹	14 (93)	0 (0)
	Partial dose delivered - number (%) ¹ (% min, max)	0 (0)	3 (20) (36, 56)
	No dose delivered - number (%)	1 (7)	12 (80)
	Minutes to deliver dose - mean ² (min,max)	0.44 (0.17, 0.78)	2.40 (1.30, 3.93)

¹ GNP delivers entire dose when plunger is fully depressed. For GEK, full dose defined as at least 90% of the targeted 1 mg dose.
² Includes only those who injected glucagon, regardless of % dose delivered. Failures to deliver not included.

868

Subcutaneous low-dose glucagon bolus in the treatment of mild hypoglycaemia in insulin pump treated patients with type 1 diabetes

A. Ranjan^{1,2}, S. Schmidt^{1,2}, S. Madsbad¹, J.J. Holst³, K. Nørgaard¹;

¹Department of Endocrinology, Copenhagen University Hospital Hvidovre, ²Danish Diabetes Academy, Odense, ³Department of Biomedical Sciences, Endocrinology Research Section, University of Copenhagen, Hvidovre, Denmark.

Background and aims: Hypoglycaemia is a common side effect to insulin treatment in patients with type 1 diabetes (T1D). Dual-hormone treatment with combined subcutaneous (s.c.) infusion of insulin and glucagon, has potential to improve glucose control without inducing hypoglycaemia. However, in order to use glucagon in a dual-hormone approach, the dose-response relationship of exogenous glucagon on plasma glucose (PG) is a prerequisite.

Materials and methods: We carried out a single-blinded, randomized, placebo-controlled four-way crossover study to determine the dose-response relationship of s.c. glucagon to increase PG during mild hypoglycaemia in 8 T1D insulin-pump treated patients (5 females, median (range) age 47 (19-64) years, HbA_{1c} 52 (43-57) mmol/mol, BMI 24 (20-25) kg/m², C-peptide 3 (3-30) pmol/l, no autonomic neuropathy and no hypoglycaemia unawareness). Each patient underwent 4 study visits. In fasting state, an s.c. insulin bolus expected to reduce PG to 3.0 mmol/l was given, however, when PG reached 3.9 mmol/l (t=0 min), 1 of 3 different low-doses of s.c. glucagon or saline was given as a bolus. A repeated measurement linear mixed model was applied and results expressed as absolute change (95% CI).

Results: Mean (95% CI) PG peak increased with 2.3 (1.7-3.0), 4.2 (3.5-4.8) and 5.0 (4.3-5.6) mmol/l after 100, 200 and 300 µg glucagon, respectively, compared with saline (all p<0.001) (figure 1). Time to peak was 30 (27-39), 40 (32-44) and 50 (43-55) min after glucagon. Within 15 min each glucagon dose significantly increased PG with 1.4 (0.4-2.5), 2.1 (1.1-3.2), and 2.0 (1.0-3.0) mmol/l. The PG values were significantly higher compared with the saline day until 120 (83-156), 189 (152-225) and 195 (185-257) min after glucagon bolus. The incremental areas under the curve (iAUC) for glucagon were 894, 1148, and 1354 mmol/l x min and for saline 550 mmol/l x min (all p<0.001 compared to saline). There was no significant difference between 200 and 300 µg glucagon doses in regard to iAUC (p=0.13) or PG values at any time points. Mean peak plasma glucagon response above baseline occurred 10 min after glucagon administration and was 100 (47-152), 217 (118-317), and 358 (190-526) pmol/l (p<0.001). However, 45 min after saline administration a PG of 3.2 (2.9-3.4) mmol/l increased plasma peak endogenous glucagon concentration with 4.5 (1.7-7.3) pmol/L above baseline (p<0.01).

Conclusion: Low-dose s.c. glucagon bolus significantly elevates plasma glucose in case of relative insulin over-bolusing. Low dose s.c. glucagon

is an alternative to oral glucose in the treatment of mild hypoglycaemia in insulin pump treated patients.

Dose-response of glucagon on plasma glucose during hypoglycemia

Targeted photodynamic therapy of insulinomas and congenital hyperinsulinism by exendin-700DX

S. Ekim, D. Bos, M. Brom, M. Gotthardt;

Department of Radiology and Nuclear Medicine, Radboud University Medical Centre, Nijmegen, Netherlands.

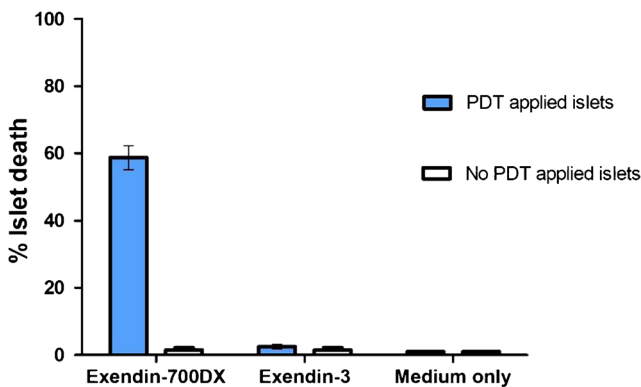

Background and aims: Insulinomas are tumors of the pancreas that are derived from beta cells. Because the tumor produces excess amounts of insulin, it can lead to hypoglycemia. Congenital hyperinsulinism is a disease that causes high levels of insulin. People with this condition have frequent episodes of hypoglycemia which can cause complications such as breathing difficulties, seizures, brain damage, and coma. Currently, treatment options are limited and there is an urgent need for novel therapeutic options. Exendin is a peptide which can specifically bind to the glucagon-like peptide 1 receptor (GLP-1R) which is expressed in the beta cells in the pancreas. Photosensitizing fluorescent dyes as 700DX can create free radicals and singlet oxygen that can be fatal to the cells, when they are subjected to laser irradiation. Labeling Exendin with 700DX can be a promising way to produce a new agent for laser induced photodynamic therapy (PDT) of insulinomas in adults and congenital hyperinsulinism in children, aimed at selective destruction of diseased beta cells. With this therapy, it would be possible to treat insulinomas or destroy diseased beta cells in a specific area of pancreas and leave a sufficient amount of beta cells to prevent diabetes. The aim of the study is development of a new agent and method for laser induced photodynamic therapy of insulinomas and congenital hyperinsulinism.

Materials and methods: Exendin-3 (Ex-3) and 700DX coupled Exendin(Ex-700DX) were used in the experiments. The therapeutic effect of the compound was examined on islets isolated from C3H mice, a rat insulinoma cell line (INS-1E) and GLP-1R expressing CHL cells. In vitro PDT experiments, were performed by incubating islets with 165 nM Ex-700DX, 165 nM Ex-3 and medium only (control) for 3 hours at 37°C. The islets and cells were irradiated for 30 min at 60 Watt, with a LED laser system that emits radiation in the 690 nm spectral band while the control plate was not laser irradiated. An hour after the PDT, cell titer glo assay was performed to detect the islet death in both plates. The effect of internalization of Ex-700DX was examined using CHL-GLP1R(+) cells by incubation at 0°C (no internalization) or 37°C (internalization).

Results: Nearly 60% islet death was detected after the targeted PDT, on the Ex-700DX treated group of islets. No significant islet death was

observed with Ex-3 and vehicle incubated groups after PDT, which proves that the compound and laser irradiation itself does not cause any islet death. (Figure) The percentage of cell death after PDT was calculated as 44% when Ex-700DX internalized into the cells, while 21% cell death was observed when Ex-700DX was only bound to GLP-1 receptors on the cells.

Conclusion: First trials on mice islets and GLP-1R positive tumor cells showed that targeted PDT with Ex-700DX efficiently destroys the target cells. For efficient PDT, Ex-700DX should be at least bound to GLP-1 receptor and the efficiency of the therapy increases nearly 2 times when Ex-700DX is internalized into the cells.

Factors associated with post-prandial hypoglycaemia in patients with remission of type 2 diabetes after bariatric surgery

G. Nosso¹, G. Saldalamacchia¹, M. Cotugno¹, E. Griffo¹, L. Angrisani², G. Riccardi¹, B. Capaldo¹;

¹Clinical Medicine and Surgery, Federico II University of Naples, ²General and Endoscopic Surgery Unit, S. Giovanni Bosco Hospital, Naples, Italy.

Background and aims: Post-prandial hypoglycemia (P-HYPO) occurs in a significant proportion of patients who achieve remission of type 2 diabetes (DM2) after bariatric surgery (BS). Aim of this study is to evaluate the factors associated with P-HYPO in patients with remission of DM2 (HbA1c <6.5%, fasting glucose <125 mg / dl in the absence of hypoglycemic therapy) after gastric bypass (BPG) or sleeve gastrectomy (SG).

Materials and methods: All participants underwent a 75 g-OGTT before and 2 years after BS. A mixed meal test and a continuous glucose monitoring (CGM) for 7 days by Dexcom G4 PLATINUM were performed after surgery. In fourteen patients (BPG / SG: 8/6, age: 49±7 years, BMI: 32±6 kg / m², diabetes duration: 3±5 years) with evidence of P-HYPO (blood glucose <70 mg / dl) and in 5 patients (BPG / SG: 1/4, age: 45±10 years, BMI: 31±6 kg / m², diabetes duration: 7±3 years) without P-HYPO (NO-HYPO) changes in insulin sensitivity (OGIS), insulin secretion (IGI) and the meal response of the entero-hormones were evaluated.

Results: The two groups were similar for age, duration of DM2 and postoperative BMI. Patients with P-HYPO showed a greater decrease in weight (ΔBMI: 13±6 vs 7±4 kg / m², p=0.042), a greater improvement in insulin sensitivity (ΔOGIS: 158±54 vs 29±22 ml min⁻¹ ml⁻², p=0.001), a higher postprandial GLP-1 peak (32±31 vs 7±2 pmol/L, p=0.031) and a lower GIP meal response (GIP peak: 209±120 vs 371±27 pg/ml, p=0.009) than NO-HYPO.

Conclusion: In patients with remission of DM2 after BS, P-HYPO is associated with greater weight loss, more marked increase in insulin sensitivity and distinct entero-hormone profile, suggesting that this complication can reflect an "extreme" form of improvement of the metabolic status.

871

Impact of early and late dumping syndrome on weight loss after bariatric surgery

E. Rebelos¹, M. Seghieri¹, V. Siciliano², D. Guarino¹, L. Fortunato², S. Molinaro², F. Denoth², M. Anselmino³, E. Ferrannini², M. Nannipieri¹;

¹Department of Clinical and Experimental Medicine, University of Pisa, ²Institute of Clinical and Experimental Physiology, CNR, ³Unit of Bariatric Surgery, AOUP, Pisa, Italy.

Background and aims: It has been postulated that weight loss after RYGB could be in part attributed to dumping syndrome following sweet ingestion with a consequent aversion for such foods. However, no study has shown a correlation between dumping syndrome and weight loss. On the other hand, other investigators have hypothesised that increased inter-meal hunger, due to reactive hypoglycaemia, could reduce weight loss. We analyzed an integrated database on bariatric subjects, asking the question if there was any correlation between reported early dumping syndrome (ED), or late dumping syndrome (LD) (i.e., reactive hypoglycaemia) and body weight change.

Materials and methods: 136 morbidly obese subjects, who had undergone bariatric surgery and have been followed for at least 30 months were evaluated. After surgery, during regular follow-up visits, a standardized questionnaire (Sigstaad and Arts questionnaires) was administered to each subject in order to diagnose ED/LD. In this dataset, ED/LD was detected 10-20 months after surgery; BMI values were recorded over the ensuing 10 months. A control group (ND) of bariatric subjects not reporting ED/LD was evaluated at the same time intervals. Once ED/LD was detected, patients were advised to change eating habits; in some cases, an OGTT was performed to confirm diagnosis.

Results: In the whole cohort, there was no significant difference in age among the 3 groups (52±10 years for the ND group, 48±11 years for the ED group and 49±11 years for the LD group, p=ns). RYGB was performed in the 72% of ND, 100% ED and 79% LD (p=ns). ED was reported in 19% of the patients and LD in 27%. LD was significantly more frequent in subjects that had undergone RYGB than in those who underwent sleeve gastrectomy (79% vs 21%, p=0.007). The prevalence of type 2 diabetes mellitus was higher in the ND compared to other groups (55, 25, 22%, p=0.01, in ND, ED and LD group, p=0.01 respectively). The ND group had higher BMIs at 10-20 months and 30 months compared to the ED and LD group (p=0.006); however the data show that ND continued to lose weight throughout the 30 months of follow-up, whereas this was not true for the LD and ED groups: once LD or ED disturb came up, subjects on these groups stopped losing weight. In total the ND group lost more weight than the LD and ED group (p=0.009). BMIs and body weights of the 3 groups at 10-20 months and 30 months are reported in table 1.

Conclusion: Patients present ED after RYGB but not sleeve gastrectomy, while LD occurs after both RYGB and sleeve gastrectomy, with a higher prevalence in the former (≈80%). LD/ED occurs more frequently in glucose tolerant than in diabetic subjects. When ED/LD occurs, subjects stop losing weight.

Table 1: BMIs and Body Weights of the 3 groups at 10-20 months and 30 months.

	ND			ED			LD			P value (for group and time interaction)

PS 080 Hypoglycaemia: implications and complications

872

Impaired awareness of hypoglycaemia and peripheral autonomic neuropathy in type 1 diabetes

S.E. Olsen¹, M.R. Bjørgaas¹, B.O. Åsvold², T. Sand³, M. Stjern³, K.B. Nilsen³;

¹Department of Cancer Research and Molecular Medicine, ²Department of Public Health, ³Department of Clinical Neurosciences, Norwegian University of Science and Technology, Trondheim, Norway.

Background and aims: Impaired awareness of hypoglycaemia (IAH) implies many-fold increased risk of severe hypoglycaemia in type 1 diabetes mellitus (T1DM). Peripheral autonomic neuropathy has been suggested as a mechanism for the development of IAH. The aim of the present study was to evaluate the association between IAH and the presence of peripheral autonomic neuropathy.

Materials and methods: We included 33 subjects with T1DM and IAH (Gold score \geq 4) and 33 with normal awareness (NAH; Gold score \leq 2), matched for age, gender and diabetes duration. A thorough clinical and laboratory evaluation including extensive cardiovascular and pupillometric autonomic function testing, nerve conduction studies as well as quantitative sensory testing was performed. Composite abnormality Z-scores were used for group comparisons. Investigators were blinded as to the hypoglycaemia awareness status of the participants.

Results: The IAH and NAH group had similar age, diabetes duration and HbA1c (Table 1). The autonomic composite score was not different between the IAH and NAH groups (mean difference -0.15 (95% CI -0.46 to 0.16; $p=0.33$), and neither were the thermal detection or nerve conduction scores (mean difference 0.15 (-0.31 to 0.61; $p=0.51$) and 0.03 (-0.43 to 0.49; $p=0.89$), respectively.

Conclusion: Sensitive and extensive measures of autonomic neuropathy were similar in closely matched IAH and NAH participants, indicating that peripheral autonomic neuropathy is not a likely mechanism for the development of IAH in subjects with T1DM.

Table 1 Clinical and biochemical characteristics of participants with type 1 diabetes

	All with diabetes	Impaired awareness	Normal awareness
Men/women, n	28/38	14/19	14/19
Age years, median (IQR)	47 (15.0)	48 (14.5)	47 (14.5)
Diabetes duration, years, median (IQR)	31 (13.3)	30 (13.5)	31 (13.5)
Current HbA _{1c} , median (IQR) %	8.0 (1.8)	7.8 (2.2)	8.1 (1.9)

Sulphonylurea induced hypoglycaemia: How often are we really seeing it?

C. McQuillan¹, M. Abouzaid¹, S. Kassim²;

¹NHSCT, ²Diabetes and Endocrinology, NHSCT, Coleraine, UK.

Background and aims: Sulphonylureas are oral medications used to reduce blood glucose levels in Type II Diabetes. The current National Institute for Health and Care Excellence (NICE) guidelines recommend their prescription as second line oral hypoglycaemic agents where blood glucose control is suboptimal despite treatment with metformin. While effective at lowering blood glucose levels, sulphonylureas are associated with serious adverse effects especially in the elderly population. These include hypoglycaemia and increased cardiovascular risk. The ultimate outcome can result in falls, fractures, psychological fear and frequent hospital admissions. The authors suspected that the prevalence of sulphonylurea induced hypoglycaemia was higher than anticipated based on in hospital observation and volume of referrals to the diabetic team. The aim of this audit was to ascertain the commonest cause of hypoglycaemia in hospitalised patients. Secondary review points included reviewing the investigations and contributing factors to hypoglycaemia as well as treatment by staff. The data collected would be used to discourage the prescription of sulphonylureas in the elderly population.

Materials and methods: Retrospective data was collected on all patients who sustained an episode of hypoglycaemia while admitted in a district general hospital over a 6 month period. The inclusion criteria required hypoglycaemia to be coded somewhere in the patient's discharge. This included patients admitted with hypoglycaemia and those where hypoglycaemia was a secondary diagnosis during admission. Particular focus was applied to medication prescription and contributing factors such as alcohol excess and prescription errors. The results were collated and statistically analysed for comparative purposes.

Results: Analysis revealed the commonest cause of hypoglycaemia in hospitalised patients to be insulin related. In total 14.3% of cases were related to sulphonylureas, much higher than anticipated from the UKPDS study where sulphonylurea associated hypoglycaemia is quoted at approximately 1.8%. Contributing factors played a relatively modest role in this subset of data. Acute kidney injury and liver failure played important roles in two patients. One elderly patient self administered twice the usual dose of insulin. The treatment in all cases was reviewed and deemed appropriate for the level of hypoglycaemia and patients clinical status.

Conclusion: Sulphonylureas are contributing to a higher than expected percentage of hypoglycaemia in hospitalised patients. There are often contributing factors as identified with this audit: A relatively small number of patients were used in the audit and the district general hospital is located near a seaside resort with a predominately retired population. Regardless of this the rate of hypoglycaemia caused by sulphonylureas is significantly higher than expected. It is also likely that we are underestimating the impact and frequency of hypoglycaemia as patients are treated by ambulance services, emergency departments and general practitioners. From this data we recommend avoiding sulphonylurea prescription in elderly patients. We also recommend discontinuing them where patients are at risk of falls, isolation and acute kidney injury. NICE guidelines recommend the use of dipeptidyl peptidase 4 (DPP-4) inhibitors and Thiazolidinediones as alternatives. This data is being used to raise awareness with GP's in the local area.

874

Brain lactate concentration is not increased during hypoglycaemia in non-diabetic subjects and patients with type 1 diabetes, as measured with ¹H-MRS

H.M.M. Rooijackers¹, E.C. Wieggers², C.J. Tack¹, A. Heerschap², M. van der Graaf^{2,3}, B.E. de Galan¹;
¹Internal Medicine, ²Radiology and Nuclear Medicine, ³Pediatrics, Radboud University Medical Center, Nijmegen, Netherlands.

Background and aims: Iatrogenic hypoglycemia is the most frequent acute complication of insulin therapy in patients with type 1 diabetes (T1DM), and limits glycemic management. Recurrent hypoglycemia initiates a process of habituation, characterized by suppression of hypoglycemic symptoms and impaired hypoglycemic awareness. Recent evidence suggests a role for increased brain lactate transport as underlying mechanism. The aim of our study was to investigate the effect of hypoglycemia on both plasma and brain lactate content in non-diabetic subjects and in T1DM patients.

Materials and methods: After an overnight fast, 5 non-diabetic subjects (2 males, mean age: 29±7 yrs, BMI 23.2±1.7 kg/m²) and 10 T1DM patients (6 males, mean age 27±7 yrs, BMI 24.4±2.5 kg/m²) underwent a stepped hyperinsulinemic (60 mU m⁻² m⁻¹) euglycemic-hypoglycemic clamp. Arterial plasma glucose and lactate levels were determined every 5 minutes. Cerebral ¹H-MRS data were acquired with a J-editing semi-LASER sequence (TE 144 ms, TR 3000 ms, 32 averages) at 3.0 T (Siemens, Trio) from a 31.25 cm³ voxel placed in the supraventricular cortex, and lactate signals were quantified using the AMARES algorithm in jMRUI.

Results: Plasma glucose levels were similar in patients and controls, both during the euglycemic and the hypoglycemic phase (euglycemia: 5.01±0.18 versus 4.92±0.20 mmol/L, hypoglycemia: 2.84±0.04 versus 2.86±0.08 mmol/L, *p*=NS for all). In non-diabetic subjects, plasma lactate levels increased from 0.87±0.22 mmol/L during euglycemia to 1.31±0.33 mmol/L during hypoglycemia (*p*=0.010). Conversely, plasma lactate levels dropped from 1.16±0.12 mmol/L to 0.92±0.14 mmol/L in T1DM patients (*p*=0.001). Brain lactate levels did not differ between the eu- and hypoglycemic condition, neither in non-diabetic subjects, nor in T1DM patients (controls: 0.50±0.06 versus 0.45±0.04 μmol/g, and T1DM: 0.48±0.07 versus 0.43±0.06 μmol/g, *p*=NS for all). In addition, brain lactate levels did not differ between patients and controls (*p*=0.69 for euglycemia, *p*=0.51 for hypoglycemia).

Conclusion: These data show divergent responses in plasma lactate levels during hypoglycemia between non-diabetic subjects and T1DM patients, which are not accompanied by changes in lactate content in the brain. This could indicate that during hypoglycemia (excess) lactate is either not taken up in the brain or that lactate is immediately utilized as a fuel, potentially to a greater extent in T1DM patients than in controls.

Recovery of cognitive function following brief exposure to hypoglycaemia in adults with type 1 diabetes

S. Mathur¹, N. Zammitt¹, B. Frier², I. Deary²;
¹Edinburgh Centre for Endocrinology and Diabetes, Royal Infirmary of Edinburgh, ²University of Edinburgh, UK.

Background and aims: Recovery of cognitive function after one hour of hypoglycaemia is delayed for a protracted period in adults. Whether a shorter period of exposure to hypoglycaemia can cause a similar delay in cognitive recovery is unknown. The aim of this study was to determine whether the duration of hypoglycaemia affects the time of recovery of cognitive function in adults with type 1 diabetes and intact hypoglycaemia awareness.

Materials and methods: A hyperinsulinaemic hypoglycaemic clamp was used to lower blood glucose to 2.5 mmol/L (45 mg/dL) (hypoglycaemia) for 20 minutes or to maintain blood glucose at 4.5 mmol/L (81 mg/dL) (euglycaemia) on two separate occasions at least two weeks apart. The order of exposure to each experimental condition was randomised and counterbalanced. A hypoglycaemia symptom questionnaire (HSQ) and cognitive test battery (Digit Symbol Substitution Test (DSST) and Four Choice Reaction Time (CRT)) were completed before, and during each experimental condition, and repeated at 10 to 15 minute intervals for 90 minutes during the recovery period. Performance on the two experimental conditions was compared using repeated measures ANOVA. A *p* value of <0.05 is considered significant.

Results: Eighteen adults (5 female) participated in the study (median age 28.5 years (IQR 23.75–33.25), median duration of type 1 diabetes 15.5 years (IQR 12.25–22.00) and median HbA1c 63 mmol/mol (IQR 59–74.25)).

Table 1 shows mean (SD) test scores and scores corrected for baseline performance. HSQ, DSST and CRT deteriorated during hypoglycaemia (*p*=0.009, <0.001 and 0.001 respectively) with an immediate improvement following restoration of euglycaemia. CRT deteriorated again 20 and 70 minutes into recovery (*p*=0.016 and 0.032 respectively) while the DSST score also deteriorated 70 minutes (*p*=0.006) into recovery but both scores had improved by the final time point (85 minutes after euglycaemia was restored).

Conclusion: Following brief hypoglycaemia, although cognitive function recovered immediately once euglycaemia was restored, subsequently a transient deterioration in reaction time was observed in a similar pattern to that observed in previous studies in which the duration of hypoglycaemia was longer. Both DSST and CRT deteriorated 70 minutes into the recovery period but were restored within 15 minutes. This could suggest an effect of boredom or fatigue rather than a direct consequence of hypoglycaemia. However, as the counterbalanced study design should ensure equal levels of ennui during both study conditions, hypoglycaemia may be affecting the ability to sustain attention for mundane, repetitive tasks during the recovery period, even after brief exposure to a low blood glucose. This has practical implications for the time required for recovery of cognitive function following hypoglycaemia in relation to activities such as driving.

TABLE 1: Mean test scores (SD) and scores corrected for baseline performance

	EUGLYCAEMIA		HYPOGLYCAEMIA		EUGLYCAEMIA corrected for baseline		HYPOGLYCAEMIA corrected for baseline		<i>p</i> values

HSQ: hypoglycaemia symptom questionnaire
 DSST: Digit symbol substitution test (the number of symbols identified in two minutes)
 CRT: Choice reaction time (mean reaction time in milliseconds)

876

The combined effects of sleep deprivation and insulin-induced hypoglycaemia on cognitive function in adults with type 1 diabetesB. Inkster¹, N.N. Zammitt¹, I.J. Deary², B.M. Frier¹;¹Diabetes and Endocrinology, Royal Infirmary of Edinburgh, ²Department of Psychology, University of Edinburgh, UK.

Background and aims: To test the hypothesis that when hypoglycaemia is induced during a state of sleep deprivation the severity of cognitive dysfunction would be greater than with hypoglycaemia alone, and that recovery following restoration of normoglycaemia would be delayed.

Materials and methods: Fourteen adults with type 1 diabetes underwent a hyperinsulinaemic, hypoglycaemic clamp on two occasions, separated by at least two weeks. Before one glucose clamp the subjects were sleep deprived overnight. Subjects were randomized and counterbalanced to the experimental condition. Cognitive function tests were performed before and during hypoglycaemia, and for 90 minutes following recovery of euglycaemia.

Results: Performance in cognitive tests assessed during hypoglycaemia did not differ significantly between the sleep-deprived and non-sleep-deprived conditions. Digit symbol substitution scores and choice reaction times were consistently poorer during recovery in the sleep-deprived state, but the difference was only significant at the final time point ($p=0.01$) for digit symbol, and at 20 and 40 minutes into recovery for choice reaction time ($p=0.02$ and 0.03 respectively). Hypoglycaemia symptom scores were significantly higher in the sleep-deprived state during all stages of recovery ($p=0.002$).

Conclusion: Hypoglycaemia per se produced a profound deficit in cognitive function and co-existing sleep deprivation did not have an additive effect. However, during restoration of normoglycaemia, sleep-deprived subjects remained more symptomatic and performed more poorly on cognitive testing for the full 90 minute recovery period.

877

Hypoglycaemia-induced changes in cerebral metabolic and reward processing: a non-invasive imaging investigation using arterial spin labellingM. Nwokolo¹, P. Choudhary¹, F.O. Zelaya², S.A. Amiel¹;¹Division of Diabetes and Nutritional Sciences, Faculty of Life Sciences and Medicine, ²Department of Neuroimaging, Institute of Psychiatry, Psychology and Neuroscience, King's College London, UK.

Background and aims: Impaired awareness of hypoglycaemia (IAH) affects 30% of people with longstanding type 1 diabetes, increasing risk of severe hypoglycaemia 6-fold. Attenuated neuroendocrine responses to hypoglycaemia are well-described; the central correlates of symptomatic counterregulatory actions are less well understood. To explore the brain responses to hypoglycaemia and the complex interplay between the regions involved we used 3D pseudo-continuous arterial spin labelling (3D pcASL) functional magnetic resonance imaging (fMRI). This approach allowed us to measure regional variation in cerebral perfusion as a surrogate marker of changes in brain activity in non-diabetic volunteers.

Materials and methods: 14 healthy, right-handed volunteers, (mean age \pm SD, 40 ± 10 years, 6 male) underwent a two-step hyperinsulinaemic (1.5 mU kg⁻¹ min⁻¹) clamp in a 3 Tesla MR scanner after an overnight fast. Two 3D pcASL scans were obtained at euglycaemia (5 mmol/L) and 2 further scans at established hypoglycaemia (2.6 mmol/L). After each scan subjects quantified autonomic symptoms using a visual analogue scale (VAS). Each pcASL scan (5 min) provided a whole brain cerebral blood flow (CBF) map with a spatial resolution of $2\times 2\times 3$ mm. Statistical parametric analysis of these images was performed using SPM-8; and a voxel-wise paired t-test was employed to examine the effect of hypoglycaemia. Only those clusters that remained statistically significant

($p<0.05$ from a cluster-forming threshold of $Z>2.31$) after family-wise error correction for multiple comparisons are reported here.

Results: During hypoglycaemia, autonomic symptom scores increased significantly (mean symptom score \pm SD, euglycaemia 12.39 ± 4.97 , hypoglycaemia 21.75 ± 8.44 $p<0.001$). A significant increase in CBF occurred in the left thalamus (a brain region associated with arousal, vigilance and recognition of stressful stimuli), right inferior orbitofrontal cortex and dorsolateral prefrontal cortex (associated with executive function, decision making and complex motivation and reward pathways). Significant decreases were detected in the right hippocampus and superior temporal cortex bilaterally (regions associated with memory and processing sensory input).

Conclusion: The cerebral response to acute hypoglycaemia reflects the activation of stress pathways but also encompasses brain regions involved in reward salience, executive function and memory. Recruitment of these higher cortical areas suggest their involvement in the behavioural response to hypoglycaemia. These networks may also influence the response to the repeat stimulus of future hypoglycaemia. Their investigation in people with type 1 diabetes and different degrees of hypoglycaemia awareness and risk will inform future therapies to reduce severe hypoglycaemia.

Hypoglycaemia and QTC prolongation in patients with type 2 diabetesK. Makrilakis¹, C. Stathi¹, I. Vlahodimitris², N. Katsilambros¹, S. Liatis¹;¹First Department of Propaedeutic Medicine, Athens University Medical School, ²Department of Cardiology, Laiko General Hospital, Athens, Greece.

Background and aims: Hypoglycaemia has been associated with increased risk of death, mainly attributed to lethal arrhythmias and QTc prolongation, both in Type 1 and Type 2 diabetes (T2D) patients. Very few studies have been performed under real-life conditions though. The aim of the present study was to examine the relationship between hypoglycaemic episodes (examined during continuous glucose monitoring subcutaneously [CGMS]) and QTc prolongation (measured by continuous ECG monitoring) in patients with T2D, during routine every-day life.

Materials and methods: A total of 40 (50% males) patients with T2D (mean age [\pm SD]: 68.3 ± 6.9 years, HbA1c: $7.45\pm 0.91\%$, diabetes duration 17.7 ± 8.7 years, BMI: 29.9 ± 1.3 kg/m², treated with insulin with or without oral hypoglycaemic medications) were studied with simultaneous CGMS and 24-hour ECG monitoring. Hypoglycaemia was defined as an episode of blood glucose <70 mg/dl (3.9 mmol/L), lasting for ≥ 20 minutes. The mean QTc during these episodes was compared with the mean QTc during the period preceding the episode. Hypoglycaemia during day- and night-time was also evaluated separately.

Results: A total of 26 non-severe hypoglycaemic episodes were recorded in 16 patients. Half of these episodes occurred during the night. Mean QTc during hypoglycaemia was significantly longer than during normoglycaemia (443.38 ± 51.38 vs. 424.46 ± 61.49 msec, $p=0.012$). Interestingly, only the night-time hypoglycaemic QTc differed significantly from the preceding period's one (459.62 ± 55.65 vs. 417.62 ± 86.13 msec, $p=0.003$), while, during the day-time, no significant difference was observed (427.15 ± 42.81 vs. 431.31 ± 18.91 msec, $p=0.58$).

Conclusion: Hypoglycaemia in patients with T2D is associated with prolongation of the QTc interval, especially during the night, and may contribute to the increased adverse outcomes seen with intensive treatment of the disease.

Hypoglycaemia reduces cognitive performance and affects cerebral blood flow in subjects with type 1 diabetes

A. Gjedde¹, M. Gejl², B. Brock², A. Møller², E. van Duinkerken³, K. Stender-Petersen⁴, C.T. Hansen⁴, P.-L. Chu⁵, H. Haahr⁴, J. Rungby⁶;

¹Dept of Neuroscience and Pharmacology, University of Copenhagen, ²Aarhus University and Aarhus University Hospital, Denmark, ³VU University Medical Center, Amsterdam, Netherlands, ⁴Novo Nordisk A/S, Søborg, Denmark, ⁵Novo Nordisk Inc., Plainsboro, USA, ⁶Gentofte University Hospital, Copenhagen, Denmark.

Background and aims: This randomised single-blinded, two-period cross-over trial investigated cognitive performance and associated regional cerebral blood flow (rCBF) during hypoglycaemia.

Materials and methods: Subjects (n=26) with type 1 diabetes underwent a hypoglycaemic and euglycaemic clamp (target plasma glucose 2.8±0.2 mmol/L and 5.5±0.55 mmol/L, respectively). Cognitive performance (working memory) was assessed by a modified digit symbol substitution test (DSST), adjusted for sight and finger movements (control DSST [cDSST]), at both visits. During DSST and cDSST, rCBF was measured in 19 pre-specified brain regions using ¹⁵O-labelled water positron emission tomography. DSST scores and response time were analysed using a linear mixed-effect model with condition and period as fixed factors and subject as a random factor. All rCBF values were normalised to grey matter and analysed using an ANOVA with condition, period and subject as fixed factors.

Results: The DSST score was significantly lower (estimated treatment difference [ETD]: -0.63 [-1.13; -0.14], p=0.014) and the response time significantly longer (ETD: 2.86 s [0.67; 5.05], p=0.013) during hypoglycaemia vs euglycaemia. During DSST, rCBF was significantly decreased (p<0.05) in medial temporal lobe (MTL) and hippocampus, and increased (p<0.05) in dorsolateral prefrontal cortex (DPC), middle and inferior frontal gyrus (MFG/IFG), superior parietal lobe (SPL) and thalamus during hypoglycaemia vs euglycaemia. During cDSST, rCBF was significantly decreased (p<0.05) in hippocampus, MTL, parahippocampal gyrus and striatum, and increased (p<0.05) in DPC, IFG, MFG, orbitofrontal cortex, superior frontal gyrus, ventromedial prefrontal cortex, SPL and thalamus during hypoglycaemia vs euglycaemia. When performing the DSST adjusted for cDSST (DSST-cDSST), rCBF was relatively increased in the striatum during hypoglycaemia vs euglycaemia.

Conclusion: Hypoglycaemia reduced cognitive performance, accompanied by significant changes of rCBF, indicating raised activity in the attentional mode network at the expense of the default mode network.

‘It makes a difference, coming here’: a qualitative exploration of clinic attendance among young adults with type 1 diabetes

L. Hynes¹, M. Byrne¹, S.F. Dinneen², D. Casey³, M. O'Hara⁴;

¹School of Psychology, ²School of Medicine, ³School of Nursing and Midwifery, National University of Ireland, Galway, ⁴Endocrinology and Diabetes Centre, Galway University Hospitals, Ireland.

Background and aims: Young adulthood is a time of challenges and risks for people with type 1 diabetes. Thus, appropriate support and education from a diabetes clinic is of particular importance. However, poor outpatient clinic attendance is common among young adults with type 1 diabetes. A significant gap exists in the research related to clinic non-attendance among young adults. The aim of this qualitative study was to develop a theory explaining attendance at a hospital-based diabetes clinic.

Materials and methods: Using a grounded theory methodology, data were collected through semi-structured qualitative interviews. Twenty nine people (21 young adults with type 1 diabetes and 8 service providers) from one hospital-based diabetes clinic were interviewed. Interviews were recorded, transcribed and analysed according to the grounded theory methodology.

Results: Relationships between young adults and service providers is the core category of this theory. Collaborative relationships between young adults and service providers increased the perceived value of attendance and reduced the vulnerability of young adults to the barriers within the existing service, such as meeting unfamiliar service providers. Relationships between young adults and service providers were developed following opportunities for contact (e.g. experiencing a crisis of diabetes or attending a structured education programme), and facilitated engagement with the service and further attendance. Relationships developed outside clinic appointments due to clinic-related barriers such as short, impersonal consultations. Barriers to clinic attendance included young adults' negative perceptions of their self-management and a lack of value associated with attending. Young adults who were engaged with the service were more likely to attend, despite barriers to attendance, due to the knowledge and confidence they had that they would benefit from attending.

Conclusion: The diabetes clinic was described as an important and valued resource by young adults and service providers. Collaborative relationships between young adults and service providers enhanced service provision in this study. Young adults gain the motivation and confidence to engage with diabetes services by experiencing collaboration with service providers. According to the results of this study, clinic attendance may be improved by increasing opportunities for relationship development between service providers and young adults. A focus on relationship development may result in more effective use of limited clinic resources by increasing engagement and reducing non-attendance.

Dysregulated IGF-system in type 1 diabetes on subcutaneous insulin therapy. Need for a change?

H.J. Arnqvist¹, K. Gutefeldt², A. Spångeus², C.A. Hedman², T. Lindström²;

¹Department of Endocrinology and Department of Clinical and Experimental Medicine, Linköping University, Linköping, ²Department of Endocrinology and Department of Medical and Health Sciences, Linköping University, Sweden.

Background and aims: Under physiological conditions insulin reaches the liver through the portal vein and the liver is exposed to a several fold higher insulin concentration than the rest of the body. In Type 1 diabetes (T1D) treated with subcutaneous insulin high IGFBP-1 and low IGF1 have been reported and this may be due to insufficient insulin delivery to the liver. Our aim was to characterize associations of IGFBP-1 and IGF1 levels to metabolic variables in a large material of patients with T1D of long duration in comparison to matched controls without diabetes.

Materials and methods: Patients diagnosed before 35 years of age, diabetes duration >20 years and not older than 65 years were invited to participate. Controls matched for age were obtained from a national population registry. IGF1 was measured by Immulite[®] and IGFBP1 by an ELISA. C-peptide was analyzed with a high sensitive ELISA. Blood samples were obtained after fasting overnight

Results: Altogether 773 patients and 708 controls participated. Mean age for the patients was 50.5±9.5 (±SD) and for controls 54.1±9.3. In spite of a long diabetes duration 80 of 578 patients were C-peptide positive and 30 had values >100 pmol/l. IGFBP-1 was 68.1 (36.0 - 159.0) µg/l (median; interquartile range) in T1D and 20.0 (11.0-34.0 in controls) p<0.0001 while IGF1 was 112±44 µg/l (mean ± SD) in T1D and 151±60 in controls p<0.0001.

IGFBP-1 was strongly associated with fasting P-glucose (r=0.405; p<0.0001) but not with HbA1c. No associations were found between P-glucose or HbA1c with IGF1. In Spearman's correlation there was a negative association between C-peptide and IGFBP-1 (p=0.011) and a positive with IGF1 (p=0.001).

Conclusion: There are pronounced changes in the IGF-system in T1D on subcutaneous insulin administration counteracted by persistent endogenous insulin secretion. Although the clinical consequences of the dysregulated IGF-system is still unclear the results raises the question of the possible advantages of intraperitoneal insulin administration.

Predicting complications and long-term outcomes in type 1 diabetes: the PRIME Diabetes Model

W.J. Valentine¹, R.F. Pollock¹, R. Saunders¹, J.P. Bae², K. Norrbacka³, B.H. Curtis², K.S. Boye²;

¹Ossian Health Economics and Communications, Basel, Switzerland, ²Eli Lilly and Company, Indianapolis, USA, ³Eli Lilly Finland, Helsinki, Finland.

Background and aims: Health economic models are important for informing healthcare policy that directly affects patients with diabetes. The utility of a model is inherently linked to its accuracy and representativeness. To date, several models of type 1 diabetes mellitus (T1DM) have been published, but often rely on historical data and/or data derived from populations without T1DM. Recent publications describing long-term follow-up from landmark trials and diabetes registries represent an opportunity to revisit T1DM modeling options. Our objective was to develop a new, product-independent model of T1DM, using data from T1DM populations to estimate complication risk, capable of predicting long-term clinical and cost outcomes.

Materials and methods: Following a systematic literature review to identify large-scale clinical trials in populations with T1DM, a model was developed (the PRIME Diabetes Model) to simulate disease progression and the risk of complications. Written in Java and externally audited, the model is structured such that individual, simulated patients are followed over time analogous to a clinical trial. At the start of a simulation, patient characteristics are assigned using a covariance matrix to ensure realistic risk profiles. Each patient is then passed to individual controllers to evaluate the risk of complications (myocardial infarction, stroke, angina, heart failure, nephropathy, retinopathy, macular edema, neuropathy, amputation, hypoglycemia and ketoacidosis), mortality and progression of risk factors such as glycated hemoglobin (HbA1c). Several approaches novel to T1DM modeling are utilized, including covariance of patient characteristics and risk factors, an HbA1c progression model derived from patient-level data, a weighted model averaging approach to estimate cardiovascular risk, and model combination to more accurately assess microvascular complication risk.

Results: Validation analysis comparing outcomes predicted by the model with those of clinical studies has shown that the PRIME Diabetes Model can project long-term patient outcomes that are consistent with those reported for a number of long-term studies in T1DM. Macrovascular endpoint data have been reliably reproduced from the EURODIAB study, the FinnDiane Registry, the Diabetes Control and Complications Trial (DCCT), the Swedish National Diabetes Registry (SNDR), and Wisconsin Epidemiologic Study of Diabetic Retinopathy study (WESDR). Similarly, macrovascular complication risk is accurately reflected in the model based on comparisons with the DCCT and the Epidemiology of Diabetes and its Complications (EDIC) study, the SNDR, EURODIAB and WESDR.

Conclusion: The PRIME Diabetes Model is product-independent, available online for academic use and has been developed in line with good practice guidelines. Validation has indicated that outcomes from long-term T1DM trials can be reliably reproduced. The model offers new approaches to long-standing challenges in T1DM modeling and may be a valuable tool for informing healthcare policy in T1DM.

Diet management, lifestyle factors and education needs by target attainment in Italian youth with type 1 diabetes from the Global TEENs study

C. Maffei¹, S. Toni¹, D. Iafusco¹, A. La Loggia¹, I. Rabbone¹, S. Tumini¹, S. Waldron², C. Domenger³, F. Calvi-Gries⁴, A. Scaramuzza¹, TEENs investigator group of ISPED;

¹Italian Society for Pediatric Endocrinology and Diabetology (ISPED/SIEDP), Torino, Italy, ²National Children and Young People's Diabetes Network, London, UK, ³Sanofi, Paris, ⁴AtlanStat, Nantes, France.

Background and aims: TEENs is an international, cross-sectional observational study, conducted in 20 countries in order to assess T1D management and psychosocial parameters in 8-25-year-olds (y/o). Data on diet management, lifestyle factors and education needs by target HbA1c attainment from the Italian cohort are reported.

Materials and methods: Data were collected at 23 centres by participant interview, medical record review and participant/parent survey from 1,009 Italian youth (46% female) in three age groups: 8-12 y/o (n=330), 13-18 y/o (n=490), and 19-25 y/o (n=189). HbA1c was measured uniformly using A1cNow[™] with target HbA1c defined as <7.5% (58 mmol/mol) for ≤18 y/o (ISPAD) and <7% (53 mmol/mol) for >18 y/o (ADA).

Results: Overall, 40% of participants met HbA1c targets. Measuring food intake based on experience was the most common method used by all age groups, followed by carbohydrate counting (Table). Of the participants who used carbohydrate counting, a higher percentage met target HbA1c than did not in all age groups, with a significant effect on target

attainment due to carbohydrate counting compared with other methods observed in 13–18 y/o ($p=0.035$). Avoiding sugars was the least common method used in all age groups. Across all age groups, participants who did not undertake any exercise were numerically less likely to reach HbA_{1c} target; on the contrary, participants who exercised 1–2 days/week were numerically more likely to reach HbA_{1c} target (Table). Performing exercise had a significant effect on target HbA_{1c} attainment in 8–12 y/o ($p=0.012$). The majority of participants were in the underweight/normal body mass index (BMI) category in all age groups, with no clear pattern between BMI class and the proportion of patients reaching HbA_{1c} target. Participants of all ages commonly requested education on diet, carbohydrate counting, how to manage T1D during illness, and how to manage blood glucose levels with exercise.

Conclusion: Carbohydrate counting and exercising at least twice per week help to attain HbA_{1c} target across all age groups. Assessment of lifestyle factors suggests that efforts targeting carbohydrate counting and exercise could promote successful health outcomes and help more patients with T1D to reach the recommended HbA_{1c} target.

Table: Diet management and lifestyle factors by age and HbA_{1c} target attainment

	8–12 y/o		13–18 y/o		19–25 y/o	
	HbA _{1c} target met n=139 (42%)	HbA _{1c} target not met n=191 (58%)	HbA _{1c} target met n=203 (41%)	HbA _{1c} target not met n=287 (59%)	HbA _{1c} target met n=59 (31%)	HbA _{1c} target not met n=130 (69%)

Freedom for life: 13 years of experience from an accredited patients' education course for type 1 diabetes. Review of long-term outcomes K. Gkastaris, S. Wylie, N. Hillier, B. Hall, A. Carling, A.M. Robinson; Diabetes department, Royal United Hospital, Bath, UK.

Background and aims: The Freedom for Life course is the accredited patients' education course for type 1 diabetes in the catchment area of Bath, UK. It is similar in principle to the DAFNE (Dose Adjustment For Normal Eating) course but with a different structure. It consists of one session a week (3 hours) for five weeks with follow up at 3 months, 6 months and 1 year (2 hours). The aim of our work was to review the long-term outcomes of the course 12 years after its introduction in eleven centres in the Bath catchment area.

Materials and methods: Using the hospital's research diabetes database (DIAMOND), records of 211 adults with Type 1 diabetes (65.5% female) were examined (baseline mean ± SD: age 45.28±12.94 years, duration of diabetes 19.29±13.21 years). Biomedical data for HbA_{1c} and body mass index (BMI) were collected before and then every 12 months after patients completed the education. Additionally, data for proportion of patients progressing to insulin pump were collected.

Results: At one year follow-up HbA_{1c} had greatly decreased from 76±15.7 to 66±12.3 ($p<0.001$). The results for the years following the

Freedom for Life course showed an improved HbA_{1c} compared to the baseline: 67±13.6 at 24 months, 69±13.6 at 36 months, 70±12.1 at 48 months, 71±13.2 at 60 months, 71±10 at 72 months, 72±12.3 at 84 months, 72±11.4 at 96 months and 73±13.4 at 108 months. Further review of the outcomes excluding patients who had insulin pump therapy revealed a significant reduction in HbA_{1c} which remained statistically significant for 6 years following the course. The mean BMI had not significantly changed before (24.35) and after (25.11) the course. Lastly 47 patients (22.27%) progressed to insulin pump with a mean interval of 2.25 years between the course and the initiation of insulin pump treatment.

Conclusion: The impact of a single Freedom for Life course on glycaemic control remains apparent in the long term. The improvement in the HbA_{1c} at 108 months compared to the baseline one remained significant (76±15 to 71±13.4 of 6.57%) even though it had deteriorated from 12 months (66±12.3 or 13.15%). Analysis of the outcomes for patients who didn't have insulin pump revealed that the reduction in HbA_{1c} remains significant for 6 years after the course. 22.3% of the patients who participated in the Freedom for Life course progressed to insulin pump treatment with a mean interval of 2.25 years. The effect of a single Freedom for Life course on glycaemic control seems to be superior to the outcomes of the other educational programmes for people with type 1 DM (both the traditional programmes and the DAFNE 5×1 day trial). This is likely due to the fact that the Freedom for Life course offers follow-up sessions at 3, 6 and 12 months. Repeat training sessions have been shown to have better outcomes in educational trials and other chronic health conditions and also lead to a better relationship between the patients and healthcare professionals.

Predictors of hospital admission in patients with type 1 diabetes following participation in the structured education programme, Dose Adjustment For Normal Eating (DAFNE)

P.R.E. Cliff¹, B. Hudson²;

¹College of Medical and Dental Sciences, University of Birmingham,

²University Hospitals Birmingham NHS Foundation Trust, UK.

Background and aims: Diabetes-related hospital admissions are not only costly to the NHS in the UK but are distressing for patients involved. Structured education programmes such as DAFNE encourage self-management and participation has been shown to reduce hospital admissions post-course. However, there continues to be some patients who are admitted despite training. We aimed to determine the rate of hospital admissions in patients with type 1 diabetes prior to and post DAFNE and examine predictors for admission post course.

Materials and methods: Using clinical case records from the PIC patient database, anonymised data from 99 adults with type 1 diabetes (T1D) who participated in DAFNE between January 2012 and September 2013, was collected and examined. Records were reviewed for evidence of hospital admission for severe hypoglycaemia, hyperglycaemia and diabetic ketoacidosis in the 12 months prior to and 12 months following course participation. Case notes were reviewed for those admitted to hospital and follow-up attendance recorded. HbA_{1c} results for all were recorded 1 year before and after DAFNE training.

Results: In the year before the course, 14 patients were admitted to hospital with a total number of 15 admissions. In the year following DAFNE, 5 patients were admitted with a total of 6 admissions. Of the 94 avoiding admission in the year following DAFNE, 83 attended at least one DAFNE review or diabetes clinic in this time (88% attendance) compared to 2 patients (40%, $p<0.05$) for those admitted. Evidence of poor blood glucose monitoring was recorded in the notes for 5 of the 5 patients (100%) and HbA_{1c} values increased in 3 of the 5 (60%).

Conclusion: As has been previously demonstrated, we show that hospital admissions for severe hypoglycaemia and diabetic ketoacidosis are

reduced in the year following the DAFNE structured education course. A predictive factor reported for ketoacidosis is a higher HbA_{1c} concentration and our findings are consistent with this. In addition, we also demonstrate that lack of engagement with diabetes services is a further predictor of hospital admission in the year following the course. We suggest that patients such as these could be identified, monitored more closely and offered extra support to improve outcomes following programmes such as DAFNE. Whilst some participants will benefit from group follow-up, these results and indeed, previous studies suggest that there is a need for ongoing individualised support and follow-up. In this way, DAFNE principles are more likely to be reinforced and maintained, and this in turn contributing to reducing hospital admissions, emergency treatment costs, and improving psychosocial outcomes for patients with type 1 diabetes. Structured education remains an important part of the management of type 1 diabetes and is recommended for all adults with the condition. Gaining a more thorough understanding of what factors influence adherence to DAFNE principles will allow for more focused care.

Partial remission period based on insulin dose-adjusted HbA_{1c} in 3,661 German and Austrian children and adolescents with type 1 diabetes

K. Nagl¹, J.M. Hermann², M. Plamper³, C. Schröder⁴, A. Dost⁵, O. Kordonouri⁶, R.W. Holl², on behalf of the DPV initiative;

¹Department of Pediatrics and Adolescent Medicine, Medical University Vienna, Austria, ²Epidemiology and med. Biometry, German Center for Diabetes Research (DZD), University of Ulm, ³Department of Pediatrics, University of Bonn, ⁴Department of Pediatrics, University of Greifswald, ⁵Department of Pediatrics, University Hospital Jena, ⁶Children's Hospital Auf der Bult, Hannover, Germany.

Background and aims: Occurrence of partial remission (PR) period shortly after onset of type 1 diabetes (T1D) might be due to amelioration of insulin sensitivity, but also due to a temporary restoration of pancreatic beta cells affecting insulin dosage. Insulin dose adjusted A1C (IDAA1C) combines required insulin dosage with HbA_{1c} and correlates with stimulated c-peptide. Applying IDAA1c, we studied PR in a large group of children and adolescents with T1D.

Materials and methods: Data of 3,661 patients with T1D (<18 years at diabetes onset, continuous follow-up) from the DPV (Diabetespatienten Verlaufsdokumentation) database were analysed. IDAA1C was calculated as $HbA_{1c} (\%) + 4 \times [\text{insulin dosage (Units per kilogram bodyweight per day)}]$ at 1, 3, 6, 12, 18, 24, 36, 48, 60 and 72 months after T1D onset. We evaluated duration of PR (IDAA1c ≤ 9, based on the first period without and the last period with PR) using Kruskal-Wallis tests and hierarchical linear regression models with random effects accounting for differences between treatment centres.

Results: Median PR period was 9 (0;21) months. After 3 months, 61% of patients had PR. In 4.7% of patients, PR even lasted until 72 months after onset. Median PR duration was lowest in patients aged <5 years at T1D onset (4.5 (0;30) months), whereas it was highest in patients older than 15 years at T1D onset (21 (9;72) months). In those >15 years, 21% still had PR 5 years after T1D onset. Duration of PR showed significant negative correlations with initial HbA_{1c} ($R = -0.15$, $p < 0.001$), positivity for islet-autoantibodies at T1D onset ($R = -0.06$, $p = 0.003$) and year of diagnosis ($R = -0.05$, $p = 0.004$). Duration of PR was longer in boys than in girls (9 (2;21) vs. 4.5 (0;15) months, $p < 0.001$). This difference remained significant after adjustment for age, HbA_{1c}, ketoacidosis, auto-antibody-positivity at T1D onset and year of diagnosis ($p = 0.01$). Subsequently, linear regression revealed that age at T1D onset >15 years, lower initial HbA_{1c}, and negativity for islet-auto-antibodies were significantly associated with longer duration of PR. Though patients with diabetic ketoacidosis at T1D onset had a significantly shorter PR than patients without, this difference did not remain significant after adjustment.

Conclusion: As IDAA1c does not discriminate between insulin sensitivity and insulin secretion, available data did not allow resolving whether the sex-difference in PR duration reflects an innate higher insulin resistance in girls, or a better beta-cell recovery in boys. Hence, the weighting of HbA_{1c} in the IDAA1c definition could cause underreporting of PR duration in girls. Yet, ketoacidosis at T1D onset, which is strongly associated with initial HbA_{1c} and has been discussed as a main risk factor for a short PR, does not show statistical significance in our regression model with adjustment for age and gender. Further research is needed to clarify the usefulness and performance of IDAA1c in clinical practice.

887

Understanding patient and clinician glucose reporting preferences in type 1 diabetes: Ambulatory Glucose Profile (AGP)

D. Mullen, S. Richter, R. Bergenstal, AGP Work Flow Study Group; International Diabetes Center, Minneapolis, USA.

Background and aims: A lack of a standardized glucose report and streamlined data acquisition across glucose monitoring devices has created frustration in clinics and reduced the use of glucose data in clinical encounters. Device specific reports are unique to each glucose monitoring device, are complex and not able to incorporate devices from different manufacturers into a single view. The AGP is simple one page report with 3 components: glucose metrics, graphic summary visualization of a 2 week glucose profile and a calendar view the glucose profiles from each of the days making up the summary profile view. The purpose of this novel research is to evaluate both patient (aim 1) and clinician (aim 3) utility and preference of streamlined standardized glucose reporting using Ambulatory Glucose Profile (AGP) reports. The first two sites participated in Time in Motion (TIM) evaluation as well as work flow mapping to determine an idealized glucose reporting work flow (aim 2).

Materials and methods: Seven geographically and demographically diverse clinics with large patient populations with type 1 diabetes were selected. Twenty patients per clinic and up to four clinicians per clinic utilized a device download station to create a standardized SMBG or CGM AGP report. Both the patients and clinicians reviewed the report then responded to a survey about the AGP reports utility and their preferences when compared with their usual glucose reports.

Results: Patients or their parents have reported a significantly higher preference for the AGP report than logbooks, device specific reports or from device displays (see Table). Patients and parents report significantly higher amounts of information, better information to support health routine changes, better understanding of their glucose patterns, more confidence in managing their glucose levels and seeing new trends from the AGP (see Table). Clinicians reported significantly higher preference of the AGP over other methods for seeing glucose trends and helping to educate patients about trends. TIM portions of the study showed significant savings in staff time (on average 4 to 15 minutes) per patient from this streamlined reporting system.

Conclusion: This novel approach to glucose reporting has the ability to save staff time, improve patient and clinician interactions through shared understanding of the patient's glucose profile and lead to more in depth individualized support for medication adjustment and health related behavior changes. Compared to the use of an HbA_{1c} and inconsistent patient reporting of adverse glucose related events, the standardized use of a one page comprehensive glucose report (AGP) resulted in more personalized clinical decision making and significantly improved clinic workflow.

Where do SGLT2 inhibitors fit in treating my patients with diabetes?

Effect of online CME and need for further education

A. Larkin, M. LaCouture, A. Csicseri, A. Le;

Medscape Education, New York, USA.

Background and aims: Successful implementation of new standards of care begins with a thorough understanding of the mechanisms of action of newer agents, and where these agents fit into modern type 2 diabetes (T2D) treatment algorithms. We sought to determine if online continuing medical education (CME) could improve the clinical knowledge and competence of primary care physicians (PCPs) regarding the use of SGLT2 inhibitors in T2D management.

Materials and methods: The effect of two educational interventions on the role of the kidney and SGLT2 in the treatment of T2D was analyzed to determine efficacy of online education presented in the form of a video lecture and interactive case-based text activity. The activities launched online in November or December, 2014 and data were collected through January, 2015. The effects of education were assessed using knowledge- and case-based matched pre-assessment/post-assessments. The effect size was calculated with Cohen's *d* (>0.8 are large, 0.8-0.4 are medium, and <0.4 are small).

Results: In total, 1566 PCPs participated. Significant overall improvements were seen for both the video lecture (*n*=455; large effect *d*=0.98) and case-based text activity (*n*=1111; large effect *d*=1.238). Specific areas of improvements seen include:

- Compared with baseline, 43% more PCPs (*P*<.0005) correctly identified the rationale for glomerular filtration rate (GFR) limits when considering use of SGLT2 inhibitors
- Compared with baseline, 33% more pulmonologists (*P*<.05) correctly identified a strategy for combating hypotension in patients on SGLT2 inhibitor therapy
- In a patient with T2D, more physicians appropriately identified the major pathological contributor to the patient's T2D after the education (47% increase, *P*<.05)
- In a patient with T2D who is starting on an SGLT2 inhibitor, more physicians appropriately educated the patient on genital mycotic

infections as the most common side effect associated with this class of antihyperglycemic agents (44% increase, *P*<.05)

Conclusion: This study demonstrates the success of a targeted educational intervention with multiple educational components (serial learning) on improving knowledge and competence of PCPs regarding the use of SGLT2 inhibitors in the treatment of T2D. Additional studies are needed to assess if improved knowledge and competence translates into improved appropriate use of these therapeutic options.

Change in HbA_{1c} associated with adherence to newly initiated metformin therapy

G.A. Nichols¹, K. Tunceli², A.G. Rosales¹, K. Kurtyka², P. Mavros²;
¹Kaiser Permanente Center for Health Research, Portland, ²Merck & Co, Inc, Kenilworth, USA.

Background and aims: Adherence to newly prescribed anti-hyperglycemic agents is essential for the attainment of glycemic goals but the association between changes in adherence and glycemic control has not been reported. We studied the association between metformin adherence and change in A1C from pre- to post-treatment levels, and the association between change in adherence and change between 2 post-treatment A1C measures.

Materials and methods: First, we analyzed 2,844 patients who newly initiated metformin monotherapy to estimate the effect of adherence on change in A1C that occurred as a result of initiating metformin. A1C change was calculated as the difference between pre-metformin A1C and the first A1C measured 6-12 months following their first metformin dispense. We used a modification of the proportion of days covered (PDC) method to estimate adherence over the 90-day period preceding each A1C to produce a “biologic response based” PDC (BRB-PDC). We categorized BRB-PDC into 4 levels: 0% (no refill of initial dispense), 1-49%, 50-79%, and $\geq 80\%$. Change in A1C was modeled as a function of BRB-PDC category. Next, we evaluated change in A1C among 2,416 patients who had at least two post-metformin A1C values. Change in A1C was calculated as the difference between the first and last post-treatment values. We estimated BRB-PDC for each A1C value and modeled change in A1C as a function of change in BRB-PDC category. Analyses were adjusted for age, sex, the first A1C value used in the relevant change calculation, and metformin dose.

Results: There was a graded relationship between adherence and change in A1C following metformin initiation. Relative to the non-adherent group, BRB-PDC 50-79% was associated with a change of -0.45% (95% CI -0.65, -0.26; $p < 0.001$), and BRB-PDC $\geq 80\%$ was associated with an A1C change of -0.73% (-0.90, -0.55; $p < 0.001$). In addition, change in BRB-PDC was associated with a significant change in A1C. Among patients with at least some initial adherence (1-79%), change to total non-adherence (BRB-PDC=0%) at the 2nd A1C measure was associated with 0.25% (0.07, 0.42; $p = 0.005$) increase in A1C, while change from some to full adherence (BRB-PDC $\geq 80\%$) was associated with an A1C decrease of 0.15% (-0.28, -0.02; $p = 0.027$). These results were magnified when limited to the 861 patients whose 1st A1C was $\geq 7\%$. Change from some to no adherence was associated with an A1C increase of 0.63% (0.27, 0.99; $p < 0.001$) while change from some to full adherence was associated with an A1C decrease of 0.40% (-0.67, -0.14; $p = 0.003$).

Conclusion: Estimating adherence over a biologically relevant time period produces a stronger association with glycemic control than has been previously reported. Changes in adherence were inversely associated with changes in glycemic control and were especially important among patients not at optimal glycemic goal.

Perceptions of diabetes control among physicians and patients with uncontrolled type 2 diabetes using basal insulin

M. Brod¹, K.M. Pfeiffer¹, A.H. Barnett², K. Berntorp³, T. Vilsbøll⁴, B. Weissenberger⁵;

¹The Brod Group, Mill Valley, USA, ²University of Birmingham, UK, ³Lund University, Malmö, Sweden, ⁴University of Copenhagen, Hellerup, Denmark, ⁵Praxis Hardhof, Basel, Switzerland.

Background and aims: While clinical definitions of diabetes control are well established, there is limited understanding of how patients perceive control and whether it differs from perceptions of control among physicians. The purpose of the study was to investigate how physicians and patients with uncontrolled type 2 diabetes (T2D) using basal insulin perceive diabetes control.

Materials and methods: A web survey of 1,012 adults with uncontrolled T2D (physician confirmed HbA_{1c} > 8% (64 mmol/mol)) and treated with basal insulin and 300 physicians was conducted in Sweden (n=240 patients and 100 physicians), Switzerland (n=152 patients and 100 physicians), and the UK (n=620 patients and 100 physicians).

Results: Analyses revealed significant differences between physicians and patients with uncontrolled T2D in their perceptions of control. In defining control, physicians were significantly more likely than patients to indicate that HbA_{1c} (85% vs. 79%, $p < .05$), complications from diabetes (89% vs. 75%, $p < .001$), and frequency/severity of hypoglycaemia (93% vs. 69%, $p < .001$) were very/extremely important for deciding whether or not diabetes is well-controlled. Patients, on the other hand, were significantly more likely than physicians to report that a wide range of other factors were very/extremely important, including energy levels (75% vs. 33%, $p < .001$), insulin units/day (78% vs. 29%, $p < .001$), how

predictable life is (72% vs. 29%, $p < .001$), and how much one has to think about diabetes (68% vs. 31%, $p < .001$). The time period for thinking about control also differed; physicians were significantly more likely than patients to think about the last three months (60% vs. 19%, $p < .001$) and less likely than patients to consider the last week or more recently (7% vs. 51%, $p < .001$). Patients also saw more obstacles making control very/extremely difficult compared to physicians, including stress (75% vs. 54%, $p < .001$), medicine side effects (70% vs. 56%, $p < .001$), other health issues (71% vs. 45%, $p < .001$), family obligations (61% vs. 33%, $p < .001$), and lack of patient support groups (56% vs. 11%, $p < .001$). Patients were significantly more likely than physicians to see uncontrolled diabetes as very/extremely interfering in different aspects of their lives, including general health (70% vs. 51%, $p < .001$), energy level (71% vs. 36%, $p < .001$), mood/emotions (63% vs. 33%, $p < .001$), how much one accomplishes during the day (62% vs. 23%, $p < .001$), keeping appointments/commitments (63% vs. 17%, $p < .001$), making plans (62% vs. 16%, $p < .001$), completing daily chores (60% vs. 21%, $p < .001$), and family responsibilities (60% vs. 18%, $p < .001$).

Conclusion: Results revealed a significant disconnect between physicians and patients with uncontrolled T2D in their perceptions of diabetes control, including how they define control, obstacles to control, and the impact of uncontrolled T2D. While physicians generally expressed a more focused and clinical view of diabetes control, patients had a much broader view, considering many different factors in their perceptions of control. The findings suggest that educating physicians about how patients' perceptions of control may differ from theirs could benefit physician/patient communication and improve diabetes management.

Discussing the need for additional oral drugs in type 2 diabetes: link between perceived physician empathy, patient bargaining and self-reported outcomes in the IntroDia™ study

A. Belton^{1,2}, M. Capehorn³, S. Down⁴, A. Alzaid⁵, V. Gamerman⁶, F. Nagel⁷, J. Lee⁷, S. Edelman⁸, W.H. Polonsky⁹;

¹International Diabetes Federation, Brussels, Belgium, ²The Michener Institute for Applied Health Sciences, Toronto, Canada, ³National Obesity Forum and Clifton Medical Centre, Rotherham, ⁴Somerset Partnership NHS Foundation Trust, Bridgwater, UK, ⁵Prince Sultan Military Medical City, Riyadh, Saudi Arabia, ⁶Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, USA, ⁷Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany, ⁸Division of Endocrinology and Metabolism, University of California San Diego and Veterans Affairs Medical Center, ⁹Department of Psychiatry, University of California San Diego and Behavioral Diabetes Institute, San Diego, USA.

Background and aims: IntroDia™ is investigating physician-patient communication during early treatment of type 2 diabetes (T2D); at diagnosis and at the time, often months or years post-diagnosis, when an additional medication is added ("add-on"). Here we examine the issue of patient bargaining (to delay additional medication) and its association with self-reported outcomes.

Materials and methods: As part of IntroDia™, 4235 T2D patients from 26 countries (median age, 46 years; male gender, 52%) were surveyed about their experience with their physician during oral medication add-on conversations (which had occurred, on average, 7.4 months ago). Patients were asked whether, during these conversations, they tried to convince their physician to postpone the additional medication. Perceived physician empathy (PPE) (using elements from CAHPS, TIPS and IPC) was measured as well as current psychosocial status (DDS and WHO-5) and self-care behaviours (SDSCA).

Results: At add-on, 80% of patients did not bargain (DNB), while 20% did bargain (DB). Of note, within the DB group, 60% of patients managed to delay initiating additional medication, while 40% did not. There were

no clinically relevant differences between DNBs and DBs on key demographic variables. The mean PPE score (scale 1=poor to 4=high [SD]) was significantly higher ($p < 0.001$) for DNBs vs. DBs (3.25 [0.71] vs. 3.01 [0.68]). DNBs were significantly less distressed by diabetes (DDS emotional score 2.63) than DBs (3.45) ($p < 0.001$). In addition, well-being (WHO-5: 63% vs. 54%) and self-care scores (SDSCA general diet: 4.8 vs. 4.1; SDSCA medication: 5.9 vs. 4.8) were significantly higher for DNBs vs. DBs, respectively (in all cases, $p < 0.001$).

Conclusion: These data show that at least 20% of patients are reluctant to start an additional medication and actively bargain with their physicians to avoid doing so. Those who bargain report poorer PPE, greater diabetes distress, and poorer well-being and self-care than those who do not bargain.

An informed shared decision making programme on the prevention of myocardial infarction for patients with type 2 diabetes: randomised, controlled trial

S. Buhse¹, I. Mühlhauser¹, T. Heller², J. Kasper³, N. Kuniss², U.A. Müller², T. Lehmann⁴, M. Lenz¹;

¹Health Sciences and Education, University of Hamburg, ²Endocrinology and Metabolic Diseases, University Hospital Jena, Germany, ³Faculty of Health Sciences, University of Tromsø, Norway, ⁴Centre for Clinical Studies, University Hospital Jena, Germany.

Background and aims: EASD/ADA and the German national guideline committee explicitly recommend the implementation of shared decision making (SDM) in diabetes care. SDM is a complex approach requiring evidence-based patient information and health professionals willing and capable to share decisions with patients. We have developed an informed shared decision making (ISDM) programme on the prevention of myocardial infarction. Diabetes educators teach patients to understand risk information including probabilities of benefits and harms of preventive options, and to set individual treatment goals. We evaluated the efficacy of this programme within a single centre study in the setting of an outpatient diabetes clinic in Germany.

Materials and methods: Patients with type 2 diabetes, 40 to 69 years, without diagnosis of ischemic heart disease or stroke were randomly assigned to the ISDM programme or control intervention. Follow-up was 6 months. The ISDM programme consisted of a patient decision aid, a 90 minutes teaching session provided by diabetes educators, and provider training. The control intervention was structurally identical but addressed lifestyle topics. Primary endpoint was the level of risk knowledge after teaching when patients define their individual treatment goals. Secondary outcomes were sufficient risk knowledge, realistic expectations, prioritisation of treatment goals, knowledge at follow-up, and achievement of treatment goals. Analyses were on intention-to-treat basis. ISDM sessions were video-taped to monitor intervention fidelity.

Results: A total of 154 patients (mean HbA1c 7.0%, blood pressure 145/82 mmHg) were randomised; 72/77 patients in the ISDM group, and 71/77 in the control group attended the teaching sessions and completed the knowledge test (score 0-12). Mean score was 8.25 for ISDM, and 2.62 for the control group (difference 5.63 [95% CI 4.82 to 6.44]; $p < 0.001$). Sufficient risk knowledge (9 correct answers) was achieved by 35/72 patients in ISDM, but no one in the control group. Mean score of realistic expectations (six questions) was 4.51 for ISDM, and 0.85 for the control group (difference 3.67 [95% CI 3.23 to 4.11]; $p < 0.001$). In the ISDM group more patients prioritised blood pressure control (51.4% vs. 25.7%; $p = 0.002$), whereas fewer prioritised glucose control (33.3% vs. 60%; $p = 0.002$). At follow-up the risk knowledge score was 3.68 for ISDM ($n = 71$) and 2.70 for controls ($n = 70$) (difference 0.98 [95% CI 0.15 to 1.80]; $p = 0.021$). More ISDM patients achieved their HbA1c goals (81.7% vs. 65.7%; $p = 0.036$). There was no difference with respect to other treatment

goals. In both groups, most patients achieved their prioritised goals. Analysis of the video-taped ISDM teaching sessions documented that the curriculum was properly implemented.

Conclusion: This study shows that the informed and shared decision making programme is effective under high fidelity conditions. Patients in the ISDM group demonstrated better understanding of risk information, more realistic expectations, and more patients achieved individual HbA1c goals. Involvement of diabetes educators may be essential to implement SDM.

Physician-patient communication at type 2 diabetes diagnosis and its links to physician empathy and patient outcomes: new results from the global IntroDia™ study

W.H. Polonsky^{1,2}, A. Belton³, S. Down⁴, M. Capehorn⁵, A. Alzaid⁶, V. Gamerman⁷, F. Nagel⁸, J. Lee⁸, S. Edelman⁹;

¹Department of Psychiatry, University of California San Diego, ²Behavioral Diabetes Institute, San Diego, USA, ³International Diabetes Federation, Brussels, Belgium and The Michener Institute for Applied Health Sciences, Toronto, Canada, ⁴Somerset Partnership NHS Foundation Trust, Bridgwater, ⁵National Obesity Forum and Clifton Medical Centre, Rotherham, UK, ⁶Prince Sultan Military Medical City, Riyadh, Saudi Arabia, ⁷Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, USA, ⁸Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany, ⁹Division of Endocrinology and Metabolism, University of California San Diego, USA and Veterans Affairs Medical Center, San Diego, USA.

Background and aims: Effective communication between physicians and type 2 diabetes (T2D) patients may improve patient self-care and outcomes. IntroDia™ is a global study investigating physician-patient communication at the time of T2D diagnosis and during early treatment, and the possible impact of early conversations on patient self-care and self-reported outcomes.

Materials and methods: As part of IntroDia™, 3628 T2D patients from 26 countries (48% male, median age 51 years) were surveyed about conversations with physicians at diagnosis. Parameters examined included the conversation's content (via a 43-item version of PACIC modified for T2D diagnosis), conversation quality (using CAHPS, TIPS and IPC scale items to ascertain perceived physician empathy [PPE]), current psychosocial status (WHO-5, DDS) and self-care behaviour (SDSCA).

Results: Using factor analysis, we identified 4 types of physician action - Collaborative (e.g. "Gave me choices about treatment to think about"), Encouraging (e.g. "Told me that a lot can be done to control my diabetes"), Discouraging (e.g. "Told me that diabetes gets harder...") and Recommending Other Resources (ROR) (e.g. "Referred me to a dietician, health educator, nurse or counselor"). PPE was positively associated with Collaborative ($\beta=0.44$, $p<0.001$) and Encouraging ($\beta=1.69$, $p<0.001$), negatively associated with Discouraging ($\beta=-1.24$, $p<0.001$) and unrelated to ROR ($\beta=0.09$, $p=0.078$). In turn, PPE was also linked to less diabetes distress (DDS: $\beta=-0.37$, $p<0.001$), greater well-being (WHO-5: $\beta=0.39$, $p<0.001$), and greater adherence to self-care behaviour (SDSCA - exercise: $\beta=0.70$, $p<0.001$; diet: $\beta=1.09$, $p<0.001$; medication taking: $\beta=0.91$, $p<0.001$).

Conclusion: Physicians' use of collaborative and encouraging conversation elements at T2D diagnosis may improve physicians' communication with patients, leading to better self-care and enhanced quality of life. Conversations using discouraging elements, however, may be counterproductive.

Physician-patient communication at prescription of an additional oral agent for type 2 diabetes: link between conversation elements, physician empathy and patient outcomes

S. Edelman^{1,2}, M. Capehorn³, A. Belton⁴, S. Down⁵, A. Alzaid⁶, V. Gamerman⁷, F. Nagel⁸, J. Lee⁸, W.H. Polonsky⁹;

¹Division of Endocrinology and Metabolism, University of California San Diego, ²Veterans Affairs Medical Center, San Diego, USA, ³National Obesity Forum, UK and Clifton Medical Centre, Rotherham, UK, ⁴International Diabetes Federation, Brussels, Belgium and The Michener Institute for Applied Health Sciences, Toronto, Canada, ⁵Somerset Partnership NHS Foundation Trust, Bridgwater, UK, ⁶Prince Sultan Military Medical City, Riyadh, Saudi Arabia, ⁷Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, USA, ⁸Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany, ⁹Department of Psychiatry, University of California San Diego Behavioral Diabetes Institute, San Diego, USA.

Background and aims: The global IntroDia™ study is investigating physician-patient communication during the early treatment of type 2 diabetes (T2D) and how such conversations may be linked to critical patient outcomes. Here we investigate patient experiences of the "add-on" moment, i.e. the consultation when, typically months or years after the T2D diagnosis, another oral agent is first prescribed, and how this conversation is associated with patient self-care and quality of life outcomes.

Materials and methods: A total of 4235 patients from 26 countries (52% male, median age 46 years) completed a self-report survey examining the content of the conversation with their physicians at add-on (via a 27-item scale of conversation elements specific for add-on). Perceived physician empathy (PPE) was measured with CAHPS, TIPS and IPC items. Current psychosocial status (WHO-5, DDS) and self-care behaviour (SDSCA) were also evaluated.

Results: Three key elements of the physician-patient conversation were identified by factor analysis - Collaborative (e.g. "Encouraged me to ask him/her questions"), Encouraging (e.g. "Told me that the new medication would improve my quality of life") and Discouraging (e.g. "Told me that my diabetes was getting worse"). PPE was positively associated with Collaborative ($\beta=1.16$, $p<0.001$) and Encouraging ($\beta=1.39$, $p<0.001$) and negatively linked with Discouraging ($\beta=-0.92$, $p<0.001$). Further, PPE was associated with less diabetes distress (DDS: $\beta=-0.39$, $p<0.001$), greater well-being (WHO-5: $\beta=0.54$, $p<0.001$) and better self-care (SDSCA - exercise: $\beta=0.56$, $p<0.001$; diet: $\beta=0.94$, $p<0.001$; medication taking: $\beta=0.76$, $p<0.001$).

Conclusion: Physician use of collaborative/encouraging conversation elements when prescribing an additional oral agent may enhance communication with T2D patients and lead to better self-care and quality of life. Conversely, discouraging elements may have the opposite effect.

Hypoglycaemia contributes to insulin discontinuation in US patients newly-initiated on basal insulin: a real-world analysis study

M.R. Dalal¹, F. Ye¹, L. Xie², M. Kazemi¹;

¹Sanofi US, Inc., Bridgewater, ²STATinMED Research, Ann Arbor, USA.

Background and aims: Hypoglycaemia and fear of hypoglycaemia remain major barriers to persistence with insulin therapy among patients with type 2 diabetes mellitus (T2DM). This study examined if US patients with T2DM who experience hypoglycaemia soon after insulin initiation are at a greater risk of insulin discontinuation.

Materials and methods: This was a retrospective cohort study using claims data from the IMPACT™ medical and pharmacy claims database. Patients (aged ≥ 18 years) with T2DM were identified if they initiated

basal insulin therapy (defined as having no prescription of basal insulin \geq 12 months before initiating insulin glargine, insulin detemir, or NPH insulin) between January 2007 and March 2013. Hypoglycaemic events were identified by health care encounters with an ICD-9-CM diagnosis code of 250.8 \times during the first 6 months of basal insulin use. Discontinuation was defined as gaps of longer than 45, 60, or 90 days in any insulin prescription coverage. A baseline was established using 12-months patient-level data prior to insulin initiation; follow-up periods of 12 and 24 months were considered. Data were adjusted for confounders using Cox regression analysis.

Results: Among 71,470 patients identified, 3,301 (4.6%) experienced hypoglycaemia within the first 6 months of insulin use. These patients were on average older than those without hypoglycaemia (56 vs 54 years; $P < 0.0001$), and were more likely to discontinue insulin use within 12 months of initiation (45-day gap: 79% vs 74%; $P < 0.001$). Data adjusted for confounders showed that patients with hypoglycaemia had a higher risk of discontinuation over 12 months (hazard ratio 1.16; 95% CI 1.03–1.32). Similar results were seen at 12- and 24-months follow-up, or when using prescription gaps of 60 or 90 days. Furthermore, patients who experienced hypoglycaemia, versus those who did not, were more likely to have a hospitalization (41% vs 23%) or an emergency department visit (56% vs 35%) (both $P < 0.001$) during the first 12 months.

Conclusion: In conclusion, in a US setting, patients with T2DM who experienced hypoglycaemia within the first 6 months after initiating basal insulin use were more likely to discontinue insulin therapy and had greater annual health care use.

Factors influencing remission phase in type 1 diabetic children

C.A. Buyukgebiz, S. Yuksel;

Pediatric Endocrinology, 0 18 klinik, Istanbul, Turkey.

Background and aims: To evaluate factors influencing the natural course and characteristics of the remission phase while residual beta cell function preservation is important.

Materials and methods: 120 patients with type 1 diabetes under the age of 18 enrolled in the study in 3 years period. Data were collected by reviewing the hospital records of patients from the time of diagnosis through the first 24 hours after diagnosis. Duration of symptoms, history of prior infection, ketoacidosis at diagnosis, length of hospitalization, initial glucose level, basal C peptide levels at diagnosis and daily insulin requirement per kg/body weight and HbA1C in each visit were recorded.

Results: 68 patients (56.5%) entered partial remission. We observed similar remission rates in those aged 10 years at diagnosis and in boys and girls. History of infection and presentation with ketoacidosis were associated with a lower rate of remission ($p < 0.001$, $p < 0.0001$ respectively) and were commonly observed under the age of 10 years ($p < 0.001$ and $p < 0.0001$ respectively). The average insulin requirements per kg at diagnosis decreased with increasing age ($r: -0.31$, $p < 0.012$). The length of time until remission was 1.36 ± 1.03 months and positively correlated with insulin requirements at discharge from the hospital ($p < 0.0001$). Mean duration of remission was 11.67 ± 5.82 months and was longer in boys than girls ($p < 0.05$). 8 patients, all boys, entered total remission for 3.80 ± 3.73 months. HbA1C levels were $7.31 \pm 1.24\%$ in the first year in remission patients with respect to 8.24 ± 1.47 in non remission patients ($p < 0.05$).

Conclusion: History of infection prior to presentation and diabetic ketoacidosis at diagnosis were associated with young age and were the most important factors negatively influencing the remission rate in newly diagnosed type 1 diabetics. Boys had a longer length of remission, and especially in puberty, had lower insulin requirement than girls. It is important to provide close follow up for patients in remission, since HbA1C levels may become elevated and remain unrecognised for a while in these patients when the remission phase is over.

897

Management and mortality in very old patients with type 2 diabetes

S. Hamada, M.C. Gulliford;

Primary Care and Public Health Sciences, King's College London, UK.

Background and aims: Less stringent treatment goals for intermediate outcome measures such as HbA1c are sometimes proposed for older patients with diabetes according to characteristics and health status of individual patients, but the appropriate ranges for the intermediate outcomes are still unclear. This study aimed to evaluate the management of very old patients with type 2 diabetes, and to explore associations of HbA1c, blood pressure (BP) and total cholesterol (TC) with all-cause mortality.

Materials and methods: A population-based cohort aged 80 years or older, diagnosed with type 2 diabetes, and registered at family practices in the UK Clinical Practice Research Datalink at 1 April 2011 was analysed. The intermediate outcomes were measured between 1 April 2011 and 31 March 2012. Patients were followed up for all-cause mortality from 1 April 2012 to death, the end of their record, or the last data collection date (31 March 2014). Associations of HbA1c, BP and TC with all-cause mortality were estimated in the Cox proportional hazards model, adjusting for age, sex, duration of diabetes, BMI, smoking status, history of coronary heart diseases and stroke, and medications including

antidiabetic, antihypertensive, lipid-lowering and antiplatelet drugs, and clustering by general practice.

Results: Data for 29,909 patients, including 16,739 (56%) of females, were analysed. During the 2-year follow-up period (median 1.8 years, IQR 1.3 to 1.9 years), there were 5,016 deaths (11.1 per 100 person-year). Mortality was higher for HbA1c <6.0% [42 mmol/mol] HR 1.33 (95% CI 1.18 to 1.50); 6.0–6.4% [42–47 mmol/mol] 1.16 (1.03 to 1.30); and ≥8.5% [69 mmol/mol] 1.49 (1.31 to 1.69); BP <130/80 mmHg 1.49 (1.38 to 1.60); and TC <4.0 mmol/L 1.20 (1.11 to 1.29). There was evidence of interaction between HbA1c and prescriptions of antidiabetic drugs (P for interaction <0.05), with low HbA1c only associated with mortality in patients on antidiabetic medications. In patients receiving no antidiabetic drugs, HbA1c 8.0–8.4% (64–68 mmol/mol) was associated with higher mortality (HR 2.07, 95% CI 1.28 to 3.33). However, in patients prescribed antidiabetic drugs, HRs for HbA1c <6.0% (42 mmol/mol), 6.0–6.4% (42–47 mmol/mol) and ≥8.5% (69 mmol/mol) were 1.42 (95% CI 1.23 to 1.64), 1.21 (95% CI 1.06 to 1.38), and 1.52 (95% CI 1.33 to 1.74), respectively. There were no interactions between BP and prescriptions of antihypertensive drugs or TC and prescriptions of lipid-lowering drugs. **Conclusion:** In very old people with type 2 diabetes, stringent targets for metabolic and BP control may not be advisable, but control of the intermediate outcomes within appropriate ranges may be required.

	Hazard ratio (95% CI)
HbA1c (%/mmol/mol)	
<6.0 (42)	1.33 (1.18 to 1.50)

Clinical inertia affects younger and older adults with type 2 diabetes mellitus equally, with or without CKD

W.D. Strain¹, P.M. Paldanius²;

¹University of Exeter Medical School, UK, ²Novartis Pharma AG, Basel, Switzerland.

Background and aims: Clinical inertia (CI) is often defined as a failure to escalate treatment in order to achieve appropriate treatment goals in management of type 2 diabetes mellitus (T2DM). There is no single identifiable fault in CI; rather, it is a multifactorial condition, with contributory factors from the people with diabetes, the physicians and the system in which they operate. The Time2DoMore in Diabetes programme suggested that physicians believe older adults with diabetes and those with chronic kidney disease (CKD) are more susceptible to CI than younger patients with few or no comorbidities, resulting in lower expectations for concordance and adherence to lifestyle changes in the older or multimorbid people with diabetes. It is widely accepted that CI affects less clinical trials, presumably due to the placebo effect. The difference between routine care and this placebo effect in trials represents a correction of non-pharmacological aspects of CI. We used this concept to explore the pre-existing CI by targeting placebo-treated patients from the large vildagliptin clinical trial programme and using CKD as a proxy of diabetes complications in general; comparing the glycaemic outcomes after a placebo intervention in older patients with or without CKD, to those in a younger population, with or without CKD.

Materials and methods: We stratified all placebo-treated subjects, both treatment-naïve or with multiple antidiabetics background medications, from the vildagliptin clinical trial programme, in a factorial design by age (<70 or >70 years) and with or without CKD (impaired renal function defined as eGFR <60 ml/min). Least Square (LS) mean change in HbA1c was assessed at 24 weeks (ANCOVA) and predictors of any differences were explored from the available baseline characteristics.

Results: Our cohort comprised 3081 placebo-treated patients from 25 studies. 80% of patients included in the analysis were <70 years old and 45% of all patients were women. As expected, the duration of T2DM was longer in patients with CKD in both younger and older groups (table), and the renal function was reduced in patients with CKD independent of their age; corresponding stage 3B in both CKD groups. The mean baseline HbA1c was comparable across the groups independent of age or CKD status. The overall mean placebo effect, with or without adjustment for baseline HbA1c value, was similar between all groups (adjusted LS mean HbA1c reductions between -0.23 and -0.32). There was no between-group difference when the HbA1c reductions from baseline were adjusted for CKD status (p=ns, for all comparisons).

Conclusion: In this exploratory analysis we were able to demonstrate a consistent placebo effect across age groups in presence or absence of CKD. This suggests that the non-pharmacological component of CI in patients with diabetes may be independent of age and comorbidities.

	Younger, non-CKD n=2176	Younger with CKD n=304	Older, non-CKD n=338	Older with CKD n=263
Demographics				
Age (years)	54.4±9.22	60.6±6.81	73.5±3.10	74.7±3.93

Impact of socioeconomic status and ethnicity on risk of stroke, hospitalisation for heart failure and death in 371,092 individuals with type 2 diabetes

B. Zethelius¹, A. Rawshani², A.-M. Svensson³, B. Eliasson⁴, A. Rosengren⁴, S. Gudbjörnsdottir⁴;

¹Dept of Public Health and Caring Sciences/Geriatrics, Institute of Clinical Sciences, Uppsala, ²Inst of Medicine, ³Dept of Molecular and Clinical Medicine, Inst of Medicine, ⁴Clinical and Molecular Medicine, Inst of Medicine, Gothenburg, Sweden.

Background and aims: Socioeconomic status (SES) and ethnicity are powerful predictors of coronary heart disease in diabetes, but whether this association extends to heart failure and stroke is unknown. We examined the impact of SES and ethnicity on the risk of stroke, hospitalization for heart failure (HF) and overall mortality in type 2 diabetes.

Materials and methods: We included 371,092 patients (contributing 2,766,349 appointments) with type 2 diabetes in the Swedish National Diabetes Register (NDR) during 2004–2012. Clinical data from the NDR was linked to national registers, whereby information on income, education, marital status, country of birth, comorbidities and events was obtained. Swedish natives were used as the reference group for ethnicity. Patients were followed until a first incident event (hospitalization for heart failure and fatal/nonfatal stroke), death or end of follow-up. The association between socioeconomic variables and the outcomes was modeled using Cox regression. Two models were computed for each outcome. The first model was adjusted for demographic and diabetes-related covariates. The second model was additionally adjusted for outcome specific covariates.

Results: Mean (SD) follow-up was 4.7 (2.5) years. HF occurred in 26,448 (7.1%) persons. Fatal/nonfatal stroke occurred in 38,480 (10.1%) persons and 49,829 died (13.4%). Immigrants from Nordic countries had 9% and 14% elevated risk of HF (Figure 1). Immigrants from the Middle East and North Africa had 22% to 50% lower risk of all outcomes. Immigrants from the Mediterranean Basin had 23% lower risk of stroke. Latin Americans had 50% lower risk of HF and 40% lower risk of overall mortality. East Asians had 60% lower risk of HF and 50% lower risk of overall death. As compared with having 9 years or less education, having a college/university degree was associated with 20% lower risk of both HF and overall mortality. Those with 10 to 12 years of education had 10% lower risk of both death and HF, compared with having 9 years or less education. Income was inversely associated with the outcomes. As compared with the highest income quintile, those in the two lowest quintiles had 50% higher risk of all outcomes. As compared with being single, being married was associated with 12% lower risk of HF. Individuals who were widowed had 10% higher risk of HF.

Conclusion: There are marked socioeconomic disparities in the risk of HF, stroke and overall mortality despite equitable access to universal health care. We find indications of a healthy immigrant phenomenon, as non-Western immigrants frequently had lower risk than native Swedes. Socioeconomic status and ethnicity are independent predictors of stroke, HF and death in type 2 diabetes.

Hazard Ratios for Heart Failure

MODEL ADJUSTMENTS: Minimally adjusted: age, sex, duration of diabetes, marital status, income, education, ethnicity. Maximally adjusted: as the minimally adjusted model and additionally smoking, systolic blood pressure, HbA1c, body mass index, previous myocardial infarction, previous stroke, diabetes treatment, blood pressure lowering medications, atrial fibrillation.

Exploring the distribution of cardiovascular disease and risk factors amongst patients with diabetes on sulfonylurea in a Canadian primary care dataset

P. Farahani¹, S. Khan², M. Oatway³, A. Dziarmaga³;

¹Department of Medicine - Division of Endocrinology, ²CPCSSN - Queen's University, Kingston, ³AstraZeneca Canada Inc., Mississauga, Canada.

Background and aims: A growing body of evidence generated from observational studies and meta-analyses has begun to illustrate the potential adverse cardiovascular (CV) risk profile associated with sulfonylurea (SU) use. Studies reported an increased risk of death with SU drugs. The use of SU was associated with increased mortality and a higher risk of stroke. Also, more CV events with SU use have been reported in subgroups of patients with history of CV disease, elderly and higher body mass index. The objective of this study was to explore the distribution of CV disease and CV risk factors amongst patients with diabetes on SU in a Canadian primary care dataset for 2013 calendar year.

Materials and methods: The Canadian Primary Care Sentinel Surveillance Network (CPCSSN), which is a multi-disease surveillance system based on primary care electronic medical record data, was utilized for this research study. Patients with a diagnosis of type 2 diabetes and exposure to SU were identified. Distribution/prevalence of CV risk profile amongst this sub-cohort was explored.

Results: Through database for 2013 calendar year there were 6146 patients who had diabetes, had at least one visit with their family doctor, and were on SU. For this sub-cohort demographic data included: age [mean

(SD)] 65.4(12.8) years-old; 56.4% male and mean BMI 31.3(10.0). Established CV disease was found in 16% of the patients with the following distribution: 13% had ischemic heart disease/myocardial infarction or coronary artery disease; 2% had stroke; and 2% had peripheral vascular disease. Regarding aggregation of CV risk factors a very significant proportion (65%) of patients without established atherosclerotic CV disease had 2 or more CV risk factors including: hypertension (62%), dyslipidemia (33%), active smoking (13%), and obesity (43%). Almost half of the cohort (45%) were males older than 55 years of age or females more than 60 years of age with at least one of the following risk factors: dyslipidemia, hypertension or current smoking, but without established cardiovascular disease. A large proportion of patients (19.5%) had a diagnosis of cardiac specific issues including ischemic heart disease, heart failure or arrhythmia. Almost 82% of patients had established atherosclerotic CV disease or 2 or more CV risk factors without established atherosclerotic CV disease.

Conclusion: This study illustrated that in this dataset a significant proportion of patients with diabetes on SU in 2013 had established CV disease and/or aggregation of multiple CV risk factors. In light of recent data on association between SU utilization and CV events and increased mortality, pharmacovigilance programs should actively monitor SU utilization in patients with diabetes and high risk CV profile in real world clinical settings.

LEADER-8: Type 2 diabetes patients at high cardiovascular risk: a comparison of Eastern and Western European participants in the trial

E. Franek¹, M. Haluzik², on behalf of the LEADER investigators; ¹Polish Academy of Sciences, Warsaw, Poland, ²Charles University, Prague, Czech Republic.

Background and aims: The prevalence of type 2 diabetes (T2D) may reach 600 million patients worldwide in 2035. There are many regional and national differences in incidence and prevalence for the disease itself as well as its complications. The 45 years of separation between Western and Eastern Europe may have resulted in some of these differences, but also in distinct differences in the cardiovascular disease (CVD) epidemiology. It is unknown how the baseline demographics and anthropometric differences for patients with T2D and high risk of CVD vary between these two regions.

Materials and methods: This study compares metabolic control, diabetic risk factors and treatment at baseline between regions (Western EU (WEU), Eastern EU (EEU) and Russia/Serbia (Ru/Se)) in a subpopulation of subjects with T2D and high cardiovascular risk (n=2845) enrolled in the Liraglutide Effect and Action in Diabetes: Evaluation of cardiovascular outcome Results (LEADER) trial. We performed descriptive statistics to describe the differences in baseline characteristics among the regions.

Results: HbA1c levels were similar between WEU and EEU, 8.3±1.3% and 8.3±1.3%, respectively. Western patients were older (65.9 years vs. 62.1, p<0.0001) and had longer diabetes duration (12.4±7.7 years vs 9.5±6.5, p<0.0001). Mean systolic blood pressure (BP) was lowest for participants from Ru/Se (137±14 mmHg), whereas diastolic BP was lowest in WEU (81.3±9.5 mmHg). Control of dyslipidaemia was best in WEU, and worst in Ru/Se. The percentage of patients meeting all three guideline targets for HbA1c (<7%), BP (140/80 mmHg), and LDL cholesterol (70 mg/dL) was 9.7%, 6.4% and 3.2% (p<0.05) in WEU, EEU and Ru/Se, respectively. For antidiabetic treatment, metformin and sulphonylurea treatment was more frequent in the EEU than in WEU. Insulin was used less frequently in EEU than in WEU and Ru/Se. Statins were used most frequently in the WEU countries and least frequently in Ru/Se.

Conclusion: In spite of longer diabetes duration and higher age, patients with T2D and high CV risk from WEU had lower BMI, better blood

pressure and lipid control than those in the EEU. The differences, however, were small and the percentage of subjects meeting all the three targets of treatment was low in all regions of Europe, suggesting that despite socioeconomic differences patients recruited in Europe were overall comparable at baseline.

Table: Baseline differences between European regions.*

Parameter	Western EU (1905)	Eastern EU (564)	Russia and Serbia (R,S) (n=376)	P value, Eastern EU vs. R,S	P value, Eastern EU vs. Western EU

LEADER-7: US and European participants in the trial are different: implications for the interpretation of the trial results

G. Rutten, on behalf of the LEADER investigators; University Medical Center, Utrecht, Netherlands.

Background and aims: The usefulness of trial results for a particular clinician depends on how well the trial population mirrors the population of patients in that clinician's practice. When participants differ with respect to attributes that modify treatment, the results will be less applicable. We examined whether there are important differences in cardiovascular risk factors among LEADER participants enrolled in the US and in Europe.

Materials and methods: The Liraglutide Effect and Action in Diabetes: Evaluation in cardiovascular outcome Results (LEADER) trial in 9340 patients with type 2 diabetes mellitus (T2DM) will provide data on the cardiovascular safety of liraglutide compared to placebo. Baseline data from US (n=2488) and European (n=3521) participants were compared, and stratified for prior cardiovascular disease (CVD). Multivariable logistic regression analyses were used to determine whether region was an independent determinant of achieved targets for HbA1c, blood pressure and LDL-cholesterol.

Results: Irrespective of CVD history, US participants were more often of non-white origin, had a longer history of T2DM and a higher body weight (Table). They had a 0.5% higher baseline HbA1c and a substantially lower blood pressure, but were less often at target for their 'region-specific' blood pressure target (OR 0.60; 95% CI 0.42-0.87). They had a marginally lower LDL-cholesterol level. In the group of patients with prior CVD less US participants had a prior myocardial infarction (15.5% vs 19.4%). 'Region' was independently associated with participants being at the HbA1c, BP and LDL-targets, likely partially due to different diabetes guidelines in Europe and the US.

Conclusion: The differences between US and EU participants and the role of the region might cause clinically important heterogeneity in treatment effects across regions and subgroups. These differences should be taken into account in the analysis and reporting of the results.

Table: Baseline differences between Europe and US patients stratified by prior CVD.*

Effectiveness and feasibility of a computerised prompt for primary and secondary care physicians to refer or refer back type 2 diabetes patients

M.C.M. Ronda¹, L.-T. Dijkhorst-Oei², G.E.H. Rutten¹;
¹Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, ²Internal Medicine, Meander Medical Center, Amersfoort, Netherlands.

Background and aims: Patients with type 2 diabetes mellitus (T2DM) are treated according to clear guidelines. However, guidelines on treatment setting (primary or outpatient clinic based care) are mostly lacking. In the Netherlands, ~85% of T2DM patients are treated by general practitioners in primary care and clear guidelines exist when to refer a patient. However, many patients are not treated in the correct setting. We introduced an automated signal in the Electronic Medical Record (EMR) of general practitioners and internists that warns if a patient should be treated in another setting, i.e. be referred or referred back. This signal gives a recommendation according to guidelines. We hypothesize that this can create a shift from primary to secondary care and vice versa in such a way that only individuals who need intensive diabetes treatment will be offered hospital based diabetes care.

Materials and methods: In a cluster randomized trial general practices and practices of hospital based specialists who all share a common EMR were randomized. In the intervention group an automated message in the EMR popped up to physicians during a consultation if their patients were not treated in the correct setting; it also recommended the preferred allocation of care. The signal was based on HbA1c, blood pressure, lipids and end organ damage. In the general practices 3 types of recommendations were provided: 1. e-consultation with a specialist; 2. referral to specialist;

3. decrease consultation frequency combined with self-monitoring by the patient. A single patient could be treated according to both recommendations 1. and 2, depending on treatment values. In the outpatient clinic specialists could receive only one signal to refer a patient back to the general practitioner. At the same time, we asked physicians if they would follow the recommendation and if not, why. The control group provided care as usual. Follow-up: 12 months. The primary outcome is the change in proportion of patients who are treated in the right care setting.

Results: We included 38 primary care and 10 specialist practices. Together they included 2779 patients (1418 intervention, 1361 control group). At the start, in the intervention group there were 818 patients (57.7%) with one or more recommendations to change treatment setting (559 for e-consult; 451 for referral to specialist care; 53 for self-monitoring and 30 for referral back). In the control group there were 764 patients (56.1%) who qualified for another treatment setting (501 for e-consult; 417 for change to specialist care; 49 for self-monitoring and 39 for change to primary care). After one year, in the intervention group 542 of these individuals (66.3%) and in the control group 552 (72.3%) still were not treated in the correct setting (p=0.29). The main reasons for not adhering to the guideline-based recommendation were: 1) at patient's request and 2) the current leading physician would like to adjust treatment first.

Conclusion: Over half of T2DM patients are not treated in the correct treatment setting as stipulated in the Dutch National Guidelines. After one year this situation was unchanged in over two-thirds of these patients. The signal to the treating physician in the EMR had no added value to improve triage and change treatment setting in this population.

Blood glucose and blood pressure related treatment target achievement: results of the prospective DIALOGUE registry

D. Tschöpe¹, R.E. Schmieder², P. Bramlage³, C. Koch⁴, T. Ouarrak⁵, A.K. Gitt⁶;
¹Herz- und Diabeteszentrum Nordrhein-Westfalen, Bad Oeynhausen, ²Schwerpunkt Nephrologie / Hypertensiologie, Universitätsklinikum Erlangen, ³Institute for Pharmacology and Preventive Medicine, Mahlow, ⁴Novartis Pharma GmbH, Nürnberg, ⁵Stiftung „Institut für Herzinfarktforschung“, Ludwigshafen, ⁶Herzzentrum Ludwigshafen, Germany.

Background and aims: Individualized treatment target achievement is difficult to predict, based on patient characteristics at baseline. Therefore, we analyzed the baseline characteristics of 6,092 patients included into the prospective, observational, multi-center DIALOGUE registry in Germany which had a 12 months follow-up to identify patients with good treatment outcomes.

Materials and methods: A total of 8,594 patients with type-2 diabetes and hypertension were included of which 6,092 had a 12 months follow-up and complete data to assess treatment target achievement. Treatment targets were individually assigned by the physicians to strict, moderate or loose blood glucose (BG) targets (HbA1c <6.5%; 6.5-<7.0%; 7.0-<7.5%) and blood pressure (BP) targets (sBP <130 mmHg; 130-<135 mmHg; 135-140 mmHg).

Results: Out of 6,092 patients 32.3% (n=1,967) had both their blood pressure (BP) and glucose (BG) controlled at 12 months according to their prespecified individualized goals. 24.6% (n=1,500) missed their BG goal, 20.8% (n=1,267) missed their BP goal and 22.3% (n=1,358) missed both treatment targets. Patients who achieved their individual BP and BG targets (BP+/BG+) were older, had a shorter diabetes duration and a lower BMI compared to the other patient groups (p<0.0001). With a mean admission HbA1c of 7.5±1.3% in this group, 30.4% had a strict treatment target of HbA1c ≤6.5% assigned which were fewer patients compared to the other groups (p<0.0001). For this purpose less

antidiabetic drugs were needed in this group after baseline. The same pattern was seen for blood pressure targets. With a mean admission BP of 137.5 ± 14.0 which was less than in the other groups, less stringent treatment targets were pursued ($p < 0.0001$). On the other hand there was no difference in the number of antihypertensive drugs used.

Conclusion: In this observational study, blood pressure and blood glucose treatment targets were achieved in a substantial portion of patients associated with being older, having a shorter diabetes duration and lower weight.

GLP-1 receptor agonist device- and regimen-related features important to injection-experienced and injection-naïve patients with type 2 diabetes mellitus: a multinational interview study

S. Grandy¹, S. Chen¹, E. Flood², B. Romero², K. Bergenheim³, A. Rydén³;

¹AstraZeneca, Gaithersburg, , ²ICON, Bethesda, USA, ³AstraZeneca, Mölndal, Sweden.

Background and aims: GLP-1 receptor agonist injectable treatments for type 2 diabetes mellitus (T2DM) vary with respect to device and regimen-related features. The objective of the study was to examine importance and acceptability of GLP-1 receptor agonist treatment features among injection-experienced and injection-naïve patients.

Materials and methods: One-on-one interviews were performed with injection-experienced and injection-naïve patients with T2DM in 5 countries: Brazil, China, Germany, Japan, and the UK. Interviews were conducted in the patients' native language by trained interviewers using a semi-structured interview guide. All patients ranked the importance of 5 device- and regimen-related attributes: dosing frequency, preparation method, needle size, device size, and need for refrigeration. Injection-naïve patients also were asked both open-ended and prompted questions about the acceptability of an injectable medication and the most important aspects of injection treatment. Interviews were audio-recorded and transcribed into English. A thematic and content analysis was performed using MaxQDA 11 software.

Results: Fifty patients, 10 in each target country, were interviewed and included injection-experienced patients (n=28, 56%; n=9, 18% exenatide QW users and n=19, 38% liraglutide users) and injection-naïve patients on oral anti-diabetic medications (n=22, 44%). Mean age was 52.8 ± 12.5 years (range 21 to 79), and 54% (n=27) were male. The 3 most important attributes were the same for both the injection-experienced and injection-naïve patients; dosing frequency (experienced: n=23, 82%; naïve: n=18, 82%), needle size (experienced: n=19, 68%, naïve: n=15, 68%), and injection preparation (experienced: n=16, 57%; naïve: n=11, 50%). For the remaining two attributes, need for refrigeration was ranked as more important than device size for the injection-naïve patients. Almost two-thirds of the injection-naïve patients (n=14; 64%) reported that they would be hesitant to use an injectable treatment. Top concerns regarding injectable treatment were related to self-injection, such as knowing how and where to inject, (n=7, 32%), side effects (n=6, 27%), dosing frequency (n=4, 18%) and preparation involved, including amount and ease of preparation (n=4, 18%). Injection-naïve patients identified important aspects of injectable treatment as needle size (n=13, 59%), the frequency of dosing (n=11, 50%), injection preparation (n=9, 41%), efficacy (n=5, 23%) and device size (n=5, 23%).

Conclusion: Injection-experienced and injection-naïve patients both identified dosing frequency, needle size and preparation as the most important device- and regimen-related attributes. Injection-naïve T2DM patients have concerns about injectable treatments and are hesitant to begin this type of therapy. Comprehensive education and support by healthcare providers on the preparation and proper use of injectable diabetes treatments would be important in relieving patients' fears and concerns about self-preparation and administration.

Sustained effects of duodenal-jejunal bypass liner on weight loss and glycaemic controlL.M. Kaplan¹, D. Maggs², A. Liao², E. Chiquette²;¹Massachusetts General Hospital and Harvard Medical School, Boston, ²GI Dynamics, Lexington, USA.

Background and aims: Behavioral and pharmacologic interventions in patients with obesity and type 2 diabetes (T2DM) have a poor record of sustainable efficacy in a real world setting. This has been thought to result from advancing disease, waning therapeutic potency and progressive non-adherence to therapy. The safety and efficacy of the duodenal-jejunal bypass liner (DJBL) for the treatment of patients with obesity and T2DM has been established during the intended 12-month implantation period. Possible longer-term effects of DJBL on weight and glycaemic control, after device removal, are not well characterized. We examined the effects of DJBL on weight and hemoglobin A1c at 12 months of implantation and 6 months after removal.

Materials and methods: Data were extracted from one controlled and five single-arm clinical studies, involving subjects who completed a 12-month DJBL implantation period and a 6-month post-explantation follow-up. Data are presented as mean±standard error of the mean.

Results: 56 subjects (aged 51.4±1.0 years; 54% male) with obesity (100±2.6 kg, BMI 36.1±0.8 kg/m²) and T2DM (A1c 8.4±0.15%) were included. The mean implant duration was 368±0.6 days. The mean change in weight from baseline to 12 months was -10.4±0.96 kg and from 12 months to 6 months post-explantation was 4.75±0.55 kg. The overall weight change from baseline to 6 months post-explantation was -5.6±1.01 kg. The percent weight change was -10.3±0.89% at 12 months and -5.5±0.95% at 6 months after explantation. The mean change in A1c was -1.05±0.2% from baseline to 12 months and 0.19±0.15% from 12 months to 6 months after explantation. The overall A1c change from baseline to 6 months post-explantation was -0.86±0.18%. At 12 months, 43/56 (76.8%) achieved ≥5% weight loss. Of these “responders,” 13/43 (30%) exhibited ≤25% weight regain 6 months after explantation. Among the 13 subjects who did not achieve ≥5% weight loss at 12 months, 8 (62%) nonetheless exhibited ≥0.5% reduction in A1c at 12 months. Similarly, 38/56 (67%) achieved ≥0.5% reduction in A1c at 12 months, and of these responders, 25/38 (66%) maintained at least 75% of this reduction 6 months after explantation (Figure 1).

Conclusion: DJBL was associated with a significant decline in both weight and A1c during the 12-month implantation period. At 6 months after device removal, there was a surprisingly modest increase in weight and A1c overall. Following a 12-month implantation with DJBL, 30% of subjects maintained their weight loss and 66% maintained their A1c 6 months after device removal. These observations, if confirmed by longer post-explantation follow-up, suggest that device may influence the underlying pathogenesis and progression of obesity and diabetes.

The EndoBarrier® gastrointestinal liner reduces food intake in obese subjects and improves postprandial glucose metabolism acutely in obese patients with type 2 diabetesU. Rohde¹, C.A. Federspiel¹, E. Langholz¹, P. Vilmann², S.U. Friis¹, T. Vilsbøll¹, F.K. Knop¹;¹Center for Diabetes Research, Gentofte Hospital, University of Copenhagen, Hellerup, ²GastroUnit, Department of Surgery, Herlev Hospital, University of Copenhagen, Denmark.

Background and aims: The EndoBarrier® gastrointestinal liner is an endoscopic deployable (and removable) duodenal-jejunal bypass sleeve (DJBS) developed to treat obesity and type 2 diabetes (T2D). To evaluate the acute effect of the EndoBarrier® gastrointestinal liner on appetite, food intake, gallbladder emptying and postprandial glucose excursions we investigated obese subjects with normal glucose tolerance (NGT) and obese patients with T2D before and one week after DJBS implantation.

Materials and methods: Eleven obese metformin-treated T2D patients (diabetes duration: 40±18 months; age: 51±12 years; body weight 108±18 kg; BMI: 36.6±3.3 kg/m²; fasting plasma glucose (FPG): 9.3±2.8 mmol/l; HbA_{1c}: 49±11 mmol/mol) and 12 gender, age and BMI-matched NGT subjects (age: 45±12 years; body weight 102±10 kg; BMI: 34.3±2.1 kg/m²; FPG: 5.5±0.5 mmol/l; HbA_{1c}: 32±5 mmol/mol) underwent a standardised 4-hour liquid mixed meal test during which blood samples were collected, gallbladder emptying measured via ultrasound and appetite evaluated using visual analogue scales, and a subsequent ad libitum meal before and one week after DJBS implantation.

Results: Postprandial glucose excursions declined significantly after one week of implantation in obese patients with T2D (AUC: 638±115 vs. 431±83 min×mmol/l, $p=0.02$), but did not change in the NGT subjects. NGT subjects experienced significantly greater fullness and satiety and less hunger and thirst and T2D patients reported less thirst after DJBS implantation. Food intake during the ad libitum meal decreased significantly and similarly in both groups after implantation (NGT: 393±42 vs. 261±34 g, $p=0.002$; T2D: 463±64 vs. 269±33 g, $p=0.02$). Gallbladder emptying did not change in any of the groups.

Conclusion: After only one week of implantation, DJBS improves postprandial glucose tolerance in obese patients with T2D and alters satiety sensation and reduces food intake in obese patients with or without T2D.

Gallbladder emptying was left intact despite lining of the duodenal mucosa by the device.

Ten months of treatment with endoscopic duodeno-jejunal bypass liner reduce glycaemic variability and partially restore the incretin effect in obese type 2 diabetic subjects

M. Mraz¹, P. Kavalkova¹, P. Trachta¹, D. Haluzikova², Z. Lacinova¹, J. Krizova¹, M. Benes³, Z. Vlasakova⁴, V. Burda⁵, D. Novak⁵, T. Pelikanova⁴, S. Svacina¹, M. Haluzik¹;

¹3rd Department of Medicine, ²Department of Sports Medicine, Charles University, ³Department of Gastroenterology, Institute of Clinical and Experimental Medicine, ⁴Department of Diabetology, Institute of Clinical and Experimental Medicine, ⁵Faculty of Electrical Engineering, Czech Technical University, Prague, Czech Republic.

Background and aims: Duodenal-jejunal by-pass liner (DJBL) is an endoscopically implantable device designed to non-invasively mimic the effects of surgical gastrointestinal by-pass operations. The aim of our study was to comprehensively assess the effects of DJBL on body composition, glucose control and metabolic and hormonal profile of subjects with obesity and type 2 diabetes mellitus (T2DM).

Materials and methods: Thirty obese patients with T2DM (22 males, age 51.8±1.8 years) underwent the implantation of the EndoBarrier DJBL (GI Dynamics, USA). Anthropometric, biochemical and hormonal parameters were measured before and 1, 6 and 10 months after the implantation of DJBL. Glycemic variability was assessed using continuous glucose monitoring (CGM). Postprandial effects of DJBL were evaluated during a 2-hour liquid meal test (LMT).

Results: Over 10 months the implantation of EndoBarrier lead to a sustained decrease in body weight (BMI 42.7±1.2 vs. 38.4±1.2, $p < 0.05$) and body fat (40.2±1.2 vs. 30.5±2.6%, $p < 0.05$) and improvement in glucose control (fasting blood glucose 12.3±0.7 vs. 9.1±0.7 mmol/l, $p < 0.05$; HbA1C 75.0±3.4 vs. 55.4±3.8 mmol/mol, $p < 0.05$) accompanied by reduction of glycaemic variability as calculated from a 7-day CGM (SD 2.5±0.2 vs. 1.8±0.2, $p < 0.05$). Conversely, the levels of fibroblast growth factor 19 (FGF-19), a potent regulator of bile acid synthesis, markedly increased after implantation (80.3±9.8 vs. 154.4±26.1 pg/ml, $p < 0.05$). Moreover, EndoBarrier also partially restored the incretin effect 1 month after insertion (serum GLP-1 at 15 min of LMT 129.7±17.0 vs. 105.8±12.0 pg/ml, $p < 0.05$).

Conclusion: The implantation of EndoBarrier DJBL leads to a lasting reduction of body weight and improvement of all measures of glycemic control. Changes in the incretin system and the increase of FGF19 might be at least partially responsible for these effects.

Advanced correction of marked hyperglycaemia with insulin administered by needle-free jet injection in patients with insulin-treated diabetes

H.M. de Wit, E.E. Engwerda, C.J. Tack, B.E. de Galan; Internal medicine, Radboud university medical center, Nijmegen, Netherlands.

Background and aims: Rapid correction of marked hyperglycaemia in patients with insulin-treated diabetes is important to reduce symptoms and revert the risk of progression to ketoacidosis or hyperosmolar hyperglycaemic states. Insulin administered by jet injection may more rapidly correct marked hyperglycaemia than injection with a conventional pen, because insulin is dispensed over a larger subcutaneous area, facilitating faster absorption, especially in patients with body weights above

normal. We compared the pharmacologic properties of the jet injector and conventional pen for the correction of marked hyperglycaemia by rapid-acting insulin.

Materials and methods: Adult, overweight or obese (BMI ≥ 25 and ≤ 40 kg/m²) patients with type 1 diabetes (n=10) or insulin-treated type 2 diabetes (n=10) were enrolled in a randomized, controlled, cross-over study. On two separate occasions, after reaching hyperglycaemia (18–23 mmol/l) by decreasing prior insulin use, they were injected with insulin aspart by jet injection or by conventional pen, in a dose based on an estimate of their individual insulin sensitivity. Pharmacologic profiles were derived from plasma glucose and insulin levels, measured for six hours after injection.

Results: Insulin administered by jet injection resulted in faster correction of hyperglycaemia (fig 1). Plasma glucose values dropped with ≥ 10 mmol/l after 147.9±14.4 minutes with jet injection versus 192.5±13.6 minutes after conventional administration (difference 44.6 [95% CI 4.3–84.8]; $P=0.03$). After one hour, plasma glucose had dropped with 4.4±0.3 mmol/l versus 3.0±0.2 mmol/l ($P=0.001$). The hyperglycaemic burden was significantly reduced during the first two hours (2041±37.2 versus 2167±26.1 mmol·min⁻¹·l⁻¹; $P < 0.012$). The risk for late hypoglycaemia was not increased after insulin administration by jet injection. The jet injector performed better in patients with a higher BMI.

Conclusion: Administration of insulin aspart by jet injection resulted in faster correction of marked hyperglycaemia compared to administration by conventional pen. The jet injector provided the most benefit in obese patients who needed high insulin doses.

Lipohypertrophy: prevalence, risk factors, clinical characteristics, and economic burden of insulin-requiring patients in China

Z. Sun¹, Q. Li², L. Ji³, G. Qin⁴, L. Hirsch⁵, Z. Wei⁶, J. Liu⁶, L. Luan⁶, D. Wang⁶, A. Chandran⁵;

¹Endocrinology, Southeast University Zhongda Hospital, Nanjing, ²Endocrinology, Chongqing MU Affiliated No. 1 Hospital, Chongqing, ³Endocrinology, Peking University People's Hospital, Beijing, ⁴Endocrinology, The First Affiliated Hospital of Zhengzhou University, China, ⁵Diabetes Care, BD, Franklin Lakes, USA, ⁶BD and Company, Beijing, China.

Background and aims: Lipohypertrophy (LH) is a poorly studied complication of insulin injection/infusion therapy that impairs insulin absorption/glycemic control. This study aims to understand the prevalence, risk factors, clinical characteristics and economic burden associated

with LH to provide optimal patient care as the insulin-requiring population in China grows.

Materials and methods: Prevalence, risk factors and clinical features of LH patients were evaluated in 4 Chinese cities. Adult patients injecting insulin by pen ≥ 1 yr provided detailed information on diabetes/injection history, injection technique/training, pen needle (PN) reimbursement, and insulin doses, followed by physical exam and HbA1c testing. Differences from those without LH were evaluated by Student's t-test or Wilcoxon rank sum test. P-values < 0.05 were considered significant.

Results: The 401 patients were mean(SD) 59.6(11.5) yrs; BMI 25.4(3.2) kg/m²; 50% male; 93.5% T2DM. HbA1c=8.0(1.7)%; total daily insulin dose=33.0(18.4) U with 2.1(1.0) injections daily. Durations of diabetes and of insulin therapy=11.9(7.6) and 5.6(4.6) yrs, respectively; 95% of patients reused PNs median 10 (max 360) times; 35.6% had PN reimbursement. LH prevalence was 53% overall (range 38–76%), mostly abdominal. Patients with LH had higher BMI and HbA1c, took 11 U (0.13U/kg or 31.7%) more insulin daily, took more injections, reused PNs more times and had less PN reimbursement (all $p \leq 0.003$) versus those without LH. LH patients rotated injection sites less and had slightly more injection training, but these were marginally significant (see Table). BMI and # daily injections remained significantly associated with LH prevalence by logistic regression ($p \leq 0.01$). Based on an estimated 8.4 million insulin injectors, the cost of excess insulin use associated with LH is estimated at RMB 3,892,593,600 (\$630 million) per year.

Conclusion: LH was present in over half of insulin-requiring patients in China. LH is associated with worse glycemic control despite higher insulin consumption. Needle reuse frequency, # daily injections, BMI and lack of PN reimbursement are risk factors, suggesting local tissue trauma and/or insulin exposure as important contributors to LH development. Additionally, patients with LH contribute to a significant and avoidable economic burden in China of up to RMB 3.9 billion due to excess insulin consumption.

Characteristic	With LH (n=213)	Without LH (n=188)	P
HbA1c	8.2 (1.8)%	7.7 (1.5)%	0.003
Daily insulin dose (Units)	38.1 (20.1)	27.1 (14.3)	<0.001
Daily insulin dose (U/kg)	0.54 (0.28)	0.41 (0.21)	<0.001
BMI (kg/m ²)	26.0 (3.3)	24.8 (3.0)	<0.001
Needle reuse, median # times	13.0	7.5	0.003
Daily injections, #	2.3 (1.0)	1.9 (0.9)	<0.001
Lack of site rotation, patients	4.7%	1.6%	0.080
Needle reimbursement, patients	27.8%	44.1%	<0.001
Injection training, patients	92.5%	87.2%	0.113
Average daily insulin costs, RMB	8.2	5.8	<0.001

Insulin injection into regions with lipohypertrophy worsens postprandial blood glucose versus injections into normal adipose tissue

L. Hirsch¹, U. Hövelmann², S. Famulla², L. Hermanski², A. Fischer², L. Heinemann², M. Kaltheuner³, T. Heise²;

¹BD (Becton Dickinson) Diabetes Care, Franklin Lakes, USA, ²Profil, Neuss, ³Gemeinschaftspraxis Kaltheuner, Leverkusen, Germany.

Background and aims: Lipohypertrophy (LHT) is a common side effect of long-standing insulin therapy; however, the impact of LHT on insulin absorption and blood glucose variability has not been investigated systematically yet. Therefore we compared the effects of subcutaneous insulin (INS) injection into LHT and regions with normal adipose tissue (NAT) on postprandial blood glucose (BG) control and INS absorption in 13 patients with type 1 diabetes (mean \pm SD age: 50.1 \pm 10.1 years, HbA1c: 7.55 \pm 1.15%) during a mixed meal tolerance test.

Materials and methods: Patients received two identical standardised mixed meals (75 g CHO) separated by at least 6 h, each covered with a single dose of 0.15 U/kg insulin lispro injected at meal start into LHT or NAT, in randomised order. LHT was assessed and confirmed by physical examination and ultrasound. Pre-meal BG was adjusted to 100 \pm 20 mg/dL. BG and INS (lispro-specific radioimmunoassay) were measured over 5 hours after each mixed meal test.

Results: Injection into LHT led to reduced INS exposure ($AUC_{INS\ 0-5h}$ 46% lower, $p=0.053$), which was in line with a less pronounced maximum exposure versus injection into NAT ($C_{max-Ins}$ 42% lower, $p=0.72$). Mean postprandial BG concentrations were significantly increased (17% higher in the first 2 hours, 58% higher from 2 to 5 h, 39% higher over 5 h, all $p < 0.05$) after injection into LHT resulting in a 25% increase in maximum BG (193 vs. 154 mg/dL, $p=0.043$) (Figure). In addition maximum BG concentrations were reached 15 min later after injection into LHT (T_{BG-max} : 60 min vs. 45 min, $p < 0.05$). Postprandial hypoglycemia ($BG \leq 50$ mg/dL) occurred slightly less frequently with LHT injection (2 vs. 6 patients, $p=0.20$), whereas postprandial hyperglycaemia ($BG \geq 300$ mg/dL) occurred only with LHT injection (2 patients).

Conclusion: Insulin injection into LHT regions leads to a pronounced impairment in insulin absorption leading to a deterioration in postprandial blood glucose control compared with injection into NAT. These results reinforce the importance of good injection technique, particularly site rotation, and provide the rationale for patients to avoid injecting insulin into areas with LHT.

Lipohypertrophy leads to blunted, more variable insulin absorption and action in patients with type 1 diabetes

S. Famulla¹, U. Hövelmann¹, A. Fischer¹, H.-V. Coester¹, L. Heinemann¹, L. Kaltheuner², L. Hirsch³, T. Heise¹;

¹Profil, Neuss, ²Gemeinschaftspraxis Kaltheuner, Leverkusen, Germany, ³BD (Becton Dickinson) Diabetes Care, Franklin Lakes, USA.

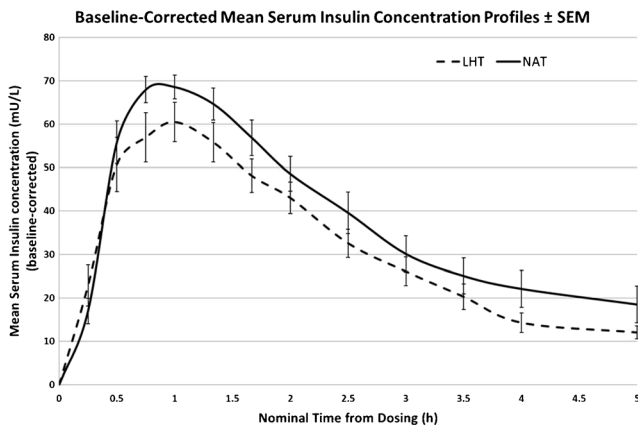

Background and aims: Lipohypertrophy (LHT) is a common side effect of long-standing insulin therapy; however, the impact of LHT on insulin (INS) absorption and efficacy has not yet been investigated using a sophisticated method such as the euglycaemic clamp technology. Therefore, we compared the pharmacokinetics (PK) and pharmacodynamics (PD) of subcutaneous injection of insulin lispro into abdominal areas with LHT and normal adipose tissue (NAT) in 13 patients with type 1 diabetes (T1D) under automated glucose clamp conditions.

Materials and methods: Patients (mean \pm SD age: 50.1 \pm 10.5 years, BMI: 26.7 \pm 2.2 kg/m², HbA1c: 7.6 \pm 1.2%) received 4 single doses of 0.15 U/kg insulin lispro approximately every 6 hours, twice into a region with LHT and twice into NAT in random order. LHT was assessed and confirmed by physical examination and ultrasound. The clamp target level after dosing was 100 mg/dL and the glucose infusion rate (GIR) and serum insulin concentration were measured for 5 hours post-dosing.

Results: Mean INS profiles are shown in the figure. Comparing LHT with NAT injection, LS-mean INS concentrations were comparable during the first 30 min ($AUC_{INS0-0.5h}$ 8.8 vs. 9.4 h* μ M/L), but significantly

lower thereafter ($AUC_{INS0-1h}$ 29.3 vs. 41.5 h*mU/L, $AUC_{INS0-4h}$ 97 vs. 154 h*mU/L, all $p<0.02$). Maximum INS exposure was reduced by 34% (C_{INSmax} 49.7 vs. 75.4 mU/L, $p<0.002$). These differences were reflected in the GIR profiles: The PD effect in the first 30 min was comparable between LHT and NAT ($AUC_{GIR0-0.5h}$ 25 vs. 23 mg/kg, $p=0.273$) but was significantly and nearly 30% lower after 4 to 5 hours with LHT injection ($AUC_{GIR0-4h}$ 529 vs. 720 mg/kg, $AUC_{GIR0-5h}$ 576 vs. 803 mg/kg, all $p<0.05$). Maximum GIR was also reduced with LHT injection but this did not reach statistical significance (GIR_{max} 5.5 vs. 6.0 mg/kg/min, $p=0.378$). Intra-subject variability was substantially higher after dosing into LHT compared to NAT (coefficients of variation 52 vs. 11% [$AUC_{INS0-4h}$], 55 vs. 15% [C_{max}], and 57 vs. 23% [$AUC_{GIR0-4h}$], all $p<0.01$).

Conclusion: This first glucose clamp study in patients with LHT explains clinical experience that both insulin absorption and action are substantially blunted and considerably more variable when insulin is injected into areas with LHT. These findings likely also apply to subcutaneous insulin infusion and warrant further study.

User interaction are associated with glycaemic control in regular-use of real-time CGM

L. Bohnett, T. Kent, T. Hall, K. Nakamura;
Dexcom, Inc, San Diego, USA.

Background and aims: The clinical benefit from real-time CGM (RT-CGM) in the management of diabetes has been demonstrated in many studies. However, there is limited information reported regarding the everyday use of RT-CGM. This study was to evaluate relationships between user interaction, demographics, and glycemic control in real-life patient daily use.

Materials and methods: The RT-CGM data was voluntarily uploaded by users seeking diagnostic technical support. The Dexcom G4 Platinum CGM system records the interaction users have with their alert settings and logs screen views. The alert settings are a customizable threshold for when to sound a hypoglycemia or hyperglycemia alarm, while screen views are button pushes that result in the display of glucose and/or glucose trend information. RT-CGM users' most common alert settings, the frequency of their average daily screen views (repeated screen views within a minute were counted as one view), and their overall glucose average and standard deviation were compared with age by grouping into four categories: Seniors (50 YO+), Adults (18 to 49 YO), Adolescents (12-17 YO) and Children (2-11 YO).

Results: A total of 229 (~50% male) users provided their CGM data and their demographics. There were ~4.6 M records of CGM data and the average time of CGM use was 77 ± 68 (mean \pm s.d.) days. As age increased, average CGM glucose decreased; the highest average glucose was 9.6 ± 1.9 mmol/l in Children and the lowest of that was 8.1 ± 1.5 mmol/l in Seniors. The average standard deviations of CGM glucose were 4.2 mmol/l in Children, 4.1 mmol/l in Adolescents, 3.6 mmol/l in Adults and 3.3 mmol/l in Seniors. There was a consistent decrease in both average standard deviation of glucose from one age group to the next. The majority used the manufacturer default glucose alert settings of 4.4 mmol/l (for low) and 11.1 mmol/l (for high), 70% and 75% of users, respectively. However, as users increased their low glucose alert settings the average CGM glucose did as well. There was a positive correlation between the low glucose alert setting and the average glucose ($r=0.313$, $p<.0001$, displayed in Figure 1). The same relationship was noted between the high glucose alert setting and the average glucose ($r=0.299$, $p<.0001$). Furthermore, an examination of daily average screen views by subject within age group revealed that Children interacted with their CGM receiver the most with an average of 59 ± 22 views per day. The next closest group was Adolescents with an average of 54 ± 48 views per day. On average, Adults and Seniors viewed their receivers 36 times per day.

Conclusion: This study found an inverse relationship between age and average glucose, and also found that the older age groups had tighter glycemic control. Furthermore, CGM alert settings are associated with glucose levels and variability. Although younger populations interact with their RT-CGM more frequently, this study suggests there may be other factors preventing them from tighter glycemic control. The impacts of user interaction in glycemic control should be evaluated further within patient age population in a larger scale study.

Resolution of the main indication and sustainability of long-term glycaemic control in type 1 diabetes with continuous subcutaneous insulin infusion

C. Quirós, M. Giménez, R. Paola, D. Roca, M. Vidal, I. Conget; Diabetes Unit, Hospital Clínic de Barcelona, Spain.

Background and aims: The effectiveness of continuous subcutaneous insulin infusion (CSII) in Type 1 diabetes (T1D) has been established in the short-term. However, less information is available regarding the impact on solving main indications for initiating CSII and whether good control can be maintained over several years. Our objective was to assess the resolution of the main indication and sustainability of long-term glycaemic control in T1D using CSII.

Materials and methods: Retrospective observational study including 178 T1D patients who started CSII treatment in our Center (2003–2008). All patients were followed in our CSII program for outpatients for at least 5 years. Data on annually HbA1c was collected and the resolution of the main indication for starting CSII was analysed.

Results: 27 out of 178 patients were excluded because of loss of follow-up or withdrawal from CSII. 151 patients (37.4±10.5 years, 64% women) were analysed. The main indications to start CSII were suboptimal metabolic control (SMC-group, 60.9%), severe hypoglycaemia/hypoglycaemia unawareness (H-group, 25.5%) and other (13.6%). HbA1c at the start of CSII was 8.0±1.2 and 7.8±1.2 after 5 years in the total cohort ($p<0.05$). In the SMC-group HbA1c dropped from 8.37±1.09% to 8.04±1.33% ($p=0.016$) and 37.4% of patients in this group had an HbA1c≤7.5% after 5 years. The resolution of the main indication was obtained in 64% of the SMC-group and 93% in H-group.

Conclusion: CSII therapy maintains long term glycaemic benefits after 5 years of follow up. In addition, the main indication for this treatment can be resolved in two thirds of T1D patients.

Figure 1. HbA_{1c} levels at baseline, 1, 2, 3, 4 and 5 years follow-up after starting CSII.

Results are shown as mean ± SEM.

915

Optimal glucose control during insulin pump therapy requires self-monitoring of blood glucose at least six times daily

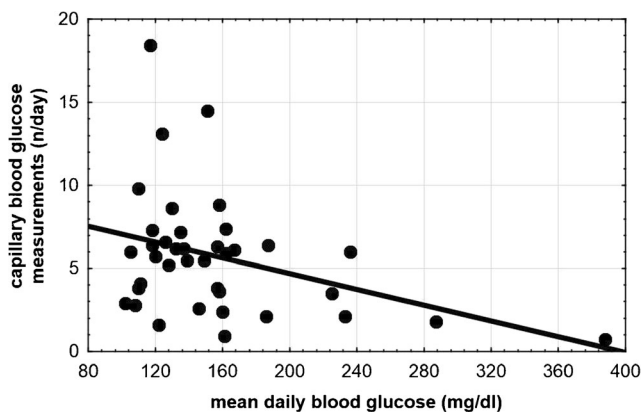

E. Szymanska-Garbacz, J. Loba, L. Czupryniak; Medical University of Lodz, Poland.

Background and aims: Due to economical reasons sensor-augmented pumps are not in common use among type 1 diabetes patients in many European countries. Subsequently, the subjects treated with continuous subcutaneous insulin infusion (CSII) are strongly advised to measure blood glucose (self-monitoring of blood glucose, SMBG) at least four times a day. However, the minimal frequency of SMBG required for having optimal glucose control remains unknown. Optimally, individuals with type 1 diabetes should maintain their HbA_{1c}<6.5%, which is equivalent to the average blood glucose (BG) <140 mg/dl [7.8 mmol/l]. We conducted a study aiming at identifying minimal frequency of SMBG which would allow type 1 diabetes patients achieving good metabolic control.

Materials and methods: The group comprised 40 type 1 diabetes patients (mean age 27±8 years, diabetes duration 9±8 years, CSII duration 3.1±2.5 years, body weight 70±12 kg, BMI 24.2±3.7 kg/m², HbA_{1c} 7.7±1.9%, average BG 155±56 mg/dl, number of SMBG 5.7±3.7/day). Data from 2 last weeks before the study visit were analysed. All subjects were treated with CSII for at least for 6 months, thus they had obtained sufficient knowledge about this therapy mode. The pump settings (basal rate, bolus wizard) were assessed with standard tests.

Results: A negative correlation between the frequency of SMBG and the average number of capillary BG measurements (figure) was revealed ($r=-0.37$; $p<0.05$); the recommended target of metabolic control was obtained in subjects who had performed SMBG at least six times a day.

Conclusion: In conclusion, CSII therapy may lead to good metabolic control, but the acceptance and willingness of a patient to measure blood glucose six or more times a day is crucial.

916

Continuous subcutaneous insulin infusion in patients with type 1 diabetes: results of a prospective study with three years of follow up

A. Kamaratos, A. Angelidi, S. Vrakas, E. Fouteris, C. Verras, I. Bakalis, C. Sagia, E. Efstratiadi, A. Bilis, S. Iraklianiou, A. Melidonis; Diabetes Center, Tzanio General Hospital, Piraeus, Greece.

Background and aims: Several studies have found improved glycaemic control with continuous subcutaneous insulin infusion compared with multiple daily insulin injections for patients with type 1 diabetes albeit for a relatively short-period of follow-up. This prospective study presents for the first time the optimization of glycaemic control with insulin pumps in a cohort of Greek patients with type 1 diabetes during a 3-year follow-up period.

Materials and methods: Seventy-nine patients (30 males), previously on intensified basal-bolus insulin therapy with poor glycaemic control, were recruited. HbA1c, hypoglycaemic and diabetic ketoacidosis episodes, pump related side effects, lipidemic profile, 24-hour urine albumin excretion, body mass index, blood pressure, total daily insulin requirements (bolus and basal) were recorded during the 3-year follow-up. Statistical analysis was initially conducted for the entire study population. Statistical analysis was performed using STATA 9.0 software.

Results: A statistically significant decrease during the 3 year period of study was noted for the following parameters: HbA1c ($p < 0.001$), basal rate ($p < 0.001$), basal/bolus ratio ($p < 0.001$), hypoglycaemic episodes ($p = 0.007$) and total/HDL-cholesterol ratio ($p = 0.01$). On multivariate analysis, an independent and significant association was observed for hypoglycaemic episodes (95%CI: $-0.014 - -0.0038$, $p = 0.001$), basal rate (95%CI: $-0.0322 - -0.0148$, $p < 0.001$) and total/HDL-cholesterol ratio (95%CI: $-0.1222 - 0.0078$, $p = 0.026$). Insulin pump treatment was not accompanied with weight changes across all body mass index strata.

Conclusion: Continuous subcutaneous insulin infusion achieved almost optimal glycaemic control, reduced hypoglycaemic episodes without weight gain and was well tolerated for the whole study period. Finally, this therapeutic approach was accompanied with lower daily insulin requirements.

917

Long-term glycaemic remission of type 2 diabetes mellitus with insulin pump therapy regardless of disease duration

S. Choi¹, E. Hong¹, E. Jeon², K. Kim², H. An², Y. Noh³;

¹Internal Medicine, Konkuk University, ²Konkuk University, Chungju, ³Biochemistry, Konkuk University, Seoul, Republic of Korea.

Background and aims: Intensive insulin therapy (IIT) is known to improve β -cell function and induce glycaemic remission in newly diagnosed type 2 diabetes mellitus (T2DM) patients. However, it is not known

whether IIT can induce long-term remission in patients with long T2DM duration. We aimed to analyze T2DM remission cases achieved by insulin pumps.

Materials and methods: The patients who experienced T2DM remission were included between March and July in 2014. We collected the medical records retrospectively and prospectively. Remission is defined as maintaining normal fasting and postprandial glucose levels for 6 months after discontinuation of all anti-diabetic medications. Blood samplings were performed at fasting and 120 minutes after ingestion of a mixed meal (500 kcal), at baseline and 6 month intervals during the treatment and follow-up periods. Values are presented as median (minimum-maximum) or mean \pm standard deviation.

Results: Nineteen patients (9 males, 10 females) were enrolled during the 5 months [age at diagnosis, 49 (32-57) years; duration of T2DM, 1.0 (0.0 - 23.0) years]. Two patients (11%) had been newly diagnosed and 17 patients (89%) were on oral anti-diabetic medications before insulin pump therapy. Baseline HbA1c level was $7.4 \pm 2.0\%$, and total daily insulin dose at the initiation of insulin pump therapy was 50 (22 - 344) IU. The time to remission was 23 (5 - 108) months and the duration of remission was 38 (12 - 108) months. During the follow-up of 5.0 (2.3 - 10.4) years, 5 subjects had T2DM relapse. After restart of insulin pump therapy, 3 subjects had remission again by 4 (3 - 8) months. In 17 patients with sustained remission, the latest HbA1c level was significantly lower than the initial level (6.1 ± 0.4 vs. $7.4 \pm 2.1\%$, $p = 0.017$) and their latest body mass index was not significantly changed (24.7 ± 3.6 vs. 25.7 ± 4.0 kg/m², $p = 0.053$). Their disposition index increased from 0.14 ± 0.09 (initial) to 0.34 ± 0.15 (maximum) ($p = 0.001$).

Conclusion: In conclusion, insulin pump therapy improved β -cell function and induced long-term glycaemic remission regardless of T2DM duration.

918

Glycaemic control in a large cohort of patients with type 1 diabetes treated with continuous subcutaneous insulin infusion

K. Markakis¹, P. Jinadev¹, A. Chapman¹, A. Urwin¹, J. Morris¹, A.J.M. Boulton^{1,2}, M.K. Rutter^{1,2}, L. Leelarathna^{1,2};

¹Manchester Diabetes Centre, ²University of Manchester & Manchester Academic Health Science Centre, UK.

Background and aims: There is limited data describing glycaemic control in patients with type 1 diabetes (T1DM) treated with continuous subcutaneous insulin infusion (CSII) during routine care. In a tertiary referral center we undertook one of the largest studies of the effectiveness of CSII in adults with T1DM.

Materials and methods: In T1DM patients with at least 12 months of CSII therapy we obtained demographic and HbA1c data from hospital records and central laboratory. For each patient the average post-CSII HbA1c was computed from results obtained over 30 months since June 2012. We also compared pre- and average post-CSII HbA1c in the subgroup with paired data.

Results: We analysed 2079 HbA1c results from 484 patients (% females 57; mean (SD) ; age: 45 (13) years, CSII duration: 4.4 (2.5) years; HbA1c tests per patient: 4.3 (2.5); time between pump start and average HbA1c 40.4 (27.5) months). Insulin pumps used were: Medtronic: 43%; Omnipod: 29%; Animas: 14%; Accu-Chek: 13%. There were no differences in HbA1c comparing different pump users ($p = 0.65$, ANOVA) or those using catheter pump vs. Omnipod (66 (15) vs. 68 (16) mmol/mol, $p = 0.34$). CSII therapy was associated with a significant improvement in glycaemic control (N=422 with paired data; mean (SD), pre vs. average post-CSII HbA1c: 73 (19) vs. 66 (15) mmol/mol, $p < 0.001$, mean (SD) change -7 (15) mmol/mol). For those with a pre-CSII HbA1c more than 69 mmol/mol, improvements in glycaemic control were even larger (N=224, pre- vs. average post-CSII HbA1c, 86 (16) vs. 74 (15), $p < 0.001$, mean (SD) change -12 (17) mmol/mol) (Figure). Despite improvements

only 30% of patients achieved good glycaemic control ($HbA1c < 58$ mmol/mol) and 39% of patients had a $HbA1c$ more than 69 mmol/mol. We found a negative correlation between post-CSII $HbA1c$ and age ($r = -0.17$, $p = 0.001$) and diabetes duration ($r = -0.23$, $p = 0.001$) but no association with CSII duration ($p = 0.30$). In contrast no demographic factors were associated with improvements in $HbA1c$ with CSII therapy.

Conclusion: We found significant improvements in glycaemic control with CSII particularly in those with a higher pre-CSII $HbA1c$ under routine care conditions. Despite improved control, a large proportion of T1DM patients treated with CSII have poor glycaemic control, highlighting the challenges of managing T1DM under real-life conditions. Further work is required to understand the factors associated with poor control.

Mean(SD) change in $HbA1c$ associated with CSII therapy by pre-CSII $HbA1c$ level

919

Diabetes distress and fear of hypoglycaemia: What are the psychological benefits of insulin pump therapy?

C. Shaban, J. Knott, E. Jenkins, M. Weiss, J. Ryder, J. Charman, H. Partridge;
Diabetes and Endocrine Centre, Royal Bournemouth Hospital, UK.

Background and aims: Living with Type 1 diabetes imposes a considerable burden on the individual to continuously self-manage their condition. As part of on-going audit the psychological outcomes of insulin pump therapy were evaluated over a 3 year period.

Materials and methods: Adult patients completed self-report questionnaires at initiation and after 12 months of pump therapy. Diabetes emotional distress was assessed using the Problem Areas in Diabetes Scale (PAID) and cognitive and behavioural aspects of fear of hypoglycaemia using the Hypoglycaemia Fear Survey (HFS-W, HFS-B). $HbA1c$ and demographic data were obtained from the clinical record. Data were analysed using Predictive Analytic Software (PASW) Version 19.

Results: Data were collected from 142 adults, mean age 40 years (range 15–72), mean duration of diabetes 22 years (range 3–57). Outcomes improved significantly from baseline to 12 months for all variables (mean (sd)): $HbA1c$ mmol/mol 73.7 (15.6), 63.2 (12.6) $p < 0.001$; PAID 24.6 (15.7), 16.7 (13.22) $p < 0.001$; HFS-W 24.9 (15.9), 16.4 (13.0) $p < 0.001$; HFS-B 19.1 (10.0), 13.8 (8.9) $p < 0.001$. Paired data analysis did

not indicate an association between $HbA1c$ reduction and reduced PAID and HFS scores. There was no between group difference in baseline psychological variables above and below $HbA1c < 70$ mmol/mol and ≥ 70 mmol/mol.

Conclusion: Pump therapy is associated with improvements in medical and psychological variables. Whilst a reduction in both diabetes emotional distress, and worries and behaviours related to fear of hypoglycaemia appear to be unrelated to improvements a reduction in $HbA1c$, the overall burden of diabetes indicated by diabetes distress and fear of hypoglycaemia is reduced significantly 12 months after initiation of insulin pump therapy.

920

Is the pump bolus calculator a useful tool or the man behind the curtain?

E. Omura¹, K.M. Miller², D.M. Maahs³, J.C. Wong⁴, S. Adi⁴, R.W. Beck², A.L. Peters¹;

¹Keck School of Medicine of the University of Southern California, Los Angeles, ²Jaeb Center for Health Research, Tampa, ³Barbara Davis Center for Childhood Diabetes, Aurora, ⁴University of California San Francisco, USA.

Background and aims: Currently, little data exist on the utility of bolus calculators included in insulin pumps. It is unclear if this feature is a crucial part of pump management, a reflection of user ability, or simply a device of the program. Their utility depends on multiple factors how well they are set up and adjusted by the provider and the patient, whether or not carb counting is done accurately and if a blood glucose level is entered into the pump so dose adjustments can be made. The aim of this analysis is to assess the frequency of bolus calculator use and determine if there are associations with demographic and clinical characteristics/outcomes among T1D Exchange clinic registry participants.

Materials and methods: Analysis included data from 1,944 T1D Exchange registry participants using an insulin pump who were age ≥ 13 years with type 1 diabetes (T1D) duration ≥ 1 year (mean age 33.1 years [range 13.0–83.7], duration 18.8 years [2.2–71.7], 60% female, 93% non-Hispanic white). Participants who self-reported using a bolus calculator most of the time or always were counted as frequent users. The most recent $HbA1c$ from the medical record was used for analysis and frequencies of ≥ 1 diabetic ketoacidosis (DKA) and severe hypoglycemic (SH), defined as seizure/loss of consciousness, events in the past 3 months were self-reported. Chi-square tests and t-tests were performed and adjusted models were conducted using logistic and linear regression.

Results: Among the 1,944 participants, 1532 (79%) reported frequently using a pump bolus wizard/calculator and 412 (21%) did not. Bolus calculator use was more common among adolescent participants, females, and participants with shorter duration of T1D and a lower education level (Table). Use of a bolus calculator was reported by 82% of participants who frequently check their blood glucose prior to giving a bolus for a meal vs. 66% among those who infrequently check ($P < 0.001$). Bolus calculator use was similar among participants who reported giving a bolus prior to a meal vs. during or after a meal (80% vs. 76%, $P = 0.06$). There were no significant differences between frequent vs. infrequent use of a bolus calculator in # of boluses per day (5.4 vs. 5.3, $P = 0.23$), $HbA1c$ (adjusted $HbA1c$ 8.0% vs. 8.1%, $P = 0.04$), occurrence of DKA in the prior 3 months (2% vs. 1%, $P = 0.18$), and occurrence of SH in the prior 3 months (6% vs. 7%, $P = 0.56$).

Conclusion: The majority of T1D patients using an insulin pump report frequently using a bolus wizard/calculator. Yet, in this study frequent use of the wizard/calculator was not a significant factor in the safe and effective use of insulin pumps. Common use of the bolus calculator should drive the development of further technology, as well as support the need for automatic entry of blood glucose values into the pump.

N=1944	Frequent Use of Bolus Wizard/Calculator	P Value

Elastargene 3C helps to improve glycated haemoglobin in children and adolescents with type 1 diabetes using insulin pump therapy

A.E. Scaramuzza¹, M. Ferrari¹, G. Zuccotti²;

¹Paediatrics, University of Milano - Luigi Sacco Hospital, ²Paediatrics, University of Milano - Ospedale dei Bambini V. Buzzi, Italy.

Background and aims: Elastargene 3C is a cream specifically designed to improve lipoatrophy in patients with diabetes. It is made by many ingredients; the most important ones are elastin, amica, collagen, caffeine, and L-carnitine. We started a 6-month, double-blind, randomized trial to test the efficacy of elastargene 3C in children with type 1 diabetes using insulin pump, in whom infusion set usually left little withe scars.

Materials and methods: Forty children and adolescents using insulin pump therapy, were randomized into 2 arms: a) n=20 elastargene 3C once a day on the skin of abdomen or other sites where infusion sets have been placed, administered before sleeping; b) n=20 placebo once a day on the skin of abdomen or other sites where infusion sets have been placed, administered before sleeping. BMI, HbA1c, insulin requirement, were determined in each child before starting the study and after 6 months.

Results: At the end of the study, 5 patients dropped using the elastargene cream or placebo and were excluded from the analysis. In elastargene group, 18 patients with type 1 diabetes were evaluated: age 15.2±4.8 yrs, diabetes duration 8.0±5.3, time using a pump 4.1±3.0; in the placebo group, 17 patients with type 1 diabetes were evaluated: age 15.1±5.7 yrs, diabetes duration 8.3±5.8, time using a pump 4.7±3.0. No significant difference has been observed for age, disease duration and time since insulin pump started. HbA1c significantly improved in patients using elastargene 3C (baseline 8.08±0.80%, after 6 month 7.51±0.53%, p=0.005, delta -0.53%), but not in placebo group (baseline 7.98±0.74%,

after 6 month 7.76±0.79%, p=0.19, delta -0.22%). No difference has been observed regarding BMI or insulin requirement. In the elastargene 3C group, withe scars completely disappeared in 8 patients and improved in 10; in the placebo group withe scars did not change in any of the patients.

Conclusion: To our knowledge this is the first time that a direct effect of elastargene 3C have been shown in improving little withe scars that appear on the skin after infusion set removal in children with type 1 diabetes using insulin pump therapy. Moreover, HbA1c significantly improved only in the elastargene 3C group, probably because improved insulin absorption.

PS 086 Fine-tuning insulin therapy

922

Effects of advanced carbohydrate counting guided by an automated bolus calculator in type 1 diabetes (ABC): a 12-month, randomised clinical trial

E.E. Hommel¹, S. Smidt², D. Vistisen¹, M. Gribhild¹, K. Neergaard¹, T. Almdal³, K. Nørgaard²;

¹Steno Diabetes Center, Gentofte, ²Hvidovre University Hospital, ³Gentofte University Hospital, Denmark.

Background and aims: Advanced carbohydrate counting (ACC) improves metabolic control in patients with type 1 diabetes (T1D). We studied whether concomitant use of an automated bolus calculator (ABC) results in further improvement in HbA_{1c}.

Materials and methods: The study was a 12-month randomised, parallel group, open-label, single-centre, investigator-initiated clinical trial. ACC-naïve and poorly controlled T1D adults on multiple daily insulin injections therapy and HbA_{1c} 64–100 mmol/mol were recruited from a specialised diabetes centre. Between August 2012 and September 2013, 168 participants (96 men, 72 women) were enrolled and randomly assigned to receive training in either ACC using mental calculations (MC-group, n=84) or ACC using an ABC (ABC-group, n=84). All patients received a 3.5-hour group training course in general T1D management guidelines as well as theoretical and hands-on training in ACC. The patients were subsequently followed in routine clinical practice for 12 months. The primary outcome was change in HbA_{1c} from baseline to 12 months.

Results: Baseline HbA_{1c} was 75.0±8.9 mmol/mol in the MC-group and 73.7±8.1 mmol/mol in the ABC-group. Drop-out rates were similar, 23.8% and 21.4%, respectively (p=0.712); 130 patients completed the study. At 12 months, change in HbA_{1c} was significant within both groups; MC-group -2.1 mmol/mol/year (95% CI -3.8 to -0.5, p=0.017) and ABC-group -4.6 mmol/mol/year (95% CI -6.2 to -3.0, p<0.0001). The decrease in HbA_{1c} was significantly greater in the ABC-group (p=0.033). No participants experienced a severe hypoglycaemic episode during the study. Patients wore a continuous glucose monitoring (CGM) device for 6 days before the intervention and for 6 days after the intervention. Glucose levels were categorized as below, within and above target, using a target range 3.9–10.0 mmol/l. We compared the distribution of CGM measurements between the two study groups. At baseline, there was no difference in time spent in the different target ranges between patients in the MC-group and the ABC-group. At 12 months, ABC-patients spent a larger amount of time within target compared with MC-patients (50% vs. 41%, p<0.001) and a smaller amount of time above target (45% vs. 55%, p=0.002). There was no difference in time spent below target (p=0.902). Overall, weight increased significantly (p=0.045) but with no indication of a difference in weight development between the ABC-group and the MC-group (0.67 vs. 0.24 kg/year, p=0.353).

Conclusion: Twelve months after training poorly controlled adult T1D patients in advanced carbohydrate counting, patients using an automated bolus calculator achieved significantly greater improvements in HbA_{1c} and spent more time in the glycaemic target range.

Efficacy and safety of standardised glycaemic control in adult and geriatric hospitalised patients with type 2 diabetes mellitus

K.M. Neubauer¹, J.K. Mader¹, F. Aberer¹, L. Schaupp¹, K. Donsa², T. Augustin², P. Beck², T.R. Pieber¹, J. Plank¹;

¹Division of Endocrinology and Metabolism, Medical University of Graz, ²HEALTH, Joanneum Research Forschungsgesellschaft mbH, Graz, Austria.

Background and aims: Insulin therapy as the preferred method is recommended to achieve glycaemic control in non-critically ill hospitalized patients with hyperglycaemia. The aim of the study was to investigate the efficacy and safety of a standardized insulin therapy supported by a computerized algorithm (GlucoTab) in adult (<70 years) and geriatric (≥70 years) hospitalized patients with diabetes mellitus type 2 (T2DM).

Materials and methods: The GlucoTab system provided automated dosing for basal-bolus insulin therapy for health care professionals in 191 non-critically ill hospitalized patients with T2DM for 8.3 days. Insulin therapy was started with a total daily dose (TDD) of 0.5 units per kg bodyweight in adult patients (<70 years) and 0.3 units per kg bodyweight in geriatric patients (≥70 years) or in patients with a creatinine value ≥2 mg/dl.

Results: 97 adult patients (30 female, age 60±7 years, BMI 31±7 kg/m², creatinine 1.7±1.4 mg/dl, HbA_{1c} 72±26 mmol/mol; mean ± SD) and 94 geriatric patients (48 female, age 77±5 years, BMI 29±6 kg/m², creatinine 1.5±0.9 mg/dl, HbA_{1c} 64±19 mmol/mol) were treated with the standardized insulin therapy using the GlucoTab system. First provided TDD was 0.49±0.16 vs. 0.37±0.24 units per kg bodyweight in adult and geriatric patients, respectively. The overall mean daily blood glucose value (BG) was 155±33 mg/dl (adult patients) and 157±31 mg/dl (geriatric patients). 69.6% vs. 71.8% of BG values were in the range 70–<180 mg/dl for adult and geriatric patients, respectively. In the range <70 mg/dl 2.5% vs. 1.3% of BG values occurred in adult and geriatric patients. In both groups no BG value <40 mg/dl was detected. 25.1% vs. 25.2% and 2.8% vs. 1.7% of BG values were in the hyperglycaemic ranges of 180–<300 mg/dl and ≥300 mg/dl in adult and geriatric patients, respectively.

Conclusion: The standardized insulin starting dose suggested by the GlucoTab with 0.5 and 0.3 units per kg bodyweight supported an efficacious and safe glycaemic control for adult and geriatric hospitalized patients.

An individualised calculation of insulin dose to correct marked hyperglycaemia in adult patients with insulin-treated diabetes

E.E.C. Engwerda¹, H.M. de Wit², B.E. de Galan¹, C.J. Tack¹;

¹Internal medicine, Radboudumc, Nijmegen, ²Internal medicine, Universiteit van Amsterdam, Netherlands.

Background and aims: Marked hyperglycaemia frequently occurs in patients with diabetes, the correction of which may be difficult because of glucose toxicity induced insulin resistance and fear that too aggressive correction may lead to hypoglycaemia. Usually, standard sliding scale insulin regimens, barely adjusted to and often underestimating individual needs, are applied both in outpatient and in-patient settings. We tested a simple formula based on the insulin sensitivity factor (ISF, calculated by dividing 100 by the total daily insulin dose [TDID]) for the estimation of the individual insulin dose needed to correct substantial hyperglycaemia in patients with insulin-treated diabetes.

Materials and methods: This analysis was part of a randomised controlled cross-over trial, comparing the efficacy of two insulin pens to

correct hyperglycaemia with the rapid-acting insulin analogue aspart. Adult patients with type 1 or type 2 diabetes on basal-bolus injection or pump therapy were instructed to decrease insulin doses in order to reach morning hyperglycaemia (18–23 mmol/l). Subsequently, aspart insulin was administered subcutaneously in a dose calculated as follows: 1.5 times the difference between the initial and target glucose value (set at 6 mmol/l) divided by the ISF. Plasma glucose levels were determined during 6 hours thereafter. The primary endpoint was the time in minutes until plasma glucose concentration had dropped by at least 10 mmol/l.

Results: 20 patients (10 type 1 diabetes, 10 type 2 diabetes, mean age 53.4 years, HbA1c 70 mmol/mol, TDID 96.1 U/day) underwent 40 experiments. Glucose values dropped from 21.3 ± 0.4 to 7.3 ± 0.4 mmol/l after injection of 21.7 ± 1.9 (range, 8–40) insulin units (figure 1). After 196.2 ± 11.7 minutes, plasma glucose levels dropped below 10 mmol/l. The fall in plasma glucose was about similar in patients with type 1 compared to those with type 2 diabetes. On 6 (15%) occasions the formula under-predicted insulin needs, and glucose values dropped to 12.3 ± 0.5 mmol/l, whereas in 7 (17.5%) occasions over-prediction required some exogenous glucose administration to prevent hypoglycaemia.

Conclusion: This easy-to-use formula was fairly accurate in calculating individualized insulin doses to correct marked hyperglycaemia in patients with insulin-treated diabetes. In the majority of patients, much larger insulin doses are required than usually recommended.

Fig 1. Changes in plasma glucose levels

Data are shown as mean \pm SE, from baseline (start of insulin administration) to six hours after insulin administration by patients with T1DM (black circles) or T2DM (open squares).

Evaluation of accuracy of continuous glucose monitoring when using capillary compared to venous samples as reference

M. Andelin¹, J. Kropff², V. Matuleviciene³, J.I. Joseph⁴, S. Attvall³, S. Dahlqvist¹, H. Imberg⁵, J. DeVries², M. Lind³;

¹NU-Hospital Organization, Institute of Medicin, Uddevalla, Sweden,

²Department of Internal Medicine, Academic Medical Center, Amsterdam,

Netherlands, ³University of Gothenburg, Sweden, ⁴Department of

Anesthesiology, Jefferson Medical College of Thomas Jefferson University, Philadelphia, USA, ⁵Statistiska Konsultgruppen, Gothenburg, Sweden.

Background and aims: Accuracy of continuous glucose monitoring (CGM) is generally evaluated using venous reference samples even though CGM-systems are calibrated with capillary glucose samples. Venous glucose might be assessed with higher accuracy and reliability than capillary samples and can be taken more frequently, and have therefor

become a prerequisite from regulatory perspective. However, capillary and venous glucose levels differ, and using venous reference could thus affect measured sensor accuracy. The aim was to evaluate the impact of using either capillary or venous samples as reference when evaluating accuracy of CGM calibrated with capillary values.

Materials and methods: We evaluated 41 patients with type 1 diabetes examined in Sweden. All patients used the Dexcom G4 during 6 days and calibrated their CGM by capillary values (HemoCue meter). At one occasion during days 1–3 and 1 occasion during days 4–6 the patients visited the research unit for measuring both capillary and venous samples at the same time using the HemoCue meter. The Mean Absolute Relative Difference (MARD) and correlation coefficient were used to estimate accuracy of CGM in relation to capillary and venous samples. The Wilcoxon Signed Rank test was used in statistical comparisons.

Results: Mean age was 51 years, 14 (34%) were women, and 31 (76%) were treated with multiple daily insulin injections (MDI). Mean HbA1c was 59.3 mmol/mol, diabetes duration 23 years and BMI 24.9 kg/m². The venous samples were overall 0.83 mmol/l lower than capillary values (8.15 vs. 8.98), $p < 0.0001$. In values below 4 mmol/l (22 values from 14 individuals) the difference was 1.25 mmol/l, $p = 0.0001$, in the range 4–10 mmol/l (153 values from 38 individuals) 0.67 mmol/l, $p < 0.0001$ and above 10 mmol/l (60 values from 24 individuals) 0.95 mmol/l difference, $p < 0.0001$. The MARD using capillary values as reference was 11.7% compared to 13.7% for venous samples as reference, $p = 0.037$. Below 4 mmol/l the MARD was 16.6% and 31.8% respectively, $p = 0.048$, at 4–10 mmol/l 12.1% and 12.6%, $p = 0.32$, and above 10 mmol/l 8.7% and 9.2% respectively, $p = 0.82$. The correlation coefficient did not differ using capillary and venous samples, 0.84 and 0.85 respectively, $p = 0.75$.

Conclusion: Measured CGM accuracy is significantly affected by the used reference method. MARD in the hypoglycaemic range is significantly lower with capillary values as reference as compared to venous samples as reference. We recommend taking capillary reference values when evaluating CGM accuracy in the hypoglycaemic range.

Point-of-care assessment of salivary protein glycosylation as a short-term glycaemic index

C.T. Roberts¹, E.S. Bean¹, P.V. Rao², S.R. Nagalla¹;

¹DiabetOmics, Inc., Hillsboro, USA, ²Nizam's Institute of Medical Sciences, Hyderabad, India.

Background and aims: Assessment of short-term (2 to 3-week) glycaemia can complement daily self-monitoring of blood glucose and long-term (3-month) average blood glucose estimation based on HbA1c levels. Short-term glycaemic monitoring can be particularly useful in individuals with type-2 diabetes, where occasional HbA1c results may not adequately reveal significant glycaemic fluctuations and the potential for adverse effects of glycaemic variability. A short-term index is also useful in determining response therapy, where a more rapid determination of efficacy can enable more efficient treatment regimes. Ideally, a short-term glycaemia test would be simple, non-invasive, and feasible in a point-of-care (POC) format. We have recently described salivary protein glycosylation (SPG) as a non-invasive biomarker for assessment of glycaemia over the previous 2–3 weeks with performance superior to that of fructosamine and 1,5-anhydroglucitol in comparison to continuous glucose monitoring reference values. We have now expanded the validation of SPG as a glycaemia biomarker in a larger population and have developed a prototype POC device (Salivary GlyChek).

Materials and methods: One hundred and thirty-two subjects (47 controls with HbA1c less than 5.7 and 85 type 2 diabetes (T2D) subjects with

HbA1c greater than 6.5) participated in a 4-week study with daily 6-point capillary blood sugar monitoring (pre and post meal). Fasting and post-breakfast saliva and serum samples were collected weekly. HbA1c levels were determined at baseline and at the end of the study. Salivary protein glycosylation (SPG) was measured using a microplate assay involving sample oxidation, neutralization, and color development with a chemical reagent under conditions optimized for detection of fucose and sialic acid residues. Serum fructosamine was measured using an automated chemistry analyzer. The SPG plate assay chemistry was also adapted to a POC format comprised of a lateral-flow test strip containing multiple zones for glycoprotein oxidation, neutralization, and color development. A proprietary hand-held reader was also developed that utilizes colorimetric diffuse reflectance for quantitative test results.

Results: Classification performance analyses demonstrated mean SPG levels of 6.3 ug/ml and 9.5 ug/ml in controls and T2D, respectively with $p < 0.0001$. Mean fructosamine values were 284 umol/L and 480 umol/l in controls and T2D, respectively with $p < 0.0001$. Baseline fasting blood glucose correlated better with SPG than with fructosamine ($r = 0.61$, $p < 0.0001$ vs $r = 0.51$, $p < 0.0001$). There were no significant differences between fasting and post-prandial sampling. 7 and 14-day mean BG measures were strongly correlated with SPG ($r = 0.82$ and 0.88 , respectively, $p < 0.0001$). The microplate and POC tests for SPG demonstrated similar performance ($r = 0.89$), and the prototype POC device exhibited a cv of 8% across the dynamic range of the assay.

Conclusion: The non-invasive GlyChek POC test, in conjunction with the hand-held reader, can greatly facilitate self-monitoring of T2D by patients and their clinical management by healthcare providers.

Which principles patients with diabetes type 2 and flexible insulin therapy use for self-adjustment of insulin dose?

G. Kramer¹, N. Kuniss¹, C. Kloos¹, N. Müller¹, B. Sanow¹, G. Wolf², U.A. Müller¹;

¹Endocrinology and Metabolic Diseases, Internal Medicine III, ²Internal Medicine III, Jena University Hospital, Germany.

Background and aims: Multiple insulin injection therapy is increasingly used in the treatment of people with diabetes type 2 (DM2) to improve metabolic control and reduce hypoglycaemia. Structured treatment and education programmes for people with flexible preprandial insulin therapy provide rules for self-adjustment of insulin dose according to carbohydrate amount of the meal, current blood glucose level, physical activity, stress or illness, which are extensively trained. The aim of this study was to analyze current principles and frequency of self-adjustment of insulin dose and the association with metabolic control in people with DM2.

Materials and methods: In a large university outpatient department for endocrinology and metabolic diseases over a period of three months 149 people with DM2 with flexible or intensive insulin therapy (mean HbA1c 7.1%, age 65y, diabetes duration 19.0y, female 38.9%, BMI 33.8 kg/m²) were interviewed. 147 (98.7%) of 149 participants had participated in a therapy specific structured education programme. Self-adjustment of insulin dose was defined as each change of insulin dosage compared with the same time the previous day. Additional and skipped injections were counted as dose adjustments. The type of insulin adjustment, insulin-to-carbohydrate ratio (insulin units per 10 g of carbohydrate) and the factor for correction (e.g. 1 insulin unit lowers plasma glucose by 1.5 mmol/l) were assessed by a structured interview. Two principles for insulin dose adjustment were set: firstly the use of adjustment patterns/rules, e.g. insulin-to-carbohydrate ratio and secondly use of personal experience without a nameable rule. The frequency of insulin dose adjustments was drawn from the last 28 days of the patients' diary.

Results: Insulin dose adjustment by pattern/rule was used in 33 people (22.1%) and by personal experience in 111 of 149 participants (74.5%).

People adjusting by rule/pattern were younger (60.9 ± 9.8 vs. 65.7 ± 9.2 , $p = 0.011$) and performed more insulin dose adjustments per 28 days (50.0 ± 31.0 vs. 33.4 ± 23.5 , $p = 0.016$). HbA1c and incidence of hypoglycaemia were comparable at time of data collection. People adjusting by pattern/rule had on average lower HbA1c three years prior to the survey than people adjusting by personal experience (6.8 ± 0.9 vs. $7.2 \pm 0.9\%$, $p = 0.026$). Moreover, no differences regarding satisfaction of treatment, quality of life as well as current well-being was found between the two groups. In case of high premeal blood glucose levels 77 of 149 participants (51.6%) reported to use a higher insulin dosage, 30 (20.2%) decrease their carbohydrate intake and 42 (28.2%) correct with increased physical activity.

Conclusion: Patients with DM2 and flexible preprandial insulin therapy in Germany are specifically trained to adjust their insulin dose using an insulin-to-carbohydrate factor respectively a factor for correction. Only 22% use this trained concept in daily life. The majority of the patients adjust their insulin dose by personal experience or feeling. Although people using insulin-to-carbohydrate ratio adjust their insulin dose more frequently, HbA1c and incidence of hypoglycaemia is similar compared to those using personal experience. The importance and effectiveness of self adjustment of insulin dose by rules has to be examined in a RCT.

Two-year clinical study of a mHealth remote diabetes care system: interim results

K. Brismar¹, J. Öhrvik²;

¹Department of Molecular Medicine and Surgery, ²Department of Medicine, Karolinska Institutet, Stockholm, Sweden.

Background and aims: There is a lack of long-term clinical data from mHealth interventions in diabetes management. The objective of this study is to evaluate the clinical and economical effects of Triabetes, a smartphone and online based decision support tool for coaching of patients with type 2 diabetes. The system coaches patients on a daily basis and remotely monitors their progress.

Materials and methods: In a two-year, open-label, parallel-group, multicenter study, nine private care clinics were randomized in clusters with healthcare professionals and adult patients ($n = 225$) with type 2 diabetes (≥ 6 months) and HbA1c ≥ 53 mmol/mol to usual quarterly follow-up or use of the smartphone based system with quarterly follow-ups. The primary endpoint was changes in HbA1c after 6, 12 and 24 months. The study further measures other clinical biomarkers and patient-reported health, prescription use and disease progression.

Results: Population characteristics are shown in Table 1. The six-month median HbA1c change was significantly larger in the intervention group than in the control group, with a 5.3 mmol/mol reduction (95% CI: -8.5 - (-2.7); p -value < 0.001). A total of 197 patients were included in the analysis. There were no significant differences in the secondary endpoints. The study is currently awaiting 12 months results.

Conclusion: Using the Triabetes software in type 2 diabetes treatment helps reduce long-term blood glucose levels with clinically relevant effects.

	Intervention n=109	Control n=108
	Mean \pm SD	Mean \pm SD
Age (years)*	53,0 \pm 10,3	57,6 \pm 11,2
Gender (male)*	77,8%	59,1%
Diabetes duration (years)	7,0 \pm 4,8	8,0 \pm 5,2
HbA1c (mmol/mol)	66,1 \pm 13,2	63,3 \pm 13,0
BMI (kg/m ²)	31,7 \pm 4,9	31,6 \pm 4,2
Waist circumference (cm)	107,5 \pm 13,0	107,4 \pm 12,3
Blood pressure (mmHg)	133/83 \pm 15/8	136/82 \pm 15/10

Which mean absolute relative difference is acceptable with respect to ISO 15197 system accuracy limits?

S. Pleus, G. Freckmann, D. Rittmeyer, T. Leucht, C. Haug; Institut für Diabetes-Technologie Forschungs- und Entwicklungsgesellschaft mbH, Ulm, Germany.

Background and aims: In the literature, the analytical quality of a blood glucose (BG) monitoring system (BGMS) is often described with respect to the system accuracy criteria of the international standard ISO 15197. Sometimes, the mean absolute relative difference (MARD) between the results of the BGMS and a comparison method is used as well; however, MARD is more commonly used to describe the analytical quality of continuous glucose monitoring systems. With regard to BGMS the question arises: which MARD corresponds to the system accuracy limits of ISO 15197?

Materials and methods: In this retrospective analysis, data from system accuracy evaluations of 69 different BGMS types (96 different test strip lots) were used to calculate the MARD between the BGMS results and the corresponding results obtained with the manufacturer’s comparison method. Additionally, the same data were used to calculate the percentage of BGMS results within the system accuracy limits of ISO 15197:2003 (± 15 mg/dL for BG concentrations below 75 mg/dL, $\pm 20\%$ for BG concentrations equal to or above 75 mg/dL) and ISO 15197:2013 (± 15 mg/dL for BG concentrations below 100 mg/dL, $\pm 15\%$ for BG concentrations equal to or above 100 mg/dL), respectively. The system accuracy data were then used to establish which MARD result will likely lead to having at least 95% of results within ISO 15197:2003/2013 accuracy limits.

Results: The MARD results for these 96 test strip lots ranged from 2.8% to 16.4%. The lowest MARD of a test strip lot that showed <95% of results within ISO 15197:2003 accuracy limits was 7.5%, whereas the highest MARD of a test strip lot that showed $\geq 95\%$ of results within ISO 15197:2003 accuracy limits was 10.2%. For the ISO 15197:2013 accuracy limits, the corresponding MARD values were 6.5% and 7.6%, respectively (see Figure).

Conclusion: Based on our analysis we conclude that a BGMS likely has acceptable analytical quality with respect to ISO 15197:2003, if its MARD result is below 7.5%. If the BGMS’ MARD result is even below 6.5%, the BGMS is likely to have $\geq 95\%$ of results within ISO 15197:2013 system accuracy limits, thus reaching an acceptable analytical quality with respect to ISO 15197:2013.

930

Long-term accuracy surveillance of a system for self-monitoring of blood glucose

G. Freckmann, A. Baumstark, N. Jendrike, T. Leucht, P. Wintergerst, D. Rittmeyer, S. Pleus; Institut für Diabetes-Technologie Forschungs- und Entwicklungsgesellschaft mbH, Ulm, Germany.

Background and aims: Systems for self-monitoring of blood glucose (SMBG) require a CE mark to be distributed in the EU. A one-time conformity assessment, e. g. according to ISO 15197, is sufficient to obtain such a CE mark. While ISO 15197:2013 was released in 2013, ISO 15197:2003 is still valid throughout a transition period of 3 years that ends in 2016. In this study, a CE-marked SMBG system was monitored over a period of 1.5 years by repeatedly evaluating system accuracy of different test strip lots.

Materials and methods: A total of 11 test strip lots were evaluated in 4 individual studies between August 2013 and February 2015. System accuracy assessments were performed following procedures described in ISO 15197 and values obtained with the SMBG system were compared to a laboratory glucose oxidase method, which is also the manufacturer’s comparison method. All materials were purchased from pharmacies; storage conditions were controlled and evaluations were performed prior to the labelled expiration dates. Results were analyzed by applying accuracy criteria of ISO 15197:2003 and criterion A of ISO 15197:2013 for every test strip lot individually. ISO 15197:2003 states that for acceptable system accuracy at least 95% of results have to fall within ± 15 mg/dL at BG concentrations below 75 mg/dL and within $\pm 20\%$ at BG concentrations equal to or above 75 mg/dL. Criterion A of ISO 15197:2013 has more stringent criteria: at least 95% of results have to fall within ± 15 mg/dL and $\pm 15\%$ for BG concentrations below and equal to or above 100 mg/dL, respectively.

Results: Out of 11 test strip lots, 9 lots fulfilled the criteria of ISO 15197:2003 with $\geq 95\%$ of the results within the stipulated limits (see table). The more stringent criteria of ISO 15197:2013 were fulfilled by 5 test strip lots. The relative bias was between 0.2% and 10.7%. No clear trend in accuracy could be observed, but lot-to-lot variations between lots evaluated at the same time seemed to have decreased over time.

Conclusion: This long-term surveillance indicates variations in system accuracy of a CE-marked SMBG system after market-release. Getting a CE mark for an SMBG system is a one-time process with long-term surveillance of system accuracy by manufacturers not being required. However, consistent acceptable system accuracy of SMBG systems is an important prerequisite of adequate insulin-based diabetes therapy. Therefore, regular post-marketing evaluations are important to identify outliers (such as lot 4) and to ensure continuing compliance with the respective standards, thus providing people with diabetes the opportunity of properly managing their diabetes.

Lot	Within ISO 15197:2003 limits	Within ISO 15197:2013 limits	Bias [%]
1 08-2013-1	194 / 200 (97%)	186 / 200 (93%)	5.1
2 08-2013-2	198 / 200 (99%)	194 / 200 (97%)	0.6
3 08-2013-3	185 / 200 (92.5%)	170 / 200 (85%)	9.2
4 11-2013-1	171 / 200 (85.5%)	154 / 200 (77%)	10.7
5 11-2013-2	198 / 200 (99%)	196 / 200 (98%)	0.2
6 05-2014-1	196 / 200 (98%)	190 / 200 (95%)	0.8
7 05-2014-2	197 / 200 (98.5%)	195 / 200 (97.5%)	2.6

Ultra-rapid BioChaperone insulin Lispro (BC-LIS): linear dose-response and faster absorption than insulin Lispro (LIS)
G. Andersen¹, B. Alluis², G. Meiffren², A. Ranson², C. Seroussi², M. Gaudier², O. Soula², A. Fischer¹, L. Nosek¹, T. Heise¹;
¹Profil, Neuss, Germany, ²Adocia, Lyon, France.

Background and aims: We investigated dose-response and dose-exposure relationship of BC-LIS, a novel, ultra-rapid formulation of the insulin analogue lispro using the BioChaperone technology, and LIS.

Materials and methods: Thirty-eight patients with type 1 diabetes mellitus (age 47.0±11.7 years, BMI 24.7±1.9 kg/m², HbA1c 7.5±0.8% [mean ± SD]) were included in this double-blind, randomised, four period crossover phase IIa study. They received single doses of 0.1, 0.2 or 0.4 U/kg of BC-LIS or 0.2 of LIS under automated euglycaemic clamp conditions (target blood glucose 100 mg/dL, clamp duration 12 h post-dosing).

Results: Mean baseline adjusted Insulin profiles are given in the figure. Ultra-rapid properties of 0.2 U/kg BC-LIS were demonstrated with significantly earlier time to maximum (t_{max}) and time to half-maximum insulin levels ($t_{50\% C_{max} \text{ early}}$), (median t_{max} 40 vs. 60 min, $t_{50\% C_{max} \text{ early}}$ 14 vs. 27 min, both comparisons $p < 0.0001$), greater early exposure up to 2 h ($AUC_{\text{ins}(0-2h)}$) 23.2 vs. 9.2 h*mU/L, $p < 0.0001$; $AUC_{\text{ins}(0-2h)}$ 132.3 vs. 122.6 h*mU/L, $p = 0.0057$) and lower late exposure ($AUC_{\text{ins}(2-8h)}$) 69.0 vs. 87.6 h*mU/L, $p < 0.0001$) than 0.2 U/kg LIS. BC-LIS had significantly earlier time to half-maximum GIR and time to maximal GIR ($t_{0.5(GIR_{max})}$) 32 vs. 42 min, $p < 0.0001$; $t_{GIR_{max}}$ 86 vs. 117 min, $p = 0.0005$), stronger early metabolic effect up to 3 h post-dosing ($AUC_{GIR(0-3h)}$) 952.8 vs. 812.9 mg/kg, $p = 0.0090$) and lower late metabolic effect ($AUC_{GIR(3-8h)}$) 357 vs. 446 mg/kg, $p = 0.0115$). Total exposure and total metabolic effect were similar with either BC-LIS or LIS. Dose-proportionality was established for early and total exposure of BC-LIS ($AUC_{\text{ins}(0-12h)}$) 102 vs 205 vs 444 h*mU/kg, 0.1 vs 0.2 vs 0.4 U/kg) and dose-linearity for early and total metabolic effect ($AUC_{GIR(0-12h)}$) 726, 1357 and 2422 mg/kg for 0.1, 0.2 and 0.4 U/kg). Ultra-rapid properties were preserved between doses as shown by unchanged t_{max} and $t_{50\% C_{max} \text{ early}}$. Both insulin formulations were well tolerated and no injection site reactions were observed with BC-LIS.

Conclusion: BC-LIS presents ultra-rapid, dose-proportional absorption, resulting in significantly improved glucose-lowering effect and dose-linear gluco-dynamic activity in subjects with type 1 diabetes. In addition, ultra-rapid properties are preserved at clinically relevant doses of up to 0.4 U/kg. Therefore, BC-LIS has the potential to improve postprandial glucose control versus currently available fast-acting insulin analogues such as LIS. Dose-proportional early and total exposures of clinically relevant doses (0.1, 0.2, and 0.4 units/kg) was established for BC-LIS

Reduced hypoglycaemia is observed with inhaled insulin versus subcutaneous insulin aspart in patients with type 1 diabetes mellitus

E. Nikonova¹, B. Bode², J. Gill¹, J. Stewart³, L. Blonde⁴;
¹Sanofi US, Inc., Bridgewater, ²Atlanta Diabetes Associates, USA,
³Sanofi Canada, Lavalle, Canada, ⁴Ochsner Medical Center, New Orleans, USA.

Background and aims: Technosphere Insulin Inhalation Powder (TI) is a dry powder formulation of regular human insulin adsorbed onto Technosphere microparticles for oral inhalation in patients with diabetes. We conducted a post hoc analysis of hypoglycaemia rates from a 24-week, phase 3 randomized study of prandial TI (N=172) versus insulin aspart (IA; N=167) added to basal insulin in patients with type 1 diabetes mellitus (T1DM).

Materials and methods: Annualised hypoglycaemia event rates were determined in the overall study population, patients taking ≥ 1 postmeal supplemental dose (TI, n=111; IA, n=91), and patients not taking a supplemental dose (TI, n=61; IA, n=76). Hypoglycaemia rates during study weeks 0-12 (dose adjustment) and 12-24 (stable dosing) were assessed. Hypoglycaemia was defined as total (all events), confirmed (blood glucose <49 mg/dL), nocturnal (0:00–6:00 AM), and severe (assistance required). Data were adjusted for baseline HbA_{1c} level.

Results: There was no significant difference in the mean number of supplemental doses taken between the TI and IA arms (34.1 vs 26.6, respectively; $P = 0.1907$). Significantly higher hypoglycaemia rates (events per patient/year) were seen for IA versus TI in the overall study population (total 81.1 vs 55.2; confirmed 15.0 vs 9.0; nocturnal 8.8 vs 5.9; and severe 0.9 vs 0.5; all $P < 0.05$) and patients taking ≥ 1 supplemental dose (total 96.3 vs 60.9; confirmed 18.6 vs 9.8; nocturnal 11.5 vs 6.5; and severe 1.1 vs 0.6; all $P < 0.05$). In patients not taking a supplemental dose, a significantly higher total hypoglycaemia rate was seen with IA versus TI (64.9 vs 46.0 events per patient/year; $P = 0.0160$). Within each arm there was a trend for higher total hypoglycaemia rates ≥ 1 hour after supplemental dosing (events per patient/year) in patients with a higher supplemental dose frequency (TI vs IA: 0.4 vs 0.4; 1.7 vs 2.2; and 4.9 vs 6.6 for patients receiving 1-5, 6-20, and 21-60 supplemental doses during the study); there was no significant difference between the TI and IA arms. In the overall study population, within both treatments arms there was a trend for a higher rate of all types of hypoglycaemia during weeks 0-12 (titration) versus 12-24 (stable dosing). In patients taking a supplemental dose, a similar trend was seen in the IA arm only. In patients not

taking a supplemental dose, there was a trend for higher total, confirmed, and nocturnal hypoglycaemia rates during weeks 0–12 versus 12–24 for IA; and total, confirmed, and severe hypoglycaemia for TI.

Conclusion: These data show that the more rapid onset and offset of action with TI versus IA was not associated with greater supplemental dosing. There was a consistently lower hypoglycaemia rate in patients with T1DM treated with TI versus IA, including those taking supplemental doses, and during dose adjustment and stable dosing. These data show that supplemental TI dosing does not result in an increased hypoglycaemia risk.

Higher early insulin exposure and greater early glucose-lowering effect with faster-acting insulin aspart vs insulin aspart in elderly and younger adults with type 1 diabetes

U. Hövelmann¹, E. Zijlstra¹, K. Stender-Petersen², J.B. Jacobsen², T. Heise¹, H. Haahr²;

¹Profil, Neuss, Germany, ²Novo Nordisk A/S, Søborg, Denmark.

Background and aims: Faster-acting insulin aspart (faster aspart) is a new formulation of insulin aspart (IAsp), with initial faster absorption following subcutaneous (s.c.) injection. This single-dose, double-blind, two period, cross-over trial compared the pharmacokinetic (PK) and pharmacodynamic (PD) profiles of faster aspart vs IAsp in elderly and younger adults with type 1 diabetes (T1D).

Materials and methods: Sixty-seven patients (n=37 aged 18–35 years; n=30 aged ≥65 years) received a single dose (0.2 U/kg body weight s.c.) of faster aspart or IAsp in a euglycaemic glucose clamp setting (blood glucose target 5.5 mmol/L (100 mg/dL); duration 12 h post-dose).

Results: For both age groups, onset of appearance with faster aspart occurred twice as fast (relative difference: 55%, elderly, 47%, younger adults; Table) than with IAsp (mean difference [95% CI]: elderly, -2.88 min [-3.83; -1.94]; younger adults, -2.78 min [-4.21; -1.35]), with a greater early insulin exposure during the first 1 h; total exposure was similar in both groups (Table). Earlier onset of action with faster aspart vs IAsp (relative difference: 35%, elderly, 33% younger adults; Table) occurred in both age groups (elderly, -10.17 min [-15.29; -5.06]; younger adults, -8.70 min [-15.07; -2.34]) and was supported by shorter t50%GIR_{max} vs IAsp (elderly, -5.58 min [-8.99; -2.17]; younger adults, -10.28 min [-15.41; -5.15]). Faster aspart also had a greater early glucose-lowering effect within 2 h post-dose vs IAsp (greatest [i.e., 2-fold] difference within the first 30 min; LSmean, mg/kg: elderly, 44.72 vs 21.41; younger adults, 42.83 vs 20.52); total glucose-lowering effect was similar [Table]). Treatment effects did not differ significantly between age groups. Both treatments were well tolerated and no safety issues were identified, including no injection-site reactions.

Conclusion: Earlier onset and greater early insulin exposure with faster aspart led to a greater early glucose-lowering effect vs IAsp, which was retained in both elderly and younger adults with T1D.

Insulin degludec/insulin aspart lowers fasting plasma glucose and rates of confirmed and nocturnal hypoglycaemia independent of baseline HbA_{1c} levels

J.S. Christiansen¹, G. Fulcher², M. Haluzik³, T.R. Pieber⁴, H. Rodbard⁵;

¹Aarhus University Hospital, Denmark, ²Royal North Shore Hospital, Sydney, Australia, ³Charles University, Prague, Czech Republic, ⁴Medical University of Graz, Austria, ⁵Endocrinology and Metabolic Consultants, Rockville, USA.

Background and aims: Individual patient characteristics can influence the selection of appropriate glycaemic targets by clinicians. The availability of individual patient data, including baseline HbA_{1c} levels may improve the achievement of individualised glycaemic targets. IDegAsp, a novel co-formulation of 70% insulin degludec (IDeg) and 30% insulin aspart (IAsp) has been previously shown to provide effective glycaemic control in individuals with type 2 diabetes mellitus (T2DM). This *post-hoc*, pooled analysis evaluated the efficacy of IDegAsp vs BIAsp 30 and IDeg OD + IAsp in adequately controlling glycaemic parameters and lowering hypoglycaemia in subjects with T2DM stratified according to baseline HbA_{1c}.

Materials and methods: Data were pooled from five 26-week treat-to-target phase 3a/b clinical trials in subjects with T2DM in the IDegAsp clinical development programme. Comparators from the individual trials were pooled and included biphasic insulin aspart 30 (BIAsp 30) twice-daily (BID) or IDeg OD + IAsp (2–4 injections). End of trial (EOT) HbA_{1c}, confirmed and nocturnal confirmed hypoglycaemia, and insulin dose were stratified according to four baseline HbA_{1c} categories: <7.5%

(n=263), ≥7.5-<8.5% (n=760), ≥8.5-<9.0% (n=309), ≥9.0% (n=476). EOT fasting plasma glucose (FPG) was stratified according to baseline FPG: 5.5-7.0-10.0 (n=523). For each separate group, continuous variables were analysed using ANOVA and event rates were analysed using negative binomial regression.

Results: There was no difference in HbA_{1c} EOT across HbA_{1c} categories between IDegAsp (n=1111) and the comparator group (n=697). FPG EOT was significantly lower in subjects in three baseline FPG categories (>5.5-7.0-10.0, n=523) with IDegAsp vs comparator (Table 1). Episodes of confirmed hypoglycaemia were significantly lower with IDegAsp (p<0.05) (Table 1) as were episodes of nocturnal confirmed hypoglycaemia in all four HbA_{1c} categories (Table 1). IDegAsp BID vs BIAsp 30 BID achieved a significant reduction in total daily insulin dose at EOT in subjects with baseline HbA_{1c} ≥7.5-<8.5% and ≥9.0 (p<0.0001). Similarly, when compared with IDeg OD + IAsp, IDegAsp was associated with a significant reduction in EOT daily insulin dose in subjects with baseline HbA_{1c} ≥7.5-<8.5% (p<0.05).

Conclusion: No differences in EOT HbA_{1c} levels were observed between IDegAsp and comparator in any of the baseline HbA_{1c} categories. IDegAsp significantly lowered FPG, particularly when baseline FPG exceeded 5.5 mmol/L. IDegAsp was associated with significantly lower rates of confirmed hypoglycaemia and nocturnal confirmed hypoglycaemia compared with BIAsp 30 and IDeg OD + IAsp, independent of baseline HbA_{1c}.

Table 1. Trial endpoints stratified by baseline HbA_{1c}

Endpoint	IDegAsp	Comparator (BIAsp 30 BID and IDeg OD+ IAsp)	Treatment contrast, p value

A novel once weekly combination of a long-acting GLP-1R agonist and an insulin analogue (^{LAPSt}Insulin Combo) offers favourable PK/PD and mitogenic properties

J. Kim¹, Y. Park¹, C. Lim¹, I. Choi¹, S. Lee¹, Y. Kim¹, J. Kang¹, M. Trautmann², M. Homepesch², S. Kwon¹;

¹Hanmi Pharmaceutical, Seoul, Republic of Korea, ²Profil institute, Chula Vista, USA.

Background and aims: Developments of a basal insulin and a GLP-1 agonist combination have received great interest due to greater efficacy and fewer side effects. However, recently developed combination products still require a once-daily administration, which may negatively affect treatment adherence. We have developed a long-acting basal insulin and an exendin-4 analog, ^{LAPSt}Insulin 115 (HM12470) and ^{LAPSt}CA-Exendin-4 (efpeglatide) with PK indicating that once-weekly administration would achieve continuous therapeutic plasma levels. This study investigated the PK/PD and mitogenic properties of ^{LAPSt}Insulin Combo (HM14220: ^{LAPSt}Insulin 115 and efpeglatide combination) *in vitro* and *in vivo*.

Materials and methods: Serum concentration of ^{LAPSt}Insulin 115 and efpeglatide were quantified after single administration of ^{LAPSt}Insulin 115 and/or efpeglatide in various species. The Human PK profile of ^{LAPSt}Insulin 115 was predicted using WajimaC_{ss}-MRT method. A thymidine incorporation assay was performed to evaluate the mitogenic effect of ^{LAPSt}Insulin Combo on SaOS2, MCF7, and COLO205 cells. DIO/STZ rats were chronically treated with ^{LAPSt}Insulin 115 and/or efpeglatide. Blood glucose and weight changes were monitored throughout the study. At the end of treatment, HbA_{1c} levels were determined. Various dosing regimens were investigated, including a forced flexible regimen (10 to 50 hr delayed administration at every other dosing). The effect on β-cell preservation was evaluated by insulin staining of pancreas of *db/db* mice after 12 weeks treatment of ^{LAPSt}Insulin 115 and/or efpeglatide. A switching study, with initial administration of either insulin glargine or liraglutide for 2 weeks, followed by administration of ^{LAPSt}Insulin Combo for another 4 weeks in *db/db* mice was conducted.

Results: After single administration, ^{LAPSt}Insulin 115 and efpeglatide showed harmonized PK without drug to drug interaction. The half-life of ^{LAPSt}Insulin 115 and efpeglatide was determined as 32.2~106.8 h and 38.4~79.6 h, respectively, in rodents and cynomolgus monkeys. Based on these results, ^{LAPSt}Insulin 115 half-life in human was predicted as 132 h which was similar to that of efpeglatide (~140 h). The addition of efpeglatide did not alter the low mitogenicity of ^{LAPSt}Insulin 115 (~5% vs. rh-Insulin) in all cell systems tested. Combined administration (Q3D) in DIO/STZ rats mimicked human once-weekly administration of ^{LAPSt}Insulin 115 and efpeglatide achieved significantly greater HbA_{1c} reductions (endpoint HbA_{1c}: 4.8±0.25%) relative to the groups treated with the individual compounds (6.3±0.28% for ^{LAPSt}Insulin 115; 5.4±1.3% for efpeglatide). The improved efficacy was maintained even after forced-flexible dosing without fluctuation in blood glucose profile. Moreover, switching from either insulin glargine or liraglutide to ^{LAPSt}Insulin Combo led to additional HbA_{1c} reduction. Finally, insulin staining indicated that ^{LAPSt}Insulin Combo showed an increased β-cell mass compared the groups treated with the individual compounds.

Conclusion: ^{LAPSt}Insulin Combo may offer the convenience of once-weekly regimen with a potential for flexible dosing together with improved effects on blood glucose for the management of diabetic patients.

Faster-acting insulin aspart by continuous subcutaneous insulin infusion: earlier exposure and greater early pharmacokinetic / pharmacodynamic effects vs insulin aspart

E. Zijlstra¹, T. Heise¹, T. Rikte², L. Thorsson², L. Nosek¹, H. Haahr²;
¹Profil, Neuss, Germany, ²Novo Nordisk A/S, Søborg, Denmark.

Background and aims: Faster-acting insulin aspart (faster aspart) is insulin aspart (IAsp) in a new formulation with a faster initial absorption after subcutaneous injection. The aims of this study were to evaluate the pharmacokinetic (PK) and pharmacodynamic (PD) properties of faster aspart during continuous subcutaneous insulin infusion (CSII).

Materials and methods: PK/PD properties were investigated in a randomised, double-blind, crossover trial in 48 patients with type 1 diabetes mellitus (mean \pm SD age: 46.3 \pm 8.6 years; HbA_{1c}: 7.4 \pm 0.6% [57 \pm 6 mmol/mol]). Patients received faster aspart or IAsp as a CSII bolus dose (0.15 U/kg) on top of basal CSII (0.02 U/kg/h) under glucose clamp conditions (ClampArt; target 5.5 mmol/l [100 mg/dl]; duration 27 h, 13 h run-in, 14 h post bolus dosing).

Results: After the bolus dose, t_{50%} C_{max} and t_{max} (Table) occurred 36% (12 min [95% CI 9;14]) and 31% (26 min [17;34]) earlier, respectively, with faster aspart compared to IAsp. Moreover, early insulin exposure in the first 2 h was greater with faster aspart than IAsp; for example, exposure was threefold greater in the first 30 min for faster aspart (AUC_{IAsp, 0-30 min}, Table), whereas total exposure was similar (AUC_{IAsp, Total}, Table). Faster aspart had earlier t_{50%} G_{IRmax} (21%; 11 min [7;15]) and t_{GIRmax} (14%; 19 min [3;34]) and a greater glucose-lowering effect during the first 2 h after bolus dosing vs IAsp; whereas total glucose-lowering effect was similar (AUC_{GIR, Total}, Table). Both treatments were well tolerated.

Conclusion: In summary, faster aspart showed enhanced early exposure and action compared with IAsp in CSII. Improvements in onset of exposure and action were more pronounced than those previously reported for subcutaneous injection of faster aspart.

Table: Pharmacokinetic and pharmacodynamic results for faster-acting insulin aspart vs insulin aspart

PK endpoints	Ratio [95% CI]	PD endpoints	Ratio [95% CI]
Early insulin exposure		Early glucose-lowering effect	
AUC _{IAsp, 0-15 min}	7.05 [3.73;136.57]*	AUC _{GIR, 0-15 min}	NA
AUC _{IAsp, 0-30 min}	2.95 [2.32;3.73]	AUC _{GIR, 0-30 min}	2.18 [1.33;5.04]*
AUC _{IAsp, 0-1 h}	1.52 [1.37;1.69]	AUC _{GIR, 0-1 h}	1.52 [1.29;1.83]*
AUC _{IAsp, 0-2 h}	1.18 [1.10;1.26]	AUC _{GIR, 0-2 h}	1.21 [1.07;1.36]
Onset of exposure		Onset of action	
t _{50% Cmax}	0.64 [0.57;0.71]*	t _{50% GIRmax}	0.79 [0.72;0.86]*
t _{max}	0.69 [0.60;0.78]*	t _{GIRmax}	0.86 [0.75;0.97]*
Total exposure		Total glucose-lowering effect	
AUC _{IAsp, Total}	0.97 [0.90;1.05]	AUC _{GIR, Total}	1.04 [0.95;1.13]
C _{max}	1.11 [1.03;1.19]	GIR _{max}	1.04 [0.94;1.14]

*Ratio calculated using Fieller's method. Endpoints were corrected for basal CSII. Ratio = faster aspart/IAsp. CSII, continuous subcutaneous insulin infusion; faster aspart, faster-acting insulin aspart; GIR, glucose infusion rate; IAsp, insulin aspart; NA, not available; PD, pharmacodynamic; PK, pharmacokinetic.

Cardiovascular events and all-cause mortality: effects of dual therapy intensification with insulin vs glucagon-like peptide-1 analogue

U. Anyanwagu¹, J. Mamza¹, R. Mehta², R. Donnelly¹, I. Idris¹, I. Idris¹;
¹Division of Medical Sciences and Graduate Entry Medicine, ²Trent Research Design Services, University of Nottingham, UK.

Background and aims: Recent observational studies have raised concerns about the CV safety of insulin therapy in type 2 diabetes (T2DM) after monotherapy with metformin (MET) has failed to maintain glycaemic control. We therefore analysed the time to non-fatal acute myocardial infarction, non-fatal stroke or all-cause mortality in patients with T2DM who had their treatment intensified with insulin or a

Glucagon like peptide-1 (GLP-1) analogue following dual therapy failure with MET and SU.

Materials and methods: A retrospective cohort study was conducted in 2003 patients who were newly treated with a GLP-1 or insulin following dual therapy (MET + SU) failure between 2006 and-2014. Data was sourced from UK General Practices via The Health Initiative Network (THIN) database. The risk of the composite outcome (CV events) was compared between 2 treatment groups: MET+SU+Insulin (N=1584) and MET+SU+GLP-1 (N=419). Follow-up was 5 yrs (total of 6614 person-years), and propensity score matching analysis and Cox proportional hazard models were employed.

Results: Mean age was 52.8 \pm 14.1 years. Overall, the number of CV events was 231 vs 11 for patients who added insulin vs GLP-1 respectively, (44.5 vs 7.7 per 1000 person-years adjusted Hazard Ratio (aHR): 0.27; 95%CI: 0.14-0.53; p<0.0001). Insulin was associated with significant increase in weight compared with GLP-1; (1.78 vs -3.93 kg; p<0.0001) but HbA_{1c} reduction was similar between both treatment groups; (-1.29 vs -0.98; p=0.156). In a subgroup analysis of obese patients, (BMI>30 kg/m²) there were 84 vs 11 composite outcomes (38.6 vs 8.1 per 1000 person-years; aHR: 0.31; 95%CI: 0.16-0.61; p=0.001) in the Insulin and GLP-1 groups respectively.

Conclusion: Therefore, in this large cohort study tracking outcomes in routine clinical practice, intensification of dual oral therapy by adding insulin is associated with a higher risk of CV events, irrespective of weight compared with adding a GLP-1 therapy as the third oral agent.

938

Rapid-acting insulin lispro products SAR342434 and US-and EU-approved insulin lispro solution show similar pharmacokinetics and pharmacodynamics in subjects with type 1 diabetes mellitus

C. Kapitza¹, I. Nowotny², A. Lehmann², H. Khatami³, K. Bergmann², B. Rothhauser², R. Becker²;
¹Profil, Neuss, ²Sanofi-Aventis Deutschland GmbH, Frankfurt, Germany, ³Sanofi, Bridgewater, USA.

Background and aims: SAR342434 solution and US- and EU-approved insulin lispro solution are rapid-acting insulin lispro products. Despite identical amino sequences, protein-based therapeutics must be shown to be pharmacologically similar to be approved as biosimilars. We compared the pharmacokinetics (PK) and pharmacodynamics (PD) of SAR342434 (T) and US-approved (R1) and EU-approved (R2) insulin lispro in a single-centre, randomized, double-blind, 3-treatment, 3-period, 6-sequence, crossover, euglycaemic clamp study.

Materials and methods: 30 male subjects with T1DM (20-59 years) were randomized to receive 0.3 U.kg⁻¹ T, R1 and R2 in separate periods;

28 subjects completed all 3 treatment periods. PK and PD (Glucose Infusion Rate, GIR) by euglycaemic clamp were assessed up to 12 hours. **Results:** Mean concentration and GIR vs time profiles for T, R1 and R2 were similar. Exposure to and activity of T, R1 and R2 were similar between treatments, with the 90% CI for the ratios of geometric least squares means contained in the pre-specified bioequivalence limit of 0.80 to 1.25, and non-significant differences in time related parameters (Table). The within-subject variability of exposure and activity across the 3 clamps was low: 6.8% (90% CI 5.9 to 8.1) for INS-AUC; 15.6% (13.5 to 18.6) for INS-C_{max}; 16.7% (14.4 to 19.9) for GIR-AUC_{0-12h}; and 15.2% (13.1 to 18.1) for GIR_{max}, indicating high day-to-day reproducibility in clamp performance, regardless of the product. Adverse events were similar for T, R1 and R2. No safety concerns were noted in laboratory, vital signs, or ECG data.

Conclusion: This study demonstrated a similar insulin lispro exposure profile, PK and PD activity for SAR342434 solution compared to both US- and EU-approved insulin lispro solution, and between both US- and EU-approved insulin lispro, rendering SAR342434 a biosimilar candidate.

Table. Analysis of the primary PK and PD parameters of rapid acting insulin lispro products, SAR342434 solution (T), and US approved (R1) and EU-approved (R2) insulin lispro.

Parameter	Treatment ratio	Point estimate (90% CI)	Parameter	Treatment difference	Hodges-Lehmann shift
INS C _{max}	T vs R1	0.97 (0.89 to 1.05)	INS t _{max} , hours	T - R1	0.17 (-0.25 to 0.08)

Exploratory study of a dose-response curve for basal insulin

C. Shaefer¹, L. Traylor², L. Gao³, T. Dex², P. Sepe⁴, N. Skolnik⁴,
¹Georgia Health Sciences University, Augusta, ²Sanofi US, Inc., Bridge-
water, ³Analstat, Somerset, ⁴Abington Family Medicine, USA.

Background and aims: Many primary care physicians (PCPs) are challenged by decisions on transitioning their patients with type 2 diabetes mellitus (T2DM) from basal insulin alone to basal insulin plus prandial therapy. PCPs often continue to titrate basal insulin beyond a point of optimal efficacy and, for many patients, this results in inadequate HbA1c control and increased risk of hypoglycaemia and weight gain. With the aim of guiding PCPs in utilizing basal insulin properly, we assessed if there is a diminishing response to increasing basal insulin by performing a post hoc analysis of 3 insulin glargine titration studies of ≥24 weeks among patients with T2DM.

Materials and methods: A total of 458 patients were included; mean age 56 years, half were male, mean BMI 33 kg/m², mean HbA1c 8.7%, and mean fasting plasma glucose (FPG) 199.6 mg/dL. Ratios for FPG change:insulin dose change were calculated and plotted at various time points.

Results: We observed that with increasing dose of basal insulin, FPG reduction becomes proportionally smaller, levelling at around 0.5 IU/kg (Figure).

Conclusion: Basal insulin shows a dose-response curve; as the basal insulin dose approaches 0.5 IU/kg, there is little incremental benefit of

further increasing the basal insulin dose. Therefore, at basal insulin doses >0.5 IU/kg it may be advisable for PCPs to consider initiating prandial therapy. In patients requiring high basal insulin doses, decreasing glucose-lowering responses may be indicative of either a dose-response curve or a greater degree of insulin resistance. However, despite a dose-response curve seen at a population level, it is important to stress that appropriate treatment decisions for patients with T2DM should be based on individualization of therapy and response.

Figure. FPG change:insulin dose change ratios; changes are from baseline to indicated time point.

Excessive daytime sleepiness, daytime napping, and risk of type 2 diabetes: a meta-analysis

T. Yamada, N. Shojima, K. Hara, T. Yamauchi, T. Kadowaki;
Department of Diabetes and Metabolic Diseases, University of Tokyo, Japan.

Background and aims: Sleep is an important component of a healthy life, along with a good diet and appropriate physical activity. Excessive daytime sleepiness is widely prevalent around the world and so is the habit of napping. Daytime naps are usually brief, but can range from a few minutes to a few hours. The frequency varies from taking an occasional nap to planned rest periods several times daily for habitual nappers. Some individuals take a nap because they are excessively sleepy during the daytime as a result of a sleep disorder. We performed a meta-analysis to investigate the association between daytime sleepiness or napping and the risk of type 2 diabetes.

Materials and methods: We searched Medline, the Cochrane Library, and Web of Science for articles published up to November 2014 using the keywords daytime sleepiness, nap, and diabetes. To ascertain the validity of the eligible studies, the quality of each report was appraised with reference to the STROBE statement. In addition, the Newcastle-Ottawa Scale for assessing the quality of observational studies in meta-analyses was used to quantify the validity of each study. The adjusted relative risk and 95% confidence interval were calculated with the random effect model. Dose-response relations were also evaluated. Two observers independently assessed eligibility, extracted data, and assessed possible bias. Sex was employed as an independent category for comparison. Publication bias was evaluated by the funnel plot, Begg's test, and Egger's test.

Results: Among 683 studies initially identified, 261,365 Asian and Western subjects stratified into 13 categories (reports) were selected. In each study, analyses were well adjusted for several confounders for diabetes. Pooled analysis revealed that excessive daytime sleepiness and a longer nap (≥ 60 min/day) each significantly increased the risk of type 2 diabetes by about 50% compared with the absence of these factors. The relative risk was 1.56 (95% CI 1.13–2.14, $p=0.006$) for excessive daytime sleepiness, while the relative risk was 1.46 (1.23–1.74, $p<0.001$) for a longer nap. In contrast, a shorter nap (<60 min/day) did not increase the risk of diabetes (0.95 (0.75–1.21, $p=0.68$)). A dose-response meta-analysis using the cubic spline model showed a J-shaped relation between nap time and the risk of diabetes (p for non-linearity=0.003), with no effect of napping up to about 40 minutes/day followed by a sharp increase in the risk of diabetes at longer times. Analyses stratified by study location, study quality, and study type also yielded similar results. Moreover, the funnel plot, Begg's test, and Egger's test did not suggest any evidence of publication bias.

Conclusion: Excessive daytime sleepiness and taking longer naps were associated with increased risk of type 2 diabetes, with a short nap not increasing this risk.

941

Curvilinear associations of irregular sleep patterns during weekends with glycaemic control in type 2 diabetes: the Hong Kong Diabetes Registry

A.P.S. Kong¹, J. Zhang², K. Choi³, Y. Zhang¹, W. So¹, R.C.W. Ma¹, Y. Wing², J.C.N. Chan¹;

¹Medicine and Therapeutics, ²Psychiatry, ³Nethersole School of Nursing, The Chinese University of Hong Kong, China.

Background and aims: Both long and short duration of sleep are associated with hyperglycemia. Nonetheless, the associations between glycaemia and sleep duration during weekdays and weekends are less well studied. We examined the associations of glycaemic control with sleep patterns during weekdays and weekends in patients with type 2 diabetes.

Materials and methods: A consecutive cohort of 2,531 type 2 diabetic patients was studied between July 2010 and February 2013. We measured indices of glycaemic control including glycated hemoglobin (HbA_{1c}) and fasting plasma glucose (FPG), and sleep parameters including sleep duration during weekdays and weekends, chronotype (a construct capturing an individual's preference for being a "morning" or "evening" person) and social jetlag (a measure of misalignment between biological and social clocks). Restricted cubic spline (RCS) regressions were used to examine the relationships between the parameters of glycaemic control and sleep pattern in the present study.

Results: In this cohort, mean age was 54.6 (standard deviation, SD 8.6) years and mean disease duration of diabetes was 7.9 (SD 7.0) years. 59.5% were men with 60.7% reported to have full or part-time employment. 4.5% were regular shift-workers. The mean sleep duration was 7.8 \pm 1.4 and 8.4 \pm 1.5 hours during weekdays and weekends respectively. After adjustment for potential confounders including employment and shift work, we found that chronotype and social jetlag had a significant U-shaped and J-shaped like relationship with HbA_{1c} and FPG respectively (p for non-linear association=0.002 and <0.001 respectively).

Conclusion: In type 2 diabetes, irregular sleep patterns with excessive and insufficient sleep compensation during weekends are associated with poor glycaemic control. These novel data underpinned the importance of regularity of sleep habits and circadian influences in glucose metabolism. *Supported by: Research Grants Council, Hong Kong (CUHK 466711)*

Serum insulin degrading enzyme level and other factors in type 2 diabetic patients with mild cognitive impairment

J. Sun¹, B. Zhang², J. Han¹, Y. Yuan¹, R. Cai¹, P. Wang¹, R. Huang¹, W. Xia¹, H. Sun¹, S. Wang¹;

¹Department of Endocrinology, The Affiliated ZhongDa Hospital of Southeast University, ²Department of Medicine, Panda Group Community Health Service Centre, Nanjing, China.

Background and aims: Insulin degrading enzyme (IDE) contributes to the degradation process of insulin and A β . We aimed to investigate the role of IDE in patients with type 2 diabetes patients with mild cognitive impairment (MCI).

Materials and methods: A total of 146 individuals with type 2 diabetes were enrolled, including 75 patients with MCI and 71 patients without MCI. Demographic characteristics, cognitive function and serum IDE level were examined.

Results: Among patients with MCI, the Montreal Cognitive Assessment (MoCA) score was positively correlated with serum IDE ($r=0.906$; $p<0.001$) but negatively correlated with fasting blood glucose (FBG) ($r=-0.314$; $p=0.026$), glycosylated hemoglobin (HbA_{1c}) ($r=-0.349$; $p=0.003$), homeostasis model assessment of insulin resistance (HOMA-IR) ($r=-0.619$; $p<0.001$) and glucose fluctuation ($r=-0.508$; $p<0.001$). Spearman rank correlation analysis demonstrated that IDE was positively correlated with MoCA score ($r=0.847$; $p<0.001$) but negatively

correlated with Trail Making Test B ($r=-0.413$; $p<0.001$), FBG ($r=-0.372$; $p<0.001$), HbA1c ($r=-0.214$; $p=0.015$), HOMA-IR ($r=-0.582$; $p<0.001$) and glucose fluctuation ($r=-0.551$; $p<0.001$) in all subjects. In logistic regression analysis for MCI, only fasting C-peptide (FCP) ($p=0.003$), HbA1c ($p=0.056$), and IDE ($p=0.010$) were independent variables.

Conclusion: This study demonstrated greater likelihood of MCI with decreasing serum IDE in patients with type 2 diabetes.

Mental disorders, suicidal ideation and diabetes mellitus: data from primary care

J. Peceliuniene¹, N. Mickuviene², V. Kasiulevicius¹, A. Norkus³, R. Bunevicius²;

¹Clinic of Internal Diseases, Family Medicine and Oncology, Vilnius University Faculty of Medicine, ²Behavioral Medicine Institute of Lithuanian University of Health Sciences, Palanga, ³Institute of Endocrinology of the Medical Academy of Lithuanian University of Health Sciences, Kaunas, Lithuania.

Background and aims: Data on mental disorders and suicidal ideation in relation to diabetes mellitus in primary care (PC) are scarce. The aim of the study was to evaluate the rate and association of depressive, anxiety disorders, and suicidal ideation in relation to diabetes mellitus (DM) in PC.

Materials and methods: A cross-sectional study was performed. 1170 adult consecutive patients approached; the final study group consisted of 998 patients. Mental status was evaluated by standard method, by using MINI International Neuropsychiatric Interview (MINI), performed by trained investigator (JP). Information on the clinical diagnoses was obtained from patients' medical records.

Results: Most commonly detected mental disorders were: major depressive episode (MDE) - 15.2%, anxiety disorders - 26.3% (generalized anxiety disorder (GAD) - 18.1%), alcohol misuse/probable alcohol abuse - 34.8%. 6.1% of the sample had suicidal ideation, according to the MINI. DM was not the main reason of the visit of the primary care patients to contact their general practitioner (1.9%). When the probability of having mood or anxiety disorders among males and females according to somatic diagnosis was calculated, GAD but not MDE had significant association with both DM and suicidality in all patients (odds ratio (OR) (95% confidence interval (CI)=3.49 (1.35-9.19) and OR (95% CI) =3.26 (1.89-5.60)), and both were found higher in men, respectively (OR (95% CI)=6.88 (1.98-23.8) and OR (95% CI)=3.7 (1.2-11.4)). Neurotic illness had significant association with DM (OR (95% CI)=2.7 (1.09-6.96)) and suicidality (OR (95% CI)=3.01 (1.76-5.12)) in all patients, and was found significantly higher in men with diabetes, and in men with suicidality (OR (95% CI)=5.54 (1.60-19.18) and OR (95% CI)=2.96 (1.60-5.47)) in PC. The differences of clinic variables between suicidal and non-suicidal patients were evaluated. Subjects with type 2 DM were at the greatest risk for suicidality (OR (95% CI)=4.3 (1.38-13.4), $p=0.012$), and the risk was greater than this of both GAD and MDE diagnoses taken together (OR (95% CI)=3.32 (1.97-5.6), $p<0.001$).

Conclusion: The rate of depressive, anxiety disorders and suicidal ideation is prevalent in PC. Psychiatric disorders are associated with DM, especially in men. Suicidal ideation is associated with male gender, mood, anxiety disorders and their coexistence, as well DM in PC. Primary care patients with type 2 DM have very high risk for suicidal ideation. General practitioners should be recommended to screen patients with diabetes for mental disorders and suicidal ideation in their routine practice.

Screening for sexual problems among type 2 diabetes patients in primary care

A. Rutte¹, A.M.J. Braamse², P.J.M. Elders¹, P. Van Oppen², G. Nijpels¹;
¹General practice and elderly care medicine, ²Psychiatry, VU University medical center, Amsterdam, Netherlands.

Background and aims: Although sexual problems are prevalent among men and women with type 2 diabetes, these problems receive little attention in diabetes care. To identify patients who are dissatisfied about their sexual functioning, routine screening was performed in primary care as part of a randomized clinical trial. The aim of this study was to determine the prevalence of sexual dissatisfaction, sexual problems and need for help among men and women with type 2 diabetes in primary care.

Materials and methods: Data was collected from January - March 2015 by practice nurses from 40 general practices in the Netherlands. The Brief Sexual Symptom Checklist for men (BSSC-M) and women (BSSC-W) was used to screen among 40-75 year old men and women with type 2 diabetes. The BSSC identifies men and women with self-reported dissatisfaction about sexual functioning, among who the self-reported type of sexual problem and need for help is further screened.

Results: In total, 251 patients with type 2 diabetes (61.4% men) were screened. Mean age did not differ between men and women: 63.2 versus 61.4 years. The prevalence of sexual dissatisfaction was 33.1%, and was significantly higher among men (39.0%) than among women (23.7%). Moreover, dissatisfied men were significantly older than satisfied men (65.1 vs. 61.9 years), yet no significant age difference was observed among women. Dissatisfied men most often reported erectile dysfunction (76.7%), low sexual desire (31.7%) and ejaculatory problems (31.7%). Among dissatisfied women, lubrication problems (52.2%), low sexual desire (39.1%), and dyspareunia (34.8%) were common. Furthermore, significantly more men (70.0%) than women (39.1%) wanted to talk about their sexual problems with their general practitioner.

Conclusion: Preliminary findings suggest that the majority of sexually dissatisfied men with type 2 diabetes would like help for their sexual problems in primary care, as well as over a third of dissatisfied women. Research should further look into the gender differences and their possible implications for care.

Living without a spouse/partner and psychosocial health: results of the second Diabetes Attitudes, Wishes and Needs (DAWN2) study

L.E. Joensen¹, I. Willaing¹, R.I.G. Holt², S. Skovlund³, J. Wens⁴, M. Peyrot⁵;

¹Health Promotion Research, Steno Diabetes Center, Gentofte, Denmark, ²University of South Hampton, UK, ³Novo Nordisk, Copenhagen, Denmark, ⁴University of Antwerp, Belgium, ⁵Loyola University Maryland, Baltimore, USA.

Background and aims: Research has shown that people living without a partner have lower quality of life compared to people living with a partner. Few studies have explored the association between living without a partner and poor psychological health in people with diabetes (PWD). The aim of the current study was to compare PWD living without a partner to those living with a partner regarding psychosocial health across countries.

Materials and methods: The present study is part of the DAWN2 study, a multinational, interdisciplinary and multi-stakeholder study conducted in 17 countries across four continents. The population comprised 8596 PWD, approximately 500 PWD from each country. Measures included *cohabitation status* (living with a partner or not), *patient characteristics*

(age, gender, complications, education and diabetes type/treatment and duration), *social support provision* (who and how many supports), *social support level* (what is the level of the support), and *psychological health* (wellbeing, diabetes distress, diabetes impact, worries of hypoglycaemia and diabetes empowerment). Analyses used multiple regression (linear and binary) to control for potential confounding with patient characteristics. The analyses examined whether associations between cohabitation status and psychological outcomes were mediated by social support. Multilevel regression models were applied to adjust for clustering within countries. Data were weighted in comparison with the general population in each country by age, gender, region and level of education.

Results: About one third of PWD lived without a partner, and there were significant country differences in the proportion of PWD living without a partner. Compared to PWD living with a partner, PWD living without a partner more often had type 1 diabetes than type 2 diabetes ($p=0.004$), more frequently were women ($p<0.0001$), had higher rates of complications ($p<0.0001$), were younger ($p=0.002$) but had longer diabetes duration ($p=0.014$). There was no significant association between cohabitation status and education. PWD living without a partner more frequently experienced lack of social support ($p<0.01$), were less empowered ($p=0.001$) and the proportion with high depressive symptom scores was larger (18% vs. 12%, $p<0.0001$) compared to PWD living with a partner. Significant differences with regards to diabetes distress and worrying about night time hypoglycaemia were found, however, these differences were small and probably clinically insignificant. There was no significant difference between PWD living with or without a partner on overall diabetes impact. Overall, the associations between cohabitation status and different psychological outcomes were not fully mediated by social support. The associations between cohabitation status and poor psychological health varied by (interacted with) age, diabetes type and country.

Conclusion: The study indicates social and psychological vulnerability of PWD living without a partner. Further research is needed into the mechanisms underlying this association. In order to enhance psychological health in PWD living without a partner appropriate support interventions have to be developed and tested.

946

Development and evaluation of a psychometric instrument to assess problems related to illness acceptance in diabetes: the Denial versus Integration of Diabetes Scale (DIDS)

A. Schmitt, A. Reimer, D. Ehrmann, B. Kulzer, T. Haak, N. Hermanns; Research Institute of the Diabetes Academy Mergentheim, Diabetes Center Mergentheim, Bad Mergentheim, Germany.

Background and aims: Insufficient diabetes acceptance has been associated with reduced self-care and glycaemic control. However, satisfactory tools to measure diabetes acceptance are lacking. Therefore, the *Denial versus Integration of Diabetes Scale (DIDS)* was developed. This report presents its development and preliminary evaluation.

Materials and methods: 56 items were generated and revised based on patient feedback and expert reviews (27 directed towards acceptance/integration, e. g. 'I accept diabetes as a part of my life', 29 towards denial/non-acceptance/avoidance, e. g. 'I often push diabetes to the back of my mind'). A four-point Likert scale (3 - 'applies to me very much' to 0 - 'does not apply to me') was used for responses. Negatively keyed items were reverse-scored; hence, higher scores indicate higher acceptance. The items were tested in a pilot study with 222 patients (age 49 ± 16 y.; 49% female; BMI 30 ± 7 ; 64% type 1 DM; duration 17 ± 11 y.; HbA_{1c} $8.5\pm 1.7\%$) to exclude unsatisfactory items and define the scale. A subsequent validation study is recruiting; at the time of this report, 66 patients (age 48 ± 13 y.; 46% female; BMI 28 ± 5 ; 62% type 1 DM; duration 14 ± 10 y.; HbA_{1c} $8.0\pm 1.0\%$) had been included, providing data on diabetes non-acceptance (AADQ), self-care (DSMQ), treatment satisfaction (DTSQ),

diabetes distress (PAID), depression (PHQ-9) and HbA_{1c} (central lab). Analyses comprised item and scale properties, exploratory factor analyses (EFA), correlations and *t*-Test.

Results: *Item selection:* Initially, 5 items were excluded for psychometric problems. Through EFA, 8 items were excluded for loadings on non-interpretable factors, finally yielding an interpretable four-factor structure. Based on this, 11 items were excluded for poor statistical or semantic fit and 4 for redundancy, leading to the final 28-item scale. *Scales/reliability:* EFA of the selected items yielded four factors (71% explained variance), interpreted as 'acceptance/integration' (7 items, Cronbach's $\alpha=0.93$), 'treatment motivation' (7 items, $\alpha=0.93$), 'denial/defence' (7 items, $\alpha=0.91$) and 'emotional suffering' (7 items, $\alpha=0.92$). The derived subscales were highly correlated, providing summing to a reliable total score ($\alpha=0.97$). Reliability was again tested on the validation sample, yielding the following α coefficients (scales in above order): 0.91, 0.91, 0.90, 0.87 and 0.96. *Validity:* A correlation of -0.76 ($P<0.01$) was found with the AADQ, a measure of diabetes non-acceptance. The correlation with HbA_{1c} was -0.45 ($P<0.01$). Patients with higher DIDS scores (suggesting higher acceptance; $n=34$) compared to those with lower ones ($n=32$; median split) reported better self-care, particularly regarding diet (6.4 ± 1.9 vs. 4.0 ± 2.0 , $P<0.01$), glycaemic self-management (8.7 ± 1.9 vs. 7.1 ± 2.3 , $P<0.01$) and physician visiting (9.2 ± 1.3 vs. 7.9 ± 3.3 , $P<0.01$), and showed better glycaemic control (HbA_{1c}: 7.6 ± 1.1 vs. $8.3\pm 1.1\%$, $P<0.05$). They also reported higher treatment satisfaction (30 ± 4 vs. 24 ± 6), less diabetes distress (21 ± 15 vs. 37 ± 16) and less depressive symptoms (6 ± 4 vs. 9 ± 6); all $P<0.01$.

Conclusion: The DIDS appears reliable and valid in assessing problems related to illness acceptance in both major types of diabetes. It may help explain inadequate self-care and suboptimal glycaemic control. Further data to expand these initial findings are being collected.

Sleep and health-related quality of life in adults with type 2 diabetes

S.T. Johnson¹, W. Qiu², C. Mundt², F. Al Sayah³, J.A. Johnson⁴; ¹Centre for Nursing & Health Studies, Athabasca University, ²Alliance for Canadian Health Outcomes in Diabetes, University of Alberta, Edmonton, ³Alliance for Canadian Health Outcomes in Diabetes, University of Alberta, Athabasca, ⁴School of Public Health, University of Alberta, Athabasca, Canada.

Background and aims: Sleep is becoming recognized as an important behavior for metabolic control and mental health. The aim of this study was to examine the relationship between objective estimates of sleep quantity and quality and health-related quality of life (HRQL) in adults with type 2-diabetes (T2DM).

Materials and methods: Adults with T2DM were recruited as a subsample of a large ongoing cohort study in Alberta, Canada. Participants completed an extensive survey of health status and health-related behaviours. HRQL was measured with the SF-12 version 2, which provides Physical and Mental Composite Summary (PCS and MCS) scores, and the EQ-5D (5-Level) index score. Participants also wore an accelerometer (Actigraph GT3X+; 60-epochs @ 30Hz) on their wrist during sleep periods over 7 consecutive days, to derive nightly estimates of total sleep time (TST), sleep latency (SLAT) and sleep efficiency (SEFF) calculated using total number of sleep minutes divided by self-reported number of minutes in bed. Multivariate linear regression models, adjusting for age, sex, diabetes duration, BMI, depressive symptoms, medical comorbidities and household income, were used to examine the association between accelerometer-derived TST, SLAT and SEFF and the PCS, MCS or EQ-5D index scores.

Results: Average age of participants (N=168) was 65 years (SD 10), BMI $31(6.5)$ kg/m², 46% female, with a diabetes duration 13(9) years.

Average TST and SLAT were 451.1 (59.1) and 9.9(7.6) minutes, respectively and SEFF was 82.7 (6.1)%. Multivariate regression models showed an inverse association between TST and PCS where every additional 60 min of sleep was associated with a 1.31 unit lower PCS ($p=0.036$); there was no relationship between TST and MCS ($p=0.86$). SEFF was positively associated with both PCS and MCS, where a 10% greater SEFF was associated with 2.73 units higher PCS ($p=0.005$) and 1.77 unit higher MCS ($p=0.056$). SLAT was not associated with either PCS or MCS, and there were no significant relationships with any sleep variable and the EQ-5D Index.

Conclusion: Among adults with T2DM, both sleep quantity and quality are important contributors to HRQL. An inverse relationship was observed between the quantity of sleep and physical health in this sample, but the magnitude of this difference was quite small. Regardless of the quantity of sleep, better sleep quality (efficiency) was associated with better physical and mental health.

Coping skills and quality of life of adolescents with type 1 diabetes

A. Lukács¹, V. Bánóczy¹, A. Nagy², K. Mayer¹, L. Barkai^{1,3};

¹Faculty of Health Care, University of Miskolc, ²Faculty of Health Sciences, Semmelweis University, Budapest, ³Velkey László Center for Child Health, Miskolc, Hungary.

Background and aims: Biological-psychological changes of puberty are a major challenge in the treatment and care of diabetic patients. In these ages, the adolescents develop various coping strategies that determine stress tolerance, quality of life (QoL) in their later life. The ultimate goal of diabetes management is to achieve good QoL perception. In our research, we compared the coping skills (resilience level) (RL), QoL and glycemic control (GC) in patients with type 1 diabetic adolescents; and we also aimed to examine the effect of regular exercise and use of insulin pump.

Materials and methods: Two hundred and twenty-nine patients with type 1 diabetes (118 males and 111 females) participated in the study. Their mean age was 15.38 ± 2.37 years. Diabetic young people were recruited from 3 Diabetes Outpatient Clinics of the country. QoL was assessed with the Pediatric Quality of Life Inventory 3.0 Diabetes Module. Coping skills were evaluated with the Resilience Scale-15 that was completed with an additional question regarding the regular exercise. GC was indicated with the HbA1c measured during the assessment. Data were analyzed with F-probe and regression analysis using the SPSS 22.0 statistical software.

Results: Regular exercise had a positive impact both on RL ($F(2,225)=8.627$, $p<.001$) and QoL ($F(2,223)=6.476$, $p=.002$), whereas the use of insulin pump positively affected QoL ($F(1,225)=14.502$, $p<.001$) and tended to affect the GC ($F(1,222)=2.948$, $p=.087$). In our regression model, RS was predicted by regular exercise ($\beta=-.207$, $t=-3.395$, $p=.001$) and QoL ($\beta=.374$, $t=6.153$, $p<.001$) ($R=.476$, $R^2=.226$). QoL was predicted by gender ($\beta=-.148$, $t=-2.482$, $p=.014$), RL ($\beta=.383$, $t=6.381$, $p<.001$) and intensive insulin therapy modality ($\beta=-.209$, $t=-3.389$, $p=.001$) ($R=.472$, $R^2=.223$). GC was significantly predicted by QoL ($\beta=-.138$, $t=-2.102$, $p=.037$) and family background ($\beta=-.187$, $t=-2.852$, $p=.005$) ($R=.239$, $R^2=.057$). Independent predictors were age, gender, diabetes duration, HbA1c, intensive insulin therapy modality (1=CSII, 2=MDI), RS, QoL, family background (1=1 parent, 2=2 parents, 3=other), and financial background (1=below average, 2=average, 3=above average)

Conclusion: In addition to the healthy physical development, regular exercise can positively affect the diabetic adolescents' coping skills and QoL. Treatment with insulin pump therapy, male gender and higher RL seemed to be determining factors of better QoL. Favorable GC showed relationship with better QoL and living in intact family. The main goals in

diabetes treatment and care are to achieve as good GC and QoL as possible. Some factors cannot be controlled as gender, family and financial background, but improving and developing coping skills, treating with insulin pump therapy and encourage patients to exercise regularly seems effective way to achieve the aims.

PS 089 Hypoglycaemia: that sinking feeling

949

Incidence of hypoglycaemia in patients with type 2 diabetes mellitus recently initiating basal insulin in a real-world US setting

M. Kazemi, F. Ye, M.R. Dalal;
Sanofi US, Inc., Bridgewater, USA.

Background and aims: Hypoglycaemia and fear of hypoglycaemia remain major barriers to persistence with insulin therapy. This retrospective cohort study of electronic medical record (EMR) data examined the incidence of hypoglycaemia soon after insulin initiation in US patients with type 2 diabetes mellitus (T2DM) and if they are at a greater risk of insulin discontinuation.

Materials and methods: The Predictive Health Intelligence diabetes dataset integrates anonymous de-identified EMR patient-level data from 20 Integrated Delivery Networks in the USA, with >325 hospitals and 300,000 providers (including some of the largest integrated delivery networks in the US). This was used to identify adult patients with T2DM who initiated basal insulin therapy (defined as having no prescription of basal insulin ≥ 12 months before initiating insulin glargine, insulin detemir, or NPH insulin) between January 2008 and March 2013. Hypoglycaemic events were identified by health care encounters with ICD-9-CM diagnosis codes for hypoglycaemia, or blood glucose values ≤ 70 mg/dL (≤ 3.89 mmol/L) during the first 6 months of basal insulin use. Discontinuation was defined as a gap of >45 days in insulin prescription coverage. A baseline was established using 12-month patient-level data prior to insulin initiation and the follow-up period was 6–24 months; all data were reported descriptively. Data were adjusted for confounders using Cox regression analysis for time to basal insulin discontinuation.

Results: Of 49,062 patients with T2DM identified, 5,159 (10.5%) experienced hypoglycaemia within the first 6 months of insulin use; 44% were identified using ICD-9-CM diagnosis codes and the remaining 56% using blood glucose values. Patients experiencing hypoglycaemia, versus those without hypoglycaemia, were older (mean age: 63 vs 60 years; $P < 0.0001$) with 49% aged ≥ 65 years; had more comorbidities (Charlson Comorbidity Index: 1.21 vs 0.67; $P < 0.0001$); had more experience of hypoglycaemia during the baseline period (18.9% vs 4.5%; $P < 0.0001$); and a greater proportion had a health care utilization during the baseline period (inpatient visits: 20.1% vs 8.7%; $P < 0.0001$). During the follow-up period, 68.1% of patients with hypoglycaemia experienced their first event in the first 3 months of treatment. In patients experiencing hypoglycaemia, versus those without hypoglycaemia, discontinuation of insulin therapy was higher at 6 months (58.7% vs 45.5%; $P < 0.0001$) and at 12 months (68.1% vs 53.9%; $P < 0.0001$). Data adjusted for confounders showed that patients with hypoglycaemia had almost twice the risk of discontinuation over 12 months compared with those without hypoglycaemia (hazard ratio 1.90; 95% CI 1.82–1.98; $P < 0.0001$).

Conclusion: This study illustrates an incidence of hypoglycaemia as high as 10% in a US setting of patients with T2DM initiating basal insulin, and that these patients are at greater risk of discontinuation of their basal insulin therapy.

Comparison of findings from the HAT study, the largest global hypoglycaemia study to date, with prior large real-world studies

U. Pedersen-Bjergaard¹, S. Alsifri², R. Aronson³, M. Cigrovski Berković⁴, G. Galstyan⁵, M. Goldfracht⁶, H. Gydesen⁷, R. Kapur⁷, N. Lalic⁸, B. Ludvik⁹, E. Moberg¹⁰, A. Ramachandran¹¹, K. Khunti¹²;
¹Endocrinology Section, Hillerød Hospital, Denmark, ²Al Hada Military Hospital, Taif, Saudi Arabia, ³LMC Diabetes and Endocrinology, Toronto, Canada, ⁴University Hospital 'Sestre Milosrdnice', Zagreb, Croatia, ⁵Endocrinology Research Centre, Moscow, Russian Federation, ⁶The Technion, Haifa, Israel, ⁷Novo Nordisk A/S, Søborg, Denmark, ⁸Clinic for Endocrinology, Diabetes and Metabolic Diseases, University of Belgrade, Serbia, ⁹Medical University of Vienna, Austria, ¹⁰Karolinska Institutet, Stockholm, Sweden, ¹¹India Diabetes Research Foundation, Chennai, India, ¹²University of Leicester, UK.

Background and aims: HAT (Hypoglycaemia Assessment Tool) was a non-interventional, 6-month retrospective and 1-month prospective real-world study to determine the extent of hypoglycaemia in 27, 585 people from 24 countries. The study outcomes were compared with similarly designed large real-world studies.

Materials and methods: A systematic literature search of PubMed (1995–2014) for population-based studies of people treated with insulin, excluding clinical trials and reviews, identified comparable reports of proportions of people experiencing hypoglycaemia or rates of events experienced. The study results that met the inclusion criteria were compared with prospective HAT data (see Table).

Results: Overall, severe and nocturnal hypoglycaemia rates varied widely between the studies identified and the HAT study (see Table). Estimated annual hypoglycaemia rates for Northern Europe and Canada in the HAT study (91.6 [T1DM]; 18.1 [T2DM]) were similar to or slightly higher than comparable studies identified in the search. However, in the HAT study, rates for overall hypoglycaemia in T2DM were higher for Latin America, Eastern Europe and Russia than for Northern Europe/Canada and lower for the Middle East and South East Asia. Rates for overall hypoglycaemia in T1DM in the HAT study were highest in Latin America and much lower in South East Asia. Similarly, severe and nocturnal hypoglycaemia rates for Northern Europe/Canada in the HAT study were comparable with other studies but differed from other regions in the HAT study. Comparable data from prior studies in non-US/European regions are sparse.

Conclusion: Findings from the HAT study revealed that more evidence from large, international, non-US/Europe-based real-world studies is needed, and highlighted that the rates of hypoglycaemia in some regions of the world may be higher than previously suggested by Europe and US-based studies. Reasons for these variations and optimisation of diabetes care in these regions are needed.

Seasonal variations of severe hypoglycaemia in patients with type 1 diabetes and type 2 diabetes in a German population

T. Wohland¹, O.-M. Patzer², T. Tiemann³, J. Holstein⁴, P. Kovacs¹, A. Holstein²;

¹IFB AdiposityDiseases Leipzig, University of Leipzig, ²1st Department of Medicine, Lippe-Deimold Hospital, ³Outpatient Diabetes Center, Rinteln, ⁴Medical Department, Division of Nephrology and Internal Intensive Care Medicine, Charité University Medicine Berlin, Germany.

Background and aims: Severe hypoglycemia (SH) is associated with a critical prognosis. In addition to its acute life-threatening potential, SH may increase cardiovascular and all-cause mortality irrespective of diabetes type. Our aim was to highlight seasonal changes in SH and the corresponding clinical circumstances in patients with type 1 diabetes (T1DM) and type 2 diabetes (T2DM) in a German population under the conditions of real life.

Materials and methods: Prospective population-based observational trial. All SH occurred between 2007 and 2014 in a large tertiary care hospital in a rural area (200.000 inhabitants) were captured. SH was defined as a symptomatic event requiring treatment with intravenous glucose or administration of glucagon and being confirmed by a blood glucose measurement of <50 mg/dl. Seasons were scaled according to meteorological conditions. Statistical significant differences between diabetes groups were calculated using the Student's t-test and chi-square test. Furthermore one-way anova with post-hoc LSD-test was used to investigate significant differences between the seasons within a diabetes group.

Results: A total of 1080 episodes of SH in 747 patients were registered: 37.5% of cases were related to T1DM, 51.7% to T2DM, 3.2% to pancreoprivic diabetes and 7.6% occurred in non-diabetic individuals. The 405 cases of SH in T1DM comprised 206 subjects. The 558 cases of SH in T2DM occurred in 453 subjects. In T1DM 50.1% and in T2DM 16.1% of hypoglycemic episodes were related to only 31 respectively to 23 patients who experienced ≥ 3 SH. Most tested basic parameters (e.g. age, HbA1c, Charlson comorbidity index, creatinine-clearance, impaired awareness of hypoglycaemia) between patients with T1DM and T2DM

were statistically significant (all $p < 0.001$). In cases with T1DM we observed significantly increased prevalence of SH in spring (27.7%) and summer (28.6%) vs. autumn (21.5%; $p = 0.04$ and $p = 0.02$ respectively) and winter (22.2%; $p = 0.04$ vs. summer). In contrast, there was a more balanced and not significant seasonal distribution of SH in subjects with T2DM (winter 25.3%, spring 26.0%, summer 25.1%, autumn 23.5%). Surprisingly, we found no significant variation in seasonal HbA1c and insulin dose in subjects with T1DM. However, at the scene of emergency there were significant lower initial blood glucose levels in spring (29.2 ± 11.1 mg/dl) vs. autumn (32.7 ± 10.1 mg/dl) and a significant lower frequency of blood glucose self-measurement per week in spring (30.1 ± 11.4) vs. summer (33.0 ± 12.9). In cases with T2DM we revealed a significantly higher HbA1c in spring (7.0 ± 1.6) compared to autumn (6.6 ± 1.0).

Conclusion: Individuals with T1DM and SH clearly distinguish from those with T2DM and SH. We found an increased frequency of SH in patients with T1DM in spring and summer which was probably due to short-term impacts like more physical activity or possibly higher alcohol consumption during these warmer seasons. Better seasonal adaptation of insulin therapy in subjects with T1DM could be an appropriate approach to prevent SH. For the cohort of mostly multimorbid geriatric patients with T2DM there was no seasonal effect for the risk of SH.

Incidence, predictive factors and direct costs of severe hypoglycaemia: results from the prospective HYPO.15 study

N.S. Chevalier¹, P. Böhme², A.-S. Durand-Lugger³, A. Bassand², J. Vouillarmet⁴, N. Marchant⁴, C. Maisondieu⁵, S. Fontaine⁶, B. Nicolascu-Catargi⁷, F.-L. Velayoudom-Céphise⁸, V. Chingan-Martino⁸, I. De Lameth⁹, R. Desailoud⁹, P. Hanon¹⁰, GEODE Group;

¹Endocrinologie-Diabétologie, CHU de Nice, ²CHU de Nancy, ³CH d'Epinal, ⁴Hospices Civils de Lyon, ⁵SAMU 75 - Hôpital Lariboisière, Paris, ⁶Hôpital Joseph Ducuing, Toulouse, ⁷CHU de Bordeaux, ⁸CHU de Pointe-à-Pitre, ⁹CHU d'Amiens, ¹⁰Lifescan, Issy-les-Moulineaux, France.

Background and aims: Severe hypoglycaemia (SH) is the most serious side effect of insulin therapy and has been associated with an increased risk of mortality. However, few data are available concerning its incidence and/or its direct cost. The observational, prospective, multicenter, French HYPO.15 study assessed the incidence of SH in patients with type 1 or type 2 diabetes.

Materials and methods: Emergency care units of 9 French University Hospital consecutively enrolled all patients with SH (diagnosed according to ADA criteria) during at least 3 months. The primary endpoint was frequency of confirmed SH. Secondary endpoints included predictive factors of SH and estimation of direct costs, including costs of emergency care and hospitalizations' costs.

Results: We included a total of 811 patients. Incidence of SH was estimated to 0,63 SH/100 patients/year (20 433 SH/year in France). Characteristics of the 811 patients were: median age $61,3 \pm 21,1$ years (59,3 years in men vs. 64,0 years in women; $p = 0,002$); duration of diabetes <5 years for 10,3% and duration of diabetes >10 years for 75,9%; previous history of SH during the past year in 62%. SH happened at home for 86,4% of the patients, during the morning (7 h–13 h) for 31,8% of them (23,8% in the afternoon; 22,7% in the evening and 21,7% during the night). 92,4% of the patients used insulin therapy, alone in 82,3% and together with oral anti-diabetics (OAD) in 10,1%. Patients with insulin therapy alone were younger (58,1 yrs vs 72,7 yrs for OAD + insulin and 76,1 yrs for OAD alone; $p < 0,0001$). Sulfonylureas were used by 51% of patients with OAD alone, but only in 20% of patients with OAD + insulin ($p = 0,0005$), whereas use of repaglinide was similar in both groups (38%). Median glycemia was 37 ± 17 mg/dL. Fasting (43%), infection (26%) and treatment misuse (17%) were the most frequent etiologies of SH in our cohort.

55,5% of patients stayed at home after intervention of emergency care unit, 25,6% were brought to the hospital for a short monitoring and 15,6% were hospitalized for more than one night. Rate of hospitalization depends of treatment and was increased for patients with OAD alone (44, 8% vs 16,9% for OAD + insulin and 10,4% for insulin alone; $p < 0,05$). Direct cost of SH was estimated to 47 834 978 € for 20 433 SH per year in France, which represents a mean cost by SH of 2 341 €.

Conclusion: HYPO.15 is the first prospective study giving the high incidence and the direct costs of confirmed SH in patients with type 1 and type 2 diabetes in France, underlying the importance of optimizing patients' treatment regimens and education. Previous history of SH and male gender appears to be the main predictive factors for SH.

Regional variation in patient definitions and rates of hypoglycaemia: findings from the HAT study of 27,585 people with type 1 and type 2 diabetes on insulin

K. Khunti¹, M. Cigrovski Berković², P. Geelhoed-Duijvestijn³, B. Ludvik⁴, E. Moberg⁵, J. Barner Lekdorf⁶, H. Gydesen⁶, U. Pedersen-Bjerggaard⁷,

¹Diabetes Research Unit, University of Leicester, UK, ²University Hospital 'Sestre Milosrdnice', Zagreb, Croatia, ³Medical Centre Haaglanden, The Hague, Netherlands, ⁴Medical University of Vienna, Austria, ⁵Karolinska Institutet, Stockholm, Sweden, ⁶Novo Nordisk A/S, Søborg, Denmark, ⁷Nordsjællands Hospital Hillerød, Denmark.

Background and aims: Hypoglycaemia is an important concern for people with diabetes, but how individuals understand and define hypoglycaemia remains unclear. The Hypoglycaemia Assessment Tool (HAT) study was a non-interventional assessment of self-reported hypoglycaemia. This *post-hoc* analysis aimed to determine patient knowledge of hypoglycaemia and associated reporting.

Materials and methods: HAT was conducted in 24 countries using questionnaires and diaries (28-day prospective period) in 27, 585 adults with type 1 (T1DM) or type 2 diabetes (T2DM) using insulin for ≥ 12 months. The patient diary defined confirmed hypoglycaemia as a blood glucose (BG) level < 3.9 mmol/L. Patients recorded in the diary if hypoglycaemia was based on BG levels, symptoms of hypoglycaemia or both.

Results: Most respondents (96.8% and 85.6% of patients with T1DM and T2DM, respectively) knew the ADA/EASD hypoglycaemia definition (see Table). However, in some regions, many patients actually identified hypoglycaemic events from symptoms alone. Reported hypoglycaemia rates varied substantially between regions, with SE Asia having a relatively high rate of unconfirmed symptomatic hypoglycaemia. Rates of severe hypoglycaemia also varied widely between regions, both for T1DM and T2DM, with lower rates in N Europe and Canada.

Conclusion: Regional variations in patient definition of hypoglycaemia may contribute to the global variations in rates of hypoglycaemia reported in the HAT study. Discrepancies between patient definitions in different countries and guidelines may highlight a need to redefine the criteria of hypoglycaemia.

Self-reported hypoglycaemia and mortality in type 2 diabetes patients treated with insulin in the diabetes care system West-Friesland, Netherlands

S.P. Rauh, F. Rutters, G. Nijpels, A.A. van der Heijden, I. Walraven, P.J. Elders, M.W. Heymans, J.M. Dekker;

VU University Medical Center, Amsterdam, Netherlands.

Background and aims: Tight glucose control trials and observational studies based on medical records have suggested that objectively measured hypoglycaemic events are associated with cardiovascular events and mortality in patients with type 2 diabetes (T2D). However, little is known about self-reported hypoglycaemia, as experienced in everyday life, and the associated risk on mortality in the general T2D population in usual care. Further, no observational studies have focused on the association between hypoglycaemia and mortality in insulin users. Our aim was to study the association between self-reported mild and severe hypoglycaemia and mortality in T2D patients in usual care treated with insulin.

Materials and methods: Demographics, clinical characteristics and mortality data were obtained from 1,667 T2D patients treated with insulin in the Diabetes Care System West-Friesland, the Netherlands. Hypoglycaemia was self-reported, including complaints like dizziness, dreaming, feeling restless, headache when getting out of bed, hunger, mood swings, palpitations, snoring, night sweats, tingling sensations around the mouth, and trembling. Mild hypoglycaemia was defined as events not requiring help from others, while severe hypoglycaemia was defined as events requiring help from other persons (either medical or non-medical). Logistic regression analysis was used to analyse the association between hypoglycaemia and mortality during follow-up. In addition, generalized linear models with an offset variable were used to allow for differences in follow-up duration.

Results: During a median follow-up of 1.9 years, 804 participants (48%) reported no hypoglycaemia, 744 (45%) reported only mild and 119 (7%) reported severe hypoglycaemia. During follow-up, 98 patients (5.9%) died. Reporting only mild hypoglycaemia was significantly associated

with lower mortality risk during follow-up (OR: 0.48, 95%CI 0.29-0.81), while reporting severe hypoglycaemia was not significantly associated with mortality (OR: 0.77, 95%CI: 0.33-1.80), compared to reporting no hypoglycaemia. These results were adjusted for age, sex, diabetes duration, HbA1c levels, hypertension, smoking, sulfonylurea use, and micro-/macro-vascular complications. Sensitivity analyses showed an OR of 1.38 (95%CI 0.31-6.11) for patients reporting severe hypoglycaemia requiring medical assistance, and 0.57 (0.23-1.46) for patients reporting severe hypoglycaemia, but not requiring medical assistance. Further, no significant interaction was found between mild and severe hypoglycaemia during follow-up. Finally, allowing for differences in follow-up duration did not lead to different results.

Conclusion: We observed that insulin-treated type 2 diabetes patients reporting mild hypoglycaemia had a lower mortality risk during a median follow-up of 2 years compared to patients reporting no hypoglycaemia. A possible explanation for this finding might be the concept of hypo-unawareness. If this finding is confirmed in other studies, it may be reassuring for T2D patients and their physicians to know that experiencing hypoglycaemic sensations not requiring medical help is associated with reduced short-term mortality risk.

Increase in hospital admissions, length of hospital stay and outpatient visits in diabetes patients one month and one year following severe hypoglycaemic events

A. Karasik¹, D. Goldstein², V. Shalev², B.L. Thorsted³, L. Elliott⁴, G. Chodick²;

¹Institute of Endocrinology, Sheba Medical Center, Tel-Hashomer, ²Maccabitech, Maccabi Healthcare Services, Tel Aviv, Israel, ³Epidemiology, Novo Nordisk A/S, ⁴Market Access, Novo Nordisk A/S, Søborg, Denmark.

Background and aims: Severe hypoglycaemia is a burden for the patient and payer alike. In this study, we aimed to quantify the resource use associated with a severe hypoglycaemic event (SHE) in patients with diabetes using the database of Maccabi Healthcare Services (MHS), a large Health Management Organization in Israel.

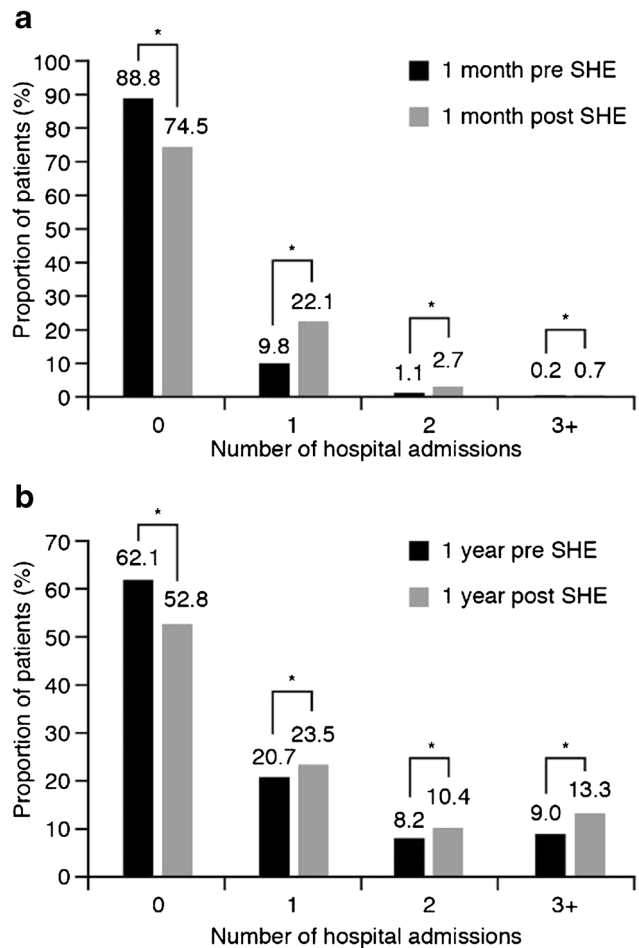

Materials and methods: This retrospective, non-interventional study compared resource use 1 month and 1 year pre and post SHE. Data collected by the MHS database included overall as well as detailed health utilisation data per patient. Patients were included if they had a diagnosis of diabetes and experienced a SHE, as identified by diagnosis codes in the MHS database, from 2005-2014.

Results: From 2005-2014, a total of 4376 patients were eligible for inclusion in the study, out of approximately 100,000 patients with diabetes in the MHS registry. The study population consisted of 6.4% T1D, 75.2% T2D and 18.4% with diabetes type undefined. Mean characteristics of the study population were age 64.5 years, HbA1c 7.4%, BMI 29.5 kg/m², 47.9% male, 42.9% insulin-treated and 60.5% were treated with oral drugs that may cause hypoglycaemia (sulphonylureas or meglitinides). Diabetes duration (years) was <5 in 20.4%, 5-9 in 45.2% and 10+ in 34.4% of cases. At baseline (time of SHE), 42% of patients had a cardiac comorbidity and 73% had hypertension. Hospital admissions increased significantly ($P<0.001$) in the month following a SHE (Figure). Of those admitted to hospital ($n=1418$), the mean duration of stay was significantly ($P<0.001$) longer during the month post (5.59 days) vs pre SHE (4.37 days). In this period, outpatient visits increased by 46% (12557 vs 18441, $P<0.001$). The greatest increases were in visits to endocrinologists (+169%), nurses (+70%) and dieticians (+66%). The number of hospital admissions also increased in the 1 year post vs the 1 year pre SHE (Figure), corresponding to a 38% increase in hospitalisations ($P<0.001$), and there was a 13% increase in outpatient visits ($P<0.001$) during this period. The mean duration of hospital stay increased from 4.81 to

6.82 days during the 1 year pre vs post SHE ($P<0.001$), however it is recognised that other factors could influence the data over the 1 year time period.

Conclusion: This real-world data analysis indicates an increased use of healthcare services, including more frequent and prolonged hospital admissions and outpatient visits after a SHE.

Proportion of patients who had hospital admissions pre and post SHE at a) 1 month and b) 1 year.

* $P<0.001$ for pre SHE vs post SHE time period.

SHE, severe hypoglycaemic event.

Incidence of severe hypoglycaemia in 2006 and 2011 in consideration of the medication in Germany: analysis based on health insurance data

N. Müller¹, C. Kloos¹, B. Gerste², M. Hartmann³, U.A. Müller¹;

¹Endocrinology and Metabolic Diseases, Internal Medicine III, Jena University Hospital, ²Wissenschaftliches Institut der AOK (WiDO), Berlin, ³Department of Pharmacy, Jena University Hospital, Germany.

Background and aims: New antihyperglycaemic agents are advertised to offer effective glycaemic control while reducing the risk of hypoglycaemia. The aim of this study was to analyze the development of the incidence of severe hypoglycaemia from 2006 to 2011 in

consideration of the medication, based on AOK (largest health insurance in Germany) routine data.

Materials and methods: All adult insured persons with diabetes mellitus type 2 (extrapolated to the German population: 6.6 million in 2006 and 7.9 million in 2011) were screened for severe hypoglycaemia (identified by ICD 10 coding) which requires hospitalization or emergency use. Antihyperglycaemic agents were identified by ATC-Code and Defined Daily Dose (DDD) of the respective medication was calculated.

Results: There was a slight increase in the incidence of severe hypoglycaemia in 2006 (0.04%, $n=28.892$) to 2011 (0.05%, $n=33.741$). Persons with severe hypoglycaemia were older (69.7y vs. 73.8y in 2006 and 70.1y vs. 74.4y in 2011) and 46.5% in 2006 and 56.2% in 2011 had nephropathy. In 2006 8.3% ($n=2.412$ of 28.892) of all persons with severe hypoglycaemia had sulfonylureas as monotherapy and 8.9% ($n=565.862$ of 6.3 Mio.) of the persons without severe hypoglycaemia (DDD 214 with vs. 248 without severe hypoglycaemia). In 2011 the prescription of sulfonylureas as monotherapy was significantly lower, 4.4% ($n=1.471$ of 33.741) of persons with as well as without severe hypoglycaemia ($n=330.175$ of 7.5 Mio.) (DDD 252 with vs. 309 without severe hypoglycaemia). A combination therapy of biguanides and sulfonylureas had 17% ($n=4.926$ of 28.892) of the persons with and 12.7% ($n=804.757$ of 6.3 Mio.) of the persons without severe hypoglycaemia in 2006 (DDD of this combination therapy was 480 with vs. 577 without severe hypoglycaemia). In 2011 this combination therapy applied 14.2% ($n=4791$ of 33.741) of the persons with severe hypoglycaemia and 10% ($n=749.878$ of 7.5 Mio.) of the persons without severe hypoglycaemia (DDD 518 vs. 664). A combination therapy of short and long acting human insulin used 17.1% ($n=4.941$ of 28.892) of the persons with and 4% ($n=254.588$ of 6.3 Mio.) of the persons without severe hypoglycaemia in 2006 (DDD 481 vs. 563) and 14.4% ($n=4.851$ of 33.741) of the persons with and 3.4% ($n=257.357$ of 7.5 Mio.) of the persons without severe hypoglycaemia in 2011 (DDD 491 vs. 592). A combination therapy of short and long acting analogue insulin was present in 6.1% ($n=1.761$ of 28.892) of the persons with and 1.3% ($n=81.898$ of 6.3 Mio.) of the persons without severe hypoglycaemia in 2006 (DDD 558 vs. 589) and 12.4% ($n=4.200$ of 33.741) of the persons with and 2% ($n=153.014$ of 7.5 Mio.) of the persons without hypoglycaemia in 2011 (DDD 570 vs. 628).

Conclusion: Comparing 2006 to 2011 showed a significant reduced prescription of sulfonylureas as monotherapy, a slightly reduced use of human insulin and a significantly increased prescription of analogue insulin. Despite the changes in drug prescription there was a slight increase in overall incidence of severe hypoglycaemia from 2006 to 2011.

PS 090 Hypoglycaemia: recognition and avoidance

Continuous Subcutaneous Insulin Infusion (CSII) and fear of hypoglycaemia in patients with type 1 diabetes: five years of study

M. Carreira¹, M.S. Ruiz de Adana², A. Orozco³, F. Linares², M. Fontalba², M. Guerrero², M.T. Anarte¹;

¹Department of Personality, Assessment and Psychological Treatment, University of Malaga. Instituto de Investigación Biomédica de Málaga (IBIMA), ²Unidad de Diabetes. Servicio de Endocrinología y Nutrición. Hospital Regional Universitario, Málaga. Biomedical Research Centre in Diabetes and Associated Metabolic Disorders (CIBERDEM). Instituto de Investigación Biomédica de Málaga (IBIMA), ³Department of Personality, Assessment and Psychological Treatment, University of Malaga, Spain.

Background and aims: Fear of hypoglycemia is one of the factors associated with poor adherence to diabetologic treatment. 1) To assess the effect of CSII in fear of hypoglycemia in patients with type 1 diabetes (DM1) after 5 years of treatment. 2) Analyze the relationship of fear of hypoglycemia with other variables.

Materials and methods: The sample consisted of 72 patients with DM1 and CSII. Patients were evaluated clinically, metabolic and psychologically at baseline, 6 months and annually. Fear of hypoglycemia was assessed with the Fear of Hypoglycemia Scale (FH-15). In addition, quality of life (DQOL), depressive symptoms (BDI-II) and anxiety (STAI) were assessed. The analyses were performed using Student's t test and the relationship between variables was analyzed with the Pearson correlation coefficient. SPSS version 15.0 was used.

Results: At baseline, 66.7% of the sample showed fear of hypoglycemia. In fact, a significant decrease in prevalence from baseline score at 6 months ($p < 0.001$) and a year of treatment ($p < 0.001$) occurs. Over 5 years of treatment, there is a statistically significant decrease in scores of fear of hypoglycemia in all assessments made with respect to the initial score, except for two years. A significant negative relationship between fear of hypoglycaemia and number of self-controls ($p=0.008$) at 5 years was found. On the other hand, between fear of hypoglycaemia and quality of life was found a positive and significant correlation at baseline ($p < 0.001$) at 6 months ($p < 0.001$), 1 year ($p < 0.001$), 2 years ($p=0.025$), 3 years ($p < 0.001$), 4 years ($p < 0.001$) and 5 years ($p < 0.001$). There is also a significant positive correlation between fear of hypoglycaemia and depressive symptoms at baseline ($p=0.019$), at 3 years ($p=0.005$) and 4 years ($p < 0.001$).

Conclusion: Preliminary results of this study show some evidence of improvement experienced by patients with DM1 treated with CSII for 5 years in the fear of hypoglycemia. Also found relationships between this variable, greater depressive symptoms, poorer quality of life and fewer self-monitoring. The results of this study have demonstrated the importance of this variable and suggest that it is necessary to assess the fear of hypoglycemia in these patients by specific protocols.

Insulin degludec/insulin aspart lowers fasting plasma glucose and rates of confirmed and nocturnal confirmed hypoglycaemia independent of disease duration

M. Haluzik¹, J.S. Christiansen², G. Fulcher³, T.R. Pieber⁴, H. Rodbard⁵; ¹Charles University, Prague, Czech Republic, ²Aarhus University Hospital, Denmark, ³Royal North Shore Hospital, Sydney, Australia, ⁴Medical University of Graz, Austria, ⁵Endocrinology and Metabolic Consultants, Rockville, USA.

Background and aims: Longer diabetes duration is linked with the need for intensification of insulin therapy. The novel co-formulation of 70% insulin degludec (IDeg) and 30% insulin aspart (IAsp) has been shown to provide effective glycaemic control with reduced rates of hypoglycaemia in individuals with type 2 diabetes (T2D). This *post-hoc* pooled analysis evaluated the efficacy of IDegAsp vs biphasic insulin aspart 30 (BIAsp 30) and IDeg OD + IAsp in improving glycaemic control and reducing risk of hypoglycaemia in subjects with T2D stratified according to disease duration (≤ 10 or > 10 years).

Materials and methods: Data were pooled from five 26-week treat-to-target and phase 3a/b clinical trials in subjects with T2D in the IDegAsp clinical development programme. Baseline HbA_{1c} was similar between all five studies. Comparators from individual trials were pooled and included BIAsp 30 twice-daily (BID) or IDeg OD + IAsp (2–4 injections). End of trial (EOT) HbA_{1c}, fasting plasma glucose (FPG) and rates of confirmed and nocturnal confirmed hypoglycaemia and insulin dose were stratified according to disease duration (≤ 10 years or > 10 years). For each separate group, continuous variables were analysed using ANOVA and event rates were analysed using negative binomial regression.

Results: There was no difference in EOT HbA_{1c} between IDegAsp and comparator in subjects with disease duration of ≤ 10 years (IDegAsp, n=430; comparator [BIAsp 30 and IDeg OD + IAsp], n=298) or > 10 years (IDegAsp, n=681; comparator [BIAsp 30 and IDeg OD + IAsp], n=399) (Table 1). Significant reductions in EOT FPG were observed with IDegAsp vs comparator (BIAsp 30 and IDeg OD + IAsp) in subjects with a disease duration of ≤ 10 years (6.1 vs 6.9 mmol/L, respectively, > 10 years (5.8 vs 6.9 mmol/L, respectively, $p < 0.0001$). IDegAsp vs comparator (BIAsp 30 and IDeg OD + IAsp) was associated with greater reductions in rates of confirmed hypoglycaemia ($p < 0.05$) and nocturnal confirmed hypoglycaemia ($p < 0.0001$) in subjects with T2D, independent of disease duration. EOT total daily insulin dose was significantly lower for IDegAsp BID vs BIAsp30 BID (60.4 vs 73.8 U, $p < 0.0001$) and IDegAsp BID vs IDeg OD + IAsp (93.8 vs 123.3 U, $p < 0.0001$) in subjects with T2D duration ≤ 10 years.

Conclusion: No differences were observed in HbA_{1c} when stratified according to disease duration. IDegAsp was associated with significant reductions in FPG and rates of confirmed- and nocturnal confirmed hypoglycaemia. IDegAsp improves glycaemic control at a significantly lower total daily insulin dose irrespective of disease duration. The lower total daily insulin dose in subjects with T2D duration > 10 years treated with IDegAsp vs comparators warrants further investigation.

Table 1. Trial endpoints stratified by duration of type 2 diabetes

Endpoint	IDegAsp	Comparator (BIAsp 30 BID and IDeg OD + IAsp)	Treatment contrast p value
HbA_{1c} (%)*			
≤ 10 years	6.9	6.9	-0.07, p=ns
> 10 years	7.0	6.9	0.10, p=ns
FPG (mmol/L)*			
≤ 10 years	6.1	6.9	-0.82, $p < 0.0001$
> 10 years	5.8	6.9	-1.04, $p < 0.0001$
Confirmed hypoglycaemia* (Events/100 PYE)			Rate ratio
≤ 10 years	624	1024	0.61, $p = 0.0002$
> 10 years	908	1201	0.76, $p = 0.0013$
Nocturnal confirmed hypoglycaemia* (Events/100 PYE)			Rate ratio
≤ 10 years	61	194	0.31, $p < 0.0001$
> 10 years	97	204	0.48, $p < 0.0001$

Sustained glycaemic control and less hypoglycaemia over 1y with new insulin glargine 300 U/ml vs glargine 100 U/ml in Japanese type 2 diabetes mellitus people on basal insulin + OAD(s) (EDITION JP 2)
 Y. Terauchi¹, M. Koyama², X. Cheng³, M. Sumi², T. Hirose⁴, on behalf of the EDITION JP 2 Study Group;

¹Yokohama City University School of Medicine, ²Sanofi, Tokyo, Japan, ³Sanofi, Beijing, China, ⁴Toho University School of Medicine, Japan.

Background and aims: In EDITION JP 2, Japanese people with T2DM managed with basal insulin plus OAD(s) receiving new insulin glargine 300 U/ml (Gla-300) achieved comparable glycaemic control with less hypoglycaemia over 6 months when compared with glargine 100 U/ml (Gla-100).

Materials and methods: Participants continued Gla-300 or Gla-100 for an additional 6 months.

Results: 222 participants completed the 12-month study (107 [88.4%] with Gla-300 and 115 [95.8%] with Gla-100). From baseline to month 12, HbA_{1c} and FPG decreased with both Gla-300 (mean [SD] change -0.28 [0.84] % and -0.7 [3.1] mmol/l) and Gla-100 (mean [SD] change -0.33 [0.79] % and -1.0 [2.4] mmol/l). At month 12, the mean daily Gla-300 dose was 25 U/day (0.36 U/kg/day) and mean daily Gla-100 dose was 21 U/day (0.30 U/kg/day), with no change in dose observed between months 6 and 12. Over 12 months, the percentage of participants experiencing ≥ 1 nocturnal confirmed (≤ 3.9 mmol/l [≤ 70 mg/dl]) or severe hypoglycaemic event was lower with Gla-300 compared with Gla-100 (38.3% vs 52.5%; relative risk 0.73; 95% CI: 0.55 to 0.97). Consistently fewer nocturnal confirmed (≤ 3.9 mmol/l [≤ 70 mg/dl]) or severe hypoglycaemic events per participant-year were seen with Gla-300 compared with Gla-100 (2.09 vs 5.30; rate ratio 0.41; 95% CI: 0.18 to 0.92). Severe hypoglycaemia was rare, with only 3 and 2 events reported with Gla-300 and Gla-100, respectively. Mean (SE) weight change over the 12-month period was -0.7 (0.2) kg with Gla-300 and 0.5 (0.2) kg with Gla-100. No between-treatment differences in the number of adverse events were seen.

Conclusion: Japanese people with T2DM managed with basal insulin plus OAD(s) showed sustained glycaemic control with less nocturnal confirmed (≤ 3.9 mmol/l [≤ 70 mg/dl]) or severe hypoglycaemia over 12 months with Gla-300 compared with Gla-100. Gla-300 was well tolerated over the 12-month study period.

960

The efficacy of degludec in improving hypoglycaemia in type 1 diabetic patients

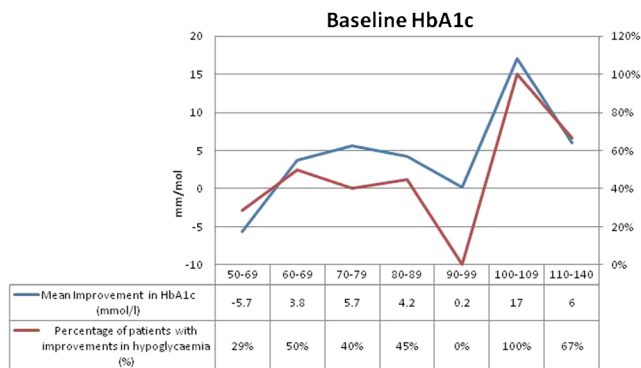

Y.W. Yap, A. Robinson, A. Basu, H. Bharaj, R. Prajapati;
Department of Endocrinology and Diabetes, Royal Bolton Hospital, Manchester, UK.

Background and aims: Insulin Degludec (Tresiba) is a recently launched ultra-long acting insulin with a steady and stable pharmacokinetic profile with minimal intra and inter-day variability, with a glucose lowering effect. Over 1,578 patients have been treated in phase 3 trials but there are few data available relating to the real world benefits in clinical practice.

Materials and methods: Data from patients attending our diabetes centre between 07/02/2013 and 09/10/2013 who were switched from their usual basal insulin to insulin Degludec were included in this study. Laboratory results, together with clinical notes from general practice and outpatient clinic correspondence were reviewed.

Results: 57 patients were analysed with 40% of males & 60% of females. Basal insulin that had been used pre-Degludec includes Glargine in 77.1% & Detemir in 15.8%. Hypurin, Insulatard, Insulin Pump & Glimepiride, each represented 1.8%. In the graph as illustrated, a trend of improvement in hypoglycaemia had been observed in the mean HbA1c values between the 60-90 mmol/l. A more significant improvement in both the mean HbA1c values and percentage of patients with improvements in their hypoglycaemic controls were observed in the group of patients with initial mean HbA1c of 100-140 mmol/l. In the initial pre-degludec group of 100-120 mmol/l, improvements of 100% of hypoglycaemic events and reduction of an average of 17 mmol/l, suggested that perhaps Tresiba is ideal in improving the glycaemic control and also in reducing hypoglycaemic events in this group of patients. Degludec that had been initiated for the group of both mixed hyperglycaemia and hypoglycaemia were noted in 3 patients. The mean initial HbA1c for this group was at 89 mmol/l. This increased to 96 mmol/l with no further reported improvements in hypoglycaemia in this group. The number of patients in this group was small and in addition, other factors need to be considered for this rise in HbA1c in this particular group of patients.

Conclusion: Our results confirms the benefits of Degludec over previously available basal insulin being translated into clinical practice, whereby modest improvements in glycaemic control are associated with significant reduction in hypoglycaemia rates. Thus, Degludec is a useful new addition to the basal insulin range & is most useful in Type 1 diabetes with hypoglycaemia as a frequent problem.

961

Glycaemic control and hypoglycaemia burden in patients with type 2 diabetes initiating basal insulin in Europe

D. Mauricio¹, L. Liao², H. Wang², A. Cali³, P. Stella³, P. Carita³, K. Khunti⁴;
¹Hospital Universitari Germans Trias i Pujol, Barcelona, Spain, ²Sanofi, Bridgewater, USA, ³Sanofi, Paris, France, ⁴University of Leicester, UK.

Background and aims: Many patients with T2DM fail to achieve the ADA/EASD recommended target of HbA_{1c} ≤7%, despite numerous treatment options. Hypoglycaemia (HG) is the main barrier to effective glucose control for people on insulin, impacting long-term treatment adherence/persistence. This study evaluated short- and long-term glycaemic target attainment and HG incidence, specifically in patients with T2DM initiating insulin using a basal insulin (BI)-only regimen.

Materials and methods: This was an observational, retrospective longitudinal analysis of electronic medical records (EMRs) from five European countries (Germany, Italy, France, Spain and UK) extracted from the Cegedim Strategic Data Longitudinal Patient Database. Insulin-naïve patients aged ≥30 years with T2DM initiating BI with or without OADs between Jan 2007 and Sep 2014 were included. Patients had ≥1 HbA_{1c} measurement pre- and post BI initiation and data available for ≥1 year pre- and ≥2 years post BI initiation. Occurrence of HG was defined either as a recorded diagnosis of HG or a fasting plasma glucose of ≤3.9 mmol/l (70 mg/dl) during an office visit. A multivariate logistic regression model assessed baseline characteristics, 3-month glycaemic control (for patients with an HbA_{1c} value 2-4 months post BI initiation) and HG for long-term (3-24 months post BI initiation) glycaemic control and HG.

Results: A total of 12,141 patients were included (mean age across countries: 65-69 years). Most patients did not achieve HbA_{1c} target ≤7%, at both 3 months (range not at target: 70.2-91.9%) and 24 months (range not at target: 66.4-82.7%) post BI initiation. Those with suboptimal control at 3 months were less likely to reach target at 24 months (p≤0.001). A similar proportion of patients experienced HG over 24 months in Germany, Spain and France (~8-9%); HG was higher in Italy (~16%) and lower in the UK (~4%). HG during the initial 3-month period was predictive (p≤0.02) of longer-term risk (between 3-24 months) (Table).

Conclusion: Across five European countries, a consistent pattern of short- and long-term suboptimal glycaemic control emerged: the majority of patients initiating BI failed to reach HbA_{1c} target ≤7% in the first 3 months, or after 2 years' follow up. Pre- and post-index glycaemic control varied between countries. Approximately 9% of patients in all countries experienced HG in the first 2 years of initiating BI, with the exception of a higher rate in Italy and a lower rate in the UK. Treatment response and HG incidence by 3 months post BI initiation are predictive of longer-term glycaemic control and HG risk, respectively. The true burden of HG is likely underestimated because only EMR-captured episodes or HG during an office visit were analysed. These results support the need for interventions that both improve glycaemic control and reduce the risk of HG.

Table: Country-specific results of patients achieving target glycaemic control (HbA_{1c} ≤7%) and percentage experiencing hypoglycaemia (HG) at 3 and 24 months post basal insulin (BI) initiation

Country	Pre-index HbA _{1c} value (%)	Pts at HbA _{1c} target of ≤7% at 3 months (%)	Pts at HbA _{1c} target of ≤7% at 24 months (%)	Odds ratio for long-term risk of not achieving target if target is not achieved in the first 3 months (p-value)	Pts who had HG during 1 year pre-index (%)	Pts who had HG in first 3 months (%)	Pts who had HG over 24 months (%)	Odds ratio for long-term risk of HG if HG is experienced in the first 3 months (p-value)
Germany (N=4064)	8.4	29.8	33.6	3.71 (<0.001)	2.9	1.8	8.7	6.72 (<0.001)

Silent hypoglycaemic episodes among well controlled type 2 diabetic patients treated with sulfonylureas

G. Simonyi¹, G. Csitári¹, R. Gasparics¹, R. Kollár¹, Á. Hegedüs¹, Z. Pál¹, K. Gencsiova¹, P. Kempler²;

¹Metabolic Center, St Imre University Teaching Hospital, ²1st Department of Internal Medicine, Semmelweis University, Budapest, Hungary.

Background and aims: Hypoglycaemia is a relevant cardiovascular risk factor. The aim of our study was to assess the frequency of silent hypoglycaemic episodes among well-controlled type 2 diabetic patients treated with sulfonylurea.

Materials and methods: 29 type 2 diabetic patients (16 men, 13 women) with HbA_{1c} ≤7% treated with sulfonylurea and/or metformin without manifest symptoms of hypoglycaemia during the past two year were involved in the study (mean age: 70.94±8.92 years, mean duration of diabetes mellitus 13.88±8.42 years, mean HbA_{1c} was 5.48±0.82%). A 120-hour long (5 days) glucose monitoring using a Continuous Glucose Monitor System (CGMS) device (Medtronic iPro2[®]) was performed. Patients were asked to document four self-monitored capillary blood glucose levels each day for calibration of the monitor, as well as to record meal times and exercise. Hypoglycaemia symptoms were also recorded. According to the EASD/ADA recommendation, glucose concentration of ≤3.9 mmol/l were classified as hypoglycaemia. The number of hypoglycaemic events ≤3.9 mmol/l and, additionally, the number of hypoglycaemic episodes <3.1 mmol/l were determined. Hypoglycaemic episodes were defined as a glucose value that persisted for at least 15 minutes with or without symptoms.

Results: Twenty nine patients were monitored for a mean period of 5744.72±1406.28 min. The mean interstitial glucose (IG) concentration was 7.07±1.12 mmol/l. The minimal IG was 2.2 mmol/l, while the maximal IG concentration was 19.3 mmol/l. 18/29 (62.01%) patients had a total number of 65 silent hypoglycaemic episodes (interstitial glucose ≤3.9 mmol/l), the mean 3.88±2.05 episodes per patients. The total duration of these hypoglycaemic episodes was 374.5±462.97 min. 8/29 (27.6%) patients had hypoglycaemic episodes of interstitial glucose ≤3.1 mmol/l. The mean frequency of these episodes was 0.88±1.01 per patient. The total number of episodes was 15. The total duration of hypoglycaemic episodes with glucose values ≤3.1 mmol/l was 72.5±120.04 min. None of our patients recorded symptoms of hypoglycaemia. CGMS measurements were generally well tolerated.

Conclusion: We demonstrated that silent hypoglycaemia is quite common in well-controlled patients with type 2 diabetes treated with a sulfonylurea with or without metformin. As a key finding, all registered hypoglycaemic episodes were silent. CGMS is a useful clinical tool for detecting silent hypoglycaemia.

963

Effects of liraglutide as add-on to insulin on counter-regulatory hormone responses, gastric emptying and glycaemic recovery during hypoglycaemia

L. Østergaard¹, C.S. Frandsen¹, T.F. Dejgaard², J.J. Holst³, H.U. Andersen², B. Thorsteinsson⁴, S. Madsbad¹;

¹Dept. of Endocrinology, Hvidovre University Hospital, ²Steno Diabetes Center, Gentofte, ³Novo Nordisk Foundation Center for Basic Metabolic Research, Copenhagen, ⁴Dept. of Cardiology, Nephrology and Endocrinology, Nordsjællands Hospital, Hillerød, Denmark.

Background and aims: There is a growing body of evidence that GLP-1 receptor agonists (GLP-1 RA) could be beneficial as add-on to insulin in patients with type 1 diabetes (T1D). GLP-1 inhibits glucagon secretion and delays gastric-emptying (GE) during euglycaemia; however, these effects have not been fully elucidated during hypoglycaemia. The aim of this study was to investigate the counter-regulatory hormone responses and GE rate during hypoglycaemia in patients with T1D treated with liraglutide 1.2 mg or placebo for 12 weeks

Materials and methods: In total 20 T1D patients were randomized to 12 weeks treatment with once-daily liraglutide 1.2 mg or placebo as add-on to pre-existing insulin treatment. Before and after 12 weeks of treatment a hyperinsulinemic hypoglycaemic clamp was performed (figure). Before both experimental days glucose was monitored using continuous glucose monitor (CGM). In case of glucose measurements <3.5 mmol/l (CGM or glucose meter) within 24 hours of the study, study procedures were postponed. On both occasions patients were studied at normoglycaemia (plasma glucose target: 5-6 mmol/l), followed hypoglycaemia (approx. 2.0 mmol/l) and during glycaemic recovery after a liquid meal (containing 600 kcal and 1.5 g of acetaminophen) served at hypoglycaemia (figure). Blood samples for analysis of counter-regulatory hormone responses, p-glucose, and p-acetaminophen were drawn.

Results: Baseline characteristics were similar between groups: (liraglutide; placebo, mean±sem): HbA_{1c} 77±4; 71±2 mmol/mol, BMI 24.9±0.8; 23.2±0.7 kg/m², diabetes duration 20±3; 22±2 years, age 36 ±3; 37±2. In the liraglutide group, no counter-regulatory differences between experimental days were seen in change in cortisol, glucagon or growth hormone (GH) from normoglycaemia to maximum response following hypoglycaemia. However, at 12 weeks change from baseline in glucagon secretion tended to lower with liraglutide compared with placebo (liraglutide vs. placebo, iAUC₀₋₂₄₀:1862±967 to 1290±993 vs. 2435 ±1239 to 2311±1295 pmol/l×min, p=0.4). The acetaminophen absorption test assessing rate of gastric emptying displayed no differences between treatments. Glycaemic recovery from hypoglycaemia did not differ between groups

Conclusion: In patients with T1D liraglutide as add-on to insulin do not affect the counter-regulatory hormone responses during hypoglycaemia. However, a trend toward lower glucagon secretion was seen after liraglutide treatment. Foremost, gastric emptying was not delayed during hypoglycaemia and glycaemic recovery from hypoglycaemia was unaffected with liraglutide adjunct to insulin treatment in T1D

Similar counter-regulatory hormone responses to hypoglycaemia with Basal Insulin peglispro (BIL) versus insulin Glargine (GL) in type 1 diabetes

T. Heise¹, C. Kapitza¹, L. Nosek¹, E. Lam², S. Choi², P. Garhyan³, S.J. Jacober³, N. Porksen³, M.J. Prince³, H. Linnebjerg³;

¹Profil, Neuss, Germany, ²Lilly-NUS Centre for Clinical Pharmacology Pte Ltd, Singapore, ³Eli Lilly and Company, Indianapolis, USA.

Background and aims: BIL is a novel PEGylated basal insulin with a flat pharmacokinetic and glucodynamic profile which has a hepato-preferential action resulting from reduced peripheral effects. This study assessed the effects of BIL and GL on the counter-regulatory response to and recovery from hypoglycaemia induced by human insulin infusion. In patients with type 1 diabetes, the glucagon response to hypoglycaemia is reduced over time and the glucose counter-regulatory response depends mainly on epinephrine. For this reason, the primary objective of the study was to assess the counter-regulatory response of epinephrine.

Materials and methods: This was an open-label, randomised, 2-period, crossover study. After once-daily, individualised, subcutaneous doses of BIL or GL for ≥ 14 days, 13 patients (mean \pm SD) age, 41.0 \pm 10.4 years; duration of diabetes, 19.0 \pm 8.7 years) underwent a hypoglycaemic clamp by infusion of human insulin (0.5 mU/kg/min) to achieve sequential blood glucose (BG) targets of 72, 58 and 45 mg/dL (BG nadir) (4.0, 3.2 and 2.5 mmol/L). The amount of glucose infusion required to recover from 45 to 72 mg/dL (2.5 to 4.0 mmol/L) was also compared.

Results: There was no statistically significant difference between treatments in the counter-regulatory response of epinephrine (Table; see also norepinephrine, cortisol and growth hormone data). Mean baseline glucagon was higher following BIL than GL; this statistically significant difference was maintained during the clamp. There were no statistically significant differences between BIL and GL in the mean amount of glucose required to reach a BG concentration of 72 mg/dL (4.0 mmol/L) from 45 mg/dL (2.5 mmol/L).

Conclusion: BIL and GL showed similar counter-regulatory responses to and recovery from hypoglycaemia, indicating that the hepato-preferential action of BIL does not impair counter-regulation.

Good glycaemic control with low incidence of hypoglycaemia: complete evaluation of data of routine care by electronic patient file

C. Kloos, D. Askitis, N. Müller, B. Milke, G. Kramer, U.A. Müller; Endocrinology and Metabolic Diseases, Internal Medicine III, Jena University Hospital, Germany.

Background and aims: Regular assessments of treatment quality is only practicable with easy data handling from routine-care integrating existing processes and treatment structures and replace paper documents and files. Since 1997 we conceived and continuously improved an electronic database and patient file, which is easy to use, and can locally be adapted to specific needs and pre-existing software structure. Exemplarily the quality of care of all patients with diabetes mellitus cared for at the outpatient department in the year 2011 is shown.

Materials and methods: A total of 1411 people with DM were seen in our outpatient department. DM1 292 (49,5% females, 50,2y, time since diagnosis 21,5y, BMI 27,2 kg/m²) and DM2 1118 (with insulin n=730, 43,6% females, age 68,5y, time since diagnosis 18,4y, BMI 33,69 kg/m²; without insulin n=388, 48,6% females, age 64,6y, time since diagnosis 8,4y, BMI 30,75 kg/m²). HbA_{1c} was DCCT adjusted (mean of healthy persons 5,05%). All patients took part in a structured patient education programme in 2011 or earlier.

Results: All people with DM1 had an intensified insulin therapy with the basal-bolus schema (74%) or a therapy with insulin pump (26%). 50% used short-acting human insulin and 50% short-acting insulin analogues, NPH-insulin 30,5%, long-acting insulin analogues 31,8% and combined human insulin 5,5%. Mean blood pressure office was 135/81 and patient self 130/77, mean HbA_{1c} 7,5%. The incidence of severe hypoglycaemia (glucose or glucagone injection) was 0,11/pat/y and the frequency of non-severe hypoglycaemia was 1,76/pat/wk. 316 (44%) of the people with DM2 on insulin had a conventional therapy (CT) with human insulin and 404 (56%) a multiple injection therapy (MIT) with human or analogue insulin. The therapy was combined with metformin in 42,2% of the cohort, in 0,4% with sulfonylureas, 2,7% with DPP4-inhibitors and 1,9% with other medications. Mean blood pressure office was 145/83 mmHg and patient self 135/77, mean HbA_{1c} 7,5%. The incidence of severe

hypoglycaemia (glucose or glucagone injection) was 0,02/pat/y and the frequency of non-severe hypoglycaemia was 0,21/pat/wk. People with DM2 without insulin were treated in 71% with oral antidiabetic agents (58% metformin, 22% sulfonylureas, 7% DDP4-inhibitors, 4% other drugs (glinides, GLP1-analogues)). Mean blood pressure office was 144/88 and patient-self 133/78, mean HbA_{1c} 6,6%. The incidence of severe hypoglycaemia was 0% and non-severe hypoglycaemia 0,05/pat/wk.

Conclusion: The easily retrieved data from routine care of a tertiary university outpatient clinic displayed a very good metabolic control within the target of near normoglycaemia. The incidence of severe hypoglycaemias under insulin therapy was low, even in the group of DM1. Severe hypoglycaemias in patients with DM2 on insulin were very rare, subjects without insulin did not report severe hypoglycaemic events. Mild hypoglycaemias occurred rarely in people with DM1 and very rarely in people with DM2, even on insulin therapy. Blood pressure self-control is considerably lower than office blood pressure well in the target range.

A single dose study in healthy subjects demonstrating pharmacokinetic and pharmacodynamic equivalence between MK-1293 and EU- and US-approved innovator insulin glargine

M. Hompesch¹, J. Palcza², K. Mostoller², C. Mahon², A.M. Barbour², Y. Xu², E. Mangin², P. Algatt-Bergstrom², L. Morrow¹, M. Crutchlow²;

¹Profil Institute for Clinical Research, Inc., Chula Vista, ²Merck & Co., Inc., Kenilworth, USA.

Background and aims: MK-1293 is a follow-on/biosimilar insulin glargine under development using EU- and US-approved innovator insulin glargine as the benchmark comparator.

Materials and methods: This double-blind, randomized, three-period balanced crossover euglycemic clamp study in healthy male subjects (age: 18-45 yrs; BMI: 18.5-25.0 kg/m²) was conducted to demonstrate pharmacokinetic (PK) and pharmacodynamic (PD) equivalence between MK-1293, innovator insulin glargine procured in the US ('US-approved innovator insulin glargine') and EU ('EU-approved innovator insulin glargine'). In each treatment period, subjects received single 0.4 units/kg S.C. doses of MK-1293, US-approved innovator insulin glargine, or EU-approved innovator insulin glargine in random sequence followed by a 24-hour assessment period for PK sampling and euglycemic clamping (clamp target 80 mg/dL [4.44 mmol/L]). An LC-MS/MS assay was used to quantify concentrations of the major circulating active glargine metabolite (M1) as well as parent glargine and the M2 metabolite.

Results: Data for the primary PK and PD endpoints are presented in the table. For all three treatment comparisons, the 90% confidence intervals for the geometric mean ratios for the primary PK endpoints and the arithmetic mean ratios for the primary PD endpoints were within 0.80 to 1.25, which was the pre-specified equivalence criterion for both PK and PD endpoints. All treatments were well tolerated.

Conclusion: This study demonstrated PK and PD equivalence between MK-1293, US-approved innovator insulin glargine, and EU-approved innovator insulin glargine, thereby supporting the potential for MK-1293 as a follow-on/biosimilar insulin glargine.

	MK-1293:US-approved innovator insulin glargine	MK-1293:EU-approved innovator insulin glargine	EU-approved innovator insulin glargine:US-approved innovator insulin glargine
Primary PK Endpoints			
AUC _{0-24h} of M1 [‡]	0.98 (0.93, 1.04)	0.97 (0.92, 1.02)	1.01 (0.97, 1.05)
C _{max} of M1*	1.01 (0.96, 1.07)	1.00 (0.95, 1.05)	1.01 (0.96, 1.06)

Superior reduction of HbA_{1c} in a double-blind, randomised study of basal insulin pегlispro (BIL) vs insulin glargine (GL) in patients with type 1 diabetes: IMAGINE 3

H. Lunt¹, R.M. Bergenstal², E. Franek³, F. Travert⁴, J. Mou⁵, M.L. Hartman⁵, M. Rosilio⁶, E.J. Bastyr III⁵, for the IMAGINE 3 Study Group; ¹Christchurch Hospital Diabetes Centre, New Zealand, ²International Diabetes Center, Minneapolis, USA, ³Centralny Szpital Kliniczny MSW, Warszawa, Poland, ⁴Hopital Bichat Claude Bernard, Paris, France, ⁵Eli Lilly and Company, Indianapolis, USA, ⁶Lilly France, Neuilly sur Seine, France.

Background and aims: Basal insulin pегlispro (BIL) is a novel basal insulin with a flat pharmacokinetic profile which has a hepato-preferential action resulting from reduced peripheral effects.

Materials and methods: In this Phase 3, 52-week, blinded study of BIL vs GL, 1114 adults with T1D (39% female) and HbA_{1c} <12% (<108 mmol/mol) (mean 7.9% [62 mmol/mol]) were randomised 3:2 to bedtime BIL or GL with prandial insulin lispro. An electronic diary facilitated data capture and insulin dosing decisions.

Results: At 52 weeks, BIL vs GL provided superior reduction of HbA_{1c} (difference -0.22% [-2.42 mmol/mol]; 95% CI: -0.32%, -0.12% [-3.47, -1.36 mmol/mol]). More patients on BIL achieved HbA_{1c} <7% (<53 mmol/mol). With BIL, patients had less glucose variability, a 47% lower rate of nocturnal hypoglycaemia (SMBG ≤3.9 mmol/l [70 mg/dl]), and weight loss. The total hypoglycaemia rate was 11% higher with BIL and may be associated with daytime bolus insulin dosing; severe hypoglycaemia rates were similar. While total insulin dose was similar, BIL patients used more basal and less bolus insulin. With BIL, LDL-C and triglycerides (TG) increased and HDL-C decreased. More BIL patients had ALT ≥3× ULN (4.8% vs 2.0%, p=0.021) with no cases of Hy's law. Liver fat content (LFC, %), assessed by MRI in 182 patients from 2 studies of BIL vs GL in T1D, increased with BIL (5.7±0.3 vs 3.5±0.4, p<0.001). Patients on BIL were more likely to have injection site reactions (13.3% vs 0.2%, p<0.001).

Conclusion: In T1D, treatment with BIL vs GL gave superior HbA_{1c} reduction, lower nocturnal hypoglycaemia, and weight loss, with increases in ALT, TG, LFC, and injection site reactions.

Efficacy, patient-reported outcomes and safety of insulin degludec U200 compared with insulin glargine in patients with type 2 diabetes requiring high-dose insulin

M. Warren¹, L.B. Chaykin², S. Jabbour³, M. Sheikh-Ali⁴, C.T. Hansen⁵, T.S.S. Nielsen⁵, P. Norwood⁶;

¹Physicians East, Greenville, ²Meridien Research, Bradenton, ³Jefferson University Hospitals, Philadelphia, ⁴University of Florida Health, Jacksonville, USA, ⁵Novo Nordisk A/S, Søborg, Denmark, ⁶Endocrinology, Valley Research, Fresno, USA.

Background and aims: This was a 32-week, open-label, crossover, treat-to-target trial that compared the efficacy, patient-reported outcomes and safety of insulin degludec (IDeg) 200 U/mL with insulin glargine (IGlar) 100 U/mL, administered once daily (OD) after 16 weeks' run-in.

Materials and methods: Adults aged ≥18 years with type 2 diabetes (T2D) for ≥6 months, receiving IGlar OD (≥65–≤100 U/day) + metformin ± one other oral antidiabetic drug for ≥3 months, with a HbA_{1c} ≥7.5% who required ≥81 U insulin after a 16-week run-in were randomised 1:1 to IDeg/IGlar or IGlar/IDeg (Figure).

Results: After 16 weeks, noninferiority of IDeg to IGlar with respect to change in HbA_{1c} was confirmed. Mean fasting plasma glucose was significantly reduced with IDeg vs. IGlar (-0.82 vs. -0.05 mmol/L; estimated treatment difference [ETD]: -0.77 mmol/L, p<0.05). For IDeg vs. IGlar, the rate of confirmed hypoglycaemia was significantly lower (estimated rate ratio [ERR]: 0.59, p<0.05) while nocturnal hypoglycaemia was numerically lower (ERR: 0.66, p=NS). Mean weight change was 0.42 kg (IDeg) vs. 1.04 kg (IGlar), p=NS. The IDeg delivery device was rated significantly better for function (ETD: 8.40, p<0.05) and less bother (ETD: 6.01, p<0.05) compared with the IGlar device, and more patients preferred IDeg treatment (54.5%) vs. IGlar (20.0%); 15.9% no preference and 2.8% didn't know.

Conclusion: IDeg U200 was effective in regulating glycaemic control as measured by HbA_{1c} (noninferiority to IGlar confirmed) and is preferred by a numerically higher proportion of patients with T2D requiring high-dose insulin.

The efficacy and safety of LY2963016 insulin glargine in patients with type 1 and type 2 diabetes previously treated with insulin glargine

I. Hadjiyianni¹, A. Asaro-Harris², D. Dahl³, L.B. Lacaya¹, R.K. Pollom¹, L.L. Ilag¹, J.S. Zielonka¹;
¹Eli Lilly and Company, Indianapolis, USA, ²Eli Lilly and Company, Basingstoke, UK, ³Gemeinschaftspraxis für Innere Medizin und Diabetologie, Hamburg, Germany.

Background and aims: LY2963016 insulin glargine (LY IGLar) and insulin glargine (IGlar) are insulin glargine products with identical primary amino acid sequences as well as similar pharmacokinetic and pharmacodynamic profiles. In 2 prospective, global, parallel, Phase 3 trials, LY IGLar had a similar efficacy and safety profile to IGLar with no clinically meaningful differences. To further assess the treatment effect and similarity of LY IGLar to IGLar, additional analyses were done in the subgroup of patients with type 1 diabetes mellitus (T1DM) or type 2 diabetes mellitus (T2DM) who reported prestudy treatment with IGLar (prior IGLar) in these 52-week open-label (ELEMENT-1) and 24-week double-blind randomised (ELEMENT-2) studies, respectively.

Materials and methods: In both studies, unit-to-unit dose conversions were used from prestudy IGLar to study LY IGLar or IGLar followed by treat-to-target titration (eg, HbA_{1c} <7.0%). The efficacy and safety of LY IGLar and IGLar were compared in the prior IGLar subgroup. Primary efficacy was defined as change in HbA_{1c} from baseline to the 24-week endpoint. Continuous data were analysed using ANCOVA. Treatment comparisons for hypoglycaemia rate were done using the Wilcoxon test. Fisher's exact test or chi-square test was used for categorical data.

Results: No significant treatment differences were observed for primary and other efficacy outcomes, including proportion of patients achieving endpoint HbA_{1c} targets, fasting plasma glucose, basal insulin dose, and prandial insulin dose (T1DM only) (Table), except for a significantly greater weight change from baseline observed in the LY IGLar group of patients with T1DM, which was not consistently observed in patients with T2DM and in the total T1DM population. For safety outcomes, a significant difference in the proportion of patients with detectable insulin antibodies at any time point of the study (overall) was noted in patients with T2DM but not for patients with T1DM. No significant difference was observed at the 52-week (T1DM) or 24-week (T2DM) endpoint (LOCF); median insulin antibody levels were low (<5%) and similar in the 2 treatment groups. Significantly fewer patients with T2DM treated with LY IGLar reported ≥1 serious adverse event, which was not seen in patients with T1DM and no treatment differences were observed for preferred terms. No significant treatment differences were observed for other safety outcomes, including total and nocturnal hypoglycaemia rates and incidences (endpoint and overall; blood glucose ≤3.9 mmol/l if available), incidence of treatment-emergent antibody response, and treatment-emergent adverse events.

Conclusion: In patients who reported prestudy treatment with IGLar in these 2 Phase 3 trials, patients randomised to LY IGLar had similar efficacy and safety outcomes as those randomised to IGLar.

Adherence to initiated basal insulin analogue treatment in type 1 and 2 diabetes

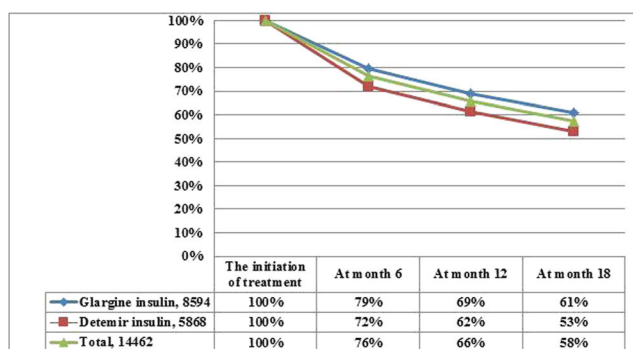

J. Westerbacka¹, H. Mihailov², T. Valle³, S. Jääskeläinen¹, J. Kaukua¹;
¹Sanofi Finland, Helsinki, ²Department of Health Policy and Management, Health Economics, University of Eastern Finland, Kuopio, ³Mehiläinen Diabetes Clinic, Helsinki, Finland.

Background and aims: Poor medication adherence is common in diabetes potentially causing poor health outcomes and complications. The aim of this study was to analyze the discontinuation rate of initiated basal insulin analog in type 1 and type 2 diabetic patients in Finland.

Materials and methods: The data was obtained from the national reimbursement registry. Study population consisted of 14 462 diabetic patients (18% had type 1 diabetes) who started basal insulin analogs (insulin glargine or insulin detemir) in 2012. Patients were followed by their insulin purchases for 18 months after the initiation. The data was analysed with χ^2 -test and logistic regression analysis. Logistic regression analysis was used to find out what variables (age, gender, type of diabetes, type of insulin analog) explain patient staying in the treatment.

Results: Type of insulin, gender, age and type of diabetes had statistically significant influence on patients' treatment adherence (p<0.001 for all). Overall 47% of patients starting insulin detemir and 39% starting insulin glargine patients discontinued their basal insulin treatment within 18 months of the initiation. Most of the patients stopped treatment within first 6 months after the initiation. In type 1 diabetic patients, 42% of insulin glargine patients and 57% of insulin detemir patients stopped the initiated treatment. In type 2 diabetic patients, 35% stopped insulin glargine and 38% insulin detemir. In only 15% of the patients discontinuing the initiated basal insulin, death or switch to other insulin or GLP-1RA explained the discontinuation suggesting non-adherence to insulin therapy from other reasons.

Conclusion: There is a considerable proportion of diabetic patients discontinuing their initiated basal insulin analog. Future studies are warranted to examine the detailed reasons for discontinuation.

% of patients who stay in initiated basal insulin treatment within 18 months of the initiation

Superior HbA_{1c} reduction with Basal Insulin peglispro (BIL) vs insulin glargine in patients with type 2 diabetic patients previously treated with basal insulin: IMAGINE 5

C. Trescoli Serrano¹, J.B. Buse², H.W. Rodbard³, J. Luo⁴, T. Ivanyi⁴, J. Bue-Valleskey⁴, M.L. Hartman⁴, M.A. Carey⁵, A.M. Chang⁴;

¹Diabetes Unit, Hospital de la Ribera, Valencia, Spain, ²University of North Carolina School of Medicine, Chapel Hill, ³Endocrine and Metabolic Consultants, Rockville, ⁴Eli Lilly and Company, Indianapolis, ⁵Ventiv Health Clinical, Blue Bell, USA.

Background and aims: Basal insulin peglispro (BIL) is a novel basal insulin with a flat profile which has a hepato-preferential action resulting from reduced peripheral effects.

Materials and methods: This Phase 3, open-label, treat-to-target 52-week study in patients with type 2 diabetes (T2D) (HbA_{1c} ≤9%) on basal insulin alone or with up to 3 oral antihyperglycaemic medications (OAMs), assessed noninferiority of BIL to insulin glargine (GL) in reducing HbA_{1c} at 26 weeks (margin=0.4%) when added to prestudy OAMs. Patients were randomised 2:1 to BIL (N=307) or GL (N=159); 162 patients underwent MRI to assess liver fat content (LFC).

Results: Superiority of BIL vs GL was demonstrated for change in HbA_{1c} at 26 and 52 weeks. In addition, more BIL patients reached HbA_{1c} <7% and lab FSG was lower with BIL. BIL patients had a 60% rate reduction vs GL in nocturnal hypoglycaemia and more patients reaching HbA_{1c} <7% without nocturnal hypoglycaemia over 52 weeks. BIL-treated patients had a lower total hypoglycaemia rate, higher basal insulin dose. BIL patients had higher triglycerides (TGs), lower LDL-C and HDL-C, no difference in non-HDL-C, and higher ALT and AST. More BIL patients had ALT ≥3× ULN (2.3 vs 0%, p=.101), with no cases of Hy's law. LFC increased from baseline in patients on BIL vs GL with stable LFC from weeks 26 to 52.

Conclusion: In summary, in patients previously treated with conventional basal insulins, BIL provided superior reduction in HbA_{1c}, less nocturnal and total hypoglycaemia, and higher TGs, ALT, and LFC compared to GL.

Superior HbA_{1c} reduction with basal insulin peglispro (BIL) vs insulin glargine (GL) and prandial insulin lispro in a double-blind study in type 2 diabetes patients: IMAGINE 4

A.M. Chang¹, T. Blevins², T.R. Pieber³, G. Colón Vega⁴, S. Zhang¹, E.J. Bastyr III¹;

¹Eli Lilly and Company, Indianapolis, ²Texas Diabetes and Endocrinology, Austin, USA, ³Division of Endocrinology and Metabolism, Medical University of Graz, Austria, ⁴American Telemedicine Center, San Juan, USA.

Background and aims: Basal insulin peglispro (BIL) is a novel basal insulin with a flat activity profile which has a hepato-preferential action resulting from reduced peripheral effects.

Materials and methods: In this 26-week, Phase 3, blinded, treat-to-target trial, 1369 patients with T2D (HbA_{1c} ≥53 mmol/mol [≥7.0%] and <108 mmol/mol [≤12.0%] on ≥1 insulin injection/day) were randomised to bedtime BIL (N=691) or GL (N=678). Patients could continue metformin. A wireless electronic diary system facilitated communication of SMBG, hypoglycaemia, and insulin dosing.

Results: At Week 26, patients on BIL vs GL demonstrated superior HbA_{1c} reduction (baseline: 69 mmol/mol [8.4%]; Week 26: 50 vs 53 mmol/mol [6.8% vs 7.0%]; treatment difference -2.30 mmol/mol [-0.21%], p<.001). BIL-treated patients had lower FSG (7.0 vs 7.3 mmol/l [125 vs 132 mg/dl], p=.015), and more reached HbA_{1c} <7% (63% vs 53%, p<.001). The improved glycaemic control with BIL vs GL was achieved with a 45% lower rate of nocturnal hypoglycaemia and more patients reaching HbA_{1c} <53 mmol/mol (<7%) without nocturnal hypoglycaemia over 26 weeks (24% vs 12%, p<.001). Total hypoglycaemia relative rate was 1.10 (BIL/GL, p=.053); severe hypoglycaemia rate and incidence did not differ between treatments. With BIL, basal insulin dose was 11% higher, but bolus and total insulin doses were similar at 26 weeks. The BIL group had greater reduction in within-day and between-day fasting and 9-point SMBG variability, and less weight gain (change from baseline, 1.3 vs 2.2 kg, p<.001). BIL treatment was associated with higher triglycerides (TG, change from baseline: 0.27 vs -0.04 mmol/l [24 vs -3 mg/dl], p<.001), lower HDL-C (change from baseline: -0.04 vs -0.01 mmol/l [-2 vs 0 mg/dl], p<.001), and similar LDL-C, with no difference in cardiovascular or other serious adverse events. At Week 26, ALT mean change from baseline was 7.6 vs -0.6 IU/l (p<.001); more BIL patients had ALT ≥3× ULN (1.9% vs 0.9%, p=0.16), with no cases of Hy's law. There were no significant differences in efficacy or safety in patients with anti-BIL treatment-emergent antibody responses.

Conclusion: In patients with T2D, BIL vs GL, in combination with insulin lispro, provided improved glycaemic control with less nocturnal hypoglycaemia, less weight gain, and increases in TG and ALT.

Liver enzyme and Liver Fat Content (LFC) results from Basal Insulin peglispro (BIL) clinical trials in type 1 and type 2 diabetes

M.L. Hartman, S. Zhang, E.J. Bastyr III, A.M. Chang, S.J. Jacober, A. Haupt, M.J. Prince;

Eli Lilly and Company, Indianapolis, USA.

Background and aims: BIL, a basal insulin analog with a flat pharmacokinetic profile, has reduced peripheral activity resulting in hepatopreferential action. To monitor hepatic safety, liver enzymes and LFC were measured in patients (pts) with T1D and T2D during BIL trials.

Materials and methods: Alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), and total bilirubin (TBL) were measured at 0, 4, 8, 12, 16, 26, 39, 52, 65, and 78 weeks (wks), depending on study duration, and 4 wks following study basal insulin withdrawal. Data were integrated for studies comparing BIL with insulin glargine (GL) in pts with T1D (1 Phase 2 and 2 Phase 3 trials; 1026 BIL and 676 GL) and T2D (1 Phase 2 and 3 Phase 3 trials; 2194 BIL and 1464 GL). LFC was measured via magnetic resonance imaging (MRI) in 3 subsets of pts (N given in table) at 0, 26, and 52 wks: 1) T1D, 2) insulin naïve (IN) T2D pts, and 3) T2D pts previously treated with insulin (PTI). A small number of T1D pts had MRI at 78 wks (26 BIL, 11 GL).

Results: In T1D and T2D pts, mean ALT increased from baseline in BIL pts and was higher than in GL pts at all time points to 78 wks (all $p < .001$) and decreased after discontinuation of BIL. Similar results were observed for AST, but no clinically meaningful changes in mean TBL or ALP occurred. More pts taking BIL had $ALT \geq 3X$ upper limit of normal (ULN) than GL but $TBL \geq 2X$ ULN was similar for BIL vs GL. $AST \geq 3X$ ULN was more common in BIL than GL pts for T2D (1.2% vs 0.4%, $p = .009$) but not for T1D. No patient had $ALT \geq 3X$ ULN with a $TBL \geq 2X$ ULN that could not be attributed to another cause; thus Hy's Law criteria were not met. Of the pts taking BIL with $ALT \geq 3X$ ULN (44 in T1D, 44 in T2D), all pts with T1D and 40 (90.9%) with T2D returned to or trended toward baseline while continuing BIL (37 in T1D, 22 in T2D) or after discontinuing BIL (7 in T1D, 18 in T2D), consistent with hepatic adaptation. Four T2D pts had insufficient follow-up to adequately assess the ALT trend. In T2D IN pts, LFC did not change with BIL but decreased significantly with GL. In T1D and T2D PTI pts, LFC increased significantly with BIL but no change occurred with GL. In T1D pts at 78 wks, LFC remained higher in BIL than GL ($6.1\% \pm 0.5\%$ in BIL, $2.9\% \pm 0.8\%$ in GL; $p = .001$). More BIL than GL pts had $LFC \geq 6\%$ (ULN). The correlation between the change in ALT and change in LFC at 52 wks was statistically significant in T1D, T2D IN, T2D PTI pts taking BIL ($R = 0.37$ to 0.47 ; all $p < .001$); it was also significant in pts taking GL in T2D IN ($R = 0.29$; $p = .029$) but not in T1D or T2D PTI pts.

Conclusion: No acute, severe, hepatocellular drug-induced liver injury was apparent with BIL treatment for up to 78 wks. LFC was significantly higher in T1D and T2D pts treated with BIL compared to GL for treatment up to 78 wks. In T2D IN pts, this difference was due to a decrease in LFC with GL. In T1D and T2D PTI pts, the difference was the result of an increase in LFC with BIL. Further research is needed to understand and characterize the potential effects, if any, of changes in LFC observed with BIL treatment in Phase 3 trials.

PS 092 Basal insulin analogue: effects on hypoglycaemia

974

Is hypoglycaemia a modifiable patient risk in type 2 diabetes: A pooled analysis of insulin glargine 300 U/mL (Gla-300) vs 100U/mL (Gla-100) trials?

Q. Zhang¹, J. Rosenstock², C. Gerrits³, L. Liao³, P. Chew³;

¹Rutgers University, Piscataway, ²Dallas Diabetes and Endocrine Center, Dallas, ³Sanofi, Bridgewater, USA.

Background and aims: Repeated episodes of hypoglycemia are associated with an increased risk of adverse clinical outcomes. Underlying patient characteristics may predispose to repeated hypoglycemia.

Materials and methods: We evaluated potential patient predisposition to documented hypoglycemia in pooled data (N=2488) from 3 T2DM clinical trials of Gla-300 vs Gla-100 and their 6-month extensions (N=1994). Study populations for the three studies are as follows: DIV>14 patients were removed due to missing baseline data. Monthly study data were analyzed with general estimating equations (GEE) to assess the impact of patient characteristics on risk of repeated hypoglycemic events over 12 months.

Results: Baseline characteristics were comparable between groups: mean age 59 years, BMI 35 kg/m², A1C 8.3%, diabetes duration 13 years, and Charlson Comorbidity Index (CCI) 0.56 for Gla-300 vs 0.60 for Gla-100. Less documented (≤ 70 mg/dL) symptomatic hypoglycemia was noted with Gla-300 vs Gla-100 (57.0% vs 63.3%, odds ratio=0.77, 95% CI: 0.65-0.90, P=0.001). Female gender (P<0.001), BMI ≤ 35 kg/m² (P<0.001), CCI >0.60 (P=0.017), and diabetes duration >10 years (P=0.001) were associated with an increased number of documented, symptomatic hypoglycemia events. Poisson regression showed a lower event rate for Gla-300 vs Gla-100 (4.4 vs. 5.2 events/year; rate ratio 0.84, 95% CI: 0.76-0.92, P<0.001) independent of patient characteristics. Furthermore, monthly percentage of patients experiencing documented hypoglycemia increased in Gla-100 but stayed unchanged in Gla-300 over CCI (P_{interaction}=0.017).

Conclusion: Repeated episodes of documented hypoglycemia in T2DM are reflective of such patient characteristics as gender, BMI, diabetes duration and comorbidity. Gla-300 is associated with a lower event rate than Gla-100 through the 12 months period. In particular, increasing hypoglycemia risk due to patient burden of comorbidity appears to be mitigated with Gla-300 compared to Gla-100.

Patient-level meta-analysis of 1y phase 3a EDITION type 2 diabetes mellitus studies: glycaemic control and hypoglycaemia with insulin glargine 300 U/ml (Gla-300) vs glargine 100 U/ml (Gla-100)

R.A. Ritzel¹, R. Roussel², A. Giaccari³, J. Vora⁴, M.-L. Grisoni⁵, C. Brulle-Wohlhueter⁶, S. Glezer⁶, H. Yki-Järvinen⁷;

¹Klinikum Schwabing, Städtisches Klinikum München GmbH, Germany, ²Assistance Publique Hôpitaux de Paris, Bichat Hospital, France, ³Endocrino-Metabolic Diseases Unit, Università Cattolica del Sacro Cuore, Rome, Italy, ⁴Royal Liverpool University Hospital, UK, ⁵AIXIAL, Levallois-Perret, France, ⁶Sanofi, Paris, France, ⁷University of Helsinki, Finland.

Background and aims: EDITION 1, 2 and 3 assessed Gla-300 vs Gla-100 in people with type 2 diabetes (T2DM).

Materials and methods: A patient-level meta-analysis of 1-year data was conducted.

Results: Glycaemic control was sustained in both groups, with more sustained HbA_{1c} reduction for Gla-300 at 1 year. LS mean (SE) change from baseline in HbA_{1c} was -0.91 (0.03) % for Gla-300 and -0.80 (0.03) % for Gla-100 (LS mean difference [95% CI] between groups -0.10 [-0.18 to -0.02] %; p=0.0174). There was a reduced risk of confirmed (≤ 3.9 mmol/l [≤ 70 mg/dl]) or severe hypoglycaemia at any time (24 h) and during the night with Gla-300 vs Gla-100. Weight gain was less with Gla-300 vs Gla-100. The slight insulin dose difference at 6 months remained at 1 year.

Conclusion: Gla-300 was associated with more sustained glycaemic control, with greater up-titration of insulin dose, primarily in the first weeks, and without increased risk of any time and nocturnal hypoglycaemia or weight gain at 1 year vs Gla-100.

Table: Efficacy and safety of Gla-300 in a patient-level meta-analysis of 1-year data from the EDITION 1, 2 and 3^a clinical trials

Sustainable effects of basal insulin have favourable outcomes on fasting blood glucose control in patients with type 2 diabetes

S. Kaneko, R. Adachi, Y. Ueda, Y. Tahara;

Diabetes, Endocrinology and Life-related Disease, Takatsuki Red Cross Hospital, Japan.

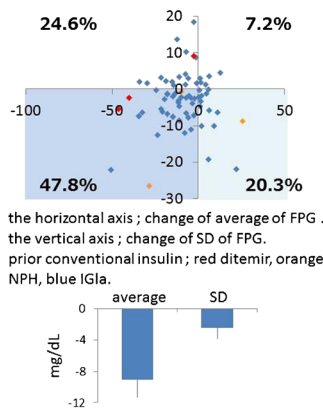

Background and aims: Recently, basal insulin formulations of longer effect have been developed. We investigated the difference in the sustainable effect of longer acting formulations on blood glucose control in patients with Type 2 diabetes. We compared insulin degludec (IDeg) therapy which has the longest effect of 42 hours with a conventional basal insulins (NPH, dimer or glargine (IGla)) therapies of which the effect is less than 24 hours.

Materials and methods: We conducted two different retrospective analyses, namely; 1) A comparison study of the newly introduced IDeg versus conventional insulin, the duration needed to achieve the target FPG and the quantity of insulin needed in both groups were analysed. and 2) In substitution study of IDeg for conventional insulin, the average and variability (SD) of FPG for 14 days prior to and after both switches were analysed.

Results: 1) Out of 332 patients with T2DM, 114 patients (60 males, 64.4 ±9.8 years old, disease duration of 7.6±7.4 years, HbA1c 10.1±2.1%, BMI 26.7±3.7, FPG 201±52 mg/dl) were newly administered IDeg once-daily, and 218 patients (95 males, 57.4±13.0 years old, disease duration of 5.6±5.6 years, HbA1c 10.4±1.8%, BMI 27.1±4.6, FPG 200±56 mg/dl) were newly administered conventional therapy once-daily or twice a day. Patients newly treated with IDeg achieved the target FPG earlier (6.7±6.9 days) than those with conventional insulin IGla (8.9 ±11.7 days) (p<0.01). Total doses of insulin IDeg (104.4±75.3 unit) needed to achieve the target FPG tended to be less than those of IGla (122.5±93.4 unit) (NS). 2) Sixty-nine patients undergoing conventional therapy were switched to IDeg for more than 30 days and then switched back to conventional therapy. For the 14 days before and after both switches, the average variability (SD) of FPG were analyzed. After switching from conventional therapy to IDeg therapy, both the average and SD of FPG decreased in 47.8% of patients (the average decreased in 72.4% and the SD of FPG decreased in 68.1%), and the amount of insulin was reduced by 10%. Nocturnal hypoglycaemia occurred in 1% and 5% of patients undergoing IDeg and conventional therapy, respectively.

Conclusion: Longer active basal insulin therapy, i.e. IDeg, provides more effective and safer control of blood glucose in T2DM. It might also be expected to reduce medical costs.

change of the average and SD of FPG for 14 days prior to and after substitution of IDeg for conventional insulin

Older people with type 2 diabetes: glycaemic control and hypoglycaemia risk with new insulin glargine 300 U/ml (Gla-300)

P. Stella¹, V. Aroda², B. Charbonnel³, R. Ritzel⁴, A. Merino-Trigo¹, M.-L. Grisoni⁵, A.J. Sinclair⁶, J.-F. Yale⁷; ¹Sanofi, Paris, France, ²MedStar Health Research Institute, Hyattsville, USA, ³Nantes University, France, ⁴Klinikum Schwabing, Städtisches Klinikum München GmbH, Germany, ⁵AIXIAL, Levallois-Perret, France, ⁶Foundation for Diabetes Research in Older People, Diabetes Frail Ltd, Droitwich Spa, UK, ⁷McGill University, Montreal, Canada.

Background and aims: In people with T2DM, a patient-level meta-analysis of EDITION 1, 2 and 3 has shown Gla-300 provides comparable glycaemic control with less hypoglycaemia over 6 months vs insulin glargine 100 U/ml (Gla-100).

Materials and methods: In this post hoc analysis, we investigated these outcomes, as well as an extended and clinically defined window of nocturnal hypoglycaemia (22:00 h to pre-breakfast SMPG) and composite endpoints, in those aged ≥65 years (n=659).

Results: Gla-300 showed comparable glycaemic control to Gla-100 (LS mean [95% CI] difference in HbA_{1c} change from baseline to month 6: 0.00 [-0.14 to 0.15] %). There was less confirmed (≤3.9 mmol/l [≤70 mg/dl]) or severe hypoglycaemia during the night irrespective of the nocturnal window analysed and a trend towards fewer any time (24 h) events for Gla-300 vs Gla-100. More Gla-300-treated participants reached HbA_{1c} targets or had HbA_{1c} reduction ≥0.5% without confirmed (≤3.9 mmol/l [≤70 mg/dl]) or severe nocturnal hypoglycaemia. Those on Gla-300 were 55-70% more likely to achieve HbA_{1c} <7% with no nocturnal hypoglycaemia (significant using both windows).

Conclusion: The comparable glycaemic control plus hypoglycaemia benefit of Gla-300 is confirmed in a potentially more vulnerable subgroup aged ≥65 years, with more people reaching HbA_{1c} targets without hypoglycaemia on Gla-300 vs Gla-100. The nocturnal hypoglycaemia benefit of Gla-300 was also confirmed when an extended window (22:00 h to pre-breakfast SMPG) was considered.

Table: Hypoglycaemia and responders to composite endpoints in people with T2DM aged ≥65 years, over 6 months in a patient-level meta-analysis of EDITION 1, 2 and 3 clinical trial data

Percentage of participants with ≥1 confirmed (≤3.9 mmol/l) or severe hypoglycaemic event, n (%) [safety population]				
	Gla-300 (n=327)	Gla-100 (n=332)	RR	95% CI
Hypoglycaemia				
Any time of day (24 h)	234 (71.6)	257 (77.4)	0.93	0.85 to 1.01
Nocturnal (00:00-05:59 h)	104 (31.8)	149 (44.9)	0.70	0.57 to 0.85
Clinically defined nocturnal (22:00 h-pre-breakfast SMPG*)	191 (58.4)	239 (72.0)	0.81	0.73 to 0.91

Responders to composite endpoints, n (%) [modified intention-to-treat population]						
		Gla-300 (n=326)	Gla-100 (n=329)	RR	95% CI	p-value

Comparison of glycaemic variations in Japanese patients with type 1 diabetes receiving insulin detemir vs insulin degludec as assessed by Continuous Glucose Monitoring (CGM)

H. Takahashi, R. Nishimura, Y. Onda, D. Tsujino, K. Ando, K. Utsunomiya;

The Jikei University School of Medicine, Tokyo, Japan.

Background and aims: Japanese patients with type 1 diabetes receiving the long-acting soluble insulin preparations insulin degludec (Deg) and insulin detemir (Det) were compared for glycaemic variation by using continuous glucose monitoring (CGM).

Materials and methods: A total of 12 patients with type 1 diabetes (males/females, 4/8) were enrolled in the study (mean age, 51.8±12.0 (SD) years; BMI, 22.1±2.5 kg/m²; and HbA_{1c}, 7.8±0.6%). The patients received one insulin preparation and were crossed over to the other for comparison. Of these, 2 patients received 1 Det injection, and 10 received 2 Det injections per day. The timing of Deg injection was set to fit the lifestyle of each patient and the amount administered was determined by

each patient in consultation with their doctors. Each patient was fitted with a CGM device in the outpatient clinic and 24-hour data were collected for comparison after they had had the same test meals. During each period, blood glucose levels were monitored with the CGM for at least 3 days. Mean glucose levels, standard deviations of glucose (SD), time in hypoglycemia (200 mg/dL), range of postprandial glucose increase, time to peak glucose values (time to peak glucose values after each meal and mean time to peak glucose values after 3 meals), and area under the concentration-time curve for glucose (AUC, > 200 mg/dL) were compared between those given Det and those given Deg by using paired t-test. All statistical analyses were performed by using SPSS 22.0. The present study was approved by the Ethics Committee of our university.

Results: Those receiving Det versus Deg had a mean glucose level of 183.3±46.2 mg/dL versus 144.5±37.2 mg/dL (P=0.025) and an SD of 77.4±20.6 mg/dL versus 59.6±17.5 mg/dL (P=0.004), indicating that the glucose values were significantly lower during degludec administration. Those receiving Det versus Deg had a SD during nighttime (midnight to 6:00 AM) was 34.5±27.6 mg/dL versus 16.5±10.4 mg/dL, with their nighttime SD being significantly lower while on Deg (P=0.048). No significant differences were seen in time in hypoglycemia (200 mg/dL) while on Det versus Deg. Their mean preprandial blood glucose level before breakfast was 165.3±83.6 mg/dL versus 102.3±72.3 mg/dL while on Det versus Deg (P=0.010) and their mean postprandial peak level after breakfast was 284.5±60.6 mg/dL versus 200.3±48.2 mg/dL while on Det versus Deg (P=0.004), with the values significantly lower while on Deg. No significant differences were seen at lunch or dinner times. Their AUC (>200 mg/dL) was 44836±36118 versus 16993±18932 while on Det versus Deg, with the AUC being significantly lower while on Deg (P=0.007).

Conclusion: Type 1 diabetic patients receiving insulin detemir or insulin degludec were compared for glycaemic variability by using CGM. Results suggested that insulin degludec appears to be superior to insulin detemir in stabilizing blood glucose levels from late at night through breakfast.

Similar HbA_{1c} reduction and hypoglycaemia with variable time and fixed time dosing of basal insulin pегlispro (BIL) in type 1 diabetes: IMAGINE 7

N.C. Schloot¹, S. Garg², J.-L. Selam³, A. Bhargava⁴, J. Luo⁵, Q. Zhang⁵, J.G. Jacobson⁵, B.J. Hoogwerf⁶;

¹Lilly Deutschland GmbH, Bad Homburg, Germany, ²Barbara Davis Center for Diabetes, University of Colorado Denver, ³Diabetes Research Center, Tustin, ⁴Iowa Diabetes & Endocrinology Center, Des Moines, ⁵Eli Lilly and Company, Indianapolis, USA.

Background and aims: Basal insulin pегlispro (BIL) is a novel basal insulin with a flat profile which has a hepato-preferential action resulting from reduced peripheral effects. The flat profile suggests some variation in dosing intervals will not affect measures of glycaemic control. This Phase 3 crossover study was designed to assess whether variable dose timing was noninferior (margin=.4%) to fixed dose timing for HbA_{1c} after 12 weeks of BIL treatment in patients with type 1 diabetes.

Materials and methods: During the lead-in phase, 212 patients received BIL (evening dosing) for 12 weeks. Of those patients, 182 completed the lead-in phase and were randomised to two 12-week crossover treatment periods comparing fixed time dosing (evening) and variable time dosing (dosing intervals were 8±2 hours to 40±2 hours, with morning dosing on Monday, Wednesday, Friday, and evening dosing on Tuesday, Thursday, Saturday, Sunday).

Results: Patients were mostly Caucasian (96%), approximately 43 years old with diabetes duration of about 20 years. During the 12-wk lead-in, mean ± SD HbA_{1c} decreased from 7.5%±.8 to 6.8%±.7; fasting serum glucose (FSG) decreased from 9.0±3.9 mmol/L (162±69 mg/dL) to 6.9±3.3 mmol/L (123±59 mg/dL). During the randomised phase, variable

timing and fixed timing groups had similar HbA_{1c}, FSG, glucose variability, total and nocturnal hypoglycaemia, and basal and bolus insulin doses (Table). Self-monitored fasting blood glucose was .46 mmol/L (8 mg/dL) lower (LS mean difference) with fixed time dosing compared to variable time dosing (p=.014). Treatment-emergent adverse events (AEs) and serious AEs were similar for both groups. Over 36 weeks, LS mean weight decreased 1.2±.3 kg (p<.001) and mean triglycerides, ALT, and AST increased significantly (all p<.001) but trended toward baseline levels by 4 weeks after BIL discontinuation. No patients met criteria for Hy's law. Twenty patients (9.4%) experienced injection site reactions including injection site swelling and lipohypertrophy.

Conclusion: We conclude that BIL allows 8±2 to 40±2 hour dosing intervals with similar HbA_{1c} compared to fixed time dosing in patients with type 1 diabetes.

Outcomes at Primary Endpoints

Reduced nocturnal hypoglycaemia with basal insulin pегlispro (BIL) compared to insulin glargine (GL): pooled analyses of 5 randomised controlled trials

M. Marre¹, J. Rosenstock², Y. Qu³, S.J. Jacober³, M.J. Prince³, A.M. Chang³, E.J. Bastyr III³;

¹Hopital Bichat Claude Bernard, Paris, France, ²Dallas Diabetes and Endocrine Center, ³Eli Lilly and Company, Indianapolis, USA.

Background and aims: Nocturnal hypoglycaemia is a significant safety concern and limits optimisation of basal insulin dosing to achieve glycaemic goals.

Materials and methods: We compared the novel basal insulin analog BIL, with its flat pharmacokinetic profile and hepato-preferential action, to GL for glucose control in 5 international studies in 3 patient groups

(type 2 diabetes [T2D] basal only, T2D basal-bolus, and type 1 diabetes [T1D]). We conducted integrated analyses to assess HbA_{1c} change and hypoglycaemia events (SMBG \leq 53 mmol/l [\leq 70 mg/dL]) across studies.

Results: Patients (N=4927) were randomised to bedtime BIL or GL in 26-, 52- and 78-week treat-to-target trials. In all patient groups, patients treated with BIL met statistical superiority in the primary outcome of reduction in HbA_{1c}, and had 36%–45% lower nocturnal hypoglycaemia rates. Total hypoglycaemia rates were not significantly different in T2D patients. In T1D patients, total hypoglycaemia rates were higher with BIL and associated with higher rates of daytime hypoglycaemia following bolus insulin administration. There were no statistically significant treatment differences in severe hypoglycaemia rates in the integrated analyses. For symptomatic hypoglycaemia events, the mean SMBG values were not different with BIL vs GL. Continuous glucose monitoring in a subset of T1D and T2D patients showed similar mean duration of individual hypoglycaemia events by treatment groups.

Conclusion: Treatment with BIL compared to GL was associated with greater HbA_{1c} reductions and fewer nocturnal hypoglycaemia events in patients with T1D or T2D.

Basal Insulin peglispro (BIL) provides better HbA_{1c} control with less nocturnal hypoglycaemia than NPH when used in combination with oral agents in type 2 diabetic patients: IMAGINE 6

G. Grunberger¹, L. Chen², Á. Rodríguez³, F.J. Tinahones⁴, S.J. Jacober², J. Bue-Valleskey²;

¹Grunberger Diabetes Institute, Bloomfield Hills, ²Eli Lilly and Company, Indianapolis, USA, ³Eli Lilly and Company, Alcobendas, ⁴Hospital Virgen de la Victoria, Malaga, Spain.

Background and aims: Basal insulin peglispro (BIL) is a novel basal insulin with a flat profile which has a hepato-preferential action resulting from reduced peripheral effects.

Materials and methods: This Phase 3, open-label, treat-to-target (TTT) study assessed if BIL was non-inferior (margin=0.4%) to NPH in reducing HbA_{1c} in insulin naïve patients with type 2 diabetes when added to prestudy oral agents (26-week endpoint).

Results: Patients were randomised to bedtime NPH (n=213) or BIL (n=428; n=213 morning and n=215 bedtime dosing). HbA_{1c} at endpoint was lower for BIL vs NPH (6.8 vs 7.1%; treatment difference [95% CI]: -0.37% [-0.50, -0.23%]; p<0.001). A greater proportion of BIL patients achieved HbA_{1c} <7% (66.3 vs 44.7%; p<0.001) and HbA_{1c} <7% without nocturnal hypoglycaemia (39.1 vs 12.6%; p<0.001). Weight gain did not differ between groups; insulin doses were higher in BIL patients (BIL: 0.40 vs NPH: 0.35 U/kg; p=0.015). Nocturnal hypoglycaemia rates (events/patient/30 d) were lower for BIL vs NPH (0.31 vs 0.61; p<0.001) and total hypoglycaemia rates were similar (BIL: 1.46 vs NPH: 1.73; p=0.092). No significant differences between groups were observed at endpoint for any lipid variables. At endpoint, ALT increased with BIL, but patients with ALT \geq 3X ULN did not differ between groups, with no cases of Hy's law. Injection site reactions were infrequent.

Conclusion: In this TTT study, BIL treatment showed clinically relevant improvements in glycaemic control and a significant reduction in nocturnal hypoglycaemia compared to NPH, consistent with a hepato-

preferential action and reduced peripheral activity.

Clinical performance of a new integrated insulin pump system in adult patients with type 1 diabetes

R. Bilous¹, R. Prager², T.R. Pieber³, S. Ramtoola⁴, P. Narendran⁵, K.D. Barnard⁶, K. Köhler⁷, U. Gelchsheimer⁸, B. Petersen⁸, L. Amstutz⁹, I. Schütz-Fuhrmann²;

¹James Cook University Hospital, Middlesbrough, UK, ²Hospital Hietzing, Vienna, ³Medical University of Graz, Austria, ⁴Royal Blackburn Hospital, ⁵University Hospital Birmingham, ⁶University of Southampton, UK, ⁷Premier Research Germany Limited, Darmstadt, ⁸Roche Diagnostics GmbH, Mannheim, Germany, ⁹Roche Diabetes Care, Inc., Indianapolis, USA.

Background and aims: The Accu-Chek® Insight diabetes therapy system combines a glucose meter with integrated bolus advice and extended data management capabilities with an insulin pump. The use of the new system was evaluated in a multicenter clinical trial conducted in Austria and the United Kingdom.

Materials and methods: Individuals with type 1 (T1) or type 2 (T2) diabetes mellitus (DM) ≥ 18 years of age, and for ≥ 6 months on intensive insulin therapy were eligible for this 6-month study of the new system. All individuals received training on the use of the new system. HbA_{1c} results were evaluated in a central laboratory. Pump signals were captured through data uploads using engineering software. User acceptance of the new system was assessed by means of a self-report questionnaire using an 11-point Likert Scale.

Results: 90 individuals with T1DM were included in the intention-to-treat analyses: age 41.8 (18–75) years, BMI 27.1 (19–41) kg/m², HbA_{1c} 7.8 (5.8–10.8) %, T1DM since 23 (1–49) years. 76 individuals had been previously on insulin pump therapy, and 14 on multiple daily injection (MDI) therapy. 81 individuals completed the study, 9 individuals discontinued the study or were withdrawn. Insulin pump experienced users maintained their mean

baseline HbA_{1c} levels (7.76 \pm 1.00%) at Month 3 (7.58 \pm 0.93%) and Month 6 (7.73 \pm 0.96) after switching from other insulin pump systems, most often the Accu-Chek® Combo system, to the Accu-Chek® Insight system. Mean HbA_{1c} levels decreased in previous MDI users from 7.96 \pm 1.20% at baseline to 7.45 \pm 1.22% at Month 3 and 7.46 \pm 1.08% at Month 6. At month 6, the mean change from baseline was significantly different from 0: -0.50, 95% CI [-0.94; -0.06]. Two episodes each of severe hypoglycemia and diabetic ketoacidosis were reported. Most frequently recorded errors were electronic for the pump, and battery life time related for the meter. User acceptance of the new system was high, with highest ratings given for the ease of use of the insulin pump.

Conclusion: In adults with type 1 diabetes, the new Accu-Chek® Insight diabetes therapy system was effective and safe to use under routine practice conditions. Glycemic control improved when switching from MDI therapy, and was maintained in previous insulin pump users. User acceptance of the new system was high.

Continuous glucose monitoring improved glycaemic control in patients with type 1 diabetes during 52 weeks of insulin pump therapy as well as with basal-bolus insulin regimen

J. Šoupal¹, M. Flekač¹, L. Petruželková², J. Škrha jr.¹, J. Škrha¹, M. Prázný¹;

¹3rd Department of Internal Medicine, 1st Faculty of Medicine, ²Department of Paediatrics, 2nd Faculty of Medicine, Charles University, Prague, Czech Republic.

Background and aims: Insulin pump therapy (CSII) improves glycemic control of patients with diabetes, both individually and in combination with continuous glucose monitoring (SAP - Sensor Augmented Pump). However, the efficacy of long-term use of real-time continuous glucose monitoring (RT-CGM) in patients on multiple daily injections (MDI) is less described. The aim of the study was to compare the efficacy of long-term use of RT-CGM on glycemic control in patients treated with CSII or MDI in comparison to more common schemes based on classical self-monitoring of blood glucose (SMBG).

Materials and methods: In this prospective study, 52 patients with type 1 diabetes were followed up for 1 year (age 36 \pm 13 years, diabetes duration 15 \pm 8 years, HbA_{1c} 68 \pm 10 mmol/mol). Patients were divided into 3 groups with comparable baseline parameters. 17 patients started to use RT-CGM. 18 patients initiated insulin pump therapy alone (without RT-CGM) and 17 patients in a control group continued on MDI and SMBG only. In the first group with RT-CGM, 10 patients started to use insulin pump and sensors (SAP) and the remaining 7 continued with MDI (MDI + RT-CGM). Prerequisite for participation in the first group was the willingness to use sensors $> 70\%$ of the time. At the baseline, all 52 patients were monitored by blinded CGM and underwent a structured education according to type of their future treatment. In addition, groups of patients without RT-CGM were monitored for a week by blinded CGM every 3 months and at the end of the study. The main endpoints were reduction of HbA_{1c}, glycemic variability expressed by the standard deviation of blood glucose (SDT) and the incidence of hypoglycemia (% of time below 3.9 mmol/L). Statistical analysis was performed by nonparametric tests (Kruskal-Wallis and ANOVA-repeated measurement).

Results: After a year, the group of patients on RT-CGM had significantly lower HbA_{1c} (67 \pm 11 vs. 55 \pm 11 mmol/mol; $p < 0.0001$), and both subgroups of patients, with SAP and with MDI + RT-CGM, showed comparable improvement in HbA_{1c}. Insulin pump therapy alone (without RT-CGM) also led to reduction of HbA_{1c} (68 \pm 9 vs. 63 \pm 8 mmol/mol; $p < 0.05$), while in the control group just on MDI significant decrease of HbA_{1c} was not reached (67 \pm 9 vs. 64 \pm 10 mmol/mol; NS). Importantly, any treatment strategy using RT-CGM was superior to insulin pump therapy alone (HbA_{1c}: 55 \pm 11 vs 63 \pm 8 mmol/mol; $p < 0.05$). As compared to the baseline, glycemic variability was lower both, in the group with RT-CGM (SDT: 4.0 \pm 0.7 vs. 3.0 \pm 0.5; $p < 0.0001$) as well as in patients with insulin pumps alone (SDT 3.8 \pm 0.7 vs. 3.4 \pm 0.6; $p < 0.01$). Moreover, reduction of time spent in hypoglycemia was observed only in patients with RT-CGM (8 \pm 4 vs. 6 \pm 3%; $p < 0.01$).

Conclusion: The usage of RT-CGM for 70% of the time or more resulted in significant HbA_{1c} reduction in patients with insulin pumps as well as in patients on MDI. This improvement was greater than the improvement with insulin pumps alone. The combination of RT-CGM and MDI can be a suitable alternative to the SAP system for some patients.

Diabetes control in type 1 diabetes mellitus patients treated with continuous subcutaneous insulin infusion vs multiple daily insulin injections in short and long term follow up

K. Chantziara, S. Koutroumpi, A. Tsartsalis, E. Souvatzoglou, G. Ioannidis, B. Vlassopoulou, V. Tsimihodimos, S. Tsagarakis, C. Vasilopoulos;
Department of Endocrinology, Diabetes & Metabolism, Evangelismos Hospital, Athens, Greece.

Background and aims: Type 1 Diabetes Mellitus (T1DM) is a chronic disease that requires continuous training of patients in order to optimize their blood glucose levels and achieve the goals set for glycated hemoglobin A1c (HbA1c). Patients are often treated with either Continuous Subcutaneous Insulin Infusion (CSII) or Multiple Daily Insulin Injections(MDII). The aim of this study was to investigate the outcome in lowering HbA1c and fasting blood glucose (FBG), as well as the result in body weight (BW) of T1DM patients treated with either CSII or MDII. **Materials and methods:** A retrospective cohort including 291 T1DM patients who were followed in the Diabetes Center of our Department between 2008 and 2014. Two groups were included: 196 patients started on treatment with CSII and 95 treated with MDII. All CSII patients were previously treated with MDII. Both groups received intensive training on how to monitor their blood glucose and how to control both hyper and hypoglycemia. Wilcoxon test was used to calculate each group at baseline vs. one-year (FU1, short-term) and five-year (FU5, long-term) follow up and Mann-Whitney test was used to compare CSII vs. MDII at baseline, one-year and five-year follow up due to not normally distributed variables. Statistical significance was defined when $p < 0.05$.

Results: The patients' age ranged from 20 to 68 years old; diabetes duration since diagnosis ranged from 4 to 48 years. At baseline, there was a statistically significant difference in BW between the two groups, CSII 74.0 kg (64.0-82.5) and MSII 69.0 kg (58.0-78.5), $p=0.043$. HbA1c was significantly reduced from baseline both at one-year as well as at five-years follow up in patients on CSII ($p < 0.001$ for both). HbA1c was reduced significantly in patients on MDII at one-year follow up 7.1% (6.3-8.3), compared to the baseline value 8.0% (6.9-9.3), $p=0.013$, but not at five-year follow up 7.1% (6.5-7.9), $p=0.181$. All other variables were not significantly different. The reduction of HbA1c, FBG and the BW difference between the two groups were not significantly different (Table 1).

Conclusion: Our study demonstrates that both CSII and MDII have comparable results in improving diabetes control both in short and long-term follow up, which could be attributed to the intensive training program applied in this T1DM patient cohort.

Table 1		CSII	MDII	p (sign)	test
BSL	HbA1c (%)	8.0 (7.3-9.1)	8.0 (6.9-9.3)	0.474	Mann Whitney test
	FBG (mg/dl)	166(115-242)	174(103-257)	0.977	
	BW (kg)	74.0 (64.0-82.5)	69.0 (58.0-78.5)	0.043

Cost savings associated with CSII therapy compared to MDI in a Swedish setting

A.-S. Brandt¹, S. de Portu², J. Hellman³;
¹Medtronic Danmark A/S, Copenhagen, Denmark, ²Medtronic International Sàrl, Tolochenaz, Switzerland, ³Uppsala University Hospital, Sweden.

Background and aims: The aim was to estimate the potential clinical and economic benefits of insulin pump therapy (CSII) compared to multiple daily injection (MDI) therapy in a real life setting in Sweden.

Materials and methods: The model used a Markov framework based on a recent meta-analysis where real life data from Uppsala Academic Hospital was used to define baseline cohort characteristics. A 100 patient cohort was modelled over a four year period. Key events modelled were: Severe Hypoglycemic events (SH), Diabetic Ketoacidosis (DKA) and death. Cost of treatment and the costs associated to address acute complications in the Swedish health care setting were retrieved from published literature.

Results: The total cost of CSII for the patient population (including societal cost) over 4 years was 21 365 608 SEK and the total cost of MDI treatment was 44 042 816 SEK. This suggests a total cost saving of 22 677 208 SEK when CSII is selected vs MDI. By avoiding events such as DKA and SH followed associated benefits with the mortality risk of these specific events. In the 4 year time horizon selected, 8 deaths were avoided by using CSII therapy.

Conclusion: The greater cost of the CSII treatment is offset by the reduced costs related to acute complications being avoided due to better control compared to MDI treatment.

986

Efficacy and safety after 1 year of insulin pump therapy in type 2 diabetes: the OpT2mise Study continuation phase

Y. Reznik¹, R. Aronson², I. Conget³, S. Runzis⁴, A.-S. Racault⁴, J. Castaneda⁵, S.W. Lee⁶, O. Cohen⁷;
¹Department of Endocrinology, University of Caen Côte de Nacre Regional Hospital Center, France, ²LMC Diabetes & Endocrinology, Toronto, Canada, ³Endocrinology and Nutrition Department, University Hospital Clinic, Barcelona, Spain, ⁴Medtronic International Trading Sàrl, Tolochenaz, Switzerland, ⁵Medtronic Bakken Research Center, Maastricht, Netherlands, ⁶Medtronic Diabetes, Northridge, USA, ⁷Chaim Sheba Medical Center, Tel Hashomer, Israel.

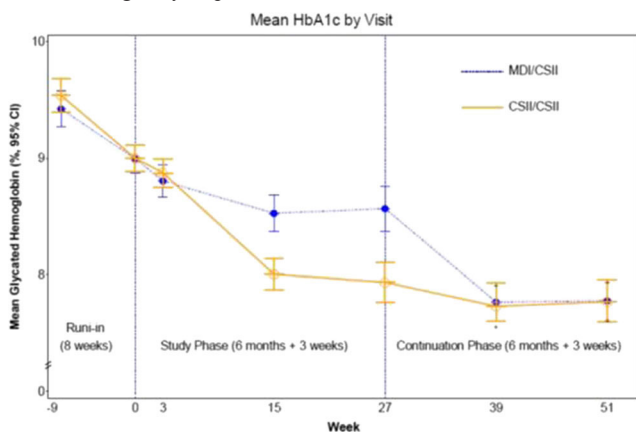

Background and aims: The impact of continuous subcutaneous insulin infusion (CSII) administered to type 2 diabetes patients failing to respond to multiple daily injections (MDI) is still debated. The OpT2mise study was a multicenter, randomized, controlled trial comparing CSII vs MDI in insulin-using patients with T2D.

Materials and methods: Subjects using MDI basal bolus regimen with rapid and slow-acting insulin analogs at a total daily dose (TDD) >0.7 U/kg/d, with persistent hyperglycemia (A1c $\geq 8\%$) after a 8-week optimization period, were randomly assigned to CSII or to continue MDI in the "study phase" (SP) of 6 months. In another 6-month "continuation phase" (CP), CSII patients continued pump therapy while MDI subjects crossed to CSII. Of 331 subjects randomized in the study phase (45.6% women, age 56.0 ± 9.6 yr, BMI 33.4 ± 7.3 kg/m², diabetes duration 15.1 ± 8.0 yr, A1c $9.0 \pm 0.8\%$), 291 completed the 12 months study.

Results: At 6 months, CSII subjects had achieved significantly greater A1c reduction than MDI subjects ($-1.1 \pm 1.2\%$ vs. $-0.4 \pm 1.1\%$, $p < 0.001$) and this effect was maintained until 12 months in the CSII subjects. MDI subjects crossing to CSII after the 6-month SP showed during the CP a -0.8% A1c reduction, with a final A1c similarly dropping at 7.8% in both arms. SP response rate (A1c $< 8.0\%$) was higher in the CSII arm (CSII 55% vs. MDI 28%) but by end of the CP, both groups had achieved

similar response rates of 57%. In the overall patient population, the decrease in A1c at 12 months was independent of diabetes duration, body mass index (BMI), education level, MoCA score, and number of blood glucose self-assessments (SMBG) performed per day. Frequency of SMBG declined similarly in both groups throughout both study phases from a mean of 4.0/day to the 12-month result of 3.4/day for MDI and 3.6/day for CSII subjects. At the end of the SP, TDD was 20.4% lower in the CSII subjects compared to the MDI subjects. During the CP, MDI subjects crossing to CSII showed a 19.0% TDD reduction and finally TDD was equivalent in both groups. There was no between-groups difference in weight gain during the whole study period (CSII: $+2.1 \pm 5.2$ and MDI: $+2.3 \pm 4.9$ kg). No ketoacidosis occurred during the whole study period in both groups. One patient in the CSII subjects and 2 in the MDI subjects experienced severe hypoglycemia during the whole study phase.

Conclusion: OPT2MISE demonstrates that CSII provides a significant advantage in glycaemic control over MDI with a safe and consistent effect in long-term treatment, proving the durability of CSII impact on glucose control during a 1 year period of treatment.

Twelve-week unsupervised day-and-night closed loop insulin delivery during free daily living in adults with type 1 diabetes: a multicentre randomised cross-over study

H. Thabit^{1,2}, L. Leelarathna^{1,2}, S. Dellweg³, J.K. Mader⁴, S. Hartnell², C. Benesch³, H. Kojzar⁴, M. Holzer⁴, L. Heinemann³, M.E. Wilinska¹, T.R. Pieber⁴, S. Arnolds³, M.L. Evans^{1,2}, R. Hovorka¹, AP@Home consortium;

¹University of Cambridge, ²Department of Diabetes and Endocrinology, Addenbrookes Hospital, Cambridge, UK, ³Profil Institut, Neuss, Germany, ⁴Division of Endocrinology and Metabolism, Department of Internal Medicine, Medical University of Graz, Austria.

Background and aims: Closed loop studies in outpatient settings have shown promising results in an up to one week day-and-night application. Prolonged day-and-night home use has not been investigated. In a 12-week open-label prospective multinational three-centre randomised crossover study, we evaluated the efficacy and safety of unsupervised day and night closed-loop insulin delivery compared to sensor augmented pump (SAP) therapy at home settings under free living conditions.

Materials and methods: Twenty-five adults with type 1 diabetes on insulin pump therapy (13 male, age 40.0 ± 9.4 years, HbA1c $8.5 \pm 0.6\%$, duration of diabetes 20.9 ± 9.3 years) underwent 5 weeks of training and optimisation on SAP, followed by two 12-week periods of SAP and day-and-night closed-loop utilising a model predictive control algorithm to direct insulin delivery overnight and between meals and prandial insulin delivery based on standard bolus wizard. The order of interventions was

random with a 4 week washout between study periods. The primary outcome was time when sensor glucose were in the target range between 3.9 and 10.0 mmol/l. Analyses were by intention to treat.

Results: The proportion of time when sensor glucose was in target range between 3.9 and 10.0 mmol/l was significantly increased during closed-loop compared to SAP ($P < 0.001$; Table). Mean glucose and time spent above target range were significantly reduced during closed loop, while time spent below target was low and comparable during both interventions. Hypoglycaemia exposure measured by AUC < 3.5 mmol/l was reduced during closed loop ($P = 0.004$). Glycaemic variability measured by standard deviation of sensor glucose was modestly reduced during closed-loop ($P = 0.001$). Reduction in mean glucose and time spent above target range during closed loop was brought about without changing the total daily insulin delivery ($P = 0.44$).

Conclusion: Prolonged home use of unsupervised day-and-night closed loop under free living conditions in adults with type 1 diabetes is feasible demonstrating improved glucose control and reduced exposure to hypoglycaemia without increasing total daily insulin requirements.

Table: Glucose control based on sensor glucose during day-and-night closed-loop insulin delivery and sensor augmented pump therapy over 12 weeks in 25 participants (mean \pm SD, median (IQR))

	Closed-Loop (n=25)	Sensor augmented pump (n=25)	P ^a
Time spent at glucose levels (%):			
3.9 to 10.0 mmol/l	57.4 \pm 10.2	56.1 \pm 15.3	<0.001
>10.0 mmol/l	29.8 \pm 11.2	40.4 \pm 17.4	<0.001
<3.9 mmol/l	2.7 (1.3, 4.7)	3.0 (1.1, 5.2)	0.15
Mean glucose (mmol/l)	8.7 \pm 1.0	9.5 \pm 1.6	<0.001
SD of glucose (mmol/l)	3.4 \pm 0.6	3.6 \pm 0.6	0.001
AUC _{<3.5} (mmol ² x min)	6.9 (1.8, 13.7)	11.0 (3.3, 23.0)	0.004
Total daily insulin dose (U)	48.7 (40.1, 55.3)	47.1 (41.1, 52.7)	0.44

Psychological aspects of evening and night closed-loop insulin delivery under free living conditions: a 2 months cross-over trial

J. Kropff¹, J. DeJong¹, S. del Favero², J. Place³, M. Messori⁴, B. Coestier³, A. Farret³, F. Boscarì⁵, S. Galasso⁵, D. Bruttomesso⁵, C. Cobelli², E. Renard³, L. Magni⁴, J.H. DeVries¹, AP@home consortium; ¹Internal Medicine, Academic Medical Center, Amsterdam, Netherlands, ²Information Engineering, University of Padova, Italy, ³Endocrinology, Diabetes, Nutrition, Montpellier University Hospital, France, ⁴Civil Engineering and Architecture, ⁵Internal Medicine, University of Padova, Italy.

Background and aims: Closed-loop glucose control or Artificial Pancreas (AP) research is currently at a level that allows assessment of psychological aspects and patients' perspective. In this study we aimed to assess the acceptance of long-term use of a current AP system and its impact on fear for hypoglycaemia and treatment satisfaction.

Materials and methods: In a multicentre, randomized cross-over trial, 35 adults with Type 1 Diabetes using an insulin pump were included. Sensor Augmented Pump (SAP) therapy was used day and night during the control period, while SAP was replaced by closed-loop glucose control from dinner until wake-up in the intervention period. Both intervention periods lasted 8 weeks, were preceded by a run-in and divided by 4 weeks wash-out. The AP acceptance questionnaire, Hypoglycaemia Fear Survey II (HFS-II) and Diabetes Treatment Satisfaction Questionnaire (DTSQs) were administered throughout the study and semi structured interviews were conducted after study completion in a subset of

patients ($n=8$). Normality of data distribution was confirmed, paired t -tests were used for analysis.

Results: Three drop-outs resulted in 32 patients available for analysis, 56.3% female, mean age 48, mean pump treatment duration 10.2 years and a total daily insulin dose of 0.54 u/kg/day. The total AP perspective score was 69.14 (SD 14.71 [95% CI 63.54, 74.73], 76.82% of 90 points max score), indicating a positive attitude towards the AP. Perceived usefulness (42.10, SD 8.73 [95% CI 38.78, 45.42], 77.97% of max score of 54) and perceived ease of use (9.62, SD 2.03 [95% CI 8.85, 10.39], 80.17% of max score of 12) were the highest scoring items in the AP questionnaire. Themes frequently mentioned by patients in the interview were ‘positive effects at work’, ‘improved blood glucose’, ‘less worries about blood glucose’, but also ‘frequent alarms, interfering with sleep and social life’, ‘technological issues’, mainly connectivity problems and ‘demand for an all-in-one device’. No significant difference between AP and SAP was found in fear of hypoglycaemia (as reflected by the HFS-II mean total score, range 0–4, reduction 0.15 vs. 0.06, $p=0.32$, difference 0.09 [95% CI -0.09, 0.27]) or worries about hypoglycaemia (as reflected by the HFS-II worry subscale, range 0–4, reduction 0.19 vs. 0.12, $p=0.53$, difference 0.07 [95% CI -0.15, 0.28]). DTSQs results showed similar treatment satisfaction scores (range 0–36) for the AP and SAP of 28.01 (SD 7.06 [95% CI 25.40, 30.67]) and 28.17 (SD 5.19 [95% CI 26.23, 30.10]).

Conclusion: Our data indicates that current acceptance of the AP is reasonably good. Positive effects of the AP include perceived improved blood glucose and better performance at work, shadowed by frequent technological hassles impacting factors such as nocturnal usability. Patients are equally satisfied with AP and SAP use, without difference in improvement of fear for hypoglycaemia. Current AP technology is promising but diminishing the frequent hassles is needed.

Evaluation of HbA_{1c} in subjects with type 1 diabetes with and without insulin pump transferred from paediatric to adult diabetes care through an adolescence unit between 2002 and 2014

M. Wittrup, E.E. Hommel, S. Hangaard, L. Jelstrup, H.-C. Andersen, M. Hviid, S. Wulff, L. Vinther, M. Ridderstråle; Steno Diabetes Center, Gentofte, Denmark.

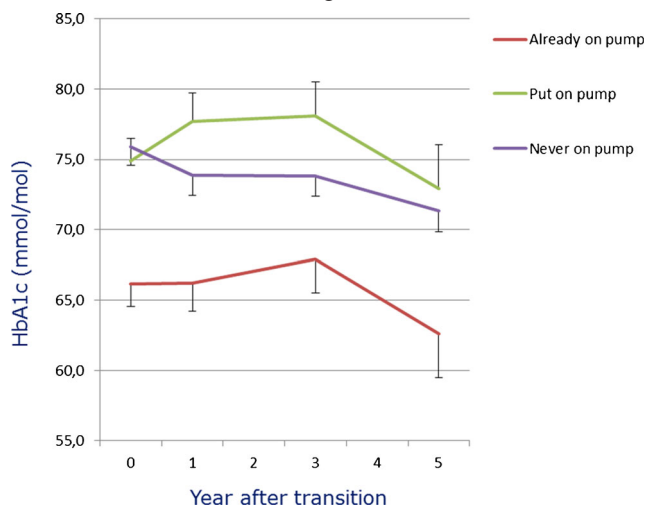

Background and aims: We wanted to evaluate the HbA_{1c} development in adolescent patients with type 1 diabetes (T1D) transferring from a paediatric to an adolescence clinic between 2002 and 2014 with a particular focus on the use of insulin pumps; continuous subcutaneous insulin infusion (CSII). Over time we have observed a decrease in HbA_{1c} at the service and wanted to investigate to what extent this decrease was due to the increased use of CSII in children and adolescents with T1D.

Materials and methods: We included adolescent patients transferred from paediatric departments to our adolescence clinic between 2002 and 2014; in total 480 subjects, 253 males and 227 females in the study. Average age at transfer was (mean \pm SD): 18.6 \pm 1.5 and 18.8 \pm 1.6 years, and diabetes duration 6.6 \pm 4.8 and 7.9 \pm 5.0 years for males and females, respectively. We divided the cohort into three groups: CSII at transfer (C, $n=96$), receiving CSII during follow-up (R, $n=53$) and multiple daily injections (M, $n=331$).

Results: The HbA_{1c} level of patients transferring from pediatric services to our adolescence center has successively and significantly decreased since 2005 up until today (e.g. from 81.1 \pm 25.5 mmol/mol in 2005 ($n=53$) to 69.0 \pm 18.4 in 2014 ($n=54$); $p<0.001$ for the whole study period by One Way Anova. In parallel, the use of CSII has increased from 0 to 40% of patients during the study period ($p<0.0001$). Baseline HbA_{1c} was significantly lower in the C compared to the R and M groups (66.1 \pm 2.2, 74.9 \pm 2.9, and 75.9 \pm 1.2, respectively; $p=0.001$). Patients already

on CSII were older at transfer (19.3 \pm 0.2, 18.8 \pm 0.2, and 18.5 \pm 0.1, respectively; $p<0.0001$), and had a significantly longer duration of diabetes (9.8 \pm 0.5, 8.4 \pm 0.7, and 6.3 \pm 0.3 years, respectively; $p<0.0001$). The 53 patients receiving CSII during follow-up were characterized by a significant decrease in HbA_{1c} between the first and fourth year after transfer (from 78.5 \pm 22.9 to 72.8 \pm 22.4 mmol/mol; $p=0.04$ ($n=27$)). The HbA_{1c} development as a function of time after transfer is illustrated in Figure 1. Over the five year follow-up period there was a non-significant decrease in the HbA_{1c} of patients already on CSII at transfer. Among the other patients there was a slight increase in HbA_{1c} in those subsequently put on pump. Their HbA_{1c} levels decreased parallel to the other patients during the follow-up. Patients considered not in need of CSII either before or after transfer were characterized by a continuous decrease in HbA_{1c} which was significant after five years ($p<0.01$).

Conclusion: Adolescence patients on CSII transitioning from paediatric to adult diabetes care appear to have a lower HbA_{1c} compared to patients on MDI. CSII users trended towards being female and having a longer duration of diabetes. Patients put on CSII post-transition also experience benefits in terms of HbA_{1c} lowering.

PS 094 The rising costs of diabetes

990

The impact of hypoglycaemia on health care use and costs in US patients with type 2 diabetes mellitus newly-initiated on basal insulin

F. Ye¹, M.R. Dalal¹, M. Kazemi¹, L. Xie²;

¹Sanofi US, Inc., Bridgewater, USA, ²STATinMED Research, Ann Arbor, USA.

Background and aims: Insulin use is associated with an increase in hypoglycaemia, which may have a negative impact on insulin therapy persistence, target HbA_{1c} achievement, and health care costs. This retrospective cohort study, of US patients, assessed health care use and costs in those with type 2 diabetes mellitus (T2DM) who experience hypoglycaemia after initiating insulin.

Materials and methods: The MarketScan™ claims databases were used to identify adult patients with T2DM who initiated basal insulin therapy (defined as having no insulin prescription ≥12 months before starting insulin glargine, insulin detemir, or NPH insulin) between January 2007 and March 2013. Hypoglycaemic events were identified by health care encounters with an ICD-9-CM diagnosis code of 250.8× during the first 6 months of basal insulin use. Data were assessed for 12 months prior (baseline) and 12 months after insulin initiation. Differences in baseline demographic and clinical characteristics between patients who had hypoglycaemia during the first 6 months following initiation with basal insulin therapy and those who did not were compared using t-tests for continuous variables, and Chi-squared tests for dichotomous variables. Outcomes were adjusted for differences in demographics, clinical characteristics and baseline health care utilization, and were adjusted using regression analyses. Logistic regression was used to model inpatient admissions and visits to the emergency department (ED). Health care costs were modelled with a generalized linear model.

Results: Of the 134,934 patients identified, 7,371 (5.5%) had hypoglycaemia during the first 6 months; there were significant differences in baseline characteristics between patients (Table). At 12 months, more patients with hypoglycaemia, versus those without, had hospitalizations and ED visits, and greater total and diabetes-related health care costs (Table).

Conclusion: Hypoglycaemia was seen in 5.5% of US patients with T2DM within 6 months after basal insulin initiation, and was associated with greater costs and health care resource use.

Table. Parameters of patients who initiated basal insulin.

Health economic impact of hypoglycaemia in a global population of patients with insulin-treated diabetes

L. Elliott¹, R. Aronson², G. Galstyan³, M. Goldfracht⁴, S.N. Alsifri⁵, R.A. Kapur⁶, K. Khunti⁷;

¹Market Access, Novo Nordisk A/S, Copenhagen, Denmark, ²LMC Diabetes & Endocrinology, Toronto, Canada, ³Endocrinology Research Center, Moscow, Russian Federation, ⁴Clalit Health Services, Tel Aviv, Israel, ⁵Al Hada Military Hospital, Taif, Saudi Arabia, ⁶Novo Nordisk A/S, Søborg, Denmark, ⁷University of Leicester, UK.

Background and aims: HAT (Hypoglycaemia Assessment Tool) was a non-interventional, multicentre, 6-month retrospective and 1-month prospective study of hypoglycaemic events in 24 countries.

Materials and methods: Questionnaires and patient diaries (28-day prospective period) were completed by adults with type 1 (T1DM) or type 2 diabetes (T2DM) and using insulin for ≥12 months (N=27,585).

Results: Patient responses to hypoglycaemia had both direct and indirect economic impact with regional variations in their extent. Direct economic impact included more frequent blood glucose self-monitoring (reported by 69.7% [T1DM] and 60.9% [T2DM] of patients), increased hospitalisation (T1DM 2.1%; T2DM 3.4% of patients) and increased medical contact in the month following hypoglycaemia (T1DM 3.8%; T2DM 6.8% of patients). Indirect economic impact included loss of productivity due to absence from work or study; 3.9% (T1DM) and 6.2% (T2DM) of patients took leave from work following hypoglycaemia. Regional differences included higher hospital admissions in Latin America vs global data (5.2 and 6.8% vs 2.1 and 3.4% of patients for T1DM and T2DM, respectively) and more clinic visits for southeast (SE) Asia vs global data (5.7 and 12.6% vs 3.8 and 6.8%). However, increased blood glucose monitoring was lower for SE Asia vs global data (53.2 and 37.5% vs 69.7 and 60.9% for T1DM and T2DM, respectively).

Conclusion: This study shows that hypoglycaemia has a significant but variable impact on the economics of diabetes healthcare globally.

Impact of the Framingham Offspring Study (FOS) vs Kaiser Permanente NorthWest (KPNW) prediction equations for diabetes mellitus in economic modelling of type 2 diabetes mellitus

C. Asseburg, P. Johansen, A. Nilsson, M. Willis;
The Swedish Institute for Health Economics, Lund, Sweden.

Background and aims: The short- and intermediate-run consequences of overweight and obesity patterns are well-known, including elevated risk of T2DM, micro- and macrovascular complications, and premature mortality. Given worrisome population weight trends in most western countries, estimation of long-term consequences is necessary to allocate health care resources for primary and secondary intervention efficiently. Because trial data of sufficient duration are seldom available, allocation of economic resources is often based on economic simulation modelling. Prediction equations for developing T2DM are a key driver of model outcomes, but the impact of choice of equation is unknown. The aim of this study is to evaluate the performance of two published risk equations in predicting outcomes in the data they were estimated with and in an external study and to compare predictions over the long horizons typical of health economic modelling.

Materials and methods: The Economic and Health Outcomes Model of Weight Management (ECHO-WM), a long-term stochastic microsimulation model, was used to estimate the conversion rate to T2DM for three cohorts of non-T2DM patients matching baseline characteristics of the Framingham Offspring Study (FOS), Kaiser Permanente Northwest (KPNW), and the Diabetes Prevention Study (DPP). ECHO-WM includes both the FOS and the KPNW T2DM equations, yielding six simulations. Key outcomes included the cumulative incidence of T2DM at 8 years for the FOS and KPNW patient cohorts and 10 years for the DPP patient cohort and 25-year cumulative incidences of T2DM and micro- and macrovascular events.

Results: The FOS equation better matched the observed FOS cumulative incidence of 5.1% (5.5% vs. 13.1%) and the KPNW risk equation better matched the observed KPNW cumulative incidence of 16.5% (16.6% vs. 7.2%). The differences were maintained at 25-years. The incidence of microvascular complications followed differences in predicted T2DM, though predicted rates of macrovascular events and life-years were similar. Quality-Adjusted Life-Years were lower with the KPNW equations. Both risk equations underestimated the ~51.8% incidence of T2DM over 10-years in the placebo arm of the enriched (impaired glucose tolerance) DPP cohort (13.8% and 28.4% incidence rates when using the FOS and KPNW equations, respectively).

Conclusion: Simulations using an economic model support the internal validity of the FOS and KPNW equations. External validity, however, was limited and the simulations lend support to concerns that recalibration of the FOS (and by extension the KPNW) equations is necessary for

extrapolation to different patient populations. The FOS and KPNW risk equations provide accurate predictions of the risks in patient populations similar to that which they were estimated from, but may be inaccurate when applied to different patients. Until more accurate prediction equations are available, it is advisable to include multiple risk equations in economic models and use the most appropriate in any given application.

Vildagliptin is cost-effective in real-world: economic evaluation evidence from EDGE study

G. Partha¹, R. Agrawal¹, P.M. Paldanius², R. Viana²;
¹Novartis Healthcare Pvt. Ltd., Hyderabad, India, ²Novartis Pharma AG, Basel, Switzerland.

Background and aims: Therapeutic benefits of vildagliptin have been extensively studied and characterised in randomised controlled trials (RCTs). It is also commonly accepted that RCTs are largely unable to reproduce real-life observations. Therefore, evaluation of outcomes in real-world clinical practice would allow a full understanding of vildagliptin usefulness as an oral antidiabetes therapy alternative. EDGE (Effectiveness of Diabetes control with vildaGliptin and vildagliptin/mEtf-ormin) was a worldwide prospective, non-interventional, ‘real-life’ observational study that compared the effectiveness and tolerability of vildagliptin-based dual combinations with other oral antidiabetes drugs in patients uncontrolled with monotherapy. Unlike sulphonylureas (SUs), vildagliptin was able to provide glycaemic control targets at the same levels as observed in RCTs. However, if this translates to cost-effectiveness in real-world, is yet to be established. Therefore, the objective of this study is to evaluate the cost-effectiveness of vildagliptin+metformin compared with generic SUs+metformin in patients with type 2 diabetes mellitus (T2DM) uncontrolled with metformin, from a real-life perspective.

Materials and methods: Cost-effectiveness was assessed by building a patient-level simulation model based on risk equations from the United Kingdom Prospective Diabetes Study Outcomes (UKPDS) model. The results were generated by simulating a cohort of 10,000 patients for a lifetime time horizon. The model predicted micro- and macro-vascular complications and mortality in yearly cycles. The base case compared metformin+vildagliptin with metformin+SUs. The patients could move on to metformin+basal insulin if they had inadequate glycaemic control (using a threshold of HbA1c >7.5%). Effectiveness parameters for the two strategies were derived from the EDGE study. Cost estimates were based on UK direct medical costs. Both costs and benefits were discounted at 3.5%. The annual therapy costs used were: £110.51, £410.53 and £806.84 for metformin+SUs, metformin+vildagliptin and insulin glargine+metformin, respectively. Hypoglycaemia rates and utility decrements were derived from the literature.

Results: Over the lifetime time horizon, fewer non-fatal diabetes-related adverse events (AEs) were observed in patients treated with metformin+vildagliptin compared to metformin+SUs treated patients that led to a differential AE cost of £190 (£783 versus £973). Nonetheless, addition of vildagliptin compared with SUs led to increased drug acquisition costs that were counter-balanced with reduced costs of AEs, managing morbidities, and monitoring patients. Metformin+vildagliptin yielded an incremental gain of 0.03 quality-adjusted life years (QALYs) and a mean per patient increase in total cost of £548, giving an incremental cost-effectiveness ratio (ICER) of £18,801 per QALY.

Conclusion: In clinical practice, treatment with metformin+vildagliptin resulted in lower incidence of diabetes-related AEs compared to metformin+SUs. Additionally, an increase in health benefits was also observed. Together, these results demonstrate that metformin+vildagliptin is a cost-effective treatment strategy for T2DM in real-life setting.

994

Cost-effectiveness of metformin plus vildagliptin versus metformin plus sulphonylurea for the treatment of type 2 diabetes: a real-life perspectiveR. Viana¹, R. Agrawal², S.-H. Ong¹, P.M. Paldanius¹, G. Partha²;¹Novartis Pharma AG, Basel, Switzerland, ²Novartis Healthcare Pvt. Ltd., Hyderabad, India.

Background and aims: Metformin plus vildagliptin has been previously shown to be cost-effective when compared with metformin plus sulphonylurea (SU) in the Portuguese setting. However, the cost-effective analysis was based on data from a head-to-head randomised controlled trial (RCT) thereby, potentially limiting the external validity and generalisability. EDGE (Effectiveness of Diabetes control with vildaGliptin and vildagliptin/mEtformin) was a worldwide, prospective, non-interventional, real-life observational study that compared the effectiveness and tolerability of vildagliptin-based dual combinations with other oral antidiabetes drugs in patients with type 2 diabetes mellitus uncontrolled on monotherapy. Unlike SUs, vildagliptin was able to provide glycaemic control targets at the same levels as observed in RCTs. However, the cost-effectiveness of vildagliptin in the real-world is yet to be established. Therefore, the aim of this analysis was to determine the cost-effectiveness of metformin plus vildagliptin using the EDGE data and to compare these estimates with the previously published cost-effectiveness results based on the RCT data in the Portuguese setting.

Materials and methods: Cost-effectiveness was assessed by building a patient-level simulation model based on risk equations from the United Kingdom Prospective Diabetes Study Outcomes (UKPDS) model. The results were generated by simulating a cohort of 10,000 patients for a lifetime time horizon. The model predicted microvascular and macrovascular complications and mortality in yearly cycles. The base case compared metformin plus vildagliptin with metformin plus SU. The patients could move on to metformin plus basal insulin if they had inadequate glycaemic control (HbA1c >7.5%). Effectiveness parameters for the two strategies were derived from the EDGE study. Cost estimates were based on direct medical costs only. Costs and benefits were discounted at 5.0%. The annual therapy costs used were: €76.70 and €662.74 for metformin plus SU and metformin plus vildagliptin, respectively. Hypoglycaemia rates and utility decrements were derived from the literature.

Results: Compared with the cost-effectiveness estimates based on the RCT data, average quality adjusted life years (QALYs) increased from 5.63 to 5.73 for metformin plus vildagliptin and 5.74 to 5.77 for metformin plus SU. Average total costs decreased from €13,052 to €12,073 for metformin plus vildagliptin and from €14,310 to €12,544 for metformin plus SU. The decrease in cost for metformin plus vildagliptin was mainly driven by reduction in costs due to complications and adverse events, namely hypoglycaemia. Overall, based on the EDGE data, treatment with metformin plus vildagliptin yielded an incremental cost-effectiveness ratio (ICER) of €11,072 per QALY. This value is within the same range observed for cost-effectiveness assessment based on the RCT data.

Conclusion: This analysis confirms that the cost-effectiveness of metformin plus vildagliptin extends beyond controlled clinical trials, and continues to be cost-effective in real-life settings.

995

Cost-effectiveness of second-line therapies in real-world setting: an economic evaluation of the EDGE study using patient level dataP. McEwan¹, M. Evans², V. Foos³, P.M. Paldanius⁴;¹Health Economics & Outcomes Research, ²University Hospital Llandough, Cardiff, UK, ³IMS Health, Health Economics & Outcomes Research, ⁴Novartis Pharma AG, Basel, Switzerland.

Background and aims: The observational, non-interventional EDGE study showed that a DPP-4 inhibitor, vildagliptin, is efficacious in patients with type 2 diabetes mellitus who have suboptimal glycaemic control on metformin monotherapy in the real-world setting, confirming the results of previous randomised clinical trials (RCTs). Simultaneously the effectiveness of second-line sulphonylurea (SU)-based regimens was decreased in EDGE vs. the results attained in RCTs. Cost-effectiveness evaluations are typically pharmaco-economic modelling based on RCT data, however, there is a growing trend towards the complementary use of real-world patient level data (PLD). Consequently, we sought to perform a health economic evaluation based on data from EDGE study using an established diabetes outcomes model and PLD drawn from the cohort worldwide.

Materials and methods: The IMS Core Diabetes Model (CDM) was used to evaluate the lifetime costs and outcomes of two different regimens: metformin+vildagliptin compared to metformin+SU. Annual therapy costs applied were for metformin+SU: £106.79 (year 1), then £110.51 (year 2+) and for metformin+vildagliptin: £410.53 (year 1), then £412 (year 2+). Therapy escalation at HbA1c of 8.5% was modeled assuming insulin glargine+metformin (cost £899.51; year1, then £806.84; year 2+). Published network meta-analysis data were used to populate the CDM with hypoglycaemia rates. Multivariate regression analysis of PLD output from CDM was undertaken using R version 2.15.2. UK costs (£UK) and health benefits were discounted at 3.5%.

Results: Overall predicted life expectancy (LE) and quality-adjusted life expectancy (QALE) were 16.24 and 11.01, respectively. In multivariate analysis, adjusting for baseline characteristics, metformin+vildagliptin was associated with an increase in LE (0.8 years, $p < 0.001$) and QALE (0.12 years, $p < 0.001$) compared to metformin+SU. Gains in LE and QALE favouring metformin+vildagliptin were driven by an 8.6% and 6.8% reduction in the cumulative incidence of major microvascular and cardiovascular complications. Total costs were £28,512 (metformin+SU) and £27,507 (metformin+vildagliptin); this cost saving favouring metformin+vildagliptin driven by reduced complications and a longer time to insulin intensification compared to metformin+SU.

Conclusion: In the real-world setting, compared to SUs, vildagliptin was estimated to be associated with lower overall costs and additional health benefits. To our knowledge, this is the first report showing the potential of cost savings achievement with use of vildagliptin in detriment of low acquisition cost SUs. These data further highlight the potential role of real-world observational data in assessing health economic value.

996

Healthcare utilisation and costs following initiation of insulin treatment in type 2 diabetes: a long-term follow-up in clinical practiceA. Kalkan¹, J. Bodegard¹, J. Sundström², B. Svennblad², C. Östgren³, P.M. Nilsson⁴, G. Johansson², M. Ekman¹;¹AstraZeneca, Södertälje, ²Uppsala University, ³Linköping University, ⁴Lund University, Malmö, Sweden.

Background and aims: Initiation of insulin is often chosen in type 2 diabetes mellitus (T2DM) patients when blood glucose control with other antidiabetics fail. However, long term changes in resource use and costs in primary and hospital care have not been reported before, important

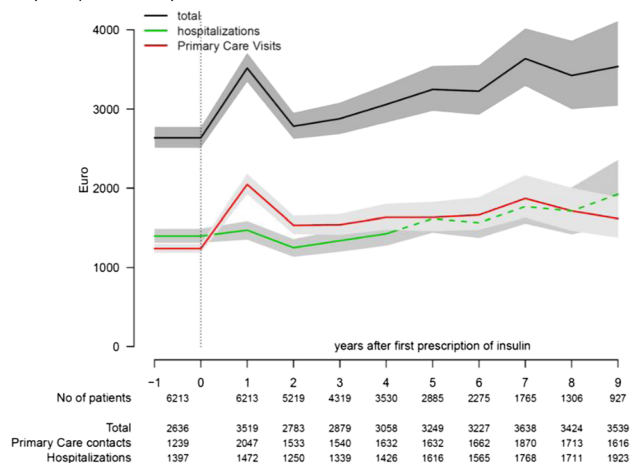

when planning type 2 diabetes health care utilization. The aim of this study was to describe how T2DM patients were initiated on insulin, and describe long-term changes in healthcare utilization and costs before and after insulin initiation.

Materials and methods: T2DM patients newly initiated on insulin were identified in primary health care records from 84 primary care centers (almost 10% of all primary care centers in Sweden), between 1999–2009. The index-date was set to date of first prescription with insulin and patients and at least a second insulin prescription within the following 15 months. Healthcare resource use data, excluding pharmaceuticals, were extracted from electronic primary care medical records in primary care and mandatory national patient register covering in- and outpatient care. The mean healthcare costs per patient are reported as annual and cumulative costs. Patients had to be on insulin treatment during follow-up and were censored when no renewed prescription of insulin was registered within one year.

Results: During a median of 3 years (maximum 9 years) follow-up; 6,213 T2DM patients (18,639 patientyears) were initiated, in combination or as monotherapy, on short-, medium-, mixed medium long and long acting insulin, 3%, 51%, 27% and 19% respectively. Patients initiated on insulin were on average 64 years, 59% men, had HbA1c 7.6%, body mass index, 29 kg/m², blood pressure 140/80 mmHg and LDL 2.7 mmol/l. Mean per patient annual healthcare costs were € 3,519 (95% CI 3,342–3,713) the first year after insulin initiation, € 2,783 (95% CI 2,621–2,955) the second year, and € 3,539 (95% CI 3,042–4,111) in year 9 (2012 unit cost values), see figure. Mean per patient cumulative healthcare costs were € 29,316 (95% CI 27,833–31,106) at 9 years of follow-up. Higher costs were seen in primary care compared with hospital care, € 15,245 (95% CI 14,122–16,578) and € 14,071 (95% CI 13,226–15,043) respectively. The 2,776 patients with HbA1c >7.5% at insulin initiation had lower mean per patient healthcare costs before insulin start compared with the 2,770 patients with HbA1c ≤7.5%, € 2,325 (95% CI 2,189–2,482) and € 2,931 (95% CI 2,717–3,168) respectively.

Conclusion: Initiation of insulin in type 2 diabetes patients were followed by increased costs in both primary and hospital care and higher costs were generated in primary care. Patients with lower HbA1c at insulin start had surprisingly higher initial costs compared to those with higher HbA1c, indicating two different clinical situations when the treatment decision was made.

Figure: Annual costs of primary- and hospital care visits one year prior to insulin prescription and up-to 9 years follow-up

Cost-effectiveness of simple insulin infusion: Sweden

O. Henriksen¹, M. Dall², J. Warner³, C. Parkin⁴;

¹Last Mile P/S, ²CeQur SA., Copenhagen, Denmark, ³CeQur SA., Marlborough, ⁴Cgparkin communications, inc, Boulder City, USA.

Background and aims: Continuous subcutaneous insulin infusion (CSII) in people with type 2 diabetes (T2DM) has proven to improve glycemic control (HbA1c) and reduce insulin dosage compared to multiple daily injections (MDI). However, CSII has not been widely adopted in T2DM due to costs, complexity and training requirements. New devices that provide simple CSII reduce complexity and training requirements. This analysis assessed the cost effectiveness in Sweden of simple insulin infusion (SII) compared to MDI in people with T2DM not in glycemic control.

Materials and methods: The UKPDS Outcomes Model was used to project long-term cost-effectiveness over 40 years, based on results of recently published studies and direct costs for Sweden. Costs and outcomes were discounted at 3%. Cost-effectiveness was pre-defined in relation to per capita gross domestic product (GDP) with Incremental Cost Effectiveness Ratios (ICERs) below 1X, respectively 3X GDP per capita per life year gained, defined as highly 'cost-effective', respectively 'cost-effective'.

Results: Our analysis showed discounted 0.3 life year gained on average and lifetime discounted savings on complication costs and insulin reductions of SEK 88,352. Based on projected direct costs and life expectancy, a simple CSII device will be highly cost-effective in Sweden at a price of SEK 36 per day and cost-effective at a price up to SEK 77. This implied an ICER at 1, 3 times per capita GDP per life year gained for the two cases, respectively. Cost effectiveness would be further supported if indirect costs (i.e. costs of premature mortality and sick leave) were included. These estimates were very robust to sensitivity analyses on both reductions in HbA1c and dose effects.

Conclusion: For people with T2DM not in glycemic control on MDI, simple CSII is highly cost-effective at a daily cost in Sweden of SEK 36 or less and cost-effective at a daily cost of SEK 77 or less in Sweden.

PS 095 Gestational diabetes: pregnancy outcomes

998

The relative importance of maternal body mass index and glucose levels for the prediction of large for gestational age births

R. Claesson¹, E. Anderberg², C. Ignell¹, K. Källén², K. Berntorp¹;¹Department of Clinical Sciences, Lund University, Malmö, ²Department of Clinical Sciences, Lund University, Lund, Sweden.

Background and aims: The risk of gestational diabetes mellitus (GDM) increases substantially with increasing maternal body mass index (BMI). GDM and maternal obesity are independently associated with adverse neonatal outcomes, in particular large for gestational age (LGA) births, which in turn increase the risk of complications among both the newborns and the mother. The aims of the present study were to evaluate the relative contribution of maternal body mass index and glucose levels on the prediction of LGA births in women giving birth in southern Sweden during 2003–2005, and to investigate whether the prediction could be further improved by adding information on maternal characteristics.

Materials and methods: Information on 10 974 pregnancies was retrieved from a population-based perinatal register. A 75-g oral glucose tolerant test (OGTT) was performed in the 28th week of pregnancy for determination of the 2-h plasma glucose concentration. Maternal BMI was calculated from weight and height measured during the first trimester. The prediction of LGA was assessed by receiver-operating characteristic (ROC) curves, with LGA defined as birth weight > +2 SD of the mean. The data set was divided into a development and a validation set. Using the development set, predictive maternal variables were identified by multiple logistic regression analysis. The predictive ability of the model was then validated in the test sample.

Results: Based on the total data set, the area under the ROC curve (AUC) of the 2-h glucose level to predict LGA was 0.54 (95% confidence interval (CI) 0.48–0.60), indicating poor performance. Factors associated with LGA in the final multiple regression analyses were BMI (per 1-step increase), 2-h glucose concentration (per 1 mmol/L increase), smoking and parity 1 (less than 2–3 reference): odds ratio (OR) (95% CI) were 1.10 (1.08–1.13), 1.09 (1.01–1.18), 0.29 (0.16–0.52) and 0.51 (0.40–0.67), respectively. Using the validation data base, the AUC for the developed model was 0.69 (95% CI 0.66–0.72), which was identical to the AUC retrieved from a model not including 2-h glucose, and larger than a model including 2-h glucose but not BMI (AUC 0.63, 95% CI 0.60–0.67).

Conclusion: Both the 2-h glucose level of the OGTT and maternal BMI had a significant impact on the risk of LGA births but the relative contribution was higher for BMI. The data support the importance of targeting healthy body weight in young women and to closer monitor weight during pregnancy as a strategy in reducing the risk of excessive fetal growth. *Supported by: Malmö University Hospital and Skåne Research and Development Foundation*

Gestational weight gain is associated with obstetric and neonatal outcome in morbid obese mothers with gestational diabetes

B. Barquiel, J.L. Bartha, L. Herranz, D. Meneses, M.A. Burgos, N. Hillman, L.F. Pallardo;
Diabetes and Pregnancy Unit, Hospital Universitario La Paz, Madrid, Spain.

Background and aims: To study the effect of gestational weight gain (GWG) on pregnancy-induced hypertensive disorders (PIHD), caesarean deliveries, neonatal ponderal index (NPI) and macrosomia in morbid

obese women with gestational diabetes (GDM) and to evaluate the best upper limit of weight gain in these women.

Materials and methods: Observational retrospective study in 2747 women with GDM (NDDG criteria) between 1986 and 2012. Multiple pregnancies, pregestational diabetes and secondary causes of hyperglycaemia were excluded. A number of 118 (4.3%) consecutive GDM women being morbidly obese pre-pregnancy (BMI ≥ 35 kg/m²) were included. GWG was measured as the difference between last prenatal weight and self-reported pre-pregnancy weight. Associations between GWG and PIHD (140 and/or 90 mmHg \pm proteinuria ≥ 300 mg/24 hours at >20 weeks' gestation), caesarean deliveries, NPI (neonatal birthweight / p50 for gestational age and sex) and macrosomia (neonatal birthweight ≥ 4000 g) were assessed. Spearman correlations or Mann Whitney U tests were used in bivariable comparisons. The effect of GWG on the associated outcomes ($p < 0.05$) was adjusted for pre-pregnancy BMI and glycaemic control (average of monthly HbA1c) in multiple stepwise forward linear or binary logistic regression models. For each model constructed, GWG threshold values to predict an outcome were examined on the basis of sensitivity (S) and specificity (E) values under the ROC curve.

Results: Median GWG was 4.5 (IQ 1.3–8.2) (range -18 to 17.5) kg. Median pre-pregnancy BMI was 37.4 (IQ 35.8–40.4) (range 35.0 to 52.1) kg/m². Concerning other risk factors for GDM, mean age was 32 \pm 5 yr, 80 (67.8%) women had family history of diabetes, 12 (10.2%) had GDM in a previous pregnancy and 15 (12.7%) previous macrosomia. Forty three (36.4%) women were nulliparous. Gestational age at GDM diagnosis was 19.8 \pm 6.0 weeks (in 48 (40.7%) cases before 24 weeks). GDM class was A1 in 71 (60.1%) and A2 in 47 (39.9%). Mean average HbA1c was 5.3 \pm 0.5%. PIHD occurred in 41 (34.7%) women and caesarean delivery in 49 (41.5%). Mean NPI was 1.03 \pm 0.17 and the rate of macrosomia was 12 (10.2%) of the newborns. GWG was 6.5 (IQ 2.7–11) in PIHD vs. 4.0 (0.9–6.6) kg in non-PIHD women ($p = 0.027$). GWG ≥ 8 kg was very specific to predict PIHD (S=40.0%, E=90.0%). GWG was not associated with caesarean delivery. GWG and NPI were positively correlated ($r = 0.227$, $p = 0.017$). GWG was related to macrosomia: 7.2 (4.4–14.0) vs. 4.4 (1.0–7.5) kg ($p = 0.044$). GWG ≥ 5.5 kg correctly classified macrosomic newborns (S=77.8%, E=61.5%) and GWG ≥ 11 kg was highly specific (S=44.0%, E=99.0%) to detect macrosomia.

Conclusion: Morbid obese women with GDM and GWG ≥ 8 kg are at a high risk of PIHD. We suggest an upper GWG threshold of 5.5 kg in morbid obese women in order to reduce macrosomia.

1000

Triglyceride-glucose index is related to neonatal overgrowth in mothers with gestational diabetes

D. Meneses¹, O. Moreno¹, B. Barquiel¹, M.A. Burgos², N. Hillman¹, L. Herranz¹;¹Diabetes, ²Obstetrics, Hospital Universitario La Paz, Madrid, Spain.

Background and aims: Diabetes during pregnancy is associated with abnormalities in protein and lipid metabolism in addition to those of glucose metabolism. A positive correlation between maternal serum triglyceride (TG) level and newborn birthweight has been reported. The TyG index, the product of fasting plasma glucose (FPG) and TG has been suggested as a surrogate of insulin resistance in healthy subjects. Our objective is to determine whether maternal TyG index is associated with newborn birthweight at term.

Materials and methods: A number of 223 consecutive women diagnosed with gestational diabetes mellitus (GDM) between 2009 and 2015 were followed. Multiple pregnancies were excluded. FPG and serum TG concentrations were determined at 27 \pm 5 (1) and 34 \pm 2 (2) weeks of gestation. The TyG index was calculated as $\ln[\text{Fasting TG (mg/dL)} * \text{FPG (mg/dL)}] / 2$. At term, neonatal weight was registered and fetal ponderal index (FPI) calculated. Infants with birthweight above the

90th percentile were classified as LGA, based on gestational age and sex-adjusted birthweight from Spanish neonatal growth charts. Pearson's correlation coefficients between TyG index, birthweight and FPI were computed, respectively. T-test were applied to calculate TyG mean differences between LGA and non-LGA neonates. A p-value <0.100 was considered statistically significant.

Results: Women's mean age was 35.1±4.6 years. Pre-pregnancy BMI was 25.8±5.4 kg/m². Gestational weight gain was 9.2±5.7 kg. Gestational age at diagnosis was 24.9±4.7 weeks. Mean FPG of oral glucose tolerance test and HbA1c were 90.5±13.2 mg/dl and 5.2±0.4%, respectively. FPG1 was 85.2±15.9 mg/dL, median TG1 175 (144-227) mg/dL and TyG1 4.8±0.2; FPG2 was 82.0±10.9 mg/dL, TG2 205 (150-254) mg/dL and TyG2 4.6±0.2 (p =0.000, 0.001 and 0.008, respectively). Gestational age at delivery was 38±1 weeks with a birthweight of 3126±504 g and a FPI 0.98 (0.92-1.06), identifying 17 (7.6%) newborns as LGA. Maternal TG1, TG2 and TyG1 levels were not correlated with birthweight and FPI and were not different in LGA newborns. TyG2 index was positively correlated with birthweight (r=0.221, p=0.023) and FPI (r=0.219, p=0.027). Mean TyG2 index was higher in LGA newborns (4.9±0.2 vs. 4.8±0.2, p=0.073).

Conclusion: The TyG index is a simple parameter of insulin resistance that can be calculated from routine laboratory data and, according to our results, it is related with birthweight. Even in well-controlled GDM pregnancies, this index at 32-36 weeks of gestation is related to neonatal overgrowth.

1001

Differences in characteristics and pregnancy outcomes between insulin- and diet-treated women with gestational diabetes

K. Robyns¹, F. Nobels², P. Van Crombrugge², N. Deprez², B. Seynave³, R. Devlieger⁴, J. Verhaeghe⁴, C. Mathieu¹, K. Benhalima¹;

¹Endocrinology, UZ Gasthuisberg, KU Leuven, ²Endocrinology, OLV ziekenhuis Aalst-Asse-Ninove, Aalst, ³Obstetrics & Gynecology, OLV ziekenhuis Aalst-Asse-Ninove, Aalst, ⁴Obstetrics & Gynecology, UZ Gasthuisberg, KU Leuven, Belgium.

Background and aims: The predictors for insulin use and the difference in pregnancy outcomes between insulin- and diet-treated women with gestational diabetes (GDM) remain unclear in different populations. Our aim was to evaluate the difference in characteristics and pregnancy outcomes between insulin- and diet-treated women with GDM in Belgian patients.

Materials and methods: Retrospective analysis of the medical files from 01-01-2010 till 31-12-2013 of women with GDM diagnosed with the Carpenter & Coustan criteria attending two large obstetrical clinics, one in a university and another in a non-university hospital. The prevalence of GDM in these centers at the time of the study was respectively 3.3% and 5.1%. Clinical and biochemical characteristics associated with insulin use were analyzed. Multivariable logistic regression was used to adjust for confounders such as age, BMI, weight gain, ethnicity and multiparity. For women attending the university hospital, indices of insulin sensitivity (the Matsuda index and the reciprocal of the homeostasis model assessment of insulin resistance, 1/HOMA-IR) and an index of beta-cell function, the Insulin Secretion-Sensitivity Index-2 (ISSI-2) were calculated.

Results: Over a 4 year period, 601 women were identified with GDM, with a mean age of 31.9±4.8 years and of whom 32.2% were overweight and 22.9% were obese at first prenatal visit. 24.2% needed insulin. Compared to diet-treated women, women on insulin more often had an ethnic minority background (33.3% vs. 21.6%, p=0.004), more often had a history of GDM (21.5% vs. 10.4%, p=0.002), were more often multiparous (59.3% vs. 47.6%, p=0.044) and were diagnosed with GDM earlier in pregnancy (weeks 25.3±4.9 vs. 27.1±3.7, p<0.0001). When undergoing an oral glucose tolerance test (100 g OGTT) women treated with insulin had a higher fasting glycaemia (97.6±18.8 vs. 87.7±10.3, p<

0.0001), a higher 1 hour glycaemia (197.7±30.1 vs. 184.5±25.8, p<0.0001), a higher 2 hour glycaemia (185.2±28.5 vs. 175.0±22.8, p<0.0001) and more often 3 and 4 abnormal values (58.1% vs. 37.8%, p<0.0001 and 24.8% vs. 7.7%, p<0.0001), with higher HbA1c levels at the time of the OGTT (5.5±0.6 vs 5.2±0.5, p<0.0001). ISSI-2 (1.3±0.5 vs. 1.7±0.5, p<0.0001) and 1/HOMA-IR [0.01 (0.001-0.002) vs. 0.02 (0.01-0.03), p=0.027] were significantly lower in women on insulin. Women on insulin more often received corticoids in preparation of preterm delivery (11.0% vs. 2.4%, p<0.0001). Insulin did not prevent adverse outcomes, as women on insulin had higher rates of large-for-gestational age infants (LGA) (28.5% vs. 13.1%, p<0.0001) and more cesarean sections (44.1% vs. 27.0%, <0.0001), remaining significant after adjustment for confounders.

Conclusion: Compared to diet-treated women with GDM, women treated with insulin have a higher metabolic risk profile, impaired beta-cell function and lower insulin sensitivity. Rates of LGA and cesarean sections were higher in insulin-treated women.

How to improve worse pregnancy outcomes in immigrant pregnant women such as in comparable Italian ones by insulin treatment and/or education

G. Silvani¹, A. Albonetti², S. Acquati³, P. Zanasi², H.N. Inostroza Vellozo²;

¹Primus Forli Medical Center, Villa Maria Hospital, ²Woman Health Service, AUSL of Forli, ³Endocrinology and Metabolic Diseases, G.B. Morgagni - L. Pierantoni Hospital, Forli, Italy.

Background and aims: Immigration of foreign workers and families to northern Italy increased more and more in the past three decades: at the same time a growing incidence of gestational diabetes (GDM) has been detected in our Diabetes Unit, owing to immigrant pregnant women more than to Italian ones. Pregnancies have been more frequent in foreign women (29.7% while foreigners percentage is only 9.6% of the whole population) and the overall incidence of GDM in the last five years has been much higher in the immigrant (22.4%) than in the Italian pregnant women (10.6%). Aim of this study was to compare maternal features and pregnancy outcomes in 2 cohorts of immigrant and Italian pregnant women with GDM, according to diagnostic criteria of IADPSG (International Workshop Conference on Gestational Diabetes) Consensus Panel (2008), enrolled from July 2010 to December 2014. Moreover we investigated whether an insulin treatment or an intensive educational program could improve the outcomes in two subgroups of immigrant women.

Materials and methods: 182 immigrant and 168 Italian pregnant women were compared for age, body mass index (BMI) before pregnancy, gestational age at diagnosis of GDM, HbA1c at diagnosis and before delivery, need of insulin treatment, weight gain, timing and mode of delivery and, as fetal outcomes, birth weight and number of LGA (Large for Gestational Age) infants. The immigrant pregnant women were a multi-ethnic population, to which an iso- or slightly hypocaloric diet was prescribed and training to self blood monitoring performed. Eventually two subgroups of immigrant pregnant women, 48 and 51 respectively, were randomly allocated to insulin treatment, analogue aspart in three doses before meals, or to an intensive educational program for six weeks, HbA1c and weight gain being evaluated.

Results: Immigrant and Italian pregnant women were well-matched for age (33.2±/−5.8 vs 39.2±/−4.8 years, p=ns) and pre-pregnancy BMI (28.6±/−5.5 vs 27.7±/−6.4 kg/sq.m, p=ns). No difference was found in HbA1c at diagnosis, need of insulin treatment (21.4 vs 19.7%, p=ns) and mode of delivery: cesarean section 44.9 vs 43.8%, p=ns (currently performed in 28.3% of pregnancies in our country). The immigrant women had a more advanced gestational age at diagnosis (27.5±/−5.1 vs 24.3±/−4.8 weeks, p<0.01) but an earlier one at delivery (38.3±/−1.6 vs 39.5±/−

1.7 weeks, $p < 0.05$), a higher pre-delivery HbA1c (5.8 ± 0.4 vs $5.2 \pm 0.4\%$, $p = 0.03$) and a greater weight gain (12.14 ± 3.87 vs 8.57 ± 3.68 kg, $p < 0.01$). Birth weight (3676 ± 652 vs 3423 ± 455 g, $p < 0.01$) and rate of LGA infants (8.1 vs 12.3% , $p < 0.05$) were higher in newborns of immigrant women. The outcomes of two subgroups on insulin or intensive education did not show any significant difference after six weeks: a comparable decrease of HbA1c (-1.1 ± 0.3 vs $-0.9 \pm 0.2\%$, $p = \text{ns}$) and a similar weight gain (2.1 ± 0.4 vs 2.0 ± 0.5 kg, $p = \text{ns}$).

Conclusion: The immigrant pregnant women and the comparable Italian ones had similar pre-pregnancy features but different outcomes, likely due to socio-economic factors and cultural barriers, in spite of the same given access to our health care system. In the two random subgroups on insulin therapy or intensive education, we surprisingly found the two treatments being both and likewise effective.

1003

Gestational diabetes mellitus after gastric bypass surgery

C. Nilsson¹, D. Ursing², H. Strevens³, M. Hillman⁴, J. Dereke⁴, M. Landin-Olsson²;

¹Department of Pediatrics, ²Department of Endocrinology, ³Department of Obstetrics and Gynecology, ⁴Diabetes Research Laboratory, Institution of Clinical Science, Lund University, Sweden.

Background and aims: The number of obese women in childbearing age is increasing and the most common and effective weight loss treatment is gastric bypass (GBP). Overweight is a risk for developing Gestational Diabetes Mellitus (GDM) and therefore all pregnant women who have undergone GBP are screened for GDM in our region. The aim of this study was to compare eventual differences in demographics and pregnancy outcome among women who had undergone a GBP and developed GDM during pregnancy against those who did not develop GDM.

Materials and methods: Since 2012 all women in our region who have undergone GBP are screened for GDM with a three day plasma glucose profile. The regular oral glucose tolerance test is not performed because of the risk for dumping symptoms. During 2012–2014 there were 73 pregnant women who had undergone a GBP earlier and not developed GDM during pregnancy and these were compared against 11 women who had undergone a GBP and also developed GDM.

Results: When comparing pregnant women who had undergone GBP against the other pregnant women who had undergone GBP and also developed GDM, there was no significant difference between the groups regarding age of the mother, ethnicity, family history of diabetes, smoking habits, education level, years after GBP surgery, first weight/height/BMI of the mother during pregnancy, the mother's weight gain during pregnancy and weight at delivery, gestational length, birth weight/length of the child, Apgar score at 1, 5 and 10 minutes of the child, weight of placenta and number of caesarian deliveries.

Conclusion: No characteristic pattern was found for those who developed GDM during pregnancy after GBP surgery. Due to the small number of observations it is important to continue screening all pregnant women who have undergone GBP for GDM.

PS 096 Gestational diabetes: predictors and consequences

1004

Gestational diabetes: metabolic risks of adult women in respect to birth weight

D. Vejrazkova¹, P. Lukasova¹, M. Vankova¹, O. Bradnova¹, G. Vacinova¹, J. Vcelak¹, V. Cirmanova¹, K. Anelova², H. Krejci³, B. Bendlova¹;

¹Institute of Endocrinology, Prague 1, ²Department of Mother and Child Care, Prague 4, ³1st Faculty of Medicine of Charles University and General University Hospital, Prague 2, Czech Republic.

Background and aims: Metabolic disorders such as obesity, insulin resistance and other components of metabolic syndrome (MetS) are associated with birth weight (BW). Low BW is associated with higher risk of developing type 2 diabetes mellitus, the mechanism is not clear. In this study, we evaluated the association between BW and anthropometric as well as biochemical components of MetS in women with a history of special diabetic condition - gestational diabetes mellitus (GDM). In part of the tested women, we evaluated metabolic changes over the years.

Materials and methods: All 456 women involved in the study gave birth at least once. Depending on the course of pregnancy, they were divided into gestational diabetics (GDM, $n = 376$) and controls (C, $n = 80$). Anthropometric characteristics of BMI, WHR, waist, hips, and abdomen circumferences were evaluated. Glucose metabolism was defined by basal glucose, insulin, proinsulin, C-peptide and glucagon. These parameters were also monitored 7 times during the 3-hour oGTT. Lipid profile included total cholesterol, HDL-CH, LDL-CH, TG and FFA. Furthermore, blood pressure, uric acid, thyroid hormones, and liver enzymes were assessed. 150 women from this cohort (100 GDM and 50 C) were completely re-examined after at least 5 years. Statistical analysis: Mann-Whitney test, Repeated Measures ANOVA (NCSS 2004).

Results: From all the components of MetS tested in the study, BW was systematically associated solely with glucose metabolism: In GDM group, low BW (below 25th percentile) was associated with higher postchallenge insulinemia during oGTT (AUC I7 $p = 0.002$), C-peptide levels (AUC C-pep7 $p = 0.0001$), and with lower indices of insulin sensitivity (Matsuda $p = 0.02$, Cederholm $p = 0.002$) compared to medium (25th–75th percentile) and high (above 75th percentile) BW categories. Re-examinations in the GDM group indicate this association lasts over the years. Repeated measures ANOVA confirms BW as a significant factor for glucose processing. In the group of controls only borderline significance between low BW and higher postchallenge glucose levels (AUC Glc7 $p = 0.04$) was found.

Conclusion: From the evaluated biochemical and anthropometric components of MetS in adult women we proved the association of low BW with glucose processing, in particular among women with a history of GDM. Low BW GDM women reveal significantly higher postchallenge insulin secretion and, accordingly, lower peripheral insulin sensitivity. This association persists long after delivery.

Hypovitaminosis D in 1st trimester may predict gestational diabetes

P. Khandavalli, R. Chawla, H. Punyani, S. Gupta;
Diabetes, Maharaja Agrasen Hospital Punjabi bagh, New Delhi, India.

Background and aims: Pregnancy is nature's gift that should be nurtured over nine months with no adverse outcome. Gestational Diabetes Mellitus affects 3 to 10% of pregnancies, depending on the population studied. The progressive increase of insulin resistance observed in pregnancy

contributes to the pathophysiology of gestational diabetes mellitus (GDM). There is controversy whether vitamin D deficiency contributes to abnormal glycemic regulation in pregnancy

Materials and methods: We tested the associations between first trimester 25-hydroxyvitamin D3(25OHD3) levels and the risk of developing GDM in a large hospital-based prospective cohort of pregnant women. Participants (n=200) were seen at first (6-13 weeks) and second (24-28 weeks) trimesters for blood samples. Each participant was selected in their first trimester and demographic parameters were recorded. Height in cms, weight was measured in kg's. BMI was calculated as weight (kg)/height (m²). Family history of Diabetes, Obstetric score for gravidity, history of previous abortion and previous history of GDM was recorded. Fasting blood sugar was measured and in those >92 mg/dl HbA1c is done and those with >6.5% were excluded. Those with FBS value of 140 mg/dl, Oral Glucose tolerance test (OGTT) was done and diagnosed as GDM or NGT based on ACOG criteria.

Results: Based on ACOG criteria, 18 participants (9%) developed GDM. 25(OH) Vitamin D level was deficient in 190 participants (95%) and subgroup analysis revealed 25(OH) Vitamin D3 level of <20 nmol/l in 48% of participants. On logistic regression analysis for GDM risk factors, Advancing age, Increased BMI and 25(OH) Vitamin D3 level of <20 nmol/l were significantly associated with risk of GDM. 25(OH) Vitamin D3 level <20 nmol/l was found to be significantly associated with increased risk of GDM however our study found this risk was evident only in advanced maternal age (29.07±1.68).

Conclusion: Severe Hypovitaminosis D was present in 48% of study participants. Pregnant females with very low vitamin D (<20 nmol/l) are at odds of 2.45 in relation to increased risk of development of Gestational Diabetes mellitus. In our study we found that advanced maternal age in parallel with simultaneous very low vitamin D level may contribute to insulin resistance and increased risk of GDM.

Table 1: Family history of Diabetes, Gravidity and history of abortion in relation to development of GDM among those with 25(OH) Vitamin D3 level <20nmol/l.

Study variable		GDM		Chi square value	p
		Yes N(%)	No N(%)		
Family History of diabetes mellitus	Yes	25 (73.5%)	9 (26.5%)	5.972	0.015*
	No	57 (91.9%)	5 (8.1%)		
Gravidity	Primigravida	30 (90.9%)	3 (9.1%)	1.128	0.27
	Multigravida	52 (82.5%)	11 (17.5%)		
History of abortion among multigravida (n=113)	Yes	12 (70.6%)	5 (29.4%)	2.308	0.12*
	No	40 (87.0%)	6 (13%)		

1006

Maternal stress predicts insulin resistance in pregnancy

G. Valsamakis¹, D. Papatheodorou¹, N. Chalarakis¹, E. Kapantais², A. Mantzou³, A. Margeli⁴, I. Papassotiriou⁴, G. Mastorakos¹;

¹Endocrine Unit, 2nd Department Obs&Gynae, Athens Medical School, ²Diabetes Obesity Metabolism, Metropolitan Hospital, ³Paidon Aghia Sofia Hospital, ⁴Biochemistry, Paidon Aghia Sofia Hospital, Athens, Greece.

Background and aims: Endometrial environment affects maternal metabolism and fetal growth during pregnancy. It is not known yet to what

extent maternal stress could affect maternal glucose metabolism and fetal growth. Aim was to investigate the association of maternal stress and fasting stress hormones (CRH and cortisol) with insulin resistance and fetal growth.

Materials and methods: The investigation was approved by the local ethical committee and it has been performed in accordance with the ethical standards laid down in the Helsinki Declaration. Consent has been obtained from each patient after full explanation of the purpose and nature of all procedures used. Eighty five pregnant, with no history of diabetes mellitus, primigravidae Caucasian women (mean ± SD); age: 27.7±3.6 years; pre-pregnancy BMI 26±2.1 kg/m² were recruited during the second trimester of pregnancy from an Obstetrics and Gynecology outpatient clinic of a university hospital. Women were seen randomly in the clinic at the second and third trimester and had their weight measured, a 75gr OGTT with insulin and glucose measured, HOMAR values were estimated and fasting (9:00 am) serum CRH, cortisol and IL6 were measured. Three women were diagnosed with gestational diabetes and were withdrawn from the study. During the visits they had fetal ultrasound (US) measurements of abdominal and head circumference. A specialist clinical psychiatrist interviewed them with STAI state and trait stress questionnaires and scored them. The STAI state questionnaire is composed of 20 questions about how the individual feels at that particular period. The STAI trait questionnaire is composed of 20 questions about how the person usually feels. A p-value of <0.05 was considered to be statistically significant.

Results: In the second trimester maternal cortisol (r=0.53), CRH (r=0.35) and STAI state score (r=0.82) were positively associated with HOMAR (p<0.05). Best predictor of HOMAR was STAI state score (p=0.01, beta=0.88) among STAI trait score, CRH, IL6 and cortisol levels and maternal weight. Best predictor of US fetal abdominal circumference was serum cortisol (p=0.028, beta=0.638) among STAI state and trait scores, CRH and IL6 levels and maternal weight. In the third trimester cortisol (r=0.65) and STAI state score (r=0.35) were associated with HOMAR and the latter was its best predictor (p=0.013, beta=0.83) among STAI trait score, maternal weight and CRH, IL6, cortisol levels.

Conclusion: Maternal stress, as assessed by STAI state score which shows how the woman feels at that particular period studied, seems to affect insulin resistance during pregnancy. The stress hormone cortisol is associated with fetal abdominal circumference. Stress assessment by STAI state score at initial stages of pregnancy could be a potential risk factor tool of insulin resistance and possibly fetal growth in the outpatient clinic.

1007

Selective screening for gestational diabetes development based on risk factors

M. Vladimirova, T. Tankova, I. Atanasova;
Clinical Center of Endocrinology, Sofia, Bulgaria.

Background and aims: Gestational diabetes (GDM) development is one of the most common complications during pregnancy. It is speculated that OGTT should be performed only on women with high risk for GDM. The aim of the present study was to assess the predictive value of risk factors for GDM established by selective screening and to identify subgroups of women at a higher risk of developing GDM.

Materials and methods: 1300 pregnant women between 24 and 28 weeks of gestation were recruited for the purposes of the study. They have undergone standard OGTT as part of screening program for GDM in Clinical Center of Endocrinology. For GDM diagnosis we have use the IADPSG criteria and logistic regression analysis for identifying significant risk factors.

Results: We found 29.1% (378) prevalence of GDM. The application of the selective screening criteria would result in the execution of an oral glucose tolerance test (OGTT) in 55.1% of women and 24 (24.0%) cases

of GDM would not be detected due to the absence of any risk factors. The presence of relatives with diabetes type 2 increase 1,394 ($p < 0,034$) risk for GDM development. Furthermore, the presence of I and II line relatives with diabetes type 2 additionally increase the risk (OR 2.523 ($p < 0.001$)). Body mass index (BMI) between 25 and 29.9 kg/m² before pregnancy increases the risk 1.629 (p30kg/m² 4,162 ($p < 0.0001$)). Women above 30 years of age have significantly higher risk (OR 2.245, $p < 0.371$). Other significant risk factors were higher random blood sugar (OR 3,883 ($p < 0.0001$)) and the need of assisted reproduction as method for conception (OR 2.123, $p < 0.001$).

Conclusion: The lack of established national screening program necessitates the active search for pregnant women at high risk for GDM development. Identifying major risk factors will categorize the women, who will benefit from performing OGTT and thus how reducing their risks, if having GDM.

The growth patterns in children born to mothers with gestational diabetes mellitus

J. Rutkowska, E. Bandurska-Stankiewicz, D. Wiatr-Bykowska, K. Myszkowska-Podgórska, E. Kuglarz, W. Matuszewski; Endocrinology, Diabetology and Internal Medicine, University of Warmia and Masuria, Olsztyn, Poland.

Background and aims: The aim of the study was to assess if gestational diabetes mellitus (GDM) influences the pregnancy outcomes and the growth patterns in children.

Materials and methods: Our prospective study cohort consisted of 261 children born to mothers with GDM and 153 control children born to non-diabetic mothers. In both groups children's birth weight, and length were assessed. Children were matched for large for gestational age (LGA) (birth weight >90th percentile for gestational age), appropriate for gestational age (AGA) (birth weight between the 10th and 90th percentile for gestational age), small for gestational age (SGA) (birth weight <10th percentile for gestational age) status. Children anthropometric measurements were made at 12, 18, 24, and 30 months after their birth. BMI was calculated. The overweight was diagnosed at BMI between 90-96 percentile, obesity between 97-100 percentile. The WHO child growth standards were implemented. The bioethics committee agreement was obtained.

Results: Among 261 children born to mothers with GDM, 80.5% were AGA, 10% SGA, 9.6% LGA; in control group - 75.2% AGA, 5.9% SGA, and 19% LGA. Birth weight of the children in GDM pregnancies was 3.30 ± 0.53 kg comparing to the control children 3.42 ± 0.54 kg, $p = 0.01$. No weight and BMI differences were found between groups in the 12th month of life. The weight >90 percentile at this period was observed in 37.7% GDM children, comparing to 32.4% in control group. BMI between 90-96 percentile was found in 15.63% and between 97-100 percentile in 15.63% GDM children comparing to 18.6% and 18.6% respectively in control group. At the age of 18 months the weight of children born to GDM mothers was >90 percentile in 54.8% comparing to the control group in 29%, $p = 0.04$; No changes were found in BMI. At the age of 24 and 30 months we found no differences in BMI between both groups.

Conclusion: We found that children who were LGA at birth were less often born to GDM mothers after implementation of dietary regiment comparing to general population. GDM did not influence the growth pattern in first 36 months of live.

A randomised trial of the effects of prenatal education of overweight or obese pregnant women to prevent childhood overweight: the ETOIG study

S. Parat¹, V. Negre², A. Baptiste¹, M.-T. Tauber³, P. Valensi⁴, A.-M. Bertrand⁵, M. Dabbas⁶, C. Elie¹, F. Lorenzini³, E. Cosson⁴;

¹AP-HP, PARIS, ²Hôpital Saint Jacques, RePPOP-FC, Besançon, ³CHU, TOULOUSE, ⁴AP-HP, BONDY, ⁵CHRU, BESANCON, ⁶AP-HP, RePPOP-IDF, PARIS, France.

Background and aims: We aimed to evaluate whether pre and perinatal education of overweight or obese pregnant women would reduce childhood overweight.

Materials and methods: Four French centers included before 20 weeks of gestation 268 pregnant women who were overweight or obese before pregnancy (BMI 32.5 ± 5.4 kg/m², obesity 62%, age 30.4 ± 5.0 years). They were randomized in a control group (n=136: routine care including at least one dietary visit) and an interventional group (n=132). This intervention which included 2 individual and 4 collective dietary counseling at 18, 26, 33 weeks of gestation and 2 months after delivery aimed to educate the future mother for infant and maternal nutritional aspects, without weight objectives. The primary objective was postnatal catch-up growth from birth to two years (>0.67 DS), which is associated with obesity in childhood.

Results: Events during pregnancy were similar in both groups, including incident gestational diabetes mellitus, maternal gestational weight gain and birth weight. The rate of postnatal catch-up growth was similar in interventional and control groups: in intention to treat (59.1 vs 60.3% respectively, $p = 0.84$), in available data (AD n=206) and in per-protocol population (PP n=177). Disappearance of maternal overweight 2 years after delivery was more frequent in the interventional group (AD, n=149: 12.9 vs 3.8%, $p = 0.04$; PP, n=128: 10.7 vs 4.2%, $p = 0.18$). The children were less likely with BMI >19 kg/m² (corresponding to the 97eme percentile) when they were 2 years old (AD, n=204: 0 vs 6.8%, $p = 0.014$; PP, n=176: 0 vs 6.4%, $p = 0.03$).

Conclusion: Intervention based on education and nutritional counseling in women with overweight / obesity, starting at more than three months of gestation, has no effect on postnatal catch-up growth but appears to prevent overweight in mothers and obesity in children two years after delivery.

Clinical Trial Registration Number: NCT00804765

Should HbA_{1c} be used for the diagnosis of glucose tolerance disorders in women with a history of gestational diabetes mellitus?

E. Anastasiou, M. Apostolakis, A. Papadimitriou, E. Zapanti, V. Vasiliou, A. Saltiki, M. Alevizaki; Alexandra Hospital, Athens, Greece.

Background and aims: Women with a history of Gestational Diabetes Mellitus (GDM) present an increased risk for Diabetes Mellitus 2 (DM2). Thus it is recommended to perform an oral glucose tolerance test (OGTT) after delivery. Recently use of A1C has been proposed as a simpler and faster method to diagnose glucose tolerance disorders. The aim of this study is to investigate whether A1C measurement can replace OGTT in the detection of pre-diabetes and diabetes in women with a history of GDM.

Materials and methods: 1336 women with a history of GDM after delivery were studied. All women had been evaluated through an OGTT and a simultaneous A1C measurement. ADA criteria were used for the assessment of dysglycemia. Sensitivity and specificity of A1C were measured for the prediction of diabetes and pre-diabetes; Cohen's coefficient of agreement (k) was also calculated. ROC analysis was performed to

evaluate the sensitivity and specificity of A1C for detection of abnormal glucose tolerance.

Results: Based on OGTT, 725 (54.3%) women were normal, Impaired Fasting Glucose (IFG)=406(30.4%), Impaired Glucose Tolerance (IGT)=48(3.6%), IFG+IGT=74 (5.5%) and 83 women presented with DM2 (6.2%). On the contrary, using A1C as a criterion of dysglycemia 1150 (94.1%) women were normal, while 49 (4.0%) had an impaired A1C and 23 (1.9%) were diagnosed as DM2. Sensitivity of A1C for the diagnosis of pre-diabetes was 5.3% in comparison to OGTT, specificity was 99.2%, while for the diagnosis of DM2 the percentages were 29.6% and 100% respectively. The consistency in classifying abnormal glucose tolerance between A1C and OGTT was 59.7% (Cohen's coefficient of agreement $k=0.116$). Performing a ROC curve, the optimal value of discriminating ability of A1C was 5% for the prediction of pre-diabetes and diabetes.

Conclusion: The study showed that A1C measurement has a very low sensitivity in detecting pre-diabetes and diabetes in women with a history of GDM. Hence, we suggest that the ADA proposed thresholds cannot be used as an alternative to OGTT in this regard.

A model for individual prediction of diabetes up to five years after gestational diabetes mellitus

C. Ignell¹, E. Anderberg², M. Ekelund¹, K. Berntorp¹;

¹Department of Clinical Sciences, Malmö, ²Department of Clinical Sciences, Lund, Lund University, Sweden.

Background and aims: Gestational diabetes mellitus (GDM) is a major risk factor for subsequent diabetes. A cumulative diabetes incidence of 30-50% within five to ten years after GDM has been described. In southern Sweden universal screening with a 75-g OGTT during pregnancy has been applied since 1995. Using the WHO criteria from 1999 to define GDM we have previously reported a diabetes incidence of 6% 1-2 years after delivery. The aim of the present study was to identify risk factors associated with diabetes development based on a 5-year follow-up of these women and to develop a prediction model to be used on an individual basis when counselling women after GDM.

Materials and methods: Five years after GDM a 75-g OGTT was performed in 362 women, excluding women already diagnosed with diabetes at the 1-2 year follow-up visit or later ($n=45$). All but 21 women had results from follow-up at 1-2 years, while 84 women were lost from that point. Predictive variables were identified by multiple logistic regression analysis. The performance of the developed model was assessed in receiver operating characteristic (ROC) curves.

Results: Five years after GDM, 28/362 (8%) women were diagnosed with diabetes whereas 187/362 (52%) had normal glucose tolerance (NGT). Among the latter, 139/187 (74%) also had NGT at 1-2 year follow-up. In univariate regression analysis, using NGT at 1-2 and 5 years as the reference, diabetes at 1-2 year follow-up or later ($n=73$) was clearly associated with easily assessable clinical variables, such as BMI at 1-2 year follow-up, 2-h OGTT glucose concentration during pregnancy and non-European ethnicity ($p<0.001$). A prediction model based on these variables, resulting in 86% correct classifications with an area under the ROC curve of 0.91 (95% CI 0.86-0.95), was applied in a function sheet line diagram illustrating the individual effect of weight on diabetes risk.

Conclusion: The results highlight the importance of BMI as a potentially modifiable risk factor of diabetes after GDM. For motivational purposes, a patient information function sheet illustrating the effects of weight versus diabetes risk is proposed as a model to be used on an individual basis, see Figure. As an example, a European woman with a height of 1.75 m, a 2-h OGTT plasma glucose concentration in pregnancy of 9.8 mmol/l and a weight of 90 kg one year after pregnancy would have a 60% risk of diabetes, declining to 20% with a weight loss of 20 kg.

Your weight versus predicted risk of diabetes

Circle your current weight and draw an arrow to your desired weight.
Put a cross each month to logg your progress towards your goal.

Figure. The prediction model applied in a function sheet line diagram of individual risk of diabetes up to five years after gestational diabetes versus weight. The individual example is depicted in the conclusion of the abstract. To confirm understanding and enforce active engagement by the woman, an appeal of interaction with the diagram is added.

Metabolic changes during oral glucose tolerance test in healthy pregnancy and gestational diabetes mellitus revealed by LC-MS-based metabolomics

B.A. Raczowska¹, M. Ciborowski², J. Godzien³, B. Telejko¹, C. Barbas³, A. Kretowski^{1,2}, M. Gorska¹;

¹Department of Endocrinology, Diabetology and Internal Medicine, ²Clinical Research Centre, Medical University of Bialystok, Poland, ³Centre of Metabolomics and Bioanalysis (CEMPIO), Universidad CEU San Pablo, Madrid, Spain.

Background and aims: Gestational diabetes mellitus (GDM) is manifested by changes in such metabolites as lysophospholipids, bile acids, fatty acids and amino acids. However, its pathogenesis and mechanisms responsible for complications caused by GDM are still not entirely clear. In order to evaluate which metabolic pathways are affected by glucose load metabolomics was applied. Serum samples obtained during oral glucose tolerance test (OGTT) were fingerprinted by LC-QTOF-MS. Among different tools used in metabolomics, LC-MS is characterized by the highest sensitivity and dynamic range therefore this method was chosen to perform the experiment. The aim of the present study was to examine serum metabolic changes in response to glucose load in patients with GDM and healthy pregnant women.

Materials and methods: The study group contained 129 pregnant women who underwent a 75 g-OGTT between 24–28 weeks of gestation. Fasting, 1 h and 2 h serum samples were collected from each participant during OGTT. Patients were divided into two groups: primary set (n=67) and validation set (62), both consisted of GDM and healthy pregnant women (control). Serum samples were fingerprinted using LC-QTOF-MS. Data was collected in ESI (+) and ESI (-) mode (50–1,000 m/z). Prior to statistical analysis, quality assurance protocol was applied to keep only metabolic features with good repeatability. Statistical analysis was performed independently in both sets and afterward only statistically significant metabolites (p-value <0.05), common in both sets, were selected for MS/MS analysis to confirm their identification. Depending on the data distribution, paired t-test or Wilcoxon signed rank test were used and obtained p-values were corrected by application of Benjamini-Hochberg false discovery rate test.

Results: Around 140 metabolic features changed significantly after glucose load. The differences concerning about a hundred of them were observed irrespective of the presence of GDM, while other changes were significant only in the control group or patients with GDM. The list of metabolites that differed significantly at 2 h of OGTT in comparison to the fasting state in both groups included dicyclohexylurea (+85%, p<10⁻⁷) and several fatty acids (e.g. eicosadienoic +120%, p<10⁻⁴; stearolic -48%, p<10⁻⁴; oleic -55%, p<10⁻⁸). A significant decrease (14–21%, p<0.03) in phosphatidylethanolamine and sphingomyelin at 2 h of OGTT was observed only in patients with GDM. On the other hand, in the GDM group we did not observe any significant changes in several metabolites, which increased markedly at 2 h of OGTT in the control group (e.g. lysophospholipids [12–20%, p<0.01] and choline [58%, p<0.01]).

Conclusion: Our results suggest that glucose load causes mainly the derangement of lipid metabolism. The changes in fatty acids were observed irrespective of the presence of GDM, whereas choline containing lipids and choline itself were affected in a different way in control and GDM samples. However, further investigations are needed to evaluate the role of observed changes in the metabolism of choline and choline containing lipids in the development of GDM and its complications.

Testing for genetic associations in gestational diabetes mellitus (GDM): preliminary results from the EFSD New Horizons study

K. Rosta¹, Z. Al-Aissa², O. Hadarits³, J. Harreiter⁴, A. Zoka², D. Bancher-Todesca¹, L. Nemeth⁵, J. Rigo⁶, A. Kautzky-Willer⁴, G. Fimeisz⁷;

¹Department of Obstetrics and Fetomaternal Medicine, Medical University Vienna, Austria, ²2nd Department of Internal Medicine, ³1st Department of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary, ⁴Department of Internal Medicine 3, Medical University Vienna, Austria, ⁵Department of Probability Theory and Statistics, Eötvös Loránd University, Budapest, Hungary, ⁶Department of Obstetrics and Gynecology, ⁷2nd Department of Internal Medicine, Semmelweis University, Hungary, Budapest, Hungary.

Background and aims: To identify maternal single nucleotide gene polymorphisms (SNPs) associated with GDM or influencing fasting and 2 hours glucose levels at OGTT.

Materials and methods: A set of 77 SNPs was selected based on their previously reported contribution to beta-cell dysfunction or genesis, incretin effect, K⁺-channel function, amyloid formation, zinc transport, insulin resistance, obesity, IGF system, glucose homeostasis, neuronal regulation of appetite, energy balance or immunoregulation. The majority of these SNPs were previously reported to be associated with either type 2 diabetes or with a metabolic trait. Thus far 149 pregnant women with GDM, 269 non-diabetic pregnant women and 154 neonates born to mothers with GDM and 274 neonates born to non-diabetic mothers were enrolled. This study was conducted in two Hungarian and one Austrian centers. Genomic DNA was isolated from a total of 846 samples using a magnetic bead based robotized approach (Hamilton Robotics, Magna Starlet). PCR-based KASP™ genotyping (FRET based) assay (LGC Genomics) was used for the bi-allelic discrimination of SNPs. Logistic regression (logit) risk model and subsequent algorithms written in "R" statistical programming language were used to assess Odds Ratios, p-values and to detect potential gene-gene interactions. Maternal gene variants were also assessed for association with fasting and 2 hours plasma glucose levels at routine OGTT (24–28th gestational week).

Results: Carrying a G allele of the rs10830963 of the melatonin receptor 1B (MNTR1B) or a G allele of the rs6832769 of the clock circadian regulator (CLOCK) genes were most significantly associated with the binary trait of GDM (OR=1.708–1.56, p<10⁻⁵). In qualitative trait analysis we found that the rs10830963 in MNTR1B was consistently associated with increased fasting and 2 hours glucose levels. The rs10871777 (G allele) of the melanocortin 4 receptor (MC4R) was associated with an increase in 2 hours plasma glucose values at OGTT. In contrast, the A allele of the rs1143634 of the interleukin 1 beta (IL1B) gene was associated with decreased fasting glucose levels. We identified significant gene-gene interactions between MC4R and CLOCK gene variants (rs10871777-rs6832769 and rs17782313-rs6892769 with OR=2.09, p=1.4×10⁻³ and OR=2.11, p=1.1×10⁻³, respectively) and between rs10830963 of MNTR1B and rs4712526 of the CDK5 regulatory subunit associated protein 1-like 1 (CDKAL1) gene (OR=2.17, p=1.7×10⁻³) when interactions were analyzed for GDM binary trait.

Conclusion: Our preliminary data suggest that a few SNPs could be associated with GDM or qualitative traits. Surprisingly, the identified gene polymorphisms are likely to participate in neuronal regulation of appetite, circadian rhythm, energy balance, immunoregulation or are with unknown function.

The role of hepassocin in gestational diabetes mellitus

H.-T. Wu^{1,2}, M.-T. Su³, P.-Y. Tsai³, H.-Y. Ou⁴, C.-J. Chang¹, C.-L. Wu⁵, P. Wu⁶;

¹Department of Family Medicine, ²Research Center of Herbal Medicine, New Drugs, and Nutritional Supplements, National Cheng Kung University, ³Departments of Obstetrics and Gynecology, ⁴Department of Internal Medicine, College of Medicine, ⁵Department of Biochemistry and Molecular Biology National Cheng Kung University Medical College, National Cheng Kung University and Hospital, Tainan, Taiwan, ⁶Institute of Institute for Science & Technology in Medicine, Keele University, UK.

Background and aims: Gestational diabetes mellitus (GDM) is hyperglycemia that is first detected during pregnancy and does not meet the criteria for manifest diabetes. GDM is associated with the development of preeclampsia, the birth of a big baby, emergency cesarean section, birth trauma, and neonatal hypoglycemia. In addition, it is a risk factor for obesity, type 2 diabetes and cardiovascular diseases in the mother and her offspring. However, there is no suitable biomarker for the screening of GDM that leads to the diagnosis of this condition is delayed. Recently, a novel physiological function of hepassocin was found that increased hepassocin levels activated ERK1/2 to induce insulin resistance; however, the role of hepassocin in GDM is still unknown. Thus, the aim of this study is to investigate the role of hepassocin in GDM.

Materials and methods: Fifteen subjects for each group including normal control and GDM groups were enrolled. GDM was diagnosed by 75-g oral glucose challenge test screening at 24–28 weeks of gestation. The plasma samples were collected to examine hepassocin concentrations by enzyme-linked immunosorbent assay. In addition, the placenta was also collected for the expression of hepassocin by reverse transcriptase-polymerase chain reaction, and western blots, as well as immunofluorescent staining. 3A-sub-E trophoblasts were used to evaluate the physiological effect of hepassocin in placenta. The effect of hepassocin on insulin-induced glucose uptake was determined by L6 myoblasts.

Results: The expression of hepassocin was detected in the placenta, and the placental expression level of hepassocin was increased in GDM as compared with control group. The result from immunofluorescent staining indicated that hepassocin was mainly expressed in the trophoblasts of placenta. In addition, interleukin-6 treatment induced the expression of hepassocin in 3A-sub-E trophoblasts. The serum concentrations of hepassocin were significantly increased in patients with GDM (N=15 for each group) ($P<0.01$). Treatment with hepassocin in trophoblasts significantly increased the migration of trophoblast through an ERK1/2-dependent pathway. In addition, hepassocin disrupted insulin signaling to decrease insulin-induced glucose uptake in L6 myoblasts.

Conclusion: Inflammation in the placenta of GDM increased the expression of hepassocin and the elevated hepassocin in circulation further led to the insulin resistance in skeletal muscle, and affected glucose utility. In addition, hepassocin increased the migration of trophoblasts and this effect might be correlated with the increased weight of placenta in GDM. Thus, we provided a novel mechanism in the development of GDM by hepassocin.

Oxidative stress and gestational diabetes: the impact on placenta, perinatal outcomes and postpartum evolution

C. López-Tinoco¹, M.M. Roca-Rodríguez², F. Visiedo-García³, C. Rosendo³, R.M. Mateos-Bernal³, M. Aguilar-Diosdado¹;

¹Endocrinology, Hospital Puerta del Mar, Cádiz, ²Endocrinology, Hospital Virgen de la Victoria, Málaga, ³Investigation Unit, Hospital Puerta del Mar, Cádiz, Spain.

Background and aims: The simultaneous existence of a placental oxidative stress and maternal-placental interactions during Gestational Diabetes Mellitus [GDM] are still not well understood. The aim of the study was to evaluate the levels of oxidative stress markers and antioxidants in women con GDM, and to assess the impact on the placenta oxidative status and perinatal outcomes.

Materials and methods: One hundred twenty six pregnant women (63 with GDM, 63 controls) were enrolled and 41 cases and 21 controls were recruited for the following-up study. Markers oxidative stress and antioxidants status were measured during 24th and 29th week of gestation and twelve months after delivery; moreover, 6 placenta from healthy pregnant women and 6 from women with GDM were studied.

Results: In the postpartum period, we found significant increases of levels of Lipoperoxides [LPO] ($p<0,001$) and catalase ($p<0,001$) and significant declines of levels of glutathione peroxidase [GPX] ($p=0,003$) in both (GDM and controls). In addition, in cases had lower levels of glutathione transferase [GST] ($p=0,003$) and in controls had lower levels of superoxide dismutase [SOD] ($p<0,001$), respectively. In order to investigate the influence of clinical and metabolic variables on postpartum period, multiple regression analysis was performed and the levels of oxidative stress and antioxidant markers postpartum were significantly associated with the GDM. We observed that the levels of GPX ($p=0.012$) and LPO ($p=0.04$) were significantly related to the percentage of Caesarean deliveries, while the percentage of macrosomia was related to the levels of GPX ($p=0.01$). In GDM placenta a significant increase was noted in the levels of carbonyl protein ($p<0,05$), LPO ($p<0,05$) and reduced antioxidants enzymatic activities of SOD ($p<0,05$) and catalase ($p<0,05$) compared to controls.

Conclusion: We concluded that increased oxidative stress and reduction in antioxidant defense mechanisms appeared in the mother and GDM placenta. These maternal and placental oxidant/ antioxidant imbalances could lead to maternal and fetal complications and should be carefully considered.

1016

Pregnancy induces an insulin resistance promotin hepatic ceramide phenotype in mice

L.I. Høllgren, C. Ingvorsen;

DTU Systems Biology, Technical University of Denmark, Kgs. Lyngby, Denmark.

Background and aims: Temporary insulin resistance (IR) develops in women during pregnancy, in order to ensure appropriate supply of nutrients to the growing fetus. This physiological adaptation can develop into a pathological insulin resistance and overt gestational-diabetes mellitus (GDM). Understanding the mechanism behind the normal pregnancy-induced IR is an important tool to elucidate key molecular mechanisms leading to GDM. Altered ceramide-metabolism has been implicated in the development of type-2 diabetes mellitus (T2DM). In particular ceramide species produced by ceramide synthase 6 (CS6) have been identified as potential inducers of hepatic IR. We therefore hypothesise that pregnancy induced IR is caused by altered ceramide metabolism, with a higher flux through CS6 and increased production of ceramide species with the ability to induce IR.

Materials and methods: Fasting glucose and insulin was analysed in age-matched non-pregnant (n=12) and pregnant mice (gestations day 18, n=10). Hepatic lipids were extracted and fractionated into different lipid classes. Ceramide content and composition was analysed using liquid chromatography-MS. Ceramide species were identified based on exact mass, fragmentation pattern and retention time. Quantification was performed using internal standard and external standard curves. Pairwise comparisons were performed using Mann-Whitney U-test. Ceramide composition was assessed by principal component analysis (PCA) and differences between principal components for pregnant (P) and non-pregnant (NP) dams was also analysed using Mann-Whitney U-test.

Results: Fasting insulin (NP: 0.18 ± 0.13 ng/mL, P: 0.45 ± 0.13 ng/mL, $p < 0.01$), but not fasting glucose (NP: 7.7 ± 1.1 mM, P: 8.4 ± 0.9 mM, $p = 0.19$), was increased at gestation day 18, compared to the non-pregnant dams. Total hepatic ceramide concentration was elevated in pregnant dams (NP: 4.9 ± 0.6 mg/g tissue, P: 8.1 ± 0.9 mg/g tissue, $p < 0.0001$), while hepatic TAG-levels were unaffected. The PCA analysis of ceramide profile strongly separated the pregnant from the non-pregnant dams along PC1 ($p < 0.0001$), which explained 46% of the variation in the data. The loading plot revealed that ceramide in pregnant dams were characterized by relatively shorter saturated acyl groups (C16:0 and C18:0), i. e. those synthesized by CS6, while the non-pregnant dams were characterized by the longer-chained, C22:0, C24:0 and C24:1, ceramides, synthesized by ceramide synthase 2. Total hepatic ceramide correlated to QUICKI (Spearman $r = -0.57$, $p = 0.03$), but the correlation to ceramide composition (given as PC1) was stronger (Spearman $r = -0.70$, $p = 0.003$).

Conclusion: In late stage of pregnancy, the hepatic ceramide profile is characterized by ceramide species that are known drivers of insulin resistance, while it in the non-pregnant state is characterized by ceramide structures that have been shown to attenuate IR in high-fat fed mice. This suggests that pregnancy-induced IR can partly be explained by altered metabolic fluxes through the different ceramide synthases pathways, resulting in altered ceramide composition. This interpretation is supported by the strong correlation between ceramide composition and QUICKI.

A role for kisspeptin in regulating beta cell mass during pregnancy

J. Bowe, T. Hill, S. Persaud, P. Jones;
King's College London, UK.

Background and aims: Whilst effects of kisspeptin on islet function have previously been studied the physiological role remains unclear. The extremely high levels of kisspeptin released by the placenta suggest a possible role during pregnancy, characterised in the islets by a rapid and reversible increase in beta-cell mass. This study therefore examined the effects of kisspeptin on beta cell mass in pregnant and non-pregnant mice.

Materials and methods: Control or pregnant mice were implanted with subcutaneous osmotic minipumps containing either saline, kisspeptin (50 nmol/day) or the kisspeptin antagonist kisspeptin-234 (200 nmol/day) and were given water containing 1 mg/ml BrdU for 10 days (from day 8-18 of pregnancy). Immunohistochemical staining of pancreas sections for BrdU and insulin followed by morphometric analysis was used to assess beta-cell proliferation, beta-cell hypertrophy and islet mass.

Results: Kisspeptin administration in non-pregnant mice had no effect on beta-cell proliferation, assessed by the extent of BrdU labelling, compared to untreated non-pregnant mice (non-pregnant: $7.83 \pm 0.72\%$, non-pregnant + kisspeptin: $8.65 \pm 1.18\%$, percentage of BrdU positive beta-cells, $n = 6$). Kisspeptin also had no significant effect on beta-cell hypertrophy in non-pregnant mice (non-pregnant: 107.8 ± 12.3 $\mu\text{m}^2/\text{cell}$, non-pregnant + kisspeptin: 116.3 ± 8.9 $\mu\text{m}^2/\text{cell}$, beta-cell size, $n = 6$). However, administration of kisspeptin-234 in pregnant mice significantly attenuated the increased beta-cell proliferation associated with pregnancy

(pregnant: $21.42 \pm 1.19\%$, pregnant + kisspeptin-234: $16.91 \pm 1.07\%$, percentage of BrdU positive beta-cells, $n = 6$, $p < 0.05$). Similarly, blocking endogenous placental kisspeptin attenuated pregnancy related beta-cell hypertrophy (pregnant: 194.3 ± 11.5 $\mu\text{m}^2/\text{cell}$, pregnant + kisspeptin-234: 162.7 ± 13.1 $\mu\text{m}^2/\text{cell}$, beta-cell size, $n = 6$, $p < 0.05$).

Conclusion: These data indicate that endogenous kisspeptin increases beta-cell proliferation and hypertrophy, supporting a role for placental kisspeptin in regulating the increase in beta-cell mass during pregnancy. The lack of significant effect of kisspeptin on beta-cell mass in non-pregnant mice suggests that this is likely to be an effect specific to the pregnant environment and may involve other factors.

The role of long non-coding RNAs in beta cell mass expansion during mouse pregnancy

A. Zhou¹, G. Sisino¹, B. Tyrberg¹, M. Soundarapandian², M. Althage¹, E.-M. Andersson¹, N. Dahr³, E. Larsson³;

¹AstraZeneca R&D Mölndal, Sweden, ²Sanford-Burnham Medical Research Institute, Orlando, USA, ³University of Gothenburg, Sweden.

Background and aims: Pregnancy is accompanied by a remarkable pancreatic islet β -cell mass expansion, whereas progression of type 2 diabetes (T2D) correlates with β -cell mass loss. Long non-coding RNA (lncRNA) is a novel RNA species with emerging evidence highlighting its multiple regulatory functions in biology and diseases. Strikingly, lncRNA tissue distribution suggests a higher degree of specificity compared to coding genes in particular cell types, such as in human islets. The aim of this study is to identify functionally important lncRNAs in β -cell expansion during pregnancy that are β -cell specific, and therefore, putative candidate drug targets or biomarkers.

Materials and methods: We performed a microarray analysis on islets isolated from non-pregnant and pregnant mice at gestational day 14.5 (peak β -cell proliferation). Bioinformatic approaches were applied to compare a public RNA-seq dataset with our microarray data to identify differentially expressed lncRNAs during pregnancy. The differential expression of candidate lncRNAs were verified using real time RT-PCR in a mouse beta-cell line (MIN6c4) and isolated primary mouse islets treated with prolactin to mimic pregnancy and induce β -cell proliferation.

Results: We identified a small number of lncRNAs that were differentially expressed in pancreatic islets during pregnancy from RNA-seq analysis ($P < 0.01$). Most of them displayed a similar expression pattern in the microarray analysis. As an initial approach, we validated the expression of 5 novel lncRNAs in prolactin-treated MIN6c4 cells and mouse islets. Mn-Lnc03 and Mn-Lnc04 were markedly induced by prolactin in both MIN6c4 cells and mouse islets: Mn-Lnc03 expression was dose-dependently induced by 24-hour treatment of prolactin 200 ng/mL ($P < 0.05$) and 500 ng/mL ($P < 0.001$) in MIN6c4 cells and by 24-hour ($P < 0.01$) and 48-hour ($P < 0.001$) treatment of prolactin 500 ng/mL in mouse islets; similarly, Mn-Lnc04 expression was dose-dependently induced by 24-hour treatment of prolactin 200 ng/mL ($P < 0.001$) and 500 ng/mL ($P < 0.001$) in MIN6c4 cells and by treatment of prolactin 200 and 500 ng/mL for 24 hours ($P < 0.05$) and 48 hours ($P < 0.01$) in mouse islets.

Conclusion: These findings suggest that pregnancy is associated with an altered expression of specific lncRNAs in islets, which may play a regulatory role in β -cell mass expansion. Although their functions in beta-cell proliferation and human relevance are currently not known, our data suggests that novel lncRNAs that could be drug targets or biomarkers are indeed regulated by pregnancy-induced adaptation in the islet.

1019

INS^{C93S} transgenic pigs: a novel large animal model for gestational diabetes

A. Martins^{1,2}, C. Braun², E. Streckel², A. Blutke³, N. Klymiuk², A. Bähr², B. Rathkolb⁴, R. Wanke³, M. Hrade de Angelis⁴, E. Wolf^{1,2}, S. Renner²;

¹MWM Biomodels, Tiefenbach, ²Gene Center, LMU, ³Institute of Veterinary Pathology, LMU, Munich, ⁴Institute of Experimental Genetics, Helmholtz Zentrum, Munich, Germany.

Background and aims: The prevalence of gestational diabetes mellitus (GDM) is steadily increasing. GDM has a negative impact on foetal development and can trigger intrauterine programming of diseases like obesity or diabetes in the offspring's later life. Due to major differences in foetal development, mouse models are not sufficient to address these questions. In contrast, prenatal development of pigs mimics the human situation more closely. We evaluated *INS^{C93S}* transgenic pigs characterised by a pre-diabetic condition (i.e. fasting normoglycaemia, reduced glucose tolerance and decreased beta cell mass) as a novel model of GDM.

Materials and methods: *INS^{C93S}* transgenic pigs express the *INS^{C93S}* coding sequence under the control of porcine *INS* regulatory sequences. *INS^{C93S}* transgenic (n=3) and wild-type (WT) sows (n=4) were oestrus synchronized and artificially inseminated with sperm of the same boar. Hyperinsulinaemic-euglycaemic clamps (HIC) were performed within the third trimester of pregnancy. At gestation day 98±1.5, sows were necropsied and foetuses were recovered. From all foetuses blood samples were taken, and body weight (BW) and crown-rump length (CRL) data were recorded. In addition, pancreas was sampled from a random subset of foetuses of both groups of pregnant sows and processed for stereological analysis. From *INS^{C93S}* transgenic sows only the WT foetuses were studied. Effects on foetal outcomes were analysed using the General Linear Models (GLM) procedure (SAS), taking sow genotype and fetal sex as fixed effects, and sow body weight and litter size as covariates into account. Data are presented as mean ± SEM.

Results: HIC showed a 35% reduced insulin sensitivity in pregnant (n=4) compared to non-pregnant (n=3) WT sows (p=0.028), and insulin sensitivity of pregnant *INS^{C93S}* transgenic sows was reduced to the same extent. While fasting blood glucose (FBG) levels were not different between the two sow groups at the beginning of pregnancy, *INS^{C93S}* transgenic sows exhibited significantly higher FBG levels at gestation day 50 (71±2.3 vs. 50.3±3.3 mg/dl, p<0.01) and even more at gestation day 95 (106.7±9.7 vs. 55.5±4.3 mg/dl, p<0.001) compared to pregnant WT sows. WT foetuses (n=14) recovered from *INS^{C93S}* transgenic dams revealed significantly higher blood glucose levels than those (n=44) from WT sows (45.4±3.9 vs. 33.7±1.1 mg/dl, p<0.01). While foetal BW was not significantly affected by maternal GDM, the relative CRL (CRL/BW^{0.33}) was significantly increased in foetuses from *INS^{C93S}* transgenic vs. WT sows (2.75±0.08 vs. 2.68±0.03; p<0.01). Additional analyses of foetal insulin and metabolite levels as well as pancreas stereology are ongoing.

Conclusion: Like humans, pigs develop reduced insulin sensitivity in the late gestational period. In pre-diabetic *INS^{C93S}* transgenic sows pregnancy-induced metabolic stress resulted in a gradual elevation of blood glucose levels to a clinically relevant extent which also projected to the corresponding fetuses. The increased relative CRL in fetuses from *INS^{C93S}* transgenic sows suggests effects on foetal growth which deserve organ specific analysis in future studies. This model is an important tool to systematically analyse the molecular and biochemical changes induced by GDM in the mother, fetuses and offspring.

Haemoglobin A_{1c} levels in the preconception period with type 1 diabetes and the risk of adverse neonatal outcomes: a systematic review and dose-response meta-analysis

Y. Ding¹, X. Zheng¹, J. Yan¹, S. Luo¹, D. Yang¹, L. Qiu¹, W. Bao², B. Yao¹, W. Xu¹, J. Weng^{1,3};

¹Endocrinology and Metabolic Disease, the Third Affiliated Hospital of Sun Yat-sen University, ²School of Public Health, the Sun Yat-sen University, ³Guangdong Provincial Key Laboratory of Diabetology, Guangzhou, China.

Background and aims: Poor peri-conceptual (i.e., in the preconception period or during first trimester of pregnancy) glycemic control significantly increased adverse neonatal pregnancy outcomes in type 1 diabetes mellitus (T1DM). Glycemic target in this period is controversial. We aimed to evaluate and quantify the potential dose-response association between peri-conceptual hemoglobin A_{1c} (HbA_{1c}) levels and the relative risk (RR) of congenital malformations and fetal loss in women with T1DM.

Materials and methods: A systematic review and dose-response meta-analysis of prospective cohort studies or nested case-control studies were performed. Relevant articles in English were identified through searching PubMed and EMBASE databases up to November 2014. The references of relevant articles were reviewed to identify potential publications. Studies that were stratified by HbA_{1c} with measures of RR, and 95% confidence intervals (CI) for congenital malformations or fetal loss in T1DM compared with non-diabetes were included.

Results: We reviewed 3958 abstracts and extracted 7 articles with data for 4153 individuals. A total of 124 congenital malformations events from 6 prospective cohort trials, and 88 fetal loss events from 5 prospective cohort trials were observed. There was a linear dose-response relationship between the peri-conceptual HbA_{1c} of women with T1DM and the relative risk of congenital malformations and fetal loss as shown in figure 1. The RR of congenital malformations was 1.61[0.58-4.49], 2.14[0.55-8.32], 3.07[1.23-7.65] and 3.29[0.58-18.71], and the RR of fetal loss was 1.54[0.61-3.91], 2.09[0.48-9.11], 3.54[0.94-13.33] and 6.23[1.65-23.47], when the maternal HbA_{1c} during preconception was 5.5%, 5.9%, 7% and 10%, respectively.

Conclusion: The risk of congenital malformation and fetal loss both increased with maternal HbA_{1c} level. If it is achievable without significant hypoglycemia, HbA_{1c} levels should be maintained as close to normal as possible in the preconception period.

Lower levels of placental growth hormone in early pregnancy in type 1 diabetic women with large for gestational age infants

L. Ringholm^{1,2}, A. Juul³, U. Pedersen-Bjergaard⁴, B. Thorsteinsson⁴, P. Damm⁵, E.R. Mathiesen¹;

¹Endocrinology, University Hospital of Copenhagen Rigshospitalet, ²Steno Diabetes Center, Gentofte, ³Growth and Reproduction, University Hospital of Copenhagen Rigshospitalet, ⁴Endocrinology Section, Nordsjællands Hospital, Hillerød, ⁵Obstetrics, University Hospital of Copenhagen Rigshospitalet, Denmark.

Background and aims: Early growth delay may occur in the first trimester of pregnancy in women with diabetes. Insulin-like Growth Factor-I (IGF-I) levels are higher in women with fetuses smaller than expected from gestational age compared with women with normal-size fetuses. Placental growth hormone (GH) levels in late pregnancy have previously been reported to be associated with fetal growth. We evaluated whether levels of placental GH and IGF-I are associated with development of large for gestational age (LGA) infants in pregnant women with type 1 diabetes.

Materials and methods: Observational study of 107 consecutive pregnant women with type 1 diabetes (median duration 16 years (range 1–36), HbA_{1c} 6.6% (4.9–10.5) in early pregnancy). At 8, 14, 21, 27 and 33 weeks blood was sampled for measurements of placental GH, IGF-I and HbA_{1c}. Weight gain in early pregnancy was calculated as the difference between weight at 14 weeks and pre-pregnancy weight. Total gestational weight gain was calculated as the difference between the last weight measured before delivery and the self-reported pre-pregnancy weight. LGA was defined as birth weight >90th percentile.

Results: Throughout pregnancy the levels of placental GH were similar in 51 (48%) women delivering LGA infants (birth weight 3930 g (3295–5620)) compared with the remaining women (3198 g (2040–3880)) except at 8 weeks where placental GH levels were lower in the women with LGA infants (1.1 ng/ml (0.1–4.3) vs. 1.7 (0.3–11.7), $p=0.02$). IGF-I levels during pregnancy were similar ($p=0.61$) in women with and without LGA infants. Gestational age at first blood sampling was similar in women with and without LGA (60 days (37–89) vs. 62.5 (42–94), $p=0.26$). Placental GH levels at 14 weeks correlated negatively with weight gain in early pregnancy ($r=-0.29$, $p=0.006$). Total gestational weight gain correlated positively with birth weight ($r=0.28$, $p=0.003$). LGA was more frequent in women with parity ≥ 1 (34 (67%) vs. 17 (33%), $p=0.001$), but was not associated with pre-pregnancy BMI. As predictors of LGA infants multivariate logistic regression analysis identified placental GH levels at 8 weeks (OR 0.4 (95% CI: 0.2–0.9), $p=0.03$; i.e. a doubling of placental GH levels implied a 60% lower risk of having an LGA infant), total gestational weight gain (1.7 (1.1–2.7), $p=0.04$; i.e. a 5 kg increase in gestational weight gain implied a 70% higher risk of having an LGA infant) and parity ≥ 1 (3.5 (1.5–8.3), $p=0.004$; i.e. parity ≥ 1 implied a 3.5 fold risk of having an LGA infant compared with primiparous women).

Conclusion: Unexpectedly, elevated levels of placental GH or IGF-I were not associated with the development of LGA infants in this cohort of women with type 1 diabetes. Women delivering LGA infants had lower placental GH levels in early pregnancy. Growth factors and maternal weight gain in early pregnancy may play an important role for healthy fetal growth.

Maternal lipids are associated with large for gestational birth weight in women with type 1 diabetes: results from a prospective single-center study

P. Gutaj, E. Wender-Ozegowska, J. Brazert;

Dept. of Obstetrics and Women's Diseases, Poznan University of Medical Sciences, Poland.

Background and aims: Despite improvement in diabetes care over the years, incidence of large for gestational age (LGA) is still very high even in a well controlled type 1 diabetic mothers. Aside from the already studied effects of glycemia, it has been suggested that maternal lipids also play an important role in influencing fetal growth. However, data on the association of lipids and LGA in women with T1DM is scarce. Therefore, the aim of our study was to determine whether changes in maternal lipids might contribute to high rates of LGA in this population.

Materials and methods: Prospective single-center study on a population of 171 women with T1DM admitted to the perinatal center for women with diabetes between June 2012 and December 2014. Anthropometric, clinical and laboratory data (HbA_{1c}, total cholesterol, HDL, LDL, triglycerides) were collected during 3 planned hospitalizations: in the first trimester (<12th week), in mid-pregnancy (20th–24th weeks) and before delivery (34th–39th weeks). All multivariate models were adjusted for maternal age, duration of diabetes, BMI, gestational weight gain, parity (multipara vs. primipara), mode of insulin therapy (CSII vs. MDI) and HbA_{1c}.

Results: Fifty-seven women were excluded from the study group due the following: multiple pregnancy, spontaneous abortions, preeclampsia, and delivery in a different hospital/loss of follow-up, giving a group of 114 women included in the final analysis (LGA=30; AGA=84). In the multivariate logistic regression analysis lower HDL concentration in the first trimester was significantly associated with LGA ($p=0.01$). Similar association was observed for the HDL concentrations in mid-pregnancy ($p=0.04$) and before delivery ($p=0.03$). Higher triglycerides concentrations in the first trimester ($p=0.02$) and before delivery ($p=0.008$) were associated with increased risk of LGA. There was no association between second trimester TG and LGA. Both total cholesterol and LDL were not associated with LGA. Higher HbA_{1c} was associated with LGA in the second trimester ($p=0.01$) and before delivery ($p=0.02$). There was no association between first trimester HbA_{1c} and LGA.

Conclusion: Decreased HDL and increased triglycerides during pregnancy might contribute to the development of LGA in women with type 1 diabetes. HbA_{1c} seems to be a significant predictor of LGA, however, only in the second part of pregnancy.

Diabetic autonomic neuropathy in type 1 diabetic pregnant women

L. Mattei, O. Bitterman, C. Festa, A. Napoli;

Clinical Sciences, Sapienza University of Rome, Italy.

Background and aims: Pregnant women undergo several metabolic and circulatory changes to meet fetal needs. Diabetic autonomic neuropathy (DAN) is a common complication of type 1 diabetes, involving cardiovascular system. Primary aim: To evaluate the pregnancy outcome of two groups of women with type 1 diabetes with and without autonomic diabetic neuropathy. Secondary aim: Longitudinal evaluation of time and frequency domain indexes and 24 h ambulatory blood pressure monitoring (24hABPM) in pregnancy.

Materials and methods: Diabetic autonomic neuropathy was diagnosed before pregnancy, according to 'SID diabetic neuropathy study group' recommendations. 22 normotensive type 1 diabetic women at enrollment, 7 with DAN (N+) e 15 without DAN (N-) underwent 24 hour Holter ECG recording (24 h ECG) and 24hABPM at the 1st and the 3rd trimester. We

analyzed time (SDNN, SDANN, SDNN INDEX, PNN50%) and frequency (LF, HF and LF-HF ratio) domain indexes derived from 24 h ECG and 24 hour blood pressure profiles. Statistics: IBM SPSS ver.20 t test, chi square and Mann Whitney.

Results: N+ showed a longer diabetes duration than N- (N+=20.2±3.9 vs N- =12.7±5.8 years, p=0.007) with a higher prevalence of microalbuminuria (N+=28.5% vs N-=0%, p=0.04) and retinopathy (N+=100% vs N-=6.6%, p=0.01). Despite HbA1c levels were similar during pregnancy, post prandial blood glucose levels were higher at lunch time in N+ at the 1st trimester (N+=150.6±45.9 vs N-=112.9±26.5 mg/dl, p=0.04). The prevalence of hypertension during pregnancy was not significantly higher in neuropathic women (N+=42.8% vs N-=33.3%, p=0.66) even though two cases of pre-eclampsia were only observed in N+ with microalbuminuria. At 1st and 3rd trimester, 24 hour systolic and diastolic blood pressure values were not significantly higher in N+. At 3rd trimester N+ were all 'non dipper' with a systolic delta day-night lower than N- (N+=4 (3-5) vs N-=8.0 (5-9) mmHg, p=0.04). Time domain indexes were lower in N+ at the 1st (SDNN index N+=78.2±21.5 vs N-=102.6±18.8 milliseconds, p=0.01, SDANN index N+=69.4±23.4 vs N-=94.1±22.7 milliseconds, p=0.04, PNN50 (N+=3.5 vs N-=11.1%, p=0.04) and at the 3rd trimester (SDNN index N+=69.7±25.1 vs N-=95.4±31.7 milliseconds, p=0.04, SDANN index N+=61.7±27.2 vs N-=81.4±30.2 milliseconds, p=0.04, PNN50 index N+=2.5 vs N-=6.0%, p=0.04). We did not find any difference in frequency domain indexes. N+ women delivered not significantly earlier than N-.

Conclusion: Diabetic autonomic neuropathy is associated with higher post prandial blood glucose values at the first trimester and worse blood pressure levels throughout gestation. Differences in vagal indexes between neuropathic and non neuropathic women were definitely unmasked in late pregnancy.

1024

Diabetic ketoacidosis in type 1 diabetic pregnancy: a case series review

J. Bujanova, E.J. Nicholson, M.H. Cummings, A. Going, C. Hall;
Department of Diabetes and Endocrinology, Portsmouth Hospitals NHS Trust, UK.

Background and aims: Diabetic ketoacidosis (DKA) in pregnancy is a rare but serious medical and obstetrics emergency associated with a high risk of fetal demise (9-35%) and maternal mortality (4-15%). Factors predisposing to development of DKA in pregnancy include reduced buffering bicarbonate capacity due to hyperventilation in 2nd and 3rd trimester, increased insulin resistance induced by pregnancy hormones, increased insulin requirements in later stages of pregnancy, emesis gravidarum and increased carbohydrate absorption due to progesterone effect on gut mobility. The most common precipitants include infection, first presentation of type 1 diabetes (T1DM), omission of insulin, hyperemesis gravidarum, steroids for fetal lung maturation or severe emotional stress. Ketonaemia, dehydration and acidosis cause reduced utero-placental blood flow and increased affinity of maternal haemoglobin to oxygen which can lead to fetal hypoxia. The aim of this case series was to review the presentations of DKA in pregnancy in patients with T1DM in our institution over the last 5 years.

Materials and methods: The electronic notes of 87 women with T1DM seen in local antenatal service with 96 separate pregnancies between 1/4/2010 to 31/3/2015 were reviewed. 5 of 87 (5.75%) women had 7 distinct episodes of DKA in pregnancy. Demographic data on each woman was collected alongside information on pre-pregnancy HbA1c, diabetes complications, degree of metabolic derangement on admission, DKA trigger and outcomes of pregnancy.

Results: 7 episodes of DKA occurred in 5 women in 6 pregnancies over 5 year period. One woman had 2 episodes of DKA in each of the 1st and 2nd trimesters of her pregnancy. Average pre-pregnancy HbA1c was

103 mmol/mol. 3/5 women had pre-pregnancy retinopathy and one woman had overt diabetic nephropathy. The majority of pregnancies (4/6) were unplanned and 4/6 women did not attend pre-pregnancy counselling clinic. DKA precipitants were influenza, mumps, dental abscess, UTI, vomiting, gastritis and omission of insulin. DKAs occurred with equal frequency in 1st trimester (3 episodes) and 3rd trimester (3 episodes) and one DKA occurred in 2nd trimester. Average blood glucose at presentation was 17 mmol/l with two DKA episodes presented with only mildly elevated glucose levels (12.7 and 8.9 mmol/l). Average pH at presentation was 7.23. Those who had blood ketones measured on admission had levels ranging between 3.7-6.9 mmol/l. In one woman the DKA episode was associated with fetal demise on admission at 9 weeks gestation. 4 women delivered by emergency caesarean section and their babies required admission to neonatal intensive care unit due to prematurity or neonatal hypoglycaemia.

Conclusion: Higher risk of DKA in pregnancy despite intensive antenatal input seems to be associated with suboptimal HbA1c prior conception and past history of DKA admissions prior to pregnancy. Our case review demonstrated that pregnant women with DKA presented predominantly to medicine. Cases presented with lower than expected glucose levels with one woman presenting with a level of 8.9 mmol/l, which might present a diagnostic challenge. One woman presented with fetal death on admission but no fetal deaths occurred after treatment of DKA was initiated which highlights importance of rapid diagnosis and rigorous treatment. All babies were delivered via emergency caesarean section and required specialist baby unit care which would suggest that DKA in pregnancy is a risk factor for these outcomes.

1025

The clinical significance of overt diabetes diagnosed in pregnancy

L. Mañé¹, D. Benaiges¹, J. Pedro-Botet¹, M. Prados², A. Payá³, J.J. Chillarón¹, A. Goday¹, R. Carreras³, R. Carreras³, J.A. Flores-LE Roux¹;
¹ENDOCRINOLOGY, Hospital Del Mar, ²ENDOCRINOLOGY, Hospital De Martorell, ³Gynecology, Hospital Del Mar, Barcelona, Spain.

Background and aims: To analyze maternal characteristics, pregnancy and neonatal outcomes in women diagnosed of overt diabetes (ODM) during pregnancy and to compare these results with those of women diagnosed with gestational diabetes mellitus (GDM)

Materials and methods: A prospective study of women who gave birth in our hospital between January 2011 and October 2014 was carried out. All women underwent screening for GDM using the two-step approach between the 24th and the 28th week of pregnancy. Those with risk factors for GDM underwent testing during the first trimester. The diagnosis of GDM was based on the recommendations of the National Diabetes Data Group. A1c levels were determined in those diagnosed of GDM. ODM was diagnosed in those who met the ADA criteria for diabetes (fasting glucose ≥ 126 mg/dl and/or a glycosylated hemoglobin $\geq 6.5\%$) but who had not a previous diagnosis of diabetes mellitus.

Results: During the study period 567 women were diagnosed of GDM and 40 fulfilled the criteria for ODM. Maternal, gestational and newborn characteristics of both study groups are shown in the Table.

Conclusion: In this patient cohort, overt diabetes in pregnancy significantly increased the risk of adverse pregnancy outcomes such as premature birth, induced delivery, caesarean section and large for gestational age babies, when compared with GDM. The majority of women diagnosed of ODM belong to ethnic minority groups and so special attention to these women should be paid in order to achieve early detection and treatment.

PS 099 Diabetic neuropathy: emerging concepts

1026

The prevalence of early somatic neuropathy in children and adolescents with type 1 diabetes and its association with the persistence of GAD-65 and IA-2 autoantibodies

F. Karachaliou¹, M. Louraki², M. Katsalouli³, C. Kanaka-Gantenbein⁴, E. Critselis⁵, N. Kafasi⁶, D. Kallinikou², C. Tsentidis², K. Karavanaki²; ¹Endocrine Department, “P&A Kyriakou” Children’s Hospital, ²Diabetic Clinic, Second Pediatric Department University of Athens, “P&A Kyriakou” Children’s Hospital, ³Neurologic Department, “Aghia Sophia” Children’s Hospital, ⁴Diabetes Center, First Department of Pediatrics University of Athens, “Aghia Sophia” Children’s Hospital, ⁵Second Pediatric Department University of Athens, “P&A Kyriakou” Children’s Hospital, ⁶Department of Immunology, ‘Laiko’ General Hospital, Athens, Greece.

Background and aims: Diabetic neuropathy (DN) is a complication of type 1 diabetes mellitus (T1D) with some well established risk factors and others that remain to be identified. We tried to evaluate the prevalence of early somatic neuropathy in children and adolescents with T1D and its association with the persistence of autoantibodies against glutamic acid decarboxylase (GADA) and islet antigen-2 (IA-2A).

Materials and methods: A cross-sectional study was conducted in a hospital-based cohort of pediatric T1D patients (n=85, mean (SD) age: 12.3±3.4 years). Peripheral neuropathy was assessed with nerve conduction studies (NCS). GADA and IA-2A titers were measured in samples collected prior to electrophysiological testing.

Results: Among the study population, 34.1% had at least one abnormal electrophysiological parameter in NCS, although usually asymptomatic. The highest rates of abnormalities were detected in the sensory fibers of the peroneal nerve. These patients were not different from the rest of the study group in terms of age, diabetes duration or glycaemic control. Among our patients with a mean (SD) T1DM duration of 5.4±3.3 years, 62.4% had positive GADA, 58.8% positive IA-2A and 41.2% double antibody positivity. Abnormal NCS correlated neither with GADA nor with IA-2A levels. However lower sensory nerve action potential (SNAP) in the peroneal nerve, which was indicative of early axonal dysfunction, was observed in patients with GADA (8.3±3.0 mV vs 10.2±4.2 mV, p=0.046) or IA-2A (7.8±3.9 mV vs 10.6±4.0 mV, p=0.002) positivity.

Conclusion: Impaired indices of subclinical peripheral sensory neuropathy were present among one third of the T1DM children and adolescents, with no difference in diabetes duration or glycaemic control. GADA and IA-2A seem to be involved in the development of axonal degeneration, in a pathway which remains to be identified.

1027

Is IGT-associated sensory neuropathy driven only by glycaemia?

Z. Putz¹, N. Nemeth¹, I. Istenes¹, O. Vagi¹, A. Korei¹, T. Martos¹, S. Kempler¹, R. Gandhi², S. Tesfaye², G. Jermendy³, A. Tabak¹, P. Kempler¹;

¹Ist Dep. of Int. Med., Semmelweis University, Budapest, Hungary, ²Royal Hallamshire Hospital, Sheffield, UK, ³Bajcsy Zsilinszky Hospital, Budapest, Hungary.

Background and aims: Traditional cardiovascular risk factors play an important role in the development of neuropathy in diabetes. In the present study, we aimed to investigate risk factors of sensory neuropathy in patients with impaired glucose tolerance (IGT) and healthy volunteers.

Materials and methods: Seventy-five people with impaired glucose tolerance and 40 age and gender matched healthy volunteers underwent a

detailed clinical examination and neurological assessment. Sensory nerve function was assessed by using Neurometer (current perception threshold [CPT]) and Medoc devices. Autonomic neuropathy was detected by the five standard cardiovascular autonomic tests. Mean 24-h systolic and diastolic blood pressures were assessed by 24-hour ambulatory blood pressure monitoring.

Results: The prevalence of sensory neuropathy was 58% in subjects with impaired glucose tolerance. The Odds ratio (OR) was 11.23 (CI: 3.57–35.35). This association was independent from the presence of autonomic neuropathy or the measure of BMI, HbA1c, BP and HR. However, adjustment for fasting plasma glucose attenuated the association notably (OR: 6.75; CI: 1.33–34.27), and the significance was lost after adjustment for 120 min glucose level (OR: 3.76; CI: 0.26–54.10). Sensory neuropathy in patients with IGT showed a strong association with 120 min glucose level (OR: 1.78; CI: 1.20–2.63) in the entire population studied.

Conclusion: Our data suggest that glycemia (120 min glucose level) is a risk factor for sensory neuropathy in subjects with IGT which is independent of all other known cardiovascular risk factors. This new knowledge may be an important addition to risk reduction strategies.

1028

Reduced sudomotor function in adult patients with long lasting type 1 diabetes and peripheral neuropathy

A. Gandecka, A. Araszkievicz, S. Pilacinski, B. Wierusz-Wysocka, D. Zozulinska-Ziolkiewicz,
Department of Internal Medicine and Diabetology, Poznan University of Medical Sciences, Poland.

Background and aims: Diabetic neuropathy is the most common chronic complication of diabetes. It often remains undiagnosed for a long time and usually leads to chronic pain and foot ulcerations. Therefore, new accurate and noninvasive methods are needed for its early diagnosis. Sweat glands are innervated by small C-fibers. Dysfunction of the sweat glands is very early clinical manifestation of diabetic neuropathy. SUDOSCAN+ device is used to noninvasively assess the function of the sweat glands, measuring electrochemical skin conductance (ESC) through reverse iontophoresis. The aim of this study was to evaluate the sudomotor function in patients with long lasting type 1 diabetes.

Materials and methods: The study included 381 adult patients with type 1 diabetes (185 women and 196 men) aged 41 years (IQR: 32–51), with disease duration of 23 (IQR: 18–30) years. The study group was subdivided into two groups depending on the presence of peripheral neuropathy identified by standard methods. Neuropathy was diagnosed in patients with two or more of the following five elements: the presence of symptoms, lack of ankle reflexes, impaired sensation of touch, temperature and/or vibration. We measured ESC with SUDOSCAN+ on feet (Feet ESC) and hands (Hands ESC) in the study group and in the control group of 63 healthy volunteers sex and age matched. We also evaluated metabolic control of diabetes using HbA1c value and skin autofluorescence (AF) measured with AGE-Reader as well as the presence of late diabetic complications.

Results: Peripheral neuropathy was diagnosed in 45% of patients. Patients with peripheral neuropathy, compared to those without it, had lower Feet ESC [68 (IQR: 46–81) vs 83 (IQR: 76–87) μ S; $p < 0.001$] and lower Hands ESC [56 (IQR: 39–69) vs 69 (IQR: 59–77) μ S, $p < 0.001$]. We found a negative correlation between the result of ESC on feet and hands and patients' age ($R_s = -0.41$, $p < 0.0001$; $R_s = -0.40$, $p < 0.0001$), duration of diabetes ($R_s = -0.33$, $p < 0.0001$, $R_s = -0.31$, $p < 0.0001$), HbA1c level ($R_s = -0.12$, $p = 0.015$, $R_s = -0.12$, $p = 0.017$), skin AF ($R_s = -0.33$, $p < 0.0001$, $R_s = -0.30$, $p < 0.0001$) and positive correlation with the eGFR ($R_s = 0.36$, $p < 0.0001$, $R_s = 0.30$, $p < 0.0001$). Feet ESC and Hand ESC did not differ between patients with diabetes without neuropathy and controls [83 (IQR: 76–87) vs 82 (IQR: 78–86) μ S, $p < 0.94$ and 69 (59–77) vs 69 (60–79) μ S, $p = 0.57$]. In a multivariate logistic regression model

electrochemical skin conductance was independently associated with the presence of peripheral neuropathy (Feet ESC OR 0.96; 95%CI: 0.95–0.98, $p < 0.0001$ and Hands ESC OR 0.97; 95%CI: 0.95–0.98, $p = 0.0001$). This association was independent from age, sex, duration of diabetes, HbA1c, skin AF and eGFR.

Conclusion: In adults with type 1 diabetes and peripheral neuropathy sudomotor function is markedly reduced. The longer duration of diabetes, worse metabolic control or reduced renal function, the greater sudomotor dysfunction is.

Sudoscan as a tool for early screening of diabetic microvascular complications: experience of a French hospital

L. Bordier, C. Garcia, M. Dolz, B. Bauduceau, H. Mayaudon;
Endocrinology Department, Hospital Bégin, Saint-Mandé, France.

Background and aims: The screening of microvascular complications in patients with type 2 diabetes is not optimal, especially for neuropathy at early stage. As sweat glands are innervated by small autonomic C-fibers the measurement of sweat function has been proposed to evaluate peripheral small fiber neuropathy, which may occur very early. This study aimed to evaluate SUDOSCAN, an easy, fast, non-invasive and quantitative measurement of sweat function for the detection and follow-up of microvascular complications of diabetes.

Materials and methods: During this study involving 189 patients with type 2 diabetes, the following tests were performed: a clinical examination including monofilament testing ($n = 154$), blood tests including MDRD clearance (Modification of the Diet in Renal Disease) measurement, ophthalmologic examination ($n = 113$), SUDOSCAN with hands and feet conductance measurements (μ S). A general risk score for autonomic neuropathy based on previous studies was also calculated. Results were expressed as mean \pm SD and comparisons were made by a Student test.

Results: The population had a mean age of 60 ± 16 years, 49% were men, HbA1c $9.0 \pm 1.3\%$. Feet conductances of patients having Fasting blood glucose > 7.2 mmol/L were significantly lower (70 ± 15 vs 74 ± 16 μ S, $p = 0.03$). Patients with MDRD clearance < 90 ml/min had significant lower conductances for hands and feet (Figure). Patients with urinary albumin excretion (UAE) ≥ 15 mg/L had significant lower feet conductances (69 ± 17 vs 75 ± 14 μ S, $p = 0.002$). Lastly, patients who presented abnormalities to monofilament testing had lower conductances for hands (57 ± 16 vs 65 ± 16 μ S, $p = 0.004$), and feet (65 ± 20 vs 75 ± 11 μ S, $p = 0.003$). Same tendency was observed in patients with retinopathy as compared to patients without (69 ± 16 vs 74 ± 14 μ S, $p = 0.13$). Global autonomic risk score using 35 as threshold had a sensitivity of 78% and a specificity of 54% to detect at least one microvascular complication. No adverse event or discomfort has been reported during or following SUDOSCAN recording.

Conclusion: This study showed lower conductances values for diabetic patients who presented abnormalities to monofilament test, assessing big myelinated fibers. These data also suggest that the conductances measured by the device correlate well with renal microvascular alterations as represented by both decreased MDRD clearance and increased UAE. These results indicate that SUDOSCAN device could be used for early detection and monitoring of both diabetic neuropathy and nephropathy.

1030

Thalamic γ -aminobutyric acid in diabetic neuropathy

I.D. Wilkinson¹, P. Shillo², M. Greig², R.A. Edden³, D. Selvarajah⁴, S. Tesfaye²;

¹Academic Radiology, University of Sheffield, ²Academic Department of Diabetes and Endocrinology, Sheffield Teaching Hospitals NHS Foundation Trust, UK, ³John Hopkins University School of Medicine, Baltimore, USA, ⁴Human Metabolism, University of Sheffield, UK.

Background and aims: The thalamus forms a major component of the ascending sensory pathway to the brain, the function of which may play an important role in patients with diabetic neuropathy (DN). Previous Magnetic Resonance (MR) studies have demonstrated thalamic metabolite involvement on Proton MR Spectroscopy (H-MRS). One such metabolite, γ -Aminobutyric acid (GABA), is an inhibitory neurotransmitter. This study assessed thalamic GABA in-vivo using specialised novel H-MRS editing techniques in patients with and without DN.

Materials and methods: 44 type 2 diabetes (T2DM) Caucasian subjects (14 Painful-DPN, 15 Painless-DPN and 15 No-DPN) and 15 healthy volunteers without diabetes (HV) underwent detailed clinical and neurophysiological assessments. T2DM subjects were divided into three groups based on the neuropathy composite score [NIS(LL)+7 and Douleur Neuropathique 4 score(DN4)]. All groups were age-matched. Subjects underwent localised H-MRS at 3 Tesla to assess GABA relative to unsuppressed water and creatine using a single-voxel, spin-echo, spectral editing technique (MEGA-PRESS; echo time=68 ms) centred over thalami. GABA resonance signal was obtained relative to that of parenchymal water

Results: Analysis of Variance revealed differences in group mean GABA/H2O ratios [ANOVA $p < 0.01$; Painless-DPN 1.47(sd=0.23), Painful-DPN 1.61(0.33), HV 1.75(0.25) and T2DM with No-DPN 1.84(0.38)]. Post-hoc comparisons indicated significantly lower mean GABA/H2O in Painless-DPN compared to No-DPN ($p < 0.005$) and significantly lower mean GABA/H2O in Painless-DPN compared with HV ($p < 0.05$).

Conclusion: This study containing a well-sized, well-characterised cohort clearly demonstrates lower relative levels of the 'H-MRS-visible' inhibitory neurotransmitter GABA in the thalamus of patients with DPN. Previous published pilot data from 7 diabetics with neuropathy and 7 non-diabetics reported lower GABA in the posterior insula in the context of DN. Our current larger sample size indicates significantly lower GABA within the thalamus often considered the sensory gateway to the brain. A further understanding of the cerebral neuronal excitatory/inhibitory balance inferred from this H-MRS technique may help determine the mechanistic basis of central nervous system involvement in pain perception associated with DN.

Neuroinflammation and neurodegeneration in the prefrontal cortex during diabetic neuropathic pain

J. Pereira, S. Oliveira, I. Tavares, C. Morgado;

Experimental Biology Department, Faculty of Medicine of Porto & I3S - Institute for Innovation and Health Research, University of Porto, Portugal.

Abstract no. 1031 (Neuroinflammation and neurodegeneration in the prefrontal cortex during diabetic neuropathic pain) has been retracted at the request of all authors as reanalysis of the data by an independent committee showed that the conclusions were not supported by the data

1032

GLP-1 analogue has anti-inflammatory effects at the spinal cord of diabetic rats

C. Morgado, L. Lopes, J. Pereira, S. Oliveira, I. Tavares;

Department of Experimental Biology, Faculty of Medicine & I3S - Institute for Innovation and Health Research, University of Porto, Portugal.

Background and aims: Diabetic neuropathy is a common complication of diabetes, often associated with chronic pain. Several studies pointed to changes at the spinal cord as possible mechanisms underlying the diabetic neuropathic pain (DNP). Neuroinflammation emerges as a possible cause of diabetes-induced spinal dysfunction. Incretin drugs, namely glucagon-like peptide 1 (GLP1) analogues, emerge as promising drugs as they were shown to present anti-inflammatory and neuroprotective effects in neurodegenerative diseases. Moreover, the GLP1 receptor was shown to be expressed by CNS immune cells, the microglia, at the spinal dorsal horn, reinforcing the possible effect of GLP1 in mediating spinal inflammatory responses. The aim of present study was to evaluate the anti-inflammatory effects of Liraglutide (LIRA, GLP1 analogue) in the spinal cord of rats with DNP.

Materials and methods: Diabetes was induced by injection of streptozotocin (i.p., STZ), whereas control rats (CTR) received vehicle solution. One week after diabetes induction, STZ-injected rats initiated a treatment with LIRA (1 g/kg s.c.) (STZ+LIRA) or were maintained untreated for 10 weeks (STZ-untreated). Blood glucose and mechanical hypersensitivity were evaluated after injections and at 4 and 10 weeks post-injections. The L4-L5 spinal segments were removed and processed

for western blot to quantify Iba1 (microglial activation marker), GFAP (astroglial activation marker) and interleukin 1 β (IL1 β) and tumor necrosis factor alpha (TNF α). Behavioral data was compared by Two Way ANOVA with repeated measures and molecular data was compared by One Way ANOVA, followed by Tukey post-hoc test for multiple comparisons. Statistical significance was settled as $p < 0.05$. Results are presented as mean \pm SEM.

Results: All STZ animals presented increased blood glucose concentration at 4 (CTR: 106.3 \pm 9.7; STZ-untreated: 462.0 \pm 37.2; STZ+LIRA: 378.0 \pm 20.5, mg/dl) and at 10 weeks post-induction (CTR: 151.3 \pm 43.8; STZ-untreated: 580.5 \pm 19.5; STZ+LIRA: 574.9 \pm 84.1, mg/dl). The treatment with LIRA significantly reduced mechanical hypersensitivity at 10 weeks of diabetes (STZ-untreated: 9.8 \pm 0.4; STZ+LIRA: 11.9 \pm 0.7, grams), but the mechanical hypersensitivity thresholds were maintained significantly lower than in control animals (CTR: 14.9 \pm 0.5; STZ+LIRA: 11.9 \pm 0.7, grams). A significant increase in the expression of IL1 β (CTR: 0.8 \pm 0.1; STZ-untreated: 1.9 \pm 0.5, optical units) and TNF α (CTR: 0.9 \pm 0.1; STZ-untreated: 2.9 \pm 0.9, optical units) was detected in the spinal cord of STZ-untreated rats. The levels of IL1 β were significantly reduced by the treatment with LIRA (STZ+LIRA: 0.5 \pm 0.1, optical units), whereas a non-significant decrease in TNF α expression was detected (STZ+LIRA: 1.6 \pm 0.6, optical units). The STZ+LIRA rats presented increased expression of Iba1 (CTR: 0.8 \pm 0.1; STZ-untreated: 0.9 \pm 0.1; STZ+LIRA: 1.2 \pm 0.2, optical units). The expression of GFAP was dramatically decreased in STZ-untreated rats (CTR: 0.9 \pm 0.1; STZ-untreated: 0.2 \pm 0.1, optical units) and was not affected by the treatment with LIRA (STZ+LIRA: 0.3 \pm 0.1, optical units).

Conclusion: This study shows that diabetes induces neuroinflammation in the spinal cord, which may be reduced by the treatment with LIRA. The anti-inflammatory effects of LIRA at the spinal cord may concur for the attenuation of diabetes-induced mechanical hypersensitivity.

AICAR-transformylase/ cyclohydrolase mediates glucotoxic complications in *C. elegans* and can be treated in an AMP-kinase dependent manner

C. Riedinger, M. Mendler, P.P. Nawroth;

Innere Medizin I, Medizinische Klinik Heidelberg, Germany.

Background and aims: As the expression *atic-1*, which codes for an enzyme that catalyzes the last two steps of purine de-novo synthesis (AICAR-transformylase/ cyclohydrolase) was found to be upregulated under high-glucose conditions in *C. elegans*, it was hypothesized that ATIC itself might be causally involved in mediating glucotoxic effects.

Materials and methods: Nematodes were cultured under standard and high glucose (HG) conditions, leading to glucose concentrations in whole animal extract of 5.5 mM and 13 mM, respectively, and treated with 1 mM AICAR. The dependency of ATIC was evaluated by using specific ATIC RNAi. Further, AMPK (*aak-2*), iron/ manganese superoxide dismutase (*sod-3*) and glyoxalase-1 (*glod-4*) mutant strains were used to evaluate downstream mechanisms. Life span, neuronal structure (microscopy of the pan neuronal GFP-expressing strain NW1229) and neuronal function (video analysis) were determined as well as accumulation of reactive oxygen species (ROS) and advanced glycation end-products (AGEs). Furthermore, concentrations of AICAR were measured.

Results: Under high glucose conditions the expression of *atic-1* is increased 3.1-fold ($p = 0.006$) compared to standard conditions. If the expression of *atic-1* is abrogated by specific RNAi, which leads to an increase of its substrate AICAR (16-fold), HG mediated shortening of lifespan (from 11.0 \pm 0.5 days to 14.4 \pm 0.9 days, $p < 0.0001$) as well as structural and functional neuronal damage (from 0.12 \pm 0.02 mm/s to 0.24 \pm 0.01 mm/s, $p = 0.012$) are prevented. This goes along with a normalization of ROS and AGEs. The normalization of mean lifespan (and

neuronal function?) by *atic-1* RNAi is dependent on AMP-K as this effect is not seen in *aak-2* mutant animals (life span from 9.5 \pm 0.3 days to 9.6 \pm 0.4 days). Conversely, ATIC overexpression shortens lifespan (from 36 days to 30 days) and negatively affects neuronal structure (0.25 damage scores to 0.75 damage scores). Corresponding to the effect of ATIC RNAi, exogenous AICAR treatment could prevent deleterious effects on neuronal structure (from 1.76 \pm 0.2 damage scores to 0.84 \pm 0.13 damage scores, $p = 0.016$) and function (from 0.09 \pm 0.04 mm/s to 0.25 mm/s, $p = 0.03$) and lifespan (from 14.8 \pm 0.9 days to 19.9 \pm 0.7 days) in high glucose cultured *C. elegans*. Additional treatment with the antioxidant butylated hydroxyanisole (BHA) and the complex-I inhibitor rotenone could not further improve the effect of AICAR treatment on normalizing lifespan (+AICAR: 16.9 \pm 0.8 days, +BHA: 16.5 \pm 1.1 days and +rotenone: 16.3 \pm 1.1 days). Finally, the life prolonging effect of AICAR under HG conditions is independent on *glod-4* (from 13.8 \pm 0.3 days to 18.3 \pm 0.9 days, $p = 0.001$) and *sod-3* (from 14.4 \pm 0.6 days to 17.9 \pm 0.6 days, $p = 0.0012$) but dependent on AMP-K (*aak-2*) (from 13.8 \pm 0.5 days to 14.0 \pm 0.8 days, $p = 0.438$).

Conclusion: The overexpression of *atic-1* seen under high glucose conditions in *C. elegans* is contributing to the deleterious effects on lifespan and the neuronal system. This can be reversed by the use of specific *atic-1* RNAi or treatment with AICAR in an AMP-K dependent manner.

PS 100 Diabetic neuropathy: identification and evaluation

1034

Validation of Neuropathy Symptoms Score (NSS) and Neuropathy Disability Score (NDS) in clinical evaluation of peripheral neuropathy in diabetes mellitus

A. Chawla, A. Chawla, R. Chawla, G. Bhasin;

Diabetes, North Delhi Diabetes Centre, New Delhi, India.

Background and aims: About one third of diabetic people are at risk of foot ulceration because of loss of protective sensation due to peripheral Neuropathy. The symptoms of neuropathy & the conventional assessment of it with Cotton wool, Vibrating tuning fork, pin prick and hot and cold sensation can give a qualitative diagnosis. Biothesiometer can quantify & pick up early cases of DPN & is an important diagnostic tool in clinical practice

Materials and methods: Present pilot study was designed to find out the prevalence of Diabetic peripheral neuropathy (DPN) incidence by bed side evaluation using NDS & NSS as per “Young et al” criterion & then to study its co-association with other diabetic complications 855 Type -2 diabetes patients who got newly enrolled at our Diabetes Centre” between July 2013 to Dec 2014 were evaluated clinically by neuropathy symptom score (NSS) & Neuropathy Disability score (NDS) as suggested by “Young et al”. Peripheral Neuropathy was diagnosed clinically if sum of NDS + NSS was >10 135 patients out of total 855 patients who had NSS 5-6 (mild symptoms) or NDS 5-6 but if sum of NDS + NSS was >10 were then evaluated by biothesiometry to validate this score. VPT >15 volts was taken as cut off for mild DPN & VPT >25 volts was considered as significant DPN. Detailed Diabetes Profile including their clinical profile namely Age, Sex, Mean duration of Diabetes, their personal habits smoking, dietary habits were evaluated. These patients were also evaluated for presence of Microalbuminuria, Retinopathy, PVD and Dyslipidaemia etc.

Results: 86 patients had monofilament impairment, 49 patients had normal monofilament test. 96 patients were detected to have DPN by VPT (60 severe, 36 mild to Moderate). Hence, applying NDS+NSS >10 as per “Young et al criterion “ could pick up early DPN in 96 out of 135 (sensitivity of 71.1% & specificity of 90%) This has a +ve predictive value of 57.14% & -ve predictive value of 94.32% as validated & documented by biothesiometer. Prevalence of DPN in total 855 patients evaluated clinically by NSS & NDS later tested by biothesiometry was found to be 15.4%.

Conclusion: Neurological examination like NSS & NDS can be an important bed side tool in the clinics for early diagnosis of DPN with a sensitivity of 71.1% & specificity of 90%. It is simple, acceptable, reproducible & validated as per our study. DPN has a strong co-association with other complications like DR (44.1% Vs 19.2%) and Microalbuminuria 61.3% Vs 38%.

COMPLICATIONS TABLE 2

Microalbuminuria	61.3%	38 %
Dyslipidaemia	36.4 %	28 %
Retinopathy	44.1 %	19.2%
VPT >15 volts	26.6% (N=36)	4.8%
VPT > 25 volts	44.4% (N=60)	5.2%
Prevalence of P-Neuropathy (Baye's Theorem)	15.4%	

TABLE 3

	NSS+NDS > 10 N=135 (Young et al)	NSS+NDS < 10 N=720	Total
VPT +ve	96	72	168
VPT -ve	39	648	687
	135	720	855
Sensitivity	96/135 = 71.1%		
Specificity	648/720 = 90%		
+ve Predictive Value	57.14%		
-ve Predictive Value	94.32%		

1035

Can a nurse successfully diagnose distal diabetic polyneuropathy?

A. Zielinska, E. Szymanska-Garbacz, J. Loba, L. Czupryniak;

Medical University of Lodz, Poland.

Background and aims: Distal symmetrical polyneuropathy (DPN) is one of the most frequent chronic complications of diabetes. Early diagnosis of DPN is of paramount importance for the prevention of diabetic foot syndrome. We conducted a study aiming at assessing whether a nurse using a Diabetic Neuropathy Symptom (DNS) score can accurately diagnose DPN. DNS is a simple 4-item questionnaire evaluating the 14-day frequency of gait abnormalities and sensory disturbances (pain, tingling and numbness) in lower limbs; answering ‘yes’ to one of the questions reflects the presence of DPN.

Materials and methods: In a single outpatient diabetes clinic 118 patients (21 with type 1, and 97 with type 2 diabetes) were first met by nurse, who administered DNS. Then they were seen by a diabetologist who performed thorough medical examination aiming at assessing the presence of DPN. The specialist was blinded to the results of nurse-conducted DNS.

Results: 71 (60%) patients replied positively to at least one of four questions in DNS, while the diabetologist confirmed the presence of DPN in 80 (68%) patients, including all who were tested positive by a nurse. Thus, the sensitivity of DNS was 0.89 (95%CI 0.84-0.89), and specificity reached 1.00 (0.95-1.00). According to the results of the nurse-conducted DNS, the most frequent complaint was tingling (31%), then numbness (27%), pain (24%) and gait abnormalities (18%). The significant risk factors for positive DNS result were disease duration, HbA1c, smoking, and recent (in the previous 3 months) change in diabetes treatment. DPN was confirmed by a diabetologist in 71% of the patients with diabetes duration >15 years and in 42% of those who had diabetes for less than 5 years, in 90% patients with HbA1c >9.0% and in 34% of those with HbA1c <7%, in 69% of ever smokers and in 46% of those who never smoked, and in 84% of those whose diabetes therapy was modified in previous 3 months and in 17% of those whose treatment remained stable recently (all differences p<0.05). Interestingly, self-declared alcohol intake level was not related to DNS results.

Conclusion: In conclusion, DNS can be a very effective tool to diagnose DPN when used by a nurse working on her own. Engaging nursing staff into DPN assessment may help diagnose the condition at its early stage.

1036

The first demonstration that the Norfolk QOL-DN scale establishes safety in painful diabetic peripheral neuropathyF. van Nooten¹, C. Poole², M. Stoker¹, R. Snijder¹, F. Lewis³, E.J. Vinik⁴, A.I. Vinik¹;¹Astellas Pharma Europe B.V., Leiden, Netherlands, ²Astellas Pharma Europe, Chertsey, ³Office of Health Economics, London, UK, ⁴Eastern Virginia Medical School, Norfolk, USA.

Back ground and aims: PACE was a Phase III, randomised, controlled, open-label, 52-week, safety study that assessed the safety and efficacy of repeat treatment with the capsaicin 8% patch plus standard of care (SOC), versus SOC alone in patients with painful diabetic peripheral neuropathy (PDPN) (N=468). The Norfolk QOL-DN scale was the primary safety endpoint and it was used to assess patient-reported functional consequences of potential impairment in small-fibre nerve function that may be due to capsaicin treatment. Secondary safety endpoints included an objective utilization of the Utah Early Neuropathy Scale (UENS) and quantitative sensory perception testing.

Materials and methods: As PACE is the first study in which the Norfolk QOL-DN scale was a safety endpoint, patient level analyses were performed to determine correlation with other safety endpoints. An additive (Gaussian) regression model, adjusted for repeated measures using an AR(1) error structure, including additional random effects and covariates was utilised. Relationship strength was assessed using F-tests.

Results: Treatment with capsaicin improved quality of life in parallel with improved UENS and sensory function. This relationship between change in Norfolk QOL-DN total and UENS total scores was observed in patients in all treatment arms ($p < 0.0001$), with a 1.0 unit decrease in UENS corresponding to a 0.4 unit decrease in Norfolk. In all treatment arms, improvement in sharp, heat, cold and vibration sensation scores were correlated with improvement in Norfolk total ($p \leq 0.01$ for all) and UENS total ($p \leq 0.0006$ for all) scores, but there were no relationships with deep-tendon reflex. Improvement in the Norfolk small fibre subscale score was correlated with improvement in UENS pinprick subscale and sharp sensation score in patients in all treatment arms ($p < 0.001$ for both). In addition, improvement in Norfolk large fibre subscale score was correlated with improvement in UENS total ($p < 0.0001$), UENS large fibre subscale ($p = 0.0025$) scores, as well as improved cold, heat and sharp sensation scores ($p \leq 0.004$ for all) in all arms. In contrast, deterioration in Norfolk total and small fibre subscale, UENS total and sharp sensation scores were all found if an increase in average daily pain occurred in patients in any arm ($p \leq 0.001$ for all).

Conclusion: In patients with PDPN treated with either capsaicin 8% patch plus SOC or SOC alone, a consistent correlation was observed between assessments with the Norfolk QOL-DN scale, UENS scale and sensory perception testing. These findings suggest that the Norfolk QOL-DN scale is sensitive to changes in small-fibre nerve function and is a relevant safety endpoint in treating neuropathic pain in PDPN.

One-leg standing time correlates with peripheral and cardiac autonomic nerve function in Japanese patients with type 2 diabetesK. Sugimoto¹, T. Hoshino², A. Tamura¹, R. Yabe¹, T. Yamazaki¹, S. Suzuki¹;¹Diabetes Center, ²Department of Physical Training and Science, Ohta Nishinouchi Hospital, Koriyama, Japan.

Background and aims: Patients with diabetes show impaired physical functional capacity and peripheral nerve function. Some evidence suggests that exercise may prevent and improve peripheral nerve dysfunction in diabetic patients. However, information is lacking regarding the

relationship between poor physical fitness and peripheral nerve dysfunction, along with possible risk factors for diabetic neuropathy, in Japanese patients with type 2 diabetes.

Materials and methods: The current study analyzed data collected from 299 Japanese patients with type 2 diabetes: 212 males (71%); mean age, 51 ± 14 years; mean duration of diabetes, 8 ± 8 years; hemoglobin (Hb) A1c, $10.4 \pm 2.5\%$; and normal cardiovascular response to exercise as determined by the double Master two-step test. Patients were excluded if they had a history of coronary heart disease, cerebrovascular disease, peripheral artery disease or psychiatric disorder. Peripheral sensory and motor nerve functions were evaluated by nerve conduction studies on the sural sensory nerve and tibial motor nerve, respectively. The coefficient of variation for normal R-R intervals (CVRR) at rest and during deep breathing was also used to assess cardiac autonomic nerve function. Furthermore, we examined body composition, muscle strength (knee extension), leg muscle quality (knee extension strength per unit leg muscle mass), functional balance (one-leg standing time with eyes open), agility performance (whole-body reaction time) and cardiopulmonary fitness (maximal oxygen uptake) in these patients. To identify independent correlates of peripheral nerve dysfunction, stepwise multiple regression analysis was performed. Covariates were age, sex, duration of diabetes, height, total body mass, fat mass, skeletal muscle mass, weight loss rate (maximal body weight minus body weight at entry divided by maximal body weight), blood pressure, brachial-ankle pulse wave velocity, ankle brachial index, carotid plaque, retinopathy, insulin use and levels of HbA1c, fasting plasma glucose, serum C-peptide, lipids, albumin and creatinine as well as urinary excretion of albumin and C-peptide. Highly skewed data were log-transformed.

Results: Multiple regression analysis showed that one-leg standing time correlated independently with sural sensory nerve conduction velocity, sural sensory nerve action potential, tibial motor nerve conduction velocity, minimal F-wave latency, compound muscle action potential and CVRR during deep breathing. Whole-body reaction time also correlated with sensory nerve conduction velocity and sensory nerve action potential. In addition, knee extension strength as percentage of body weight and in kilograms and leg muscle quality were related to motor nerve conduction velocity, minimal F-wave latency and CVRR at rest, respectively.

Conclusion: Based on these results, poor physical fitness as indicated by decreased one-leg standing time, increased whole-body reaction time and decreased knee extension strength correlated with impaired peripheral and cardiac autonomic nerve function in Japanese patients with type 2 diabetes. In particular, decreased one-leg standing time was most predictive of peripheral nerve dysfunction and thus offers a novel risk factor for diabetic neuropathy in these patients.

Atrophy of both extensor digitorum brevis muscle may be a useful sign for diagnosis of diabetic symmetric polyneuropathy in Japanese diabetic menH. Sasaki¹, K. Ogawa¹, H. Tanaka¹, S. Kurisu^{1,2}, H. Furuta², M. Nishi², T. Akamizu², K. Nanjo³;¹Department of Medicine, Wakayama Medical University, Katsuragi Cho, ²First Department of Medicine, Wakayama Medical University, ³Wakayama Rosai Hospital, Japan.

Background and aims: Though atrophy of small muscles of feet has been known as a cause of diabetic foot lesions, diagnostic significance of small muscles atrophy on diabetic symmetric polyneuropathy (DPN) has not been established. We aimed to evaluate the validity and reliability of observation of typical small muscle as extensor digitorum brevis muscle (EDB) EDB atrophy for diagnosis of DPN. Firstly, we examined the relations between EDB atrophy and neurological findings in the regional population-based Japanese subjects (Study I). Secondly, we investigated

the relations between EDB atrophy and quantitative neurological findings in the hospital-based diabetic patients (Study II).

Materials and methods: **Study I.** 367 non diabetic persons (128 male, 239 female) who received medical screening program of Katsuragi-Town were subjected. Subjective symptoms (numbness in toes and sole, pain in feet, paresthesia in feet), vibratory perception at both medial malleolus (VP; using C-128 tuning fork), bilateral Achilles tendon reflexes (ATR) and EDB atrophy were evaluated. We judged EDB atrophy as positive when both EDB could not be identified by inspection and palpation in the position of toe extension. We also interviewed about Seiza habit (Japanese sit-down style with the buttocks on top of the ankles). **Study II.** In 193 diabetic patients (109 male, 84 female), neurological examination as same as Study I were examined. Additional 8 objective nerve function tests such as: 4 parameters of nerve conduction study, 2 parameters of coefficient of variation of ECG R-R intervals, fall in systolic blood pressure during head-up tilt and quantitative vibratory perception threshold were evaluated. The relationships among these findings were analyzed.

Results: **Study I.** Prevalence (%) of EDB atrophy and Seiza habit in female (46, 67) were significantly higher than those in male (14, 26), respectively. Prevalence of EDB atrophy in positive Seiza habit subjects was significantly higher than that in Seiza habit negative subjects (53 vs 29, $p=0.001$). Therefore, female and male were separately analyzed. Only in male, EDB atrophy was significantly associated with ATR reduction and VP impairment. **Study II.** EDB atrophy was observed in 49% of women and in 27% of men. Only in male, EDB atrophy was significantly more prevalent in diabetic compared to non-diabetic subjects (27 vs 14, $p=0.011$). In male diabetic patients, all items of 8 quantitative nerve tests were significantly associated with EDB atrophy. In female, only 4 items were associated with EDB atrophy. We evaluated the predictive power of EDB atrophy for diagnosing the probable DSPN of Toronto consensus in diabetic men. The sensitivity, specificity and positive predictive value of EB atrophy to determine probable DSPN were 48%, 92% and 83%, respectively.

Conclusion: EDB atrophy was also seen in non-diabetic subjects, but EDB atrophy was significantly associated with peripheral neuropathy. EDB atrophy was more frequent in female than male. The gender difference seemed to depend the lifestyle such as Seiza habit. In diabetic men, EDB atrophy clearly reflected the DPN and EDB atrophy indicated the presence of DPN in approximately 90% of probability.

Initial findings in the relationship between diabetic peripheral neuropathy and microvascular reactivity in the foot

A. Barwick¹, J. Tessier², X. Janse de Jonge³, V. Chuter¹;

¹Podiatry, University of Newcastle, Ourimbah, ²Medical Radiation Science, University of Newcastle, Callaghan, ³Exercise Science, University of Newcastle, Ourimbah, Australia.

Background and aims: Microvascular dysfunction is common in people with diabetes resulting in diabetic nephropathy, retinopathy and neuropathy of both the large and small fibre nerves. In the periphery it contributes to diabetic ulceration via both peripheral neuropathy and changes to microvascular function. Post-occlusive reactive hyperaemia is a measure of microvascular reactivity (vasodilation capacity) that has been implicated in the diabetic foot complications. This study aimed to investigate the relationship between large and small fibre neuropathy and the post-occlusive reactive hyperaemia response in the diabetic foot.

Materials and methods: Diabetic participants were recruited from podiatry clinics for this cross-sectional study. They underwent testing for large fibre neuropathy (vibration perception threshold and monofilament detection), small fibre neuropathy (temperature and pain perception) as well as post occlusive reactive hyperaemia at the hallux (using laser Doppler). Correlations between presence of large and small fibre neuropathy, post-occlusive reactive hyperaemia parameters (time to peak and peak as a %

of baseline) and demographics characteristics including sex, HbA1c, age, height, weight and duration of diabetes were performed. Binary logistic regressions were performed on factors associated with the presence of large fibre neuropathy and small fibre neuropathy.

Results: Eighty-eight participants were included in the analysis. Significant but weak correlations were observed between presence of large fibre neuropathy and age ($r=0.20$; $p<0.05$), height ($r=-0.35$; $p<0.05$), and time to peak ($r=-0.21$; $p<0.05$). Correlations were observed between small fibre neuropathy and height ($r=0.34$; $p<0.05$), and time to peak ($r=0.24$; $p<0.05$). Binary logistic regression analyses demonstrated presence of large fibre neuropathy was associated with several demographic factors including increasing age (OR of 1.08 (95%CI: 1.02-1.15, $p<0.05$) and greater height (OR of 1.1 (95%CI: 1.04-1.15, $p<0.05$) and time to peak perfusion after occlusion (OR of 1.02 (95%CI: 1-1.04, $p<0.05$). Presence of small fibre neuropathy in taller people (OR of 1.09 (95%CI of 1.03-1.15, $p<0.05$) and those with an increased time to peak perfusion after occlusion (OR 1.02, 95%CI 1-1.03).

Conclusion: Greater height is associated with increased likelihood of the presence of both large and small fibre peripheral neuropathy. An increased time to peak following occlusion was also associated with increased likelihood of both types of neuropathy suggesting microvascular dysfunction measured by post occlusive reactive hyperaemia (specifically increased time to peak) is associated with higher likelihood of the presence of peripheral neuropathy.

Association between biomarkers of subclinical inflammation and nerve conduction in individuals with newly diagnosed diabetes: German Diabetes Study

C. Herder^{1,2}, I. Schamarek^{1,2}, B. Nowotny^{1,2}, K. Straßburger^{3,2}, M. Carstensen-Kirberg^{1,2}, P. Nowotny^{1,2}, A. Strom^{1,2}, S. Püttgen^{1,2}, K. Müssig^{1,2}, J. Szendroedi^{1,2}, D. Ziegler^{1,2}, M. Roden^{1,2};

¹Institute for Clinical Diabetology, German Diabetes Center, ²German Center for Diabetes Research (DZD e.V.), ³Institute for Biometrics and Epidemiology, German Diabetes Center, Düsseldorf, Germany.

Background and aims: Biomarkers of subclinical inflammation are associated with distal sensorimotor polyneuropathy, but their relationship to electrophysiological measures has not been assessed. Therefore, the aim of this study was to investigate associations between inflammation-related biomarkers and nerve conduction velocity (NCV) in the German Diabetes Study (GDS).

Materials and methods: Motor and sensory NCV was assessed in 513 patients with newly diagnosed type 1 and type 2 diabetes (161 T1D and 352 T2D; mean age 47 ± 14 years, 64.5% male, BMI 29.5 ± 6.4 kg/m², time since diagnosis of diabetes 6 ± 3 months). NCV sum scores were calculated using z-transformed NCV for motor (N. medianus, N. ulnaris, N. peroneus) and sensory (N. medianus, N. ulnaris, N. suralis) conduction. Associations between biomarkers of subclinical inflammation (C-reactive protein [CRP], interleukin [IL]-6 and IL-18, total and high-molecular-weight [HMW] adiponectin) and NCV sum scores were estimated using multiple linear regression models adjusted for time since diagnosis of diabetes, HbA1c, waist circumference, height, hypertension, cholesterol, smoking, physical activity, medication and history of myocardial infarction and/or stroke.

Results: In persons with T2D serum IL-6 and CRP were inversely associated with motor NCV ($p=0.011$ and $p=0.052$, respectively), and both total and HMW adiponectin were inversely associated with motor and sensory NCV (p between 0.001 and 0.033). In persons with T1D, total and HMW adiponectin showed positive associations with motor NCV (both $p=0.02$), but not with sensory NCV. Serum IL-18 was neither associated with motor nor sensory NCV in T1D and T2D.

Conclusion: Our results indicate that IL-6 may play a role in slowed motor NCV, but not in slowed sensory NCV in individuals with recent-

onset T2D. The lack of associations for CRP and IL-18, in contrast to IL-6, points to a differential rather than general association between inflammation-related biomarkers and NCV. The fact that associations between adiponectin and NCV appear to depend on diabetes type is intriguing and may reflect differences in the pathogenesis of both diabetes types.

The centre of sub-basal corneal nerve fibres can best reflect alterations in the blood glucose concentrations in diabetes mellitus

J. Leckelt¹, A. Kott¹, O. Stachs², S. Baltrusch¹;

¹Institute of Medical Biochemistry and Molecular Biology, ²Department of Ophthalmology, University of Rostock, Germany.

Background and aims: Small fibre neuropathy belongs to one of the most common long-term complications of diabetes mellitus (DM). In the assessment of diabetic neuropathy (DN), visualization and quantification of small nerve fibre damage is hitherto only possible by skin biopsy, thus, an invasive diagnostic tool. Another method, in vivo corneal confocal microscopy (IVCCM) is currently a matter of investigation to be established as a non-invasive procedure. The aim of this study was to elucidate the impact of streptozotocin (STZ) induced hyperglycaemia and subsequent insulin treatment on corneal and intraepidermal nerve fibre changes in thy1-YFP mice.

Materials and methods: Neuronal yellow fluorescent protein expressing B6.Cg-Tg(Thy1-YFP)16Jrs/J mice were injected by multiple low-dose injection of STZ (diabetic group n=15) or an equal volume of sodium citrate buffer (control group n=10). After induction of DM at day 20, half of the diabetic animals were treated with insulin releasing pellets. By using IVCCM, the subbasal nerve plexus in the centre of the cornea was examined at day 10, 20, 40 and 80. Corneal nerve fibre length (CNFL in mm/mm²) was quantified by NeuronJ. At the endpoints, day 20 and 80, mice were euthanized for tissue extractions. Using fluorescence microscopy ex vivo, the nerve fibres from the periphery and the centre of the cornea were examined as well as skin biopsies taken from the plantar surface of the hind paw. Intraepidermal nerve fibre density (IENFD in number/mm) was determined according to the guidelines of the European Federation of Neurological Societies (EFNS).

Results: STZ-treated mice showed hyperglycaemia (23.87±0.87 vs. 8.36±0.44 mmol/l; p<0.0001), a significant increase in HbA1c values (46.89±1.36 vs. 22.09±1.42 mmol/mol; p<0.0001) and a decrease in body weight. Insulin treatment resulted in a normalization of blood glucose concentration (8.24±1.72 vs. 6.26±0.29 mmol/l; p<0.29), HbA1c values (26.78±1.94 vs. 20.00±1.17 mmol/mol; p<0.02) and body weight. However, higher levels of advanced glycation end products (AGEs) (24.62±1.32 vs. 16.07±1.73 ng/ml; p<0.005) were observed at day 80. At day 20, the decrease of in vivo CNFL inversely correlated with hyperglycaemia. Ex vivo analyses revealed changes in the centre of the cornea, but not in peripheral parts. At day 80, in insulin treated mice recovery of central CNFL was observed. IENFD showed no significant changes to the diabetic group or age-matched controls at any time point.

Conclusion: Our study demonstrated that acute hyperglycaemia triggers subbasal corneal nerve fibre damage, whereas intraepidermal nerves remained unaffected. We hypothesize a higher susceptibility of the cornea to advanced glycation end products. However, after insulin therapy and blood glucose normalization, corneal nerve fibres start to regenerate. Additionally, it could be shown by ex vivo fluorescence analyses that nerve fibre damage and repair in DM take place from the centre of the cornea with a tendency to the inferior whorl. Integration of IVCCM in the diagnosis of DN in addition to quantitative sensory tests seems to be helpful, but needs further investigation to be a valuable tool.

PS 101 Autonomic neuropathy

Nocturnal antihypertensive treatment restores 24 hour blood pressure profile in type 1 diabetic patients with autonomic neuropathy

H.Ø. Hjortkjær¹, T. Jensen¹, K.F. Kofoed², U.M. Mogensen², L. Køber², K. Hilsted¹, H. Corinth¹, S. Theilade³, J. Hilsted¹;

¹Endocrinology, ²Cardiology, Rigshospitalet, Copenhagen University Hospital, ³Steno Diabetes Center, Gentofte, Denmark.

Background and aims: Cardiac autonomic neuropathy (CAN) and elevated nocturnal blood pressure are independent risk factors for cardiovascular disease in patients with diabetes and associations between CAN, non-dipping of nocturnal blood pressure and coronary artery disease have been demonstrated. The objective of the present study was to test the efficacy of bedtime dosing (BD) versus morning dosing (MD) of the angiotensin converting enzyme (ACE) inhibitor enalapril on 24 h blood pressure profile in patients with type 1 diabetes.

Materials and methods: In a randomised, double-blind, two-way crossover study, 24 normoalbuminuric patients with long-term type 1 diabetes with CAN were treated for 12 weeks with either MD or BD of 20 mg enalapril, followed for 12 weeks of switched treatment regimen. During each treatment period, two 24 hour ambulatory blood pressure measurements were performed. The systolic blood pressure (SBP) and diastolic blood pressure (DBP) were measured automatically every 20 min during daytime (between 07 and 23 h) and once every hour during nighttime (between 23 and 07 h). SBP, DBP and mean arterial pressure (MAP) during daytime and nighttime and the dipping percentage was calculated using Spacelabs Healthcare Ambulatory Blood Pressure Report Management System version 3.0.0.9. Furthermore two computed tomography (CT) scans were performed after each treatment period measuring the left ventricle mass (LVM) and the left ventricle volume (LVV). The mean age of the patients were 60 ± 7 (SD) years, 40% were males, BMI was 24.5 ± 4.0 (SD), HbA_{1c} was 62 ± 7 (SD) mmol/mol, creatinine was 66 ± 13 (SD) µmol/L and the diabetes duration was 36 ± 11 (SD) years. Sixty percent of the patients were treated with antihypertensive drugs (median 2 drugs) before the study.

Results: Nighttime SBP dipping increased 2.4 (0.03 - 4.9) % (p<0.05) with BD of enalapril compared with MD. Also, there was seen a trend towards a MAP dipping increase of 2.2 (-0.1 - 4.5) % (p=0.07) and a nighttime MAP reduction of 1.7 (-3.6 - 0.2) mmHg (p=0.07) with BD compared with MD. Daytime SBP and DBP were not significantly different between the two treatment regimens. A small, but insignificant reduction in pulse pressure was observed. No significant difference was found on LVM or LVV between the two treatment regimens. No adverse events were registered during nighttime treatment of blood pressure and no drop outs occurred during the study.

Conclusion: This study demonstrates for the first time that high risk long-term type 1 diabetic patients with autonomic neuropathy favourably and without risk can be treated with an ACE inhibitor during night. The potentially beneficial effect on long-term cardiovascular risk remains to be determined.

Diabetic nephropathy lesions associate with cardiovascular autonomic neuropathy in Pima Indians with type 2 diabetes

K.M. Wheelock¹, M. Jaiswal², C.L. Martin², G.D. Fufaa¹, J.E. Weil¹, E. Feldman³, F.C. Brosius², W.C. Knowler¹, R.G. Nelson¹, R. Pop-Busui²; ¹Phoenix Epidemiology and Clinical Research Branch, ²Department of Internal Medicine, ³Department of Neurology, University of Michigan Medical School, Ann Arbor, USA.

Background and aims: Cardiovascular autonomic neuropathy (CAN) and diabetic kidney disease (DKD) are thought to be linked. The association of CAN with renal structure is unknown. To identify the renal lesions that associate with CAN in Pima Indians with type 2 diabetes (T2D).

Materials and methods: Sixty-three Pima Indians (27% men) with T2D underwent kidney biopsy at baseline. Masked unbiased random sampling morphometric methods were used to measure renal structural parameters of DKD. Glomerular filtration rate (GFR; iohalamate), urinary albumin/creatinine ratio (ACR), and other clinical variables were measured at an examination within a median of 46 days of the biopsy. CAN was assessed after a mean follow-up of 9 years by standard cardiovascular reflex testing (deep-breathing test) and heart rate variability studies. Measures of CAN analyzed, included the expiration/inspiration ratio (E/I) and the standard deviation of the normal R-R intervals (sdNN). Associations of CAN with structural variables were assessed by Spearman's correlations and by multiple linear regression after adjusting for age, sex, diabetes duration, HbA1c, ACR and GFR. E/I and sdNN were log-transformed for linear regression modeling due to skewed distributions.

Results: Mean age at kidney biopsy was 46±9 years, diabetes duration 16±6 years, mean HbA1c 9.1±1.9%, mean GFR 156±57 ml/min, and median ACR 25 mg/g (IQR=9-68 mg/g). At follow-up, 95% of participants had CAN (E/I<1.17, median=1.04, IQR=1.03-1.08). E/I correlated positively with percentage of fenestrated endothelium (FE; $r=0.26$, $p=0.040$) and negatively with mesangial fractional volume (VvMes; $r=-0.39$, $p=0.002$) and glomerular basement membrane (GBM) width ($r=-0.40$, $p=0.001$). sdNN (median=18 ms, IQR=11-27 ms) correlated positively with glomerular filtration surface density (Sv; $r=0.35$, $p=0.005$) and negatively with VvMes ($r=-0.34$, $p=0.007$) and GBM width ($r=-0.42$, $p=0.001$). Neither E/I nor sdNN correlated with ACR or GFR. In linear regression analyses adjusted for age, sex, diabetes duration, HbA1c, ACR, and GFR, E/I was positively associated with FE ($r=0.33$, $p=0.011$) and negatively associated with VvMes ($r=-0.32$, $p=0.018$) and GBM width ($r=-0.28$, $p=0.034$). sdNN was positively associated with FE ($r=0.31$, $p=0.019$) and Sv ($r=0.41$, $p=0.001$) and negatively associated with VvMes ($r=-0.28$, $p=0.035$) and GBM width ($r=-0.42$, $p=0.001$). Adjusted associations between sdNN and morphometric variables are shown in Figure

Conclusion: Pima Indians with T2D and DKD have a high prevalence of CAN, which is more severe in those with more severe renal structural damage.

Hypoxia as a reversible cause of cardiovascular autonomic dysfunction in patients type 2 diabetes and impaired renal function

L. Bernardi¹, P. Esposito², L. Bianchi¹, R. Mereu¹, G. DeBarbieri¹, A. Dal Canton², P.-H. Groop³; ¹Department of Internal Medicine, ²Department of Nephrology, Pavia University, Italy, ³Nephrology and Folkhälsan Research Center, University of Helsinki, Finland.

Background and aims: Cardiovascular autonomic dysfunction, characterized by an imbalance between sympathetic and parasympathetic activities, is common in patients with diabetes mellitus. Although this is conventionally considered to be an organic, irreversible disorder, it has already been demonstrated in patients with type 1 diabetes that baroreflex sensitivity (BRS) could be corrected by deep breathing, thus suggesting a functional component to the disorder. In this study we tested this hypothesis in the type 2 diabetic patients with or without renal impairment.

Materials and methods: Twenty-six patients affected by type 2 diabetes were enrolled (age 61.1±0.8 years, Mean±SEM; diabetic duration 10.5±2 years, BMI 29.9±0.7 kg/m², GFR, [CKD-EPI formula]: 68.1±5.5 ml/min (range 18-105 ml/min). Six patients presented microalbuminuria and five macroalbuminuria. Twenty-four healthy subjects (age 58.5±1.0 years) were enrolled as controls. BRS was obtained from recordings of RR interval and systolic blood pressure fluctuations during spontaneous and slow, deep (6 breaths/min) controlled breathing. Then, the entire protocol was repeated in hyperoxia (breathing 5 L/min oxygen).

Results: During normal breathing diabetic patients presented higher HR and lower BRS compared with the control participants (5.5±0.6 vs 11.8±2.0 ms/mmHg, $p<0.005$). Deep breathing and oxygen administration significantly increased arterial saturation, reduced HR and increased BRS in both the diabetic patients and the control group and (to 9.6±1.9 and 15.3±2.3 ms/mmHg, respectively, $P<0.05$, hyperoxia vs normoxia). Twelve diabetic patients presented chronic kidney disease (CKD), defined by the presence of proteinuria and reduced GFR. CKD patients compared with non-CKD subjects showed a longer duration of diabetes and a poorer glycaemic control, with a significant inverse correlation between diabetes duration and GFR values ($r^2=0.20$, $p=0.02$). However, also this group of patients presented a significant improvement of BRS during slow breathing and hyperoxia ($p<0.05$ vs spontaneous breathing in normoxia).

Conclusion: Our results show that autonomic dysfunction present in type 2 diabetic patients is further aggravated in CKD. However, this condition can be partially reversed by increasing oxygen supply, suggesting a possible role of hypoxia in the origin of diabetic complications. This finding supports the hypothesis that interventions known to relieve tissue hypoxia, like physical activity, may be useful in the prevention and management of complications in diabetic patients. The severity of autonomic dysfunction and response to oxygen seen in CKD call attention on hypoxia as a reversible pathogenic factor of the renal damage in diabetic patients.

1045

Erectile dysfunction among Bangladeshi diabetic men

S. Selim¹, M.A.J. Chowdhury², M.N. Karim³; ¹Endocrinology, ²Internal Medicine, Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh, ³Department of Epidemiology and Preventive Medicine Faculty of Medicine Nursing and Health Science, Monash University, Melbourne, Australia.

Background and aims: Erectile dysfunction (ED) is an important impediment to quality of life of men. ED is approximately, three times more common in diabetic than non-diabetic men, and diabetic men develop ED earlier than age matched non-diabetic subjects. Glycemic control and other factors may contribute in developing and or deteriorating ED. The

aim of the study was to determine the prevalence of ED and its risk factors in type 2 diabetic (T2DM) men in Bangladesh.

Materials and methods: During 2013–2014, 3980 diabetic men aged 30–69 years were interviewed at the out-patient departments of seven diabetic centers in Dhaka by using the validated Bengali version of the questionnaire of the international index of erectile function (IIEF) for evaluation of baseline erectile function (EF). The indexes indicate a very high correlation between the items and the questionnaire is consistently reliable. Data were analyzed with Chi-squared (χ^2) test using SPSS software. $P \leq 0.05$ was considered significant.

Results: Out of 3790, ED was found in 2046 (53.98%) of T2DM men. The prevalence of ED was increased with age from 10.5% in men aged 30–39 years to 33.6% in those aged over 60 years ($P < 0.001$). In comparison with patients with reported diabetes lasting ≤ 5 years (26.4%), the prevalence of ED was less than in those with diabetes of 6–11 years (35.3%) and of 12–30 years (42.5%, $P < 0.001$). ED increased significantly in those who had poor glycemic control. The prevalence of ED in patients with good, fair and poor glycemic control was 22.8%, 42.5% and 47.9% respectively ($P = 0.004$). Treatment modalities (medical nutrition therapy, oral agents, insulin and insulin plus oral agents) had significant association with ED and its severity ($P < 0.001$).

Conclusion: Prevalence of ED is very high among T2DM men in Bangladesh and can be reduced the burden by improving glycemic status. Glycemic control, duration of diabetes, treatment modalities, increasing age are associated with ED.

Low gastrointestinal symptom burden in a Swedish population based cohort with insulin dependent diabetes mellitus

J.E.A. Brun, H. Tömbloom, G. Ringström, E. Olausson, M. Simrén; Gastroenterology & Hepatology, Internal Medicine, Gothenburg, Sweden.

Background and aims: Long-standing diabetes mellitus (DM) is afflicted with a wide variety of complications that may cause symptoms from multiple organ systems including the gastrointestinal (GI) tract. Data from other centers have claimed that autonomic neuropathy affects up to 30–40% of patients with long-standing disease and as many as 75% of patients attending DM clinics report significant GI symptoms. The aim of our study was to understand the extent to which a defined cohort of Swedish patients with DM suffers from GI symptoms.

Materials and methods: Patients with insulin dependent DM type 1 (IDDM1) and type 2 (IDDM2) who attended the diabetic outpatient clinics at two county hospitals were included in the study. They were sent the Patient Assessment of upper Gastrointestinal Symptom Severity Index (PAGI-SYM) questionnaire for assessment of GI symptom severity which consists of 20 questions answered by use of a six-point Likert response scale, ranging from 0 (none) to 5 (very severe). The Gastroparesis Cardinal Symptom Index (GCSI) can be calculated by use of the first nine questions of PAGI-SYM resulting in scores for total symptom burden, nausea/vomiting, postprandial fullness/early satiety and bloating. Hospital anxiety and depression (HAD) scale was used for psychological assessment and the short form (SF) 36 questionnaire summary measures for physical and mental health. For those who answered the questionnaires (one reminder to non-responders), clinical information was retrieved from medical records regarding complications related to long-standing DM such as manifestations from large vessel atherosclerosis (ischemic heart disease and stroke), peripheral neuropathy, retinopathy and nephropathy.

Results: We included 754 patients (mean age 48 years (range 18–82 years)). The questionnaire was answered by 436 patients (response rate 57.8%), and 363 (83.3%) of these had IDDM1 and 73 (16.7%) had IDDM2. The duration of insulin treatment was 21 ± 13 years. The mean GCSI total score in the cohort was 0.7 ± 0.8 . Females with IDDM had significantly higher GCSI total score (0.853 vs. .622; $p = 0.003$), GCSI nausea/

vomiting score (0.42 vs. 0.28; $p = 0.019$) and GCSI bloating score (1.2 vs. 0.81; $p = 0.001$) compared to males. There was a strong correlation ($p = 0.001$) between SF-36, HAD and the GCSI total, nausea/vomiting and bloating scores. There was no significant difference between sexes for GCSI postprandial fullness/early satiety score. There was no significant difference in GCSI scores comparing patients with IDDM1 and IDDM2, also not within sexes. Patients with one or more complications related to long-standing DM reported GI symptoms to the same extent as those with no complications and more complications was not associated with higher GCSI scores.

Conclusion: Females with IDDM reported more GI symptoms compared with males. Although the total GI symptom burden in our study corresponded to “very mild” there was a highly significant correlation between the GCSI subscores; total, nausea/vomiting, bloating and mental and physical health and anxiety and depression. Furthermore it appears that the number complications to long standing DM do not per se imply an increase in reported GI symptoms.

Cardiovascular autonomic neuropathy predicts development of diabetic foot ulcer in patients with type 2 diabetes mellitus

S.-A. Cha¹, T.-S. Lim¹, J.-S. Yun¹, S.-D. Moon², H. Seok³, Y.-B. Ahn¹, S.-H. Ko¹;

¹Internal Medicine, The Catholic University of Korea, St. Vincent's hospital, Suwon, ²Internal Medicine, The Catholic University of Korea, Incheon St. Mary's Hospital, ³Internal Medicine, The Catholic University of Korea, Uijeongbu St. Mary's Hospital, Republic of Korea.

Background and aims: We investigated potential risk factors that might influence the development of diabetic foot ulcers in patients with type 2 diabetes.

Materials and methods: From January 2003 to December 2004, a total of 1,534 patients with type 2 diabetes were consecutively enrolled. Significant diabetic foot ulcer was defined as a full-thickness break in the epithelium with a minimum width of 5 mm. Patients were checked every 3–6 months for status of diabetic foot ulcer, or amputation during the follow-up periods. A cardiovascular autonomic function test (AFT) was performed to diagnose cardiovascular autonomic neuropathy (CAN) using heart rate variability parameters. We used a Cox proportional hazard regression analysis to test associations between diabetic foot ulcer and potential explanatory variables.

Results: The median follow-up time was 9.7 years. The mean age was 55.6 ± 10.8 years, and the duration of diabetes was 8.3 ± 7.0 years. During the follow-up periods, 135 patients (8.8%) developed new ulcer, and 26 patients (1.7%) underwent an amputation. The patients in the diabetic foot ulcer group had a longer duration of diabetes ($p < 0.001$), higher baseline HbA_{1c} levels ($p < 0.001$), higher rates of smoking ($p = 0.001$), albuminuria ($p < 0.001$), retinopathy ($p < 0.001$), and received more insulin treatment ($p < 0.001$). A Cox hazard regression analysis revealed that the development of diabetic foot ulcer was significantly associated with the presence of cardiovascular autonomic dysfunction (normal vs early CAN, HR 2.06, 95% CI 0.95–4.45; $p = 0.066$; normal vs definite CAN, HR 2.50, 95% CI 1.18–5.26; $p = 0.010$) after adjusting for sex, age, diabetic duration, mean HbA_{1c}, albuminuria, retinopathy, and treatment of insulin.

Conclusion: The development of diabetic foot ulcers was independently associated with cardiovascular autonomic dysfunction in patients with type 2 diabetes.

Short-term beat-to-beat QT-interval variability in patients with impaired glucose tolerance

C. Lengyel¹, A. Orosz², S. Nyiraty¹, N. Németh³, Z. Putz³, R. Takács¹, A. Nemes⁴, T.T. Várkonyi¹, I. Baczkó², G. Ábrahám¹, P. Kempler³, J.G. Papp^{2,5}, A. Varró^{2,5},

¹1st Department of Medicine, ²Department of Pharmacology and Pharmacotherapy, University of Szeged, ³2nd Department of Medicine, Semmelweis University, Budapest, ⁴2nd Department of Medicine and Cardiology Centre, University of Szeged, ⁵MTA-SZTE Research Group of Cardiovascular Pharmacology, Hungarian Academy of Sciences, Szeged, Hungary.

Background and aims: Determination of short-term QT-interval variability (QTV) is a non-invasive method for assessment of proarrhythmic risk. The aim of the present study was to evaluate the QTV in patients with impaired glucose tolerance (IGT).

Materials and methods: 18 IGT patients (age: 63.0±2.7 years, BMI: 31.4±1.5 kg/m², fasting glucose: 6.0±0.1 mmol/l, 120 min postload glucose: 9.0±0.2 mmol/l, HbA1c: 5.9±0.1%; mean±SEM) and 18 healthy controls (age: 56.1±2.2 years, BMI: 27.3±1.3 kg/m², fasting glucose: 5.2±0.1 mmol/l, 120 min postload glucose: 5.5±0.3 mmol/l, HbA1c: 5.4±0.1%) were enrolled into the study. ECGs were recorded, processed, stored and analyzed off-line using a computer based analyzing system. The RR and QT intervals were expressed as the average of 31 consecutive beats. The ventricular repolarization was characterized by uncorrected QT-interval and QT intervals corrected by Bazett (QTc-b), Fridericia (QTc-f) and Hodges (QTc-h) formula. The spatial repolarization inhomogeneity was specified by QT dispersion (QTd). To evaluate the short-term temporal instability of beat-to-beat repolarization, Poincaré plots of the QT intervals were constructed, where each QT value is plotted against its former value. QTV was calculated using the following formula: $QTV = \sum |QT_n + 1 - QT_n| (30 \times \sqrt{2}) - 1$. Autonomic function was assessed by means of five standard cardiovascular reflex tests using the same analyzing system.

Results: Comparison of the two groups (IGT vs control) revealed no difference in the uncorrected QT (410±10.2 ms vs 409±11.5 ms), QTc-b (431±5.8 ms vs 427±6.8 ms), QTc-f (424±6.3 ms vs 421±7.8 ms), or QTc-h (424±6.9 ms vs 420±8.2 ms) intervals. There was no difference in the QTd between IGT and control individuals (43.8±3.0 ms vs 43.1±5.6 ms). The QTV, however, was increased in the IGT patients relative to those for the control group (4.95±0.16 ms vs 3.82±0.23, p=0.0004).

Conclusion: The short-term QT variability may be elevated in patients with impaired glucose tolerance. This enhanced temporal QT variability may early indicate the increased instability of cardiac repolarization.

Changes in vago-sympathetic activity and its influence on heart rate and insulin response to oral glucose load

S. Bathaei, C. Cussac-Pillegand, S. Chiheb, R. Dutheil, M. Fysekidis, E. Cosson, P. Valensi;

Department of Endocrinology Diabetology Nutrition, Jean Verdier hospital, AP-HP, CRNH-IdF, CINFO, Bondy, France.

Background and aims: We showed that cardiac parasympathetic activity is often altered in non diabetic obese patients and similarly in metabolically healthy obese patients. The aim of this study was in obese patients

with a metabolically healthy phenotype to examine the influence of the changes in vago-sympathetic activity on heart rate and insulin response to oral glucose load (OGTT).

Materials and methods: We recruited 24 patients, aged 34±13 years, BMI 42.2±6.9 kg/m², with only one criterion of the metabolic syndrome (hyperglycemia in only one patient) in addition to large waist circumference. An oral glucose tolerance test (OGTT, 75 g) was performed. Composite indexes of insulin secretion (insulinogenic index=IGI=Δinsulinemia(T0-T30)/Δglycemia(T0-T30), and oral disposition index=ODI=IGI/insulinemia) were calculated. Cardiac parasympathetic activity (HF-HR), sympatho-vagal balance (LF/HF-HR), and vascular sympathetic activity (LF-SBP) were evaluated by spectral analysis of heart rate and systolic blood pressure (SBP) variations (Finapress®), and plasma epinephrine and norepinephrine levels were measured at fasting and during the OGTT.

Results: Patients were separated in two groups according to cardiac parasympathetic activity at fasting: high or low (HF-HR> or < median value: 2.78). During OGTT the patients with high parasympathetic activity at fasting maintained a higher HF-HR (p<0.001) despite a transient decrease after insulin peak. These patients had lower LF/HF-HR at fasting which remained lower during OGTT (p=0.019). Epinephrine and norepinephrine response did not differ significantly between the two groups. A significant acceleration of heart rate occurred during OGTT in the two groups (p=0.002) but heart rate was lower both at fasting and during OGTT in the patients with high parasympathetic activity (p=0.03). High parasympathetic activity was associated with higher ODI (p=0.035).

Conclusion: Among obese patients with metabolically healthy phenotype those with a higher parasympathetic activity keep a higher parasympathetic activity after glucose intake. This profile accounts for a lower heart rate at fasting and after glucose load and seems to contribute to a greater insulin secretion.

Why not to use the handgrip test in the assessment of cardiovascular autonomic neuropathy?

A.E. Körei¹, Z. Putz¹, I. Istenes¹, M. Kempler¹, O. Vági¹, R. Nagy¹, K. Keresztes¹, V. Spallone², P. Kempler¹;

¹1st Department of Medicine, Semmelweis University, Budapest, Hungary, ²Department of Systems Medicine, University of Rome Tor Vergata, Italy.

Background and aims: The cardiovascular autonomic reflex tests (CARTs) have been considered as gold standard in the assessment of cardiovascular autonomic neuropathy (CAN). However, only four of the five tests have been currently suggested to be performed - sympathetic function should be evaluated by the orthostatic hypotension (OHT) test while measuring diastolic blood pressure (BP) response to sustained handgrip is omitted in recent guidelines. Aim of our study was to assess the relationship of handgrip test with the other tests in detecting CAN as well as to identify the factors having impact on the handgrip test results in diabetic patients.

Materials and methods: Our study involved 353 patients with diabetes (age: 60,2±7,4 years; female: 57,2%; BMI: 29,3±2,1 kg/m²; diabetes duration: 15,6±9,9 years; HbA1c: 8,2±1,9%; with type 1 diabetes: 18, 1%). CAN was assessed by five CARTs: the deep breathing test, Valsalva ratio, 30/15 ratio, handgrip and OHT test. CARTs based on heart rate changes mainly reflect parasympathetic while those based on BP response to manoeuvres explore sympathetic function. Connection between results of the handgrip and the other CARTs as well as clinical parameters of the study population were analysed using Kendall monotony coefficient (γ) and Spearman's correlation (ρ). Dichotomous variables were analysed using χ²-test.

Results: Definite diagnosis of CAN according to recent guidelines as well as abnormal results of the deep breathing, Valsalva ratio, 30/15 ratio,

handgrip test and OHT test were present in 49,3%, 86,1%, 35,1%, 4,5%, 22%, and 32,3%, respectively. Results of the handgrip test did not show any association with results of the deep breathing test ($p=0,897$) and 30/15 ratio ($p=0,357$), as they did not do with the results of the partially sympathetically controlled Valsalva ratio, either ($p=0,781$). An association between handgrip and OHT failed to be proven ($p=0,833$). Sensitivity, specificity, positive and negative predictive value of the handgrip test versus definite diagnosis of CAN were 22,9%, 78,8%, 51% and 51,3%, respectively. The results of handgrip test did actually show a significant negative association with the presence of hypertension ($\gamma=-0,315$, $p=0,009$), whereas the diastolic BP elevation during the manoeuvre was inversely related to the baseline diastolic BP ($\rho=-0,283$, $p=0,013$). In multiple logistic regression analysis, the significant inverse association between abnormality of the handgrip test and hypertension was independent of age, gender, BMI, diabetes duration, type of antihypertensive medication, insulin treatment as well as presence of sensory loss and neuropathic pain medication. OHT was associated with the severity of the parasympathetic impairment ($\gamma=0,303$, $p<0,0001$) and with Valsalva ratio abnormality ($\gamma=0,342$, $p<0,0001$). Presence of hypertension had no effect on the results of OHT test ($p=0,97$).

Conclusion: Our data may provide evidence that the handgrip test should no longer be part of the cardiovascular autonomic testing being highly dependent of the hypertensive status and baseline blood pressure. The putative mechanism for the inverse association between abnormal results of the handgrip test and hypertension could be an exaggerated exercise pressor reflex related to increased sympathetic cardiovascular activation in patients with diabetes and hypertension.

1051

Integrated cardiovascular/respiratory control in type 1 diabetes

L. Bianchi¹, C. Porta¹, A. Rinaldi¹, C. Gazzaruso², P. Fratino³, P. DeCata², P. Protti¹, R. Paltro¹, L. Bernardi^{1,4},

¹Department of Internal Medicine, University of Pavia, ²Department of Internal Medicine and Endocrinology, IRCCS Fondazione S.Maugeri, Pavia, ³ASL Pavia, Italy, ⁴Folkhälsan Institute of Genetics, Folkhälsan Research Center, University of Helsinki, Finland.

Background and aims: Diabetic autonomic dysfunction and ventilatory control abnormalities both increase cardiovascular risk. Cardiovascular (baroreflex) and respiratory (chemoreflex) control mechanisms were studied separately in diabetes, but their reciprocal interaction had never been assessed. We hypothesized that prevalent autonomic neuropathy would depress both chemoreflexes and the arterial baroreflex mechanisms, whereas prevalent autonomic imbalance through sympathetic activation would depress the baroreflex but enhance chemoreflex mechanisms.

Materials and methods: In 46 type-1 diabetic subjects (33±1 yr, 22 female) and in 103 age-matched controls we measured RR interval, continuous noninvasive blood pressure (Colin®), minute ventilation, oxygen saturation (SaO₂) and end-tidal carbon dioxide (CO₂) at rest and during progressive normoxic hypercapnia (from baseline to 55 mmHg) and progressive isocapnic hypoxia (from baseline down to 80% SaO₂). Baroreflex sensitivity was estimated by a battery of 6 standardized methods (based on spectral analysis and spontaneous sequences of RR interval and Systolic Blood pressure variabilities), hypercapnic and hypoxic chemoreflex sensitivities were obtained by the slopes of the linear regressions linking minute ventilation to CO₂ increase and to SaO₂ decrease, respectively. Autonomic neuropathy was evaluated by a standard battery of cardiovascular reflex tests (deep breathing, lying-to-standing, handgrip, Valsalva manoeuvre, blood pressure changes to tilting).

Results: Mild signs of autonomic neuropathy were present in 26/46 diabetics (average score 1.42±0.14, group N+), and absent in 20/46 patients (group N-). Baroreflex sensitivity was reduced in the entire diabetic group (9.8±0.9 vs controls: 13.4±0.8 ms/mmHg, $p<0.01$), and particularly in

group N+ (8.5±0.9 ms/mmHg, $p<0.01$), whereas although reduced, it was not significantly different in N- diabetics (11.7±1.6 ms/mmHg, $p:ns$). The hypercapnic chemoreflex was significantly increased in the entire diabetic group (1.86±0.19 vs 1.41±0.13 L/min/mmHgCO₂ in controls, $p<0.05$), and particularly in N+ diabetics (2.18±0.28 L/min/mmHgCO₂, $p<0.05$). Conversely, the hypoxic chemoreflex was slightly depressed in the entire diabetic group (0.73±0.9 vs controls: 0.91±0.07 L/min/%SaO₂, $p:ns$), and equally reduced in N+ and N- groups.

Conclusion: Thus, a reduced sensitivity to hypoxia seems a primary factor leading to reflex sympathetic activation (enhanced hypercapnic chemoreflex and depression of baroreflex), hence suggesting a functional origin of autonomic abnormalities in initial diabetes.

1052

Parasympathetic autonomic dysfunction rather than central afferent impairment is the early sign of neuropathy in recently diagnosed type 2 diabetes

T.T. Várkonyi¹, S. Nyiraty¹, K. Fehértemplomi¹, R. Takács¹, A. Orosz², F. Tóth³, L. Rovó³, C. Lengyel¹, J. Kiss³, P. Kempler⁴, G. Ábrahám¹;

¹1st Department of Medicine, ²Department of Pharmacology and Pharmacotherapy, ³Department of Oto-Rhino-Laryngology, University of Szeged, ⁴1st Department of Medicine, Semmelweis University, Budapest, Hungary.

Background and aims: It is well known that hyperglycemia has a long-term harmful effect on nerve fibres, but the shortest period of diabetic exposure leading to the appearance of different neuronal dysfunctions is poorly documented. The aim of this study was to characterize the presence and severity of autonomic and central nerve function in patients with recently diagnosed type 1 or type 2 diabetes (DM).

Materials and methods: 40 patients with type 1 or type 2 DM were involved (type 1: n=21, age: 28.8±2 years, duration of DM: 2.1±0.5 months; type 2 DM: n=19, age: 48.4±3.9 years, duration of DM: 3.3±0.8 months; mean±SE). Age and sex matched subjects served as controls. Cardiovascular reflex tests (CRT) were applied for the assessment of autonomic neuropathy (AN). The afferent central pathways were measured by analysis of the latencies of the four waves (I-IV/V) of brainstem auditory-evoked potentials (BAEP).

Results: The results of the CRT-s and the latencies of BAEP did not differ from controls among recently diagnosed type 1 DM patients. The overall AN score was higher in recently discovered type 2 DM than in controls (AN score: 2.16±0.5 vs 0.33±0.1, $p<0.01$; diabetic vs control). The heart rate response to breathing was lower in type 2 DM patients than in controls (17±2.1 vs 23.1±2.3 min., $p<0.05$) and a negative correlation was found between Valsalva ratio and the wave V latency of BAEP ($r=-0.61$, $p<0.01$). There was a non-significant tendency of longer latencies of all BAEP waves in type 2 DM patients than in controls.

Conclusion: The autonomic and central neuronal function seems to be intact among type 1 diabetic patients with short duration. Early to moderate impairment of parasympathetic cardiovascular autonomic function was found in patients with recently diagnosed type 2 diabetes. The more abnormal values of a parasympathetic test correlated with the latency of a wave of the auditory-evoked potentials. Our data support that autonomic parasympathetic dysfunction rather than central afferent impairment should be considered as the early sign of neuropathy in recently diagnosed type 2 diabetes.

1053

Main determinants of autonomic dysfunction in subjects with normoglycaemia and newly-diagnosed type 2 diabetes

R. Dimova, T. Tankova, N. Chakarova, L. Dakovska, G. Grozeva; Department of Diabetology, Clinical Centre of Endocrinology, Medical University, Sofia, Bulgaria.

Background and aims: Cardiovascular autonomic dysfunction (CAD) is a serious and common complication of diabetes associated with increased cardiovascular morbidity and mortality. As it occurs even at the early stages of glucose intolerance and insulin resistance the present study aims to outline main predictors of CAD in subjects with normal glucose tolerance (NGT) and newly-diagnosed type 2 diabetes (NDT2D) with or without metabolic syndrome (MetS).

Materials and methods: A total of 200 subjects - 108 females and 92 males (mean age 49.8±10.3 years, mean BMI 31.1±5.8 kg/m²), divided into two age- and BMI-matched groups according to their glucose tolerance: 100 with NGT and 100 with NDT2D, and subdivided into 4 groups according to the presence of MetS; and into two groups according to the presence of CAD - 42 with CAD and 158 controls, were enrolled. Glucose tolerance was studied during OGTT. Anthropometric indices, blood pressure (BP), HbA1c, serum lipids and hsCRP were measured. ECG for calculating QTc interval was performed. AGEs were evaluated by skin autofluorescence (AGE-Reader). Body composition was estimated by impedance analysis (InBody 720). Cardiovascular autonomic function (CAF) was assessed by ANX-3.0 using frequency-domain analysis at rest and during deep breathing, Valsalva and standing from a seated position. Statistical analysis was performed using SPSS v.20.0.

Results: A higher prevalence of CAD in NDT2D as compared to NGT - 27/100 (64.3%) vs 15/100 (35.7%), OR 1.4 (95%CI: 1.05 to 1.84), $p=0.037$ was observed. Despite the trend toward lower autonomic power in the subgroups with MetS, the difference was not statistically significant. CAF showed a significant negative correlation with age, visceral fat area, total body fat, systolic BP, AGEs, and QTc interval in both groups with NDT2D and NGT. Although significantly elevated levels of triglycerides, total cholesterol, BP, HbA1c, fasting glucose, AGEs, QTc interval and age were found in the group with CAD in comparison to controls, after performing logistic regression analysis, $\chi^2(4)=26.385$, $p<0.0001$ with R^2 of 0.021, correctly classifying 81.0% of cases, only increasing age - OR 1.06 (95%CI: 1.02 to 1.1), $p=0.005$ and the presence of hypertension - OR 2.8 (95%CI: 1.2 to 6.7), $p=0.019$ were associated with an increased likelihood of CAD - AUC 0.762 (95%CI: 0.682 to 0.842), $p<0.0001$.

Conclusion: Our results demonstrate increased frequency of CAD in NDT2D independently of the presence of metabolic syndrome. Hypertension and age seem to be the main predictors of CAD in the early stages of impaired glucose metabolism.

Vitamin B12 deficiency is associated with cardiovascular autonomic neuropathy in patients with type 2 diabetes

C.S. Hansen¹, M. Ridderstråle², J. Fleischer³, D. Vistisen¹, M.E. Jørgensen¹;

¹dept. of epidemiology 469, Steno Diabetes Center, Gentofte, Denmark,

²Outpatient clinic, Steno Diabetes Center, Gentofte, ³Medical Research Laboratories, Clinical Institute of Medicine, Aarhus University, Denmark.

Background and aims: Cardiovascular autonomic neuropathy (CAN) is a severe diabetic complication associated with increased cardiovascular mortality. The risk of CAN in diabetes 2 patients could be additionally increased by vitamin B12 deficiency which is known to be a risk factor for peripheral neuropathy and has also been associated with markers of CAN in non-diabetic patients. Type 2 diabetes patients are prone to B12

deficiency by the use of metformin and possibly proton pump inhibitors (PPIs). We aim to be the first to investigate the possible cross-sectional association between serum levels of Vitamin B12 and CAN in patients with type 2 diabetes.

Materials and methods: 512 type 2 diabetes patients (mean diabetes duration 10.0 years, mean age 58.7 year, 34.9% men, 14.5% with CAN) had serum vitamin B12 measured and were screened for CAN using 3 standard cardiovascular reflex tests (CARTS): deep breathing test (E:I-ratio), lying-to-standing test (30/15) and the Valsalva maneuver. 5 minute resting heart rate (5 min RHR) was also measured. CAN was diagnosed if at least 2 of 3 CARTS were abnormal. Associations between vitamin B12 and outcomes were assessed by using logistic and linear regression models adjusting for age and sex.

Results: We found associations between levels of serum vitamin B12 and the E:I-ratio, an early marker of CAN. A 25 pmol/l increase of vitamin B12 was associated with an increase in E:I-ratio of 0.22% ($P=0.038$, 95%CI 0.01-0.43). No significant associations between 5 min RHR, the 30/15 test, the Valsalva maneuver or the CAN diagnosis were found possibly be due to lack of statistical power.

Conclusion: Serum vitamin B12 is associated with early CAN in patients with type 2 diabetes prompting the need for annual vitamin B12 screening in high risk patients e.g. those treated with metformin and/or PPIs.

PS 103 Assessment of the diabetic foot

1055

Patients and health care provider related delay in the treatment of diabetic foot ulcers

A. Rasmussen, K. Engelhard, A. Pedersen, N. Bonnichsen, M. Ridderstråle;
Steno Diabetes Center, Gentofte, Denmark.

Background and aims: Diabetic foot ulcer is a life threatening complication and very costly both for the health care system and the patient. Prompt treatment is necessary to reduce the risk of deep infections and amputations. Time from ulcer to treatment is an important determinant of treatment outcome. The aim was to study factors that influence healing time in patients with diabetic foot ulcers seen in a multidisciplinary outpatient clinic.

Materials and methods: Newly referred patients between Sep. 9th 2013 and March 9th 2014 were identified and primarily analysed for time between ulcer to contact, and contact to appointment in relation to various baseline and outcome variables. Data are shown as mean±standard deviation (SD). Non-parametric statistical analyses were used, and a p-value below 0.05 was considered statistically significant.

Results: 118 patients presenting 193 ulcers were identified: Age 65.9±1.1 years (89 [75%] males), diabetes duration 27.8±1.3 years (47 type 1 diabetes [40%]), BMI 29.8±0.5 kg/m², HbA1c 66.9±1.4 mmol/mol, total cholesterol 4.6±0.1 mmol/L, LDL-cholesterol 2.3±0.1 mmol/L, HDL-cholesterol 1.3±0.05 mmol/L, triglycerides 2.3±0.2 mmol/L, and blood pressure 137±1.8/74±1 mm Hg. 21% were smokers and 29% had a previous history of amputation; more common among males (35%) than females (10%), p=0.01. Total loss of vibration sense >50 volt was seen in right 59% and left foot 66%, and only 17% showed no signs of retinopathy. 29 patients were normoalbuminuric (26%), 47 micro- (42%) and 37 had macro-albuminuria (33%). 45% had lacking palpable peripheral pulses. Time before contacting the service (contact delay time) was 17±2 days, and wound healing time was 8±0.6 weeks (n=164). Patients were offered an appointment within 24 hours for 165 of the wounds (86%), and within a week for another 11%. There was no difference in contact delay time between males and females (p=0.6). Wound healing time was positively correlated with contact delay time (r=0.2, p=0.01) which was also the only independent predictor of wound healing time as judged by a multiple regression analysis including relevant co-variables such as age, gender, diabetes duration, metabolic control, co-morbidities and complications, although the model explained less than 10% of the variability in healing time (r²=0.09, p=0.02).

Conclusion: Diabetic foot ulcer healing in a multidisciplinary setting is dependent on patient lag time to contact the clinic. Further investigation as to the underlying reasons and remedies for this delay is warranted in order to further improve the long term prognosis of diabetic foot ulcers.

1056

Patients' adherence to customised diabetic insoles as objectively assessed by a temperature sensor

D. Ehrmann¹, M. Spengler², M. Jahn², H. Siebert³, D. Niebuhr³, T. Haak¹, B. Kulzer¹, N. Hermanns¹;

¹Research Institute Diabetes Academy Mergentheim (FIDAM), Bad Mergentheim, ²IETEC orthopaedic insoles, Kuenzell, ³University of Applied Sciences, Fulda, Germany.

Background and aims: Customized diabetic insoles reduce the mechanical stress by re-distributing pressure to the plantar tissue. Thus, customized diabetic insoles are an effective means to prevent the reoccurrence of neuropathic diabetic foot ulcerations. However, the efficacy of these insoles is highly dependent on patients' adherence. By recommendation,

patients should wear their customized diabetic insoles as much as possible for the prevention of diabetic foot problems. However, adherence data often rely on self-report since objective parameters are not available. The aim of this study was to objectively assess patients' adherence with a temperature sensor directly incorporated into their insoles.

Materials and methods: In a pilot study, the cut-off value for optimal temperature was determined that differentiates between wearing and not wearing footwear. For this purpose, a ROC analysis was conducted that yielded an area under the curve of .996 (p<.0001). A cut-off value of 25°Celsius was determined that achieved a sensitivity of 95.3%, a specificity of 99.8%, a positive predictive value of 98.7%, and a negative predictive value of 99.2%. In the main study, temperature sensors were incorporated into the specialized diabetic insoles of 26 patients with type-2-diabetes and diabetic foot syndrome (age: 67.5±10.8 yrs.; 35% female; BMI: 30.3±4.7 kg/m²; diabetes duration: 10.4±6.8 yrs.; HbA1c: 7.7±0.6%).

Results: On average, data from 133.5 days per patient could be analysed. Patients wore their diabetic footwear (temperature>25°C) on an average (median) of 3.4 hours per day (inter-quartile-range (IQR): 0.5 - 6.9 hours/per day). On an average (median) of 51% of days, patients did not wear their diabetic footwear (IQR: 16.9 - 81.8%).

Conclusion: Wearing time of diabetic insoles and other specialized diabetic footwear can be objectively and validly assessed by temperature sensors. This study offers objective data regarding patients' adherence to their customized diabetic insoles. Nearly every second day, patients did not wear their insoles at all. Results of this study indicate that the utilization of specialized diabetic footwear is suboptimal in order to prevent re-ulcerations and other diabetes foot problems. Future studies should examine how the adherence of patients with a high risk for foot ulcerations can be enhanced, e.g. by patient education or technological assistance or reminders.

1057

The ABCDEF classification of perfusion in the diabetic foot

C.A. Manu¹, M. Bates¹, N. Petrova¹, A. Donaldson², M. Simmgen³, P. Vas³, K. Winkley⁴, H. Rashid⁵, M. Edmonds³;

¹Diabetic Foot Clinic, King's College Hospital, Croydon - London, ²Bio-statistics, Diabetic Foot Clinic, King's College Hospital, ³Diabetic Foot Clinic, King's College Hospital, ⁴Diabetes Research Group, King's College London, ⁵Vascular Surgery, King's College Hospital, London, UK.

Background and aims: The diabetic ischaemic foot is difficult to assess and treatment is often delayed. There is no consensus on a standardised assessment of foot perfusion in patients presenting with diabetic foot ulceration. A new classification system that grades the varying degrees of perfusion in the diabetic foot is needed to match assessment with management in individual patients. The aim was to create a new classification that reflects the spectrum of perfusion.

Materials and methods: We recruited consecutive patients attending the diabetes foot clinic with an ulcer in one or both feet. We measured brachial and toe blood pressure (TBP) and derived the toe brachial index (TBPI) in both feet. We then measured transcutaneous oxygen tension (TcPO₂), at the dorsum of both feet in the supine position and on the forearm, and derived the baseline TcPO₂ Index as a ratio of TcPO₂ on the foot compared to the arm. If the foot TcPO₂ was ≥40 mmHg, we then measured it after a provocation test of 30° leg elevation for 5 minutes. If the supine TcPO₂ was <40 mmHg, we measured it after an oxygen challenge (inhalation of 100% oxygen for 10 min), to assess the restoration of the TcPO₂ Index after oxygen inhalation. All measurements were done with the PeriFlux System 5000.

Results: We studied 236 limbs in 130 patients. Hundred and seven limbs had a TBPI of ≥0.7 and baseline TcPO₂ Index of 0.84±0.19 (Mean ± SD), indicating that these limbs had good perfusion and were graded as Group

A. There were 129 limbs with TBPI <0.7 of which 91 had $TcPO_2 \geq 40$ mmHg; 46/91 of these limbs had a sustained $TcPO_2$ that did not fall on leg elevation and were graded as Group B, but 45/91 limbs had a fall of ≥ 10 mmHg on elevation and were graded as Group C. TBP was significantly greater at 75 ± 25 mmHg in Group B compared with 56 ± 18 mmHg in Group C [$p < 0.001$]. Thirty eight of the 129 limbs with TBPI <0.7 had $TcPO_2 < 40$ mmHg. Eleven of the 38 limbs responded to the oxygen challenge, with restoration of their $TcPO_2$ Index (1.06 ± 0.15) and were graded as Group D, but 27/38 did not respond to oxygen challenge. Sixteen of the 27 were graded as Group E, with a baseline $TcPO_2 \geq 10$ mmHg but < 40 mmHg and the remaining 11 were graded as Group F, having a baseline $TcPO_2 < 10$ mmHg. TBP were not significantly different between Group E and F, 48 ± 21 vs 40 ± 28 mmHg respectively [$p = 0.203$], but Groups E and F were distinguished by their response to oxygen inhalation, the $TcPO_2$ Index after oxygen inhalation being 0.55 ± 0.15 in Group E vs 0.26 ± 0.25 in Group F [$p < 0.001$].

Conclusion: We have classified 6 grades of perfusion, using a 3 step approach of TBPI, $TcPO_2$ and a provocation test. Group A: TBPI ≥ 0.7 , Group B: TBPI < 0.7 $TcPO_2 \geq 40$ mmHg sustained on elevation, Group C: TBPI < 0.7 , $TcPO_2 \geq 40$ mmHg falling on elevation, Group D: TBPI < 0.7 , $TcPO_2 < 40$ mmHg with restoration of $TcPO_2$ Index on oxygen challenge, Group E: TBPI < 0.7 , $TcPO_2 < 40$ mmHg but > 10 mmHg with failure to restore $TcPO_2$ Index and Group F: TBPI < 0.7 , with failure to restore $TcPO_2$ Index and $TcPO_2 < 10$ mmHg. This study has derived a novel classification of diabetic foot perfusion, namely the ABCDEF classification, which objectively stratifies the diabetic foot into 6 groups, thus facilitating the standardisation of assessment and management of the diabetic foot.

Toe-brachial index is associated more strongly with outcome of chronic diabetic foot ulcers than ankle-brachial index in patients with type 2 diabetes

D.-H. Cho, J.-O. Chung, D.-J. Chung, M.-Y. Chung;
Chonnam National University Hospital, Gwangju, Republic of Korea.

Background and aims: Chronic diabetic foot ulcers remain a significant problem in individuals with diabetes and precede 84% of all diabetes-related lower-leg amputations. Such ulcers are responsible for a prolonged period of hospitalization and co-morbidities caused by infected diabetic foot ulcers. Both micro- and macroangiopathy strongly contribute to the development and delayed healing of diabetic wounds. Peripheral arterial disease (PAD) can be diagnosed noninvasively by segmental blood pressure measurement and calculating an ankle-brachial index (ABI) or toe-brachial index (TBI). The toe vessels are less susceptible to vessel stiffness, which makes the TBI useful. The objective of this study was to determine whether ankle-brachial index or toe-brachial index can influence outcome of chronic diabetic foot ulcers in patients with type 2 diabetes.

Materials and methods: We recruited a total of 89 type 2 diabetic patients (58 men and 31 women) with chronic nonhealing diabetic foot ulcers with Wagner grade 1 or 2 ulcers that are ≥ 2 cm in largest diameter at diagnosis for more than 1-month duration. The age was 67.4 ± 15.9 years, and the diabetes duration was 15.8 ± 12.3 years. Anthropometric, clinical, and laboratory data were measured. All patients were seen bi-weekly for debridement, offloading, and other treatments during the initial 8 weeks. All patients subsequently underwent ABI and TBI testing. ABI and TBI measurements were performed with the subject in a supine position, and were determined as the ratio of ankle or toe systolic blood pressure to the brachial systolic blood pressure, with both determined using an automatic device.

Results: At 8 weeks, 56 of the 89 ulcers had completely healed. The patients were assigned into healed group ($n = 56$) or unhealed group ($n =$

33) according to clinical outcome of ulcer healing at 8 weeks. There were not significantly different in age, duration of diabetes, HbA1c, or initial wound size in diameter of the ulcer between the healed and unhealed groups. The healing time of foot ulcers in healed group was 4.3 ± 3.1 weeks (range 2.1–7.8). The TBI was significantly ($P < 0.05$) lower in the unhealed group (0.58 ± 0.21 cm/s) as compared with the healed group (0.71 ± 0.19 cm/s). ABI was not significantly different between unhealed and healed group. Age ($r = 0.533$; $p < 0.01$), duration of diabetes ($r = 0.459$; $p < 0.05$) and ABI ($r = 0.725$; $p < 0.001$) were significantly correlated with TBI. But BMI, cholesterol levels, HbA1c, and systolic and diastolic BP were not correlated with TBI. Univariate analysis revealed that TBI was significantly correlated with healing rate of diabetic ulcers ($r = 0.296$, $p < 0.05$) and duration of diabetes ($r = 0.403$, $p < 0.05$).

Conclusion: This study demonstrated that toe-brachial index is more strongly associated with the healing time of diabetic ulcers than ankle-brachial index. We suggest that the measurement of toe-brachial index may help to identify ulcers at risk of poor healing in chronic diabetic foot ulcers in patients with type 2 diabetes.

1059

Do ulcer characteristics and cardiovascular risk factors predict healing and mortality in people with diabetic foot ulcers in northern England?

N. Holman¹, P. Chadwick², J. McAdam², S. Haycocks², B. Young²;
¹Institute of Cardiovascular and Medical Sciences, University of Glasgow, ²Salford Royal Foundation NHS Trust, UK.

Background and aims: This population based study examines foot disease and non-foot disease associations with ulcer healing and mortality among people with incident diabetic foot ulcers in a 'real world' longitudinal cohort.

Materials and methods: In the city of Salford routine electronic clinical records are kept by podiatrists for all people with an incident diabetic foot ulcer. Where possible these records have been linked to complementary primary and secondary care electronic health records to identify patient characteristics, cardiovascular risk factors and death registrations to June 2013. Regression and survival models were created to examine factors associated with ulcer healing and mortality.

Results: The foot care records of 1728 out of 2977 Salford residents presenting with foot ulcers between 2001 and 2012 could be linked to their general health record to provide sufficient data for analysis. 55.1% of ulcers healed within 90 days. Age (OR 0.99 per additional year of age, 95% CI 0.98–0.99) and being male (OR 0.74 95% CI 0.60–0.92), increased depth (probing to bone) (OR 0.22 95% CI 0.08–0.60), rear foot location (OR 0.68 95% CI 0.49–0.92), peripheral vascular disease (OR 0.52 95% CI 0.39–0.69) and blood pressure below the current NICE recommended target for people with vascular disease (130/80) (OR 0.64 95% CI 0.51–0.79) were associated with a lower chance of healing in 90 days. Total cholesterol below 5 mmol/l was linked with ulcer healing (OR 1.20 95% CI 1.01–1.41) in 90 days, whereas kidney function was inversely related to the chance of healing in 90 days (OR compared to eGFR 90+ for eGFR 60–89 1.27 95% CI 1.01–1.60, eGFR 30–59 1.71 95% CI 1.19–2.47, eGFR < 30 4.57 95% CI 0.52–39.92). Cellulitis, type of diabetes, HbA1c, body mass index and smoking were not associated with ulcer healing rates at 90 days. In this cohort mortality one year from initial presentation was 13.1% and 19.5% at two years. Increasing age (HR 1.10 per additional year of age, 95% CI 1.09–1.11) and being male (HR 1.31 95% CI 1.08–1.60) were associated with shorter survival. Peripheral vascular disease (HR 1.61 95% CI 1.30–1.99) and rear foot ulcers (HR 1.72 95% CI 1.35–2.20) were associated with shorter survival. Smokers had significantly higher mortality than those who had never smoked (HR 1.71 95% CI 1.30–2.25) whilst ex-smokers showed a non-significant raised risk of dying (HR 1.19 95% CI 0.97–1.47). Blood pressure below 130/80 was associated with higher mortality (HR 1.39 95% CI 1.15–

1.69). Poor kidney function was associated with higher mortality but only reached statistical significance with very advanced disease (eGFR <15 (OR 9.71 95% 2.38–39.64). The depth of the incident ulcer and cellulitis, type of diabetes, HbA1c, body mass index and lipid profile were not significantly associated with differential mortality.

Conclusion: High risk characteristics for poor healing of diabetic foot ulcers identified in this record linkage extend beyond the well-recognised age, male sex, ulcer location and depth and peripheral vascular disease to dyslipidaemia, low blood pressure and chronic kidney disease. Similar factors plus smoking were associated with early mortality. In this analysis HbA1c, weight and cellulitis were not related to healing or death. More intensive vascular and renal management may be necessary to improve outcomes in people with diabetic foot ulcers.

Prolonged hospital stay and increased readmission of lower limb cellulitis in type 2 diabetes patients

F. Wu^{1,2}, S. Wijayaratna¹, S. Sehgal¹, T. Cundy², G. Gamble², S. Wijayaratna², P.L. Drury¹;

¹Auckland District Health Board, ²Auckland University, New Zealand.

Background and aims: Incidences of soft tissue infections in people with and without diabetes are increasing. Cellulitis, perhaps by damaging the lymphatic vessels, is prone to recur. However, there is little data on hospitalization rates of lower limb (LL) cellulitis, specifically in the diabetes population. We quantify the impact of this condition and assess the factors associated with prolong stay and readmissions.

Materials and methods: Retrospective case-control study conducted in an urban hospital, servicing a multi-ethnic population of nearly 0.4 million adults, including ~27000 (7%) with known type 2 diabetes (T2DM). Adults with T2DM and those without diabetes admitted with LL cellulitis between 2008–2013 were identified from discharge coding and medical records. Length of stay, patient demographics, HbA1c, presence of LL ulceration, and subsequent readmission with LL cellulitis >1 month from the index admission were recorded.

Results: T2DM patients were over-represented, with 719 patients accounting for 22% of the 4600 LL cellulitis admissions in the 6 year period. ~3% of the estimated T2DM population were admitted at least once during that time, compared to 0.8% of the non-diabetic population ($p < 0.0001$). T2DM was associated with a significantly longer length of stay (median 5.3 vs 3.0 days, $p < 0.001$), regardless of age, ethnicity and despite relatively good glycaemic control (mean HbA1c 61 mmol/mol). Ulceration commonly accompanied LL cellulitis, particularly in T2DM subjects (52% vs 18%, $p < 0.001$), and increased the length of stay (T2DM: ulcer vs no ulcer: 7.9 vs 3.7 days, $P < 0.0001$; control: ulcer vs non ulcer: 5.9 vs 2.9 days, $p < 0.0001$). Amputation was almost exclusively performed in patients with ulceration, more commonly in T2DM patients (10% vs 0.1%, $p < 0.001$), particularly in those with HbA1c >89 mmol/mol. The risk of readmission during the mean 37 months of follow-up was increased in the T2DM group compared with control (HR 1.73, 95% CI 1.4–2.4, $p < 0.001$) and remained elevated even in the absence of ulceration (HR 1.67, 95% CI 1.2–2.4, $p < 0.01$). Non-diabetic patients without ulceration were at the least risk of readmission (Figure). Ethnicity, age, HbA1c, and length of index admission were unrelated to the risk of readmission. We estimate that 3% of the total T2DM patients account for 1/3 of the 26364 cellulitis-related bed days and the average annual cost of €3.4 million during the study period.

Conclusion: This study highlights the huge economic and social burden of LL cellulitis admissions and its recurrent nature, posed by a small proportion of the population. Patient demographics and chronic glycaemic control do not predict readmission risk. Exploring other clinical factors that may influence recurrence and response to antibiotic prophylaxis in the T2DM population will enable targeting of high risk patients.

Figure 1. Proportion of patients readmitted over follow up period.

Diabetic foot disease, self-care, and clinical monitoring in adults with type 2 diabetes: the Alberta's Caring for Diabetes (ABCD) cohort study

J.A. Johnson¹, F. Al Sayah², A. Soprovich², W. Qiu², A.L. Edwards³;
¹School of Public Health, University of Alberta, ²University of Alberta, Edmonton, Canada, ³Department of Medicine, University of Calgary, Canada.

Background and aims: Diabetic foot disease is a major cause of morbidity, disability and mortality, and contributes to increased healthcare cost. Throughout the world, up to 70% of leg amputations are performed on people with diabetes, the majority of which are preceded by a foot ulcer and considered preventable. Our aim was to examine the prevalence and predictors of foot disease, self-care and clinical monitoring in adults with type 2 diabetes (T2D) in Alberta, Canada.

Materials and methods: We used data from the baseline survey of a large prospective cohort of adults with T2D. Data were collected via a mailed self-administered questionnaire. Assessment of foot disease included self-reported peripheral neuropathy, peripheral vasculopathy, foot or leg ulcer/infection or gangrene/amputation. Foot self-care was assessed using the Summary of Diabetes Self-Care Activities, and clinical monitoring was assessed by patient-report of having feet checked for lesions or sensory loss by a health professional. Multivariable logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals (CI) for potential predictors of diabetic foot disease, good foot self-care and clinical monitoring.

Results: Mean age of respondents (N=2040) was 64 (SD 10.6) years, 45% were female, and 91% Caucasian. Peripheral neuropathy was reported by 18% of the respondents, peripheral vasculopathy by 28%, ulcer/infection by 6%, and gangrene/amputation by 1.4%. Only 14% of respondents performed recommended foot self-care behaviours ≥ 6 days/week, and only 41% and 34% had their feet clinically checked for lesions or sensory loss respectively. Predictors of increased risk of diabetic foot disease included longer diabetes duration, history of smoking, depressive symptoms, low self-efficacy, and a history of cardiovascular diseases. Predictors of good foot self-care included older age (OR 1.8; 95%CI 1.0, 3.1), female sex (1.4; 1.1, 1.8), longer diabetes duration (1.7; 1.3, 2.3), inadequate health literacy (1.4; 1.0, 2.0), and presence of hyperlipidemia (0.6; 0.5, 0.8). Predictors of clinical monitoring included female sex (0.8; 0.7, 0.9), residing in urban areas (1.6; 1.3, 2.0), longer diabetes duration (1.5; 1.2, 1.8), current smoking (0.7; 0.5, 0.9), presence of heart disease (1.4; 1.1, 1.8) or hyperlipidemia (1.2; 1.1, 1.5).

Conclusion: Peripheral neuropathy and vasculopathy were the most commonly reported foot problems in this population. Recommended foot self-care is generally infrequent, and clinical monitoring is performed for less than half of these patients, with significant variations by patient demographics and clinical presentation. We found it particularly interesting that smokers, who have a higher risk of developing foot disease, were less likely to receive a clinical foot exam compared to non-smokers. Our

results underline the importance of a detailed exploration of clinical monitoring of diabetic foot disease by care providers, and the development of standards, resources and tools for health care providers to enhance these preventive services.

Long-term follow-up of a cohort with a history of diabetic foot ulcer in Austria

A. Ribitsch, W. Haas, J.K. Mader, J. Samonigg, K. Horvath, G. Köhler, H. Sourij, T.R. Pieber, J. Plank;

Internal Medicine / Endocrinology and Metabolism, Medical University of Graz, Austria.

Background and aims: Patients with previous diabetic foot ulcer are prone to re-ulceration and (re-)amputation. To evaluate the rate of foot related complications and mortality in a high-risk population of patients with diabetic foot syndrome over a decade.

Materials and methods: A cohort of 91 patients with recently healed diabetic foot ulcer were invited for follow-up 1, 6 and 11 years after inclusion. Patient characteristics at inclusion were: 65 ± 11 years, 44 women, diabetes type 1 ($n=6$) or 2 ($n=85$), BMI 28.5 ± 4.4 kg/m², and HbA1c $8.4 \pm 1.6\%$. Patients presented with clinical signs of neuropathy ($n=91$), peripheral vascular disease ($n=42$), history of minor ($n=25$) or major ($n=5$) amputation, nephropathy ($n=40$) and retinopathy ($n=53$).

Results: Over the follow-up period ulceration recurred in 71 (78%) patients, time to first recurrence was 1.8 ± 2.4 years (mean \pm SD). 21 patients (23%) had to undergo a new amputation (minor $n=19$, major $n=2$), time to new amputation was 3.6 ± 1.9 years. Over time 3 further major amputations were required in patients with an initial minor amputation. 33 of the initially included patients completed the follow-up period of 11.0 ± 0.6 years. 58 (64%) patients died during the observational period, time until exitus was 5 ± 3 years in this group. Causes of death were the following: 56.9% cardiovascular, 17.2% infections, 6.9% cancer, 19% other causes. Microvascular complications were not predictive for a composite of amputation or death, while peripheral artery disease was significantly predictive ($p < 0.0001$).

Conclusion: Our data highlights the high recurrence rate of ulcerations and the poor longterm prognosis in high-risk patients with a diabetic foot syndrome. More research is urgently needed to improve the outcome of this patient cohort.

PS 104 Treating and salvaging the diabetic foot

Inflammatory cytokines role in extracellular matrix turnover induces in human skin fibroblasts by AGEs exposure

A.I. Serban¹, L. Stanca¹, O.I. Geicu^{2,1}, A. Dinischiotu²;

¹Preclinical Sciences, University of Agronomic Sciences and Veterinary Medicine, Faculty of Veterinary Medicine, ²Biochemistry and Molecular Biology, University of Bucharest, Faculty of Biology, Bucharest, Romania.

Background and aims: AGEs accumulation in the skin affects extracellular matrix (ECM) turnover and triggers diabetes associated skin conditions and skin ageing. The receptor of AGEs (RAGE) has an essential contribution to cellular dysfunction driven by chronic inflammatory responses. TGF- β 1 is also critical in dermal homeostasis and inflammation. We investigated the contribution of RAGE and TGF- β 1 to the modulation of inflammatory response and ECM turnover in AGEs milieu, and the effects generated by their blockade in order to delineate a potential therapeutic strategy.

Materials and methods: Human skin fibroblasts (CCD-1070Sk) were exposed for 12 and 24 h to 50, 100 and 200 μ g/ml glycated BSA (AGEs-BSA) and unglycated BSA (control). Anti-RAGE and anti-TGF- β 1 blocking antibodies were applied to the 200 μ g/ml AGEs exposed cells for 24 h. Secreted TGF- β 1, IL-2, IL-4, IL-6, IL-8, granulocyte-macrophage colony-stimulating factor (GM-CSF), IFN- γ and TNF- α were determined by multiplex immunoassay, while RAGE, TGF- β 1, collagen I and III and metalloproteinase (MMPs) protein levels were evaluated by western blot. The gene expression was quantified by real-time RT-PCR, and activity of MMPs was evaluated by gelatin zymography.

Results: The 12 h exposure to AGEs-BSA induced a dose dependent upregulation of RAGE, TGF- β 1, collagen I and III, increasing the relative gene expression ratio (R) to 4.1, 3.1, 5.9, and 2.7, after exposure to 200 μ g/ml AGEs-BSA, whereas their protein expression was affected to a lesser extent. Notably, after 24 h, the increases of collagen III gene and protein expression exceeded those of collagen I. MMP-2 was activated after 12 h of AGEs-BSA exposure, while MMP-9 activity was not detected. MMP-2 protein expression was induced in a dose dependent manner by AGEs-BSA exposure, with a maximal 2 fold increase after 12 and 24 h. While RAGE blockade diminished MMP-2 activation, TGF- β 1 didn't significantly inhibit it. All cytokine levels increased after 12 h of exposure to AGEs-BSA in a dose dependent manner; IL-8 and TNF- α had the highest expression levels and increased over 1.7 fold, while after 24 h, TGF- β 1, IL-6, GM-CSM and TNF- α increased over 2 fold. R of collagen I and III decreased after RAGE blockade to 0.14 and 0.52 compared to 200 μ g/ml AGEs-BSA exposed cells, while TGF- β 1 blockade only inhibited collagen III expression. IL-2, IL-8, and TNF- α protein levels were diminished by RAGE blockade, which also mildly decreased active TGF- β 1 secretion. TGF- β 1 blockade diminished IL-6 and GM-CSF levels in AGEs milieu, as opposed to IL-8 and TNF- α which were additionally increased.

Conclusion: The pro-inflammatory effect of AGEs on human skin fibroblasts involved both the activation of TGF- β 1 and RAGE-NF- κ B-TNF- α signaling axes. The activation of MMP-2 and over-expression of collagen I and III probably prompted an increased ECM turnover. Additionally, after 24 h, collagen III expression ratio dominance over collagen I could suggest diminished ECM mechanical stability. RAGE blockade markedly decreased collagen I level, and inhibited MMP-2 activation, while TGF- β 1 blockade decreased collagen III expression and mildly inhibited MMP-2 activity, as it induced IL-8 expression. TGF- β 1 blockade overall effect could contribute to restore the collagen I/III ratio, in favor of the former.

Direct revascularisation based on angiosome model reduces major amputations and increases life expectancy in diabetic patients with critical limb ischaemia and diabetic footE. Iacopi¹, A. Coppelli¹, I. Bargellini², C. Goretti³, A. Cicorelli², A. Lunardi², R. Cioni², S. Del Prato¹, A. Piaggese³;¹Diabetology Unit - Medicine Department, University of Pisa, ²Interventional Radiology Department - Pisa University Hospital, ³Diabetic Foot Section - Medicine Department, University of Pisa, Italy.

Background and aims: The role of AM to guide revascularization procedures is debated. We evaluated whether direct or indirect revascularization, based on Angiosome model (AM), affects clinical outcomes in type 2 diabetic patients (T2DM) with critical limb ischemia (CLI) undergoing percutaneous trans-luminal angioplasty (PTA).

Materials and methods: We retrospectively evaluated 445 consecutive successful lower limb PTA performed in 370 T2DM patients (M/F: 257/113; age: 73.5±9.3 yrs; BMI: 27.4±4.8 Kg/m²; diabetes duration: 21.4±12.8 yrs; HbA1c 7.8±1.6%) because of CLI and diabetic foot ulceration (DFU). Patients were divided into 2 groups: direct (DG - 266 pts, 72%) or indirect (IG - 104 pts, 28%) depending on whether the flow to the artery directly feeding the site of ulceration, as determined by AM, was successfully identified or not. No significant difference was apparent between groups regarding main clinical characteristics. Ulcer healing (HR), major amputation (MA) and death (D) rates were compared in the 2 groups during a follow-up of 18.9±12.4 months (range 0.7-43.2).

Results: HR was achieved in 68% of DG vs. 52% of IG ($\chi^2=9.6$; $p<0.05$). MA was needed in 11% of DG vs. 4% of IG ($\chi^2=9.4$; $p<0.02$). Cumulative mortality rate during follow-up was 14% in DG and 27% in IG ($\chi^2=8.7$; $p<0.02$).

Conclusion: Our data show that direct revascularization of arteries supplying the DFU site by means of AM is associated with higher rate of healing and lower risk of amputation and mortality as compared to indirect PTA procedure. These results support use of AM for PTA guiding in diabetic patients with DFU.

1065

Trends in lower extremity amputations over 5 years at a tertiary hospital

T. Macriyiannis, J.T. Dales, D. Tesh, M.-F. Kong;

Department of Diabetes, University Hospitals of Leicester NHS Trust, UK.

Background and aims: Around 6000 people with diabetes have leg, foot or toe amputation each year in England. Up to 80% people die within 5 years of having an amputation. Amputations remain a common outcome of diabetic foot disease and have an impact on individuals economically, socially and psychologically. It has been estimated that a reduction of 50% late referrals to specialist foot teams could save £34 million (47 million Euros) a year by a reduction in amputations. We analysed all lower extremity amputations between 2009 and 2013 in our tertiary referral hospital and evaluated patient characteristics and trends in amputations.

Materials and methods: We performed a retrospective review of data on hospital discharges of patients who were coded as having had a lower extremity amputation from 2009 to 2013 in our hospitals which cover a relatively static population. Data were collected from the hospital coding activities from 1 January 2009 to 31 December 2013. For each amputation, diabetes status was ascertained by looking through our diabetes register and the pathology system. The demographic, admission details and relevant medical history were also collected.

Results: 30-40% of amputations occurred in patients with diabetes, comparable with other series. The total number of patients with diabetes in the region in 2011 was 49,645, 52,428 in 2012 and 59,611 in 2013, with a

calculated mean incidence of 0.56/1000 diabetic population in 2011, 0.53/1000 diabetic population in 2012 and 0.55/1000 diabetic population in 2013 for major amputations. The figures for minor amputations were 1.13/1000, 1.28/1000 and 1.16/1000 diabetic population respectively. In our local population, the mean incidence over the 3 years was 1.74/1000 diabetic population for all foot amputations, 0.55/1000 for major amputations and 1.19/1000 diabetic population for minor amputations. The amputation rate per 1000 diabetic population in England over the same 3 year period was 2.6 for all amputations, 0.9 for major foot amputations and 1.7 for minor foot amputations.

Conclusion: Increasing numbers of people with diabetes in the population area is expected to lead to a rise in the number of lower extremity amputations. Our major and minor amputation rates have remained unchanged from 2011 to 2013. The trend is an increase in the number of minor amputations from 2009-2010 to 2011-2013. An early minor amputation can prevent a later major amputation. Thus, minor amputations may reflect improved quality of care with earlier intervention; consequently preventing the progression from minor to major amputation.

Year	2009	2010	2011	2012	2013
Total major amputations	82	78	88	76	90
Below Knee Amputations	35	39	29	30	38
Above Knee Amputations	47	39	59	46	42
Number with diabetes	34	30	28	28	33
% with diabetes	41.5	38.5	31.8	36.8	36.7
Total minor amputations	56	64	88	86	89
Number with diabetes	44	46	56	67	69
% with diabetes	78.6	71.9	63.6	77.9	77.5

1066

Nationwide lower extremity amputation rates in patients with diabetes in secondary care in the Netherlands (DUDE-7)L. Nijenhuis - Rosien^{1,2}, S. Hendriks¹, N. Kleefstra^{1,3}, H.J.G. Biló^{1,3}, G.W.D. Landman^{1,4};¹Diabetes Centre Isala, ²InnoFeet Footcentre Nijenhuis, Zwolle, ³Department of Internal Medicine, University of Groningen, University Medical Centre Groningen, ⁴Department of Internal Medicine, Gelre Hospital, Apeldoorn, Netherlands.

Background and aims: Patients with diabetes are at increased risk for lower extremity amputation as a consequence of micro- and macrovascular complications. Almost one in five European patients with a diabetic foot ulcer ends up with a below knee amputation (EuroDiale). The estimated amputation rate estimates from the general diabetes population in the UK were 0.25% and in the Netherlands between 0.36 and 0.55% in at the end of the last century, treated in both primary and secondary care. The primary aim of this study was to estimate the annual incidence rate of amputations in secondary care treated patients with diabetes. The secondary aim was to estimate the amputation rate in secondary care treated patients diagnosed with diabetic retinopathy.

Materials and methods: The study population consisted of all patients for whom an insurance claim was made for treatment of diabetes in secondary care. Patients were selected from a nationwide database that collects data on insurance claims. Physicians are required to record Diagnosis-treatment-codes (DTC) for receiving reimbursement of hospital care using. Each DTC code contains information about the specialism that recorded the DTC, the diagnosis and type of treatment. From this database, patients with diabetes were selected and incidence rates of non-traumatic lower extremity amputation and retinopathy were selected between 2007 and 2011. The percentage of claims for amputations was identified for the whole study group and for the subgroup with retinopathy.

Results: Total number of secondary care treated patients with diabetes in the Netherlands increased from 132,499 to 137,049 between 2007 and 2011 (table 1). The annual rate of total non-traumatic lower-extremity amputation was 0.5% and remained stable over the years. The percentage of patients diagnosed with retinopathy by an ophthalmologist ranged from 13.7% to 15.0%. Annual rate of lower extremity amputations was 1.2% for those with retinopathy, see table 1.

Conclusion: The Dutch annual incidence rates of non-traumatic lower extremity amputations in the Netherlands in secondary care patients with diabetes between 2007 and 2011 were comparable to the rates 20 years ago and higher compared to data from the UK (2005–2008), although the most recent UK data concerned primary and secondary care treated patients. The annual amputation rate in patients with retinopathy was higher, indicating a higher risk on lower extremity amputation when (other) microvascular complications are present.

	2007	2008	2009	2010	2011
Patients with diabetes (n)	132,499	134,027	134,877	138,486	137,049
Patients with retinopathy (% of total patients)	18,232 (13.8%)	19,879 (14.8%)	19,775 (14.7%)	20,742 (15.0%)	18,795 (13.7%)
Patients with lower extremity amputation (% of total patients)	573 (0.4%)	707 (0.5%)	663 (0.5%)	683 (0.5%)	629 (0.5%)
Patients with lower extremity amputations and retinopathy (% of all patients with diagnosis retinopathy)	157 (0.9%)	245 (1.2%)	252 (1.3%)	274 (1.3%)	253 (1.4%)

Efficacy, quality of life and treatment satisfaction with capsaicin 8% patch versus standard of care in painful diabetic peripheral neuropathy

S. Perrot^{1,2}, E. Ortega³, E.J. Vinik⁴, L. Pazdera⁵, M. Stoker⁶, F. van Nooten⁶, R. Snijder⁶, C. Poole⁷, F. Lewis⁸, N. Katz⁹, A.I. Vinik⁴,
¹Hôpital Hôtel Dieu, Paris, ²Paris Descartes University, France, ³Hôpital Rio Hortega, Valladolid, Spain, ⁴Eastern Virginia Medical School, Norfolk, USA, ⁵Vestra Clinics, Rychnov nad Kneznou, Czech Republic, ⁶Astellas Pharma Europe B. V., Leiden, Netherlands, ⁷Astellas Pharma Europe, Chertsey, ⁸Office of Health Economics, London, UK, ⁹Analgesic Solutions and Tufts University, Boston, USA.

Background and aims: PACE was a Phase III, randomised, controlled, open-label, 52-week, safety study that assessed the safety and efficacy of repeat treatment with the capsaicin 8% patch plus standard of care (SOC) versus SOC alone in painful diabetic peripheral neuropathy (PDPN). Secondary efficacy, quality of life (QoL) and treatment satisfaction results are presented.

Materials and methods: Patients (N=468) with mean [SD] duration of PDPN 4.4 [3.6] years, glycosylated haemoglobin 7.4% [1.0], average daily pain 5.6 [1.3] and European quality of life in 5 dimensions visual analogue scale (EQ-5D VAS) 54.6 [14.7], were randomised (1:1:1) to capsaicin 8% patch 30 min plus SOC (n=156), capsaicin 8% patch 60 min plus SOC (n=157), or SOC alone (n=155). Capsaicin arms received 1-7 treatments with at least 8-week intervals. Results for the secondary endpoints BPI-DN pain severity index, BPI-DN pain interference index, EQ-5D dimensions, VAS and utility, and self-assessment of treatment (SATII) are presented. No formal statistical testing was performed and treatment deltas were compared with a 90% CI in this safety study.

Results: Regarding pain severity index, the mean [SD] change from baseline to end of study (EoS) was -1.9 [1.8], -2.2 [1.9] and -0.9 [1.7] with capsaicin 30 min, capsaicin 60 min and SOC, respectively; mean difference [90% CI] with capsaicin 30 min and 60 min versus SOC was -0.9 [-1.3, -0.6] and -1.2 [-1.6, -0.9], respectively. With pain interference index, the mean change from baseline to EoS was -1.9 [2.1], -2.0 [2.3] and -0.8 [1.9] with capsaicin 30 min, capsaicin 60 min and SOC, respectively; mean difference for capsaicin 30 min and 60 min versus SOC was -1.0 [-1.4, -0.6] and -1.2 [-1.6, -0.8], respectively. A greater mean

improvement in EQ-5D utility index of 0.07 was observed in both capsaicin arms versus SOC from baseline to Month 12. Regarding EQ-5D items, a greater proportion of patients at EoS in both capsaicin arms versus SOC had no problems with mobility, self-care, usual activities, pain or discomfort and anxiety or depression. Regarding EQ-5D VAS, the mean change from baseline to EoS was 10.4 [18.5], 11.2 [21.4] and 5.5 [18.1] with capsaicin 30 min, capsaicin 60 min and SOC; mean difference with capsaicin 30 min and 60 min versus SOC was 4.9 [1.1, 8.6] and 5.7 [2.0, 9.4], respectively. With SATII at EoS, a greater proportion of patients in both capsaicin arms versus SOC reported improvements in pain level, activity level, quality of life, willingness to undergo treatment again, and also preferred treatment compared with their previous treatment.

Conclusion: Repeat treatment with the capsaicin 8% patch in PDPN over 52 weeks was associated with improvements in pain severity and interference, QoL and treatment satisfaction compared with SOC alone, further supporting the broad effectiveness of capsaicin treatment in PDPN.

Capsaicin 8% patch repeat treatment versus standard of care in painful diabetic peripheral neuropathy: a randomised, open-label, 52-week study

A.I. Vinik¹, S. Perrot², E.J. Vinik¹, L. Pazdera³, H. Jacobs⁴, M. Stoker⁴, S. Long⁴, R. Snijder⁴, M. van der Stoep⁴, E. Ortega⁵, N. Katz⁶,
¹Eastern Virginia Medical School, Norfolk, USA, ²Hôpital Hôtel Dieu, Paris, France, ³Vestra Clinics, Rychnov nad Kneznou, Czech Republic, ⁴Astellas Pharma Europe B. V., Leiden, Netherlands, ⁵Hôpital Rio Hortega, Valladolid, Spain, ⁶Analgesic Solutions and Tufts University School of Medicine, Boston, USA.

Background and aims: PACE assessed the safety and efficacy of repeat treatment over 52 weeks with the capsaicin 8% patch plus standard of care (SOC) versus SOC alone in painful diabetic peripheral neuropathy (PDPN). The Norfolk QOL-DN scale was utilised to assess any patient-reported functional consequences of potential small-fibre dysfunction that may be induced by capsaicin treatment. Sensory testing, including the Utah Early Neuropathy Scale (UENS), was also performed to assess capsaicin safety.

Materials and methods: PACE was a Phase III, randomised, controlled, open-label, 52-week, safety study. Patients with painful, distal, symmetrical, sensorimotor diabetic polyneuropathy, glycosylated haemoglobin $\leq 9\%$ and average daily pain ≥ 4 , were randomised (1:1:1) to capsaicin 8% patch 30 min plus SOC, capsaicin 8% patch 60 min plus SOC, or SOC alone. Capsaicin arms received 1-7 treatments with at least 8-week intervals. The primary endpoint was percentage change from baseline to end of study (EoS) in Norfolk QOL-DN total score. Secondary endpoints were UENS score, ratings of evoked sensations, average daily pain, $\geq 30\%$ pain response and patient global impression of change (PGIC). No formal statistical testing was performed and treatment deltas were compared with a 90% CI in this safety study.

Results: In total, 468 patients with mean [SD] duration of PDPN 4.4 [3.6] years, glycosylated haemoglobin 7.4% [1.0], average daily pain 5.6 [1.3], Norfolk QOL-DN total score 41.4 [18.7] and UENS total score 16.4 [6.9], were randomised to capsaicin 30 min (n=156), capsaicin 60 min (n=157) or SOC alone (n=155). A greater improvement from baseline to EoS in mean Norfolk QOL-DN total score was observed with capsaicin 30 min versus SOC (mean difference [90% CI]: -20.9% [-31.7, -10.1]) and capsaicin 60 min versus SOC (-26.1% [-36.8, -15.4]). Subscale scores for symptoms, physical functioning/large fibre, small fibre, autonomic and activities of daily living improved with capsaicin over SOC. Mean [SD] changes in UENS total score from baseline to EoS also showed improvement and were -2.1 [5.0], -3.0 [5.1] and -1.2 [4.2] in capsaicin 30 min,

capsaicin 60 min and SOC arms, respectively. A greater reduction in average daily pain score from baseline to EoS was observed with capsaicin 30 min versus SOC (-1.0 [-1.4, -0.6]) and capsaicin 60 min versus SOC (-1.2 [-1.6, -0.9]). The 30% responder rate by EoS was 67.3%, 67.5% and 40.6% in the capsaicin 30 min, capsaicin 60 min and SOC arms, respectively. With regard to PGIC at EoS, a very much improved or much improved general state of health since study start was reported by 24.2%, 24.5% and 9.5% of patients in the capsaicin 30 min, capsaicin 60 min and SOC arms, respectively.

Conclusion: Repeat treatment with capsaicin 8% patch over 52 weeks in patients with PDPN was well tolerated, not associated with any functional consequences arising from potential impaired small-fibre function, or any sensory deterioration, and pain relief was sustained and progressively improved compared with SOC.

Capsaicin 8% patch versus standard of care in painful diabetic peripheral neuropathy: efficacy of seven consecutive treatments over 52 weeks versus SOC

R. Snijder¹, E. Ortega², S. Perrot^{3,4}, E.J. Vinik⁵, L. Pazdera⁶, H. Jacobs¹, S. Long¹, M. Stoker¹, M. van der Stoep¹, N. Katz^{7,8}, A.I. Vinik⁵;

¹Astellas Pharma Europe B. V., Leiden, Netherlands, ²Hôpital Rio Hortega, Valladolid, Spain, ³Hôpital Hôtel Dieu, Paris, ⁴Paris Descartes University, France, ⁵Eastern Virginia Medical School, Norfolk, USA, ⁶Vestra Clinics, Rychnov nad Kneznou, Czech Republic, ⁷Analgesic Solutions, Natick, USA, ⁸Tufts University School of Medicine, Boston, USA.

Background and aims: PACE was a Phase III, randomised, controlled, open-label, 52-week, safety study that assessed the safety and efficacy of repeat treatment with the capsaicin 8% patch plus standard of care (SOC), versus SOC alone in painful diabetic peripheral neuropathy (PDPN). Efficacy results in patients who received seven consecutive capsaicin 8% patch treatments versus SOC are presented.

Materials and methods: Patients (N=468) with painful, distal, symmetrical, sensorimotor diabetic polyneuropathy, glycosylated haemoglobin $\leq 9\%$ and average daily pain ≥ 4 , were randomised (1:1:1) to capsaicin 8% patch 30 min plus SOC, capsaicin 8% patch 60 min plus SOC, or SOC alone. Capsaicin arms received 1-7 treatments with at least 8-week intervals. Efficacy endpoints were average daily pain, Brief Pain Inventory-Diabetic Neuropathy (BPI-DN) pain severity index, BPI-DN pain interference index and patient global impression of change (PGIC). No formal statistical testing was performed and treatment deltas were compared with a 90% CI in this safety study.

Results: The SOC arm comprised 155 patients and seven treatments were received by 84/156 (53.8%) and 83/157 (52.9%) patients in the capsaicin 30 min and 60 min arms, respectively. Baseline mean [SD] daily pain was 5.6 [1.3], 5.7 [1.4] and 5.7 [1.3] in the capsaicin 30 min subset, 60 min subset and SOC arm, respectively. From baseline to end of study (EoS), the mean change in average daily pain was -2.4 [1.7], -2.6 [2.1] and -1.1 [2.0] in capsaicin 30 min subset, 60 min subset and SOC arm, respectively; mean difference [90% CI] between capsaicin 30 min and 60 min versus SOC was -1.3 [-1.8, -0.9] and -1.5 [-2.0, -1.1], respectively. Regarding pain severity index, the mean change from baseline to EoS was -2.3 [1.6], -2.4 [1.8] and -0.9 [1.7] in capsaicin 30 min subset, 60 min subset and SOC arm, respectively; mean difference between capsaicin 30 min and 60 min versus SOC was -1.4 [-1.8, -1.0] and -1.5 [-1.9, -1.1], respectively. The mean change in pain interference index from baseline to EoS was -2.2 [1.7], -2.5 [2.0] and -0.8 [1.9] in capsaicin 30 min subset, 60 min subset and SOC arm, respectively; mean difference between capsaicin 30 min and 60 min versus SOC was -1.4 [-1.8, -0.9] and -1.6 [-2.1, -1.2], respectively. With regard to PGIC at EoS, a very much

improved or much improved general state of health since study start was reported by 22.6%, 27.7% and 9.5% of patients in the capsaicin 30 min subset, 60 min subset and SOC arm, respectively. Compared with observations in the total capsaicin arms who received 1-7 treatments, numerically similar or larger improvements in all efficacy endpoints versus SOC were observed following seven consecutive capsaicin treatments.

Conclusion: In patients with PDPN, seven consecutive treatments with the capsaicin 8% patch over 52 weeks were associated with sustained and progressively improved pain relief, reduced pain severity and pain interference indices, as well as an improved global impression of change compared with SOC treatment.

Capsaicin 8% patch versus standard of care in painful diabetic peripheral neuropathy: safety of seven consecutive treatments over 52 weeks

H. Jacobs¹, S. Perrot^{2,3}, E.J. Vinik⁴, L. Pazdera⁵, M. Stoker¹, R. Snijder¹, S. Long¹, M. van der Stoep¹, E. Ortega⁶, N. Katz^{7,8}, A.I. Vinik⁴;

¹Astellas Pharma Europe B. V., Leiden, Netherlands, ²Hôpital Hôtel Dieu, Paris, ³Paris Descartes University, France, ⁴Eastern Virginia Medical School, Norfolk, USA, ⁵Vestra Clinics, Rychnov nad Kneznou, Czech Republic, ⁶Hôpital Rio Hortega, Valladolid, Spain, ⁷Analgesic Solutions, Natick, USA, ⁸Tufts University School of Medicine, Boston, USA.

Background and aims: PACE was a Phase III, randomised, controlled, open-label, 52-week, safety study that assessed the safety and efficacy of repeat treatment with the capsaicin 8% patch plus standard of care (SOC), versus SOC alone in painful diabetic peripheral neuropathy (PDPN). The Norfolk QOL-DN scale was utilised to assess any patient-reported functional consequences of potential small-fibre nerve dysfunction that may be due to capsaicin treatment. Sensory testing, including the Utah Early Neuropathy Scale (UENS), was also performed to assess capsaicin safety. Safety results in patients who received seven consecutive capsaicin 8% patch treatments versus SOC are presented.

Materials and methods: Patients (N=468) with painful, distal, symmetrical, sensorimotor diabetic polyneuropathy, glycosylated haemoglobin $\leq 9\%$ and average daily pain ≥ 4 , were randomised (1:1:1) to capsaicin 8% patch 30 min plus SOC, capsaicin 8% patch 60 min plus SOC, or SOC alone. Capsaicin arms received 1-7 treatments with at least 8-week intervals. The primary endpoint was percentage change from baseline to end of study (EoS) in Norfolk QOL-DN total score. Secondary safety endpoints were UENS score and ratings of evoked sensations (warm, cold, sharp and vibration), plus assessment of deep-tendon reflexes.

Results: The SOC arm comprised 155 patients and seven treatments were received by 84/156 (53.8%) and 83/157 (52.9%) patients in the capsaicin 30 min and 60 min arms, respectively. Baseline mean [SD] daily pain was 5.6 [1.3], 5.7 [1.4], 5.7 [1.3], and Norfolk QOL-DN total score was 41.5 [20.1], 42.4 [19.8], 41.0 [18.5], in capsaicin 30 min subset, 60 min subset and SOC arm, respectively. The mean percentage reduction (improvement) from baseline to EoS in Norfolk QOL-DN total score was -31.2% [50.9], -40.5% [38.8] and -6.7% [54.1] in capsaicin 30 min subset, 60 min subset and SOC arm, respectively. Regarding UENS total score, the mean reduction (improvement) from baseline to EoS in capsaicin 30 min subset, 60 min subset and SOC arm was -2.3 [4.8], -4.1 [5.3] and -1.2 [4.2], respectively. Ratings of evoked sensation for warm, cold and sharp at EoS compared with baseline indicated that fewer patients within all three treatment arms reported no sensation and a numerically greater proportion reported slightly diminished or normal sensation by EoS. Ratings for vibration followed a similar trend from baseline to EoS within the capsaicin 30 min and 60 min subsets, but no noticeable changes were observed within the SOC arm. There were no noticeable

differences from baseline to EoS within all three treatment groups for ratings of deep-tendon reflexes. All safety observations in the capsaicin subsets were consistent with the total capsaicin arms.

Conclusion: In patients with PDPN, seven consecutive treatments with the capsaicin 8% patch over 52 weeks were well tolerated and not associated with any functional consequences from potential impaired small-fibre function, or adverse sensory effects.

Hyperglycaemia and hypoxia induce overexpression of GLUT1 in models of diabetic retinopathy

S.M. Calado^{1,2}, L.S. Alves^{1,3}, S. Simão¹, G.A. Silva^{1,4};

¹University of Algarve, Centre for Biomedical Research, ²PhD Program in Biomedical Sciences, ³Masters in Biomedical Sciences, Department of Biomedical Sciences and Medicine, Faro, ⁴Universidade Nova de Lisboa, CEDOC, Nova Medical School/ Faculdade de Ciências Médicas, Lisbon, Portugal.

Background and aims: Diabetes mellitus is a group of metabolic diseases characterized by high blood glucose that leads to several complications, including diabetic retinopathy (DR). DR is a blinding disease characterized by retinal microvascular changes caused by chronic exposure to hyperglycemia leading to low tissue oxygenation and ultimately to neovascularization. It has been hypothesized that an increase in glucose transporters such as GLUT1 is responsible for increased glucose levels in retinal cells. In the retina, glucose is the only fuel source for the cells and its cellular intake occurs exclusively through GLUT1. GLUT1 expression is also controlled by HIF-1, a key player in neovascularization. To understand the role of GLUT1 in DR, we have characterized the GLUT1 expression in both in vitro and in vivo models of DR.

Materials and methods: Retinal epithelium cells (D407), subjected to normoxia and hypoxia were cultured in DMEM with different glucose concentrations, corresponding to non-diabetic (5 mM of glucose) and diabetic conditions (25 mM of glucose). GLUT1 expression and localization were analyzed by Western Blot and immunofluorescence. Analysis of GLUT1 in vivo was performed using retinas of 6 month-old Ins2Akita diabetic mice by western blot and immunofluorescence and compared with the retinas of age-matched non-diabetic mice (C57Bl6 WT).

Results: Our in vitro results show an increase in GLUT1 expression in a glucose-dependent manner, under hypoxia conditions. This increase is associated to the translocation and stabilization of GLUT1 in the cell membrane, as observed by immunofluorescence. In vivo, GLUT1 was overexpressed in the retina of Ins2Akita mice compared with the non-diabetic mice. The immunofluorescence analysis of the retina of diabetic mice shows an accumulation of GLUT1 in the cell membrane of the innermost layers of the retina, such as the photoreceptors' layer, which is avascular and known to be under hypoxic conditions in diabetic environment. As expected, this was not observed in the retina of the WT mice, corroborating our in vitro results.

Conclusion: In this study the expression of GLUT1 was analyzed in vitro in conditions simulating DR and in vivo in a mouse model of DR. The results show an overexpression of GLUT1 induced by hyperglycemia and low oxygen supply. This overexpression was associated to an increase of GLUT1 in the cell membrane of the cells, which points to a significant contribution of GLUT1 to the progression of DR.

High glucose-induced metabolic and structural changes in mitochondria promote retinal Müller cell loss associated with diabetic retinopathy

J. Zhang, D. Kim, S. Roy;

Ophthalmology and Medicine, Boston University School of Medicine, USA.

Background and aims: Müller cells are the principal glial cells in the retina located in the inner nuclear layer with processes extending toward the outer limiting membrane and in the opposite direction toward the inner limiting membrane. These processes come in frequent contact with retinal blood vessels allowing coupling between Müller cells and vascular cells necessary for cell survival and retinal vascular homeostasis. Müller cell loss in the diabetic retina can have a profound effect on retinal dysfunction associated with diabetic retinopathy. However, it is currently unclear how high glucose promotes Müller cell loss in diabetes. In this study, we determined whether high glucose compromises mitochondrial structure and function, and thereby promotes apoptosis in rat retinal Müller cells (rMC-1).

Materials and methods: To determine if high glucose (HG) induces changes to mitochondrial metabolic function, rat retinal Müller cells (rMC-1) were grown in normal (N, 5 mM glucose) or HG (30 mM) medium for 7 days and subjected to bioenergetic assay using the XF24 analyzer. In particular, altered mitochondrial metabolic function under HG was assessed by measuring oxygen consumption rate (OCR) and extracellular acidification rate (ECAR). In parallel, differential staining method was performed to identify cells undergoing apoptosis, and digital images of mitochondria stained with MitoTracker Red were captured through live cell imaging under confocal microscopy. Images were analyzed for mitochondrial morphology changes based on Form Factor (FF) and Aspect Ratio (AR).

Results: rMC-1 grown in HG showed a significant decrease in steady state OCR (100.5 ± 23 vs. 155 ± 6 pmol O₂/min in normal; $p < 0.05$) and maximum OCR (85.5 ± 26 vs. 171.5 ± 16 pmol O₂/min in normal; $p < 0.05$), compared to those in cells grown in N medium. Similarly, ECAR was significantly decreased in cells grown under HG condition compared to those grown in N medium ($40 \pm 4\%$ of normal; $p < 0.05$). Cells grown in HG exhibited significant increase in the number of apoptotic cells ($202 \pm 29\%$ of control; $p < 0.05$), and the mitochondria became fragmented and punctate compared to the long, tubular mitochondrial networks seen in cells grown in normal medium.

Conclusion: Findings from this study indicate that HG induces changes to mitochondrial metabolic function by altering OCR and ECAR while inducing mitochondrial morphology and structural changes in retinal Müller cells. Such changes are likely contributing to retinal Müller cell loss associated with diabetic retinopathy.

1073

Hydroquinone-damaged human retinal pigment epithelial cell proliferation by advanced glycation end-products via up-regulation of VEGF geneH. Tsujinaka¹, A. Itaya-Hironaka¹, A. Yamauchi¹, S. Sakuramoto-Tsuchida¹, H. Ota¹, T. Fujimura¹, R. Shobatake¹, N. Ogata², S. Takasawa¹;¹Department of Biochemistry, ²Department of Ophthalmology, Nara Medical University, Kashihara, Japan.

Background and aims: Age-related macular degeneration (AMD) is the important cause of irreversible blindness in elderly patients. The disease has been classified into dry and wet forms. The dry form AMD was defined as progressive destruction of retinal pigment epithelial (RPE) cells. While, exudative form AMD is characterized by choroidal neovascularization, which is led by some angiogenic cytokines such as vascular endothelial growth factor (VEGF). Although recent research showed that

advanced glycation endproduct (AGE), which is accumulated by the history of diabetes mellitus, and hydroquinone (HQ), which is generated by the smoking, are strongly correlated to the pathogenesis of AMD, the mechanism how AGE and HQ induce or accelerate AMD remains elusive. In the study, we investigated effects of AGE on RPE cell proliferation and *VEGF* expression in HQ-damaged human RPE cells.

Materials and methods: ARPE-19 and h1RPE7 cells, human RPE cell lines, were treated HQ (20–40 μ M), AGEs (300 μ g/ml), and HQ+AGE for 12 h. After the treatment, viable cell numbers, apoptosis, and replicative DNA synthesis was measured by WST-8 cleavage, TUNEL method, and 5'-iodo-2'-deoxyuridine (IdU) incorporation, respectively. *VEGF* mRNA was measured by real-time RT-PCR and VEGF, secreted into culture medium, was measured by ELISA. Reporter plasmids containing several length of *VEGF* promoter and mutants of potential binding sites for SP1 (GC box) were constructed on pGL4.17 vector and introduced them into RPE cells. After 12 h incubation with HQ and/or AGE, cells were recovered and promoter activity was determined.

Results: The viable cell numbers of ARPE-19 and h1RPE7 were markedly reduced by HQ ($P < 0.0001$). The addition of AGE to the HQ-treated cells increased cell numbers ($P < 0.002$). HQ significantly increased apoptosis ($P = 0.0002$). AGE alone did not change apoptosis and the addition of HQ+AGE did not prevent the HQ-induced apoptosis. Replicative DNA synthesis was increased by the addition of AGE in HQ-treated cells (No addition vs HQ+AGE, $P = 0.0013$; HQ vs HQ+AGE, $P = 0.0001$), indicating that AGE increases cell number by activating HQ-treated cell replication. Real-time RT-PCR revealed that *VEGF* mRNA was increased by the combined addition of HQ+AGE. The increase of VEGF in the HQ+AGE treated cell culture medium was confirmed by ELISA ($P = 0.0064$ vs no addition, $P = 0.0433$ vs HQ, $P = 0.0063$ vs AGE). Inhibitors for VEGF/VEGF receptor (sulochrin, Ki8751, and CBO-P11) as well as *siVEGF* attenuated the HQ+AGE-induced increases in RPE cell numbers ($P < 0.05$). Introduction of *siRNA for receptor of AGE (RAGE)* into RPE cells attenuated the HQ+AGE-induced increase in RPE cell numbers ($P = 0.0175$). Deletion analysis of *VEGF* promoter revealed that GC boxes in the -102~-43 region were essential for the *VEGF* promoter activation. Site-directed mutations of the GC boxes in the *VEGF* promoter and knockdown experiment using *SP1 siRNA* revealed that SP1 is an essential transcription factor for *VEGF* expression in RPE cells.

Conclusion: HQ induces RPE cell apoptosis and leads to dry AMD. AGE stimulation enhances *VEGF* transcription via the AGE-RAGE pathway in HQ-damaged cells. As a result, the secreted VEGF acts as an autocrine/paracrine growth factor for RPE and/or adjacent vascular cells, causing wet AMD.

1074

The role of erythropoietin in physiological angiogenesis of mouse retina

J. Lin, J. Wang, S. Wetzel, H.-P. Hammes;

University of Heidelberg, 5th Medical Department, Mannheim, Germany.

Background and aims: Diabetic retinopathy (DR) is a prevalent microvascular complication and it is characterized by increased vascular permeability, ischemia and neovascularization. Angiogenesis is modulated by growth factors such as vascular endothelial growth factor and angiopoietin-2. Recently, it has been found that erythropoietin, besides neuroprotection, has angiogenic effects and its level is highly elevated in vitreous fluids of patients with proliferative diabetic retinopathy. However, the role of erythropoietin in physiological angiogenesis of the retina and its cooperation with angiopoietin 2 remains unclear. This study investigated the effects of erythropoietin on the physiological angiogenesis of the mouse retina.

Materials and methods: C57Bl/6 wild type and angiopoietin 2 transgenic mice were intraperitoneally injected at postnatal days P1, P3, P5, P7

and P9 with human recombinant erythropoietin at doses of 256 IU/kg. Retinae at P10 were stained with isolectin B4, NG2 and Iba1 antibodies, respectively. Angiogenic parameters of retinal vasculatures were analyzed using a Leica confocal microscope TCS SP2 system.

Results: Erythropoietin promoted the outgrowth of the deep vessels by 21% (* $p < 0.05$) and increased pericytes recruitment in the superficial and deep layer by 23% and by 42%, respectively (* $p < 0.05$). The microglial number was reduced in the superficial layer of retinal vessels (27%, * $p < 0.05$), but increased in the deep layer (60%, *** $p < 0.001$). Microglia were located in front of tip cells and acted as a bridge to connect neighboring sprouts. Angiogenic activity was elevated in the deep layer of the retinal vascular plexus, especially with cooperation of angiopoietin 2.

Conclusion: Erythropoietin promotes angiogenesis and the maturation of the vascular plexus in the mouse retina.

Identification of pro-apoptotic markers responsible for hypoxia and hyperglycaemia-induced pericyte apoptosis

E. Beltramo¹, A.I. Arroba², A. Mazzeo¹, R. Simò^{3,4}, M. Porta¹, A.M. Valverde²;

¹Dept Medical Sciences, University of Turin, Italy, ²Instituto de Investigaciones Biomédicas Alberto Sols, Madrid, ³Vall d'Hebron Research Institute (VHIR), Universitat Autònoma de Barcelona, ⁴CIBERDEM, Barcelona, Spain.

Background and aims: Loss of pericytes is the key-event in the pathogenesis of microvascular diabetic retinopathy. We have previously demonstrated that human retinal pericytes (HRP) are more vulnerable to intermittent than stable high glucose concentrations, with an increase in their apoptosis. Somatostatin, a well-known neuroprotective drug, may protect retinal cells, both microvascular and neuronal, from stress conditions. The aim of the present study was to investigate the effects of hypoxia combined with high glucose on HRP and explore the expression of molecules involved in the pro-apoptotic and survival pathways. This research will further clarify the mechanisms of action of these diabetic-like stress stimuli.

Materials and methods: HRP were exposed intermittently at 48 hr-intervals to high (28 mM)/physiological (5.6 mM) glucose for 8 days (intHG) and/or hypoxia for the last 48 hrs, with or without the addition of somatostatin. Cell proliferation was assessed by cell counting and BrdU incorporation, and apoptosis as DNA fragmentation (ELISA). The expression of pro-apoptotic (FasL, pro-caspase-8, active-caspase-8, Bid, t-Bid, Bax, calpain-2) and anti-apoptotic (PCNA, p-Akt) molecules were evaluated by Western blot.

Results: Hypoxia, alone and combined with intHG, is able to increase HRP apoptosis (+27 and +34%, respectively, $p < 0.05$ vs ctrl) and decrease their proliferation (-28 and -31% vs ctrl, $p < 0.005$). Pro-apoptotic molecules (FasL, active caspase-8, t-Bid, Bax) were significantly increased in HRP cultured in hypoxic conditions, both in physiological and intHG conditions, while no significant differences, but a trend towards decrease, were observed in the expression of survival markers (PCNA, p-Akt).

Conclusion: Diabetic-like conditions (intHG and hypoxia) are able to stimulate pericyte apoptosis through activation of pro-apoptotic molecules, thus leading to an imbalance between pro-apoptotic and survival signaling pathways. Our identification of such intermediates could help finding new therapeutic approaches for the prevention of DR.

Decreasing diabetes-induced overexpression of lysyl oxidase prevents development of retinal vascular lesions associated with diabetic retinopathy

D. Kim¹, S. Amin¹, E. Bae¹, S. Wong¹, J. Zhang¹, R.P. Mecham², S. Roy¹;

¹Ophthalmology and Medicine, Boston University School of Medicine, ²Cell Biology and Physiology, Washington University School of Medicine, St. Louis, USA.

Background and aims: Retinal capillary basement membrane (BM) thickening is closely associated with the development of vascular lesions in diabetic retinopathy (DR). Thickened capillary BM has been shown to compromise blood-retinal-barrier (BRB) characteristics and thereby contribute to retinal vascular permeability, a significant clinical manifestation of DR. We have previously shown that high glucose increases the expression and activity of lysyl oxidase (LOX), a cross-linking enzyme, in retinal endothelial cells. Additionally, concomitant with overexpression of LOX, increased vascular permeability was observed in streptozotocin (STZ)-induced diabetic rat retinas. However, it is unknown whether decreased LOX expression may have beneficial effects against development of retinal vascular lesions in diabetes.

Materials and methods: To examine whether reduced LOX expression has protective effects against diabetes-induced development of retinal vascular lesions characteristic of DR, four groups of mice: wild type (WT) control mice, STZ-induced diabetic mice, LOX +/- mice, and STZ-induced diabetic LOX +/- mice were used for this study. Diabetes was induced via STZ and maintained for 3 months; at the end of the study, retinas were assessed for LOX protein level by Western Blot (WB) analysis. Retinal capillary networks were isolated from the four groups of animals and retinal trypsin digest (RTD) was performed with hematoxylin/periodic acid Schiff staining. Digital images of the stained retinal capillary networks were captured to assess the number of acellular capillaries (AC) and pericyte loss (PL). In parallel, retinal vascular permeability was determined in retinal whole mounts following FITC-dextran injection.

Results: WB analysis showed significant increase in LOX expression in the diabetic retinas (135.13±23.6% of WT) compared to those of the WT control retinas, and a significant decrease in LOX expression in the diabetic LOX +/- retinas (105.29±9.8% of WT) compared to those of the diabetic retinas. RTD images exhibited a significant increase in the number of AC (197±52% of control; $p < 0.05$) and PL (566±26% of control; $p < 0.05$) in the retinas of diabetic mice compared to those of the WT control mice. Interestingly, the number of AC and PL was significantly decreased in the retinas of the diabetic LOX +/- mice compared to those of the diabetic mice (42%, $p < 0.05$; 19%, $p < 0.05$, respectively). Additionally, retinal vascular permeability was decreased in the retinas of the diabetic LOX +/- mice compared to those of the diabetic mice.

Conclusion: Findings from this study suggest that reducing diabetes-induced LOX overexpression may have beneficial effects against the development of retinal vascular lesions characteristic of DR. Therefore, LOX overexpression may be a potential therapeutic target in preventing retinal vascular cell loss and excess permeability associated with DR.

Deficiency in nucleoside diphosphate kinase B aggravates the development of diabetic retinopathy through upregulation of angiotensin-2 via FOXO1

Y. Qiu¹, D. Zhao¹, E.Y. Skolnik², H.-P. Hammes³, T. Wieland¹, Y. Feng¹; ¹Institute for Experimental and Clinical Pharmacology and Toxicology, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany, ²Division of Nephrology, New York University Langone Medical Center, New York, USA, ³Fifth Medical Department, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany.

Background and aims: Nucleoside diphosphate kinase B (NDPKB) is a ubiquitous enzyme required for the synthesis of nucleoside triphosphates. It is thus involved in many cellular functions. Based on its role in endothelial cells and glucose metabolism, we hypothesize that NDPKB may play a role in diabetic retinopathy (DR).

Materials and methods: Diabetes was induced in NDPKB knockout (KO) and wild type (WT) mice with streptozotocin. Pericyte (PC) coverage and acellular capillary (AC) formation were evaluated in the retina 6 months after diabetes induction. The expression of angiotensin-2 (Ang2) and forkhead box protein O1 (FOXO1) was assessed by western blotting and/or immunofluorescence staining in the diabetic retinas *in vivo*, and in NDPKB knockdown human umbilical vein endothelial cells (HUVEC) as well as in Müller cells isolated from NDPKB KO retinas and stimulated with high glucose (HG) *in vitro*. The knockdown of NDPKB and FOXO1 was performed by transfection with specific siRNAs.

Results: The number of PCs in the non-diabetic (NC) NDPKB KO retinas (1542/mm² capillary area) was significantly decreased compared to WT NC retinas (1741/mm² capillary area, $P < 0.01$) and similar to diabetic (DC) WT retinas (1586/mm² capillary area, $p < 0.05$ vs. WT NC). Diabetic conditions further decreased PC number in NDPKB KO retinas (1400/mm² capillary area) compared with KO NC and WT DC ($p < 0.05$). Additionally, diabetes significantly enhanced the formation of AC in WT retinas (DC: 34/mm² retinal area, NC: 25/mm² retinal area, $p < 0.05$). The number of AC in NDPKB KO NC retinas (28/mm² retinal area) was similar to WT NC retinas. However, NDPKB KO DC retinas displayed a significant enhancement in AC formation (44/mm² retinal area) compared with WT DC retinas and KO NC retinas ($p < 0.05$). Concerning the essential role of Ang2 in pericyte loss in diabetic retinopathy, we determined the Ang2 levels in the NDPKB KO retinas. Compared to WT NC retinas, the expression of Ang2 was significantly upregulated in NDPKB KO NC retinas ($p < 0.05$ vs. WT NC) and to a similar extent in WT DC retinas ($p < 0.05$ vs. WT NC). No difference in Ang2 expression was detected between NDPKB KO DC and NDPKB KO NC retinas. Endothelial and Müller cells are the main source of Ang2 in the retina. As shown by western blotting and immunofluorescence in HUVEC as well as in Müller cells, HG and NDPKB depletion similarly increased Ang2 expression, which was paralleled by enhanced FOXO1 levels and activity. Conversely, Ang2 expression was dramatically suppressed in the NDPKB- and FOXO1- double depleted HUVEC.

Conclusion: Our data indicate that NDPKB deficiency aggravates the development of diabetic retinopathy through an upregulation of Ang2 in endothelial and Müller cells. The NDPKB-dependent expression and activity of the transcription factor FOXO1 likely regulates Ang2 levels. *Supported by: EFSD/Novartis, DFG (GRK1874)*

Mechanism of action of calcium dobesilate in the early stages of diabetic retinopathy

C. Sola-Adell^{1,2}, P. Bogdanov^{1,2}, L. Corraliza^{1,2}, C. Hernandez^{1,2}, S. Ballarini³, C. Pasquali³, R. Simo^{1,2};

¹Diabetes and Metabolism Research Unit, Vall d'Hebron Institut de Recerca, ²Centro de Investigación Biomedica en Red de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Barcelona, Spain, ³Vifor Pharma/OM Pharma, Geneva, Switzerland.

Background and aims: Calcium Dobesilate (CaD) has been prescribed to prevent the progression of diabetic retinopathy (DR). However, its clinical efficacy is still a matter of controversy. Recently, it has been reported that administration of the CaD in patients with DR may reduce the serum levels of endothelin-1 (ET-1). It should be noted that ET-1, a potent vasoconstrictor, is involved in the development of DR and also contributes to retinal neurodegeneration. The aim of the present study was to determine the effect of CaD in preventing retinal neurodegeneration and early microvascular abnormalities induced by diabetes in a murine model (db/db mouse). In addition, the effect of CaD on ET-1 and its receptors were also assessed.

Materials and methods: For this purpose we evaluated a total of 24 diabetic mice (db/db) aged 8 weeks that were randomly assigned to daily oral treatment with CaD (200 mg/kg/day) ($n = 12$) or vehicle ($n = 12$) for two weeks. Twelve non-diabetic mice (db/+) were used as control group. Retinal neurodegeneration was evaluated by measuring glial activation (GFAP immunofluorescence) and apoptosis (TUNEL, cell count in ganglion cell layer). Glutamate excitotoxicity, ET-1 pathway and VEGF expression were assessed by immunohistochemistry and Western blotting analysis. Functional retinal abnormalities were measured by focal electroretinography (fERG). Statistical analysis was performed by unpaired t-student test and results were expressed as mean \pm SEM.

Results: In summary, we found that CaD significantly decreases the main hallmarks of retinal neurodegeneration (glial activation and apoptosis). In addition, a significant improvement of ERG parameters was observed. CaD also reduces glutamate excitotoxicity induced by diabetes. Furthermore, CaD prevented the up-regulation of ET-1 and its cognate receptors in diabetic retinas. Finally, we have found that CaD treatment reduces the expression of VEGF and preserves the sealing function of the blood retinal barrier (BRB).

Conclusion: Our results suggest that CaD treatment could be effective in preventing neurodegeneration and microvascular abnormalities (disruption of BRB) in early DR. Better understanding of the mode of action of CaD could be important to guide physicians in targeting the treatment more appropriately.

PS 106 Diabetic retinopathy: pathogenesis and predictors

1079

Prevalence and progression of diabetic retinopathy in people with type 2 diabetes dependent on the duration of diabetes

M. Voigt¹, S. Schmidt¹, N. Müller¹, B. Milke¹, U.A. Voigt², G. Wolf³, U.A. Müller¹;

¹Endocrinology and Metabolic Diseases, Internal Medicine III, ²Dept. of Ophthalmology, ³Internal Medicine III, Jena University Hospital, Germany.

Background and aims: At present the guideline for diabetic retinopathy of the DDG (German diabetes association) and the NVL (national guideline for diabetic eye disease) recommend annual screening of patients with type 2 diabetes and no prior retinopathy. It is because the onset of diabetes complications under good glycaemic control is a matter of years that this practice presumably leads to frequent superfluous examinations. The aim of our investigation was to examine the prevalence of retinopathy dependent on the diabetes duration in order to assess the probability of the disease progressing.

Materials and methods: In a retrospective database analysis from a university outpatient department for endocrinology and metabolic diseases we analyzed 17461 consultations of 4513 patients with type 2 diabetes (age 64,5 years, duration of diabetes 12,8 years, BMI 31,4 kg/m², HbA_{1c} DCCT adjusted 7,4% / 51,9 mmol/mol, blood pressure 146/82 mmHg, 50,3% women). The obtained data included clinical evidence from 1987 to 2014. 50,5% of the patients (n=2279) had at least one documented result of fundoscopy and were enclosed in the analysis (age 65,4 years, duration of diabetes 14,9 years, BMI 31,6 kg/m², HbA_{1c} DCCT adjusted 7,25% / 52,2 mmol/mol, blood pressure 145/80 mmHg, 47,3% women).

Results: 25,8% of the patients had retinopathy (20,2% non-proliferative, 4,7% proliferative, 0,7% were not classified, 0,1% blindness). The prevalence of retinopathy dependent on the duration of diabetes was 1,1% at diagnosis, 6,6% after 0<5 years, 12% after 5<10 years, 24% after 10<15 years, 39,9% after 15<20 years, 52,7% after 20<25 years, 58,7% after 25<30 years and 63% after ≥30 years. From 586 (25,7%) patients retinal photography of three consecutive years could be obtained and evaluated. Out of these 7,3% showed deterioration after one year and 13% after two years. On the other hand 3,4% improved after one year and 3,6% after two years. 201 (34,3%) of these patients had less than 10 years diabetes and showed an even lower tendency of deterioration (4,5% worsened after one and 9,5% after two years). Notably these patients mainly transformed from no retinopathy at all to non-proliferative retinopathy. Only four patients (2%) developed a proliferative retinopathy within this period.

Conclusion: The prevalence of the diabetic retinopathy increases with the duration of diabetes. Within the first ten years of diabetes the prevalence of retinopathy is low and the progression of the disease infrequent. Most patients have a non-proliferative form which can be reversible and requires no intervention in most cases. In patients with type 2 diabetes and no prior retinopathy as well as good glycaemic control, intervals of fundoscopy could be widened from annual to two yearly screenings within the first five years of diabetes duration given that an initial examination of the eyes has been obtained.

Lipoprotein(a) predicts development of diabetic retinopathy in patients with type 2 diabetes mellitus

Y.-B. Ahn¹, T.-S. Lim¹, J.-S. Yun¹, S.-A. Cha¹, H. Seok², S.-D. Moon³, S.-H. Ko¹;

¹Internal Medicine, The Catholic University of Korea, Suwon, ²Internal Medicine, The Catholic University of Korea, Uijeongbu, ³Internal Medicine, The Catholic University of Korea, Incheon, Republic of Korea.

Background and aims: We investigated factors that might influence the development of diabetic retinopathy (DR) in patients with type 2 diabetes.

Materials and methods: From January 2003 to December 2004, a total of 767 patients with type 2 diabetes without diabetic retinopathy were consecutively enrolled. The serum lipoprotein(a) [Lp(a)] concentration was measured by a one-step sandwich enzyme-linked immunoassay, and a standardized clinical examination and retinal photographs were checked annually by ophthalmologist. We used a Cox proportional hazard regression analysis to test the associations between diabetic retinopathy and Lp(a).

Results: Of the 765 patients who were enrolled in this study, 483 (63.1%) completed the follow-up evaluation. The median follow-up time was 10.3 years. The mean age was 53.9±10.6 years, and the duration of diabetes was 6.4±5.6 years. During the follow-up period, 225 patients (46.6%) developed DR. The patients in the DR group had a longer duration of diabetes ($p<0.001$), higher baseline HbA_{1c} levels ($p<0.001$), received more insulin treatment ($p<0.001$) and a higher level of Lp(a) (12.6 [Interquartile range 7.9-24.0] vs 15.2 [9.2-29.7] mg/dl; $p=0.010$). A Cox hazard regression analysis revealed that the development of DR was significantly associated with the high level of serum Lp(a) level (hazard ratio 1.13; 95% CI 1.03-1.24; $p=0.008$) per 10 mg/dl Lp(a) increase after adjusting for sex, age, diabetic duration, mean HbA_{1c}, treatment of insulin, ACE inhibitor/angiotensin receptor blocker and lipid lowering agents.

Conclusion: The development of DR was independently associated with serum Lp(a) level in patients with type 2 diabetes.

1081

Cognitive function may be a predictor of retinopathy progression in patients with type 2 diabetes

L. Borio¹, M. Salassa¹, A. Baltatescu², V. Paganin¹, P. Passera¹, L. Charrier³, F. Cavallo³, M. Porta², M. Trento¹;

¹Medical Sciences, Laboratory of Clinical Pedagogy, ²Medical Sciences, Center of Diabetic Retinopathy, ³Public Health and Pediatric Sciences, University of Turin, Italy.

Background and aims: Cognitive function, depression and anxiety may be associated with type 2 diabetes (T2DM) and its complications. In particular diabetic retinopathy (DR) is a complication that affects people with diabetes.

In an observational prospective study of a cohort of T2DM patients followed for 8 years, we monitored a number of clinical, psychological and cognitive variables to identify possible predictors of progression of DR.

Materials and methods: Patients (n=498) with T2DM, of which 249 not treated by insulin (NIT) and 249 on insulin treatment (IT), were enrolled at baseline. The following variables were recorded: age, gender, diabetes duration, schooling, occupation, social status, smoking, self-monitoring of blood glucose, hypertension, menopausal status, fasting blood glucose, HbA_{1c}, BMI, total and HDL cholesterol, triglyceride, retinopathy grading, presence of foot ulcers, depression and anxiety scores (Zung questionnaire) and cognitive function (Minimal Mental State Examination, MMSE). The same variables were collected again after 4 (JEI 37,79-85, 2014) and 8 years. DR assessment was by grading of digital 45° photographs of the macular and nasal areas. Grading of the worst eye was considered.

Results: Out of 477 patients for whom fundus evaluation was available at baseline, 240 (160 IT and 80 NIT) had no DR, 110 (48 NIT and 62 IT) had mild non proliferative DR and 127 (24 NIT and 103 IT) had moderate or more severe DR. After 8 years, 357 patients were available for analysis, of whom 191 had remained with no or mild DR and 166 had developed moderate or more severe DR. Patients who had moderate or more severe DR at baseline were not included in the follow-up analysis. On multivariate analysis, being on insulin treatment (OR 1.90, 95%CI 1.02;3.55, $p=0.043$) and having mild vs no DR at baseline (OR 4.51, 2.44;8.31, $p<0.0001$) were associated with progression to moderate/more severe DR, whereas male gender (OR 0.49, 0.26;0.92, $p=0.028$) and a higher MMSE score (indicative of better cognitive ability) (OR 0.90 per scoring point; 0.83;0.99, $p=0.026$) were protective. None of the other baseline variables was associated with progression of DR in this cohort.

Conclusion: Lower MMSE score may represent a novel risk factor for progression of DR, on top of other known determinants. Microangiopathy might develop at both brain and retinal level and manifest itself with changes in cognitive function and retinopathy.

Evaluation of medically treatable risk factors in subjects with significant diabetic retinopathy from a local health economy area in the UK

W.J. Fusi-Rubiano¹, G. Ramsamy¹, S. Gillani¹, A. Bhatnagar², B. Singh¹, R. Raghavan¹;

¹Diabetes, ²Ophthalmology, New Cross Hospital, Wolverhampton, UK.

Background and aims: Diabetic retinopathy is the leading cause of blindness in people of working age in the western world. People with high risk retinopathy are also at risk of other diabetes and vascular complications. The aim of this study was to categorize and evaluate people with high risk diabetic retinopathy within our local health economy. We aimed to assess HbA_{1c} and four other key risk factors in this group to develop an understanding of the current provision of care.

Materials and methods: People with high-risk diabetic retinopathy (DR) were identified from our local health economy centralized electronic diabetes register and ophthalmic laser register. All known subjects with either currently active or previously treated significant diabetic retinopathy were included. People who were out of area or who had laser treatment for non-diabetic reasons were excluded. Prevalence was ascertained for each stage of DR. Data was derived from local IT systems for HbA_{1c} and four other important medically manageable risk factors- Blood pressure (BP), Creatinine, albumin/creatinine ratio (ACR) and cholesterol. These were then classified into good or poor control in accordance with internationally recognized standards such as BHS and NICE. Glycaemic control was assessed according to HbA_{1c} (%) categories as denoted: HbA_{1c}<7=A; 7.0-8.5=B; 8.5-10=C; HbA_{1c}>10=D. Number of risk factors not controlled were then assessed and analyzed for different grades of retinopathy and correlated against HbA_{1c} and other risk factors.

Results: Of 16,693 people with diabetes, 1440 (8.6%) were identified to have high-risk current or previously treated diabetic retinopathy (age range 20-94). 32 subjects were excluded from analysis due to incomplete dataset. Mean age was 63.2±14.6 and M:F ratio 1.5:1 (F=571). 1095 (78%) subjects had type 2 diabetes. 868 subjects (61.6%) were insulin treated. Breakdown of retinopathy grading: R1 940 (67%), R2 231 (16%), R3 239 (17%); M1 952 (67.6%). HbA_{1c} categories: A=529 (38%), B=317 (23%), C=330 (23%), D=234 (16%). BP of <140/80 mm Hg was achieved in 922 (65%) and Cholesterol of <4 mmol/l in 570 (40%). Diabetic Nephropathy (microalbuminuria and Creatinine>120) was seen in 392 (27%). All risk factors were controlled in 60 females (4.2%) and 64 males (4.5%). 845 (60%) subjects had 2 or more risk factors uncontrolled. For subjects with HbA_{1c} categories A,B,C positive correlation found between proportion of people with R3 and increase in number of

risk factors above defined threshold. Significant positive correlation ($p<0.01$) was also found between retinal score and HbA_{1c} and ACR on individual variate analysis.

Conclusion: Available retinopathy grades and risk factor data suggests that this group of high risk individuals have accessed local healthcare services within the recent past in the majority of cases (>97%). Despite this over one third of subjects with significant diabetic retinopathy had poor or very poor glucose control & suboptimal blood pressure control. Nearly two thirds of these subjects had 2 or more risk factors which were above a significant threshold. A correlation between degree of retinopathy and HbA_{1c} and ACR underlines the significance of managing microvascular risk factors in this cohort. Overall this study suggests that it is the service element that needs to be addressed in this group to target data driven care & improve outcomes.

1083

Multiparametric in-vivo imaging in degenerative retinopathy

M. Kolibabka¹, Y. Feng^{1,2}, S. Hoffmann³, N. Gretz³, H.-P. Hammes¹;

¹5th Medical Department, ²Institute of Experimental and Clinical Pharmacology and Toxicology, ³Medical Research Center, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany.

Background and aims: The transgenic polycystic-kidney-disease rat (PKD) develops neurodegeneration and subsequent vasoregression morphologically similar to diabetic retinopathy. The neurodegeneration over time has already been characterized using different parameters that are the in-vivo measurements of electroretinograms and the ex-vivo quantified retinal thickness histologically measured in retinal sections. In this study we analyzed the timecourse of the neurodegeneration with a multiparametric in-vivo imaging device to establish a method allowing us to monitor structural and functional changes over time and to identify specific sets of markers suitable to define the outcome of possible therapeutics.

Materials and methods: PKD rats were analyzed at different timepoints (1, 2, 3, 5, 7 and 12 months of age) matching our previously published ex-vivo results. Age matched Sprague Dawley (SD) rats served as controls. All measurements were performed using the RETImap multi-parametric imaging device. Retinal thickness was measured with the optical coherence tomography (OCT) module quantifying the thickness in five locations at the border of the central and peripheral retina equivalent to the area measured histologically. For the determination of the retinal function the multifocal electroretinography (mfERG) module with a seven frame focal algorithm centered on the optic nerve head was used. The groups were compared to each other and the retinal thickness was compared to our already published histological analysis.

Results: The in-vivo analysis showed a similar timecourse of disease progression as the histological data with a significantly decreased retinal thickness from one month on in PKD rats compared to SD rats ($p<0.001$). Comparing the OCT-data to the histological data we achieve a Pearson Correlation Coefficient of $R^2=0.97$ for SD and $R^2=0.87$ for PKD rats (both $p<0.05$). For the retinal function the A-wave amplitude, reflecting the function of photoreceptors, revealed no significant difference between SD and PKD, the B-wave amplitude, reflecting the function of interneurons but also of glial cells, is decreased from two months on in PKD ($p<0.01$). In order to identify a functional parameter reflecting also the structural changes, we correlated them with the OCT-data showing a Pearson Correlation Coefficient for the B-wave amplitude of $R^2=0.88$ in SD and $R^2=0.83$ in PKD rats (both $p<0.05$).

Conclusion: In this study we demonstrate the suitability of the multi-parametric in-vivo imaging device RETImap to detect and monitor retinal pathological changes affecting structure and neuroretinal function. By using this device it is possible to check the outcome of therapeutic interventions and to dramatically reduce the number of animals needed to perform this kind of studies. We also are able to show that the B-wave amplitude measured by mfERG is the most suitable parameter to determine early changes in neuroretinal function as it adequately takes the structural changes into account. This again suggests an impact of Müller cell function on the development of degenerative retinopathies.

Genome-wide association study of severe diabetic retinopathy in type 1 diabetes

N. Vuori^{1,2}, N. Sandholm^{1,2}, I. Toppila^{1,2}, K. Hietala^{3,1}, C. Forsblom^{1,2}, P. Summanen³, P.-H. Groop^{1,2};

¹Folkhälsan Institute of Genetics, Folkhälsan Research Center, Helsinki, ²Abdominal Center Nephrology, University of Helsinki and Helsinki University Hospital, ³Department of Ophthalmology, Helsinki University Central Hospital, Finland.

Background and aims: The aim of the study is to find genetic risk factors for severe diabetic retinopathy (SDR) in type 1 diabetes with genome-wide association studies (GWAS) in the Finnish Diabetic Nephropathy (FinnDiane) Study. We also estimated the heritability of SDR.

Materials and methods: The patient population in the FinnDiane GWAS consisted of 1518 cases with SDR and 1622 controls without SDR. Type 1 diabetes was defined as being diagnosed <39 years of age and insulin treatment started within 1 year of diagnosis or if not available, a basal C-peptide level ≤ 0.2 pmol/ml. Patients were not excluded based on duration of diabetes. SDR was defined at baseline visit as presence of severe non-proliferative diabetic retinopathy or worse in ophthalmic exam/fundus photography or a history of scatter laser treatment (panretinal photocoagulation). This is equivalent to an ETDRS-score of 50 or worse in FinnDiane. Participants with mild or no retinopathy were considered as controls (ETDRS-score 45 or lower). The GWAS in FinnDiane was genotyped using Illumina 610Quad chip and SNP imputation was performed with HapMap II CEU reference population. The GWAS was performed using multiple logistic regression model with SDR status as the dependent variable and allele dosage as the independent variable (PLINK). Covariates in the analysis included age, gender, HbA_{1c} measured at baseline, diabetes duration, and quadratic transformation of duration (duration²) all of which were significantly associated with retinopathy. The heritability estimation of SDR was calculated using GCTA (Genome-wide Complex Trait Analysis) with and without the covariates. A prevalence of 30% was used and samples with estimated relatedness of 0.025 or higher were excluded.

Results: 14 SNPs showed a p-value of $<10^{-5}$. The lowest p-value for SDR was found for a SNP on chromosome 1p13.3 with an odds ratio of 0.72 (95% confidence interval 0.707–0.819) and a p-value of 1.1×10^{-6} on *AKNAD1* gene. The results from the heritability estimation show heritability of SDR of <1% (heritability: 1×10^{-6} , standard error (S.E.) = 0.130, p = 0.5) without covariates. However, when including covariates (age, sex, HbA_{1c}, duration, duration²) the heritability was estimated to 18% (S.E. = 0.158, p = 0.119).

Conclusion: Although no locus reached genome-wide significance, our finding show suggestive evidence of an association on chr1 to SDR in patients with type 1 diabetes. The heritability of SDR in our study is ~18% when the major covariates such as age, sex, HbA_{1c}, duration and duration² are considered.

Implication of genetic loci identified in genome-wide association studies of diabetic retinopathy in Chinese patients with type 2 diabetes

C.Y.Y. Cheung¹, E.Y.L. Hui¹, K.H.M. Kwok¹, Y.C. Woo¹, P.C.H. Lee¹, W.S. Chow¹, C.H.Y. Fong¹, M.M.A. Yuen¹, R.L.C. Wong¹, A. Xu^{1,2}, D.S.H. Wong^{3,2}, P.C. Sham^{4,5}, K.S.L. Lam^{1,2};

¹Department of Medicine, The University of Hong Kong, ²Research Centre of Heart, Brain, Hormone and Healthy Aging, HKU, Hong Kong, ³Department of Ophthalmology, ⁴Department of Psychiatry, The University of Hong Kong, ⁵Centre for Genomic Sciences, HKU, Hong Kong, China.

Background and aims: Diabetic retinopathy (DR), a leading cause of blindness, is the most common microvascular complication of type 2 diabetes (T2DM). Recent genome-wide association studies (GWAS) had identified novel DR-susceptibility genetic loci in various populations. If validated, these genetic markers may be utilised for risk profiling of DR in patients with diabetes and facilitate their early diagnosis. This study aimed to examine the association of the newly identified DR-associated single nucleotide polymorphisms (SNPs) with severe DR in Chinese T2DM patients.

Materials and methods: We conducted a cross-sectional case-control study on sight-threatening DR (STDR) based on Chinese subjects of the Hong Kong West Diabetes Registry. STDR cases were T2DM patients with either proliferative DR (PDR) or pre-PDR, or clinically significant macular oedema, or with photo-coagulation (with laser photocoagulation marks). Non-STDR controls were T2DM patients with no retinopathy. The grading of retinopathy was based on 2-field fundal photographs, according to the United Kingdom National Screening Committee (NSC) classification. A total of 36 SNPs showing top association signals with DR in previous GWAS were genotyped in 567 STDR cases, including 309 subjects with PDR, and 1490 non-STDR controls. Multiple logistic regression models with adjustment for confounding factors, including age, gender, duration of diabetes, and presence of hypertension, were employed.

Results: The strongest association was found at rs2115386, an intronic SNP in the insulin receptor gene *INSR*: adjusted P = 9.13×10^{-4} (OR[95%CI]: 1.28[1.11–1.48]) for STDR, and adjusted P = 1.12×10^{-4} (OR: 1.44[1.20–1.74]) for PDR. rs599019 located downstream of *COLEC12* (adjusted P = 0.019; OR: 1.19[1.03–1.38]) and rs4462262 located at an intergenic region between *ZWINT* and *MRPS35P3* (adjusted P = 0.041; OR: 1.38[1.01–1.89]) were also found to be significantly associated with STDR, but not with PDR alone. On the other hand, rs10199521 (*MYT1L-LOC729897*; adjusted P = 0.022; OR: 1.25[1.03–1.51]), and rs899036 (*API5*; adjusted P = 0.049; OR: 1.36[1.00–1.85]) showed significant independent associations only with PDR. Similar results were obtained when glycated hemoglobin (HbA_{1c}) was also included in the adjustment models. The combined genetic risk score constructed of the significant SNPs showed an OR of 1.24 (adjusted P = 1.20×10^{-5}) and 1.35 (adjusted P = 2.00×10^{-6}) for each additional risk allele with STDR and PDR, respectively, in the combined genetic risk analyses.

Conclusion: We have successfully confirmed the significant independent associations of several SNPs identified in previous GWAS with severe DR (STDR and/or PDR) in our Chinese T2DM patients. Their highly significant combined genetic risk scores suggest potential applications in risk stratification for enhanced DR screening. Our findings on rs2115386 of the insulin receptor gene *INSR* are supportive of the role of insulin resistance, or the compensatory hyperinsulinaemia, in the pathogenesis of DR.

Hyperglycaemia down-regulates levels of miR-126 in endothelial cells

R. Sanguineti¹, A. Puddu¹, C.E. Traverso², M. Nicolò², G.L. Viviani¹; ¹Department of Internal Medicine and Medical Specialities, ²Department of Neuroscience, Ophthalmology and Genetics, University of Genova, Italy.

Background and aims: MicroRNAs have been implicated in the epigenetic regulation of key pathways in many diseases including type 2 diabetes (DM). miR-126, a microRNA expressed in endothelial cells, regulates expression of genes involved in neovascularization and vascular permeability, including Vascular Endothelial Growth Factor-A (VEGF-A) and hypoxia-inducible factor-1 α (HIF-1 α). VEGF-A has a pathologic role in microvascular diabetic complication, such as Diabetic retinopathy (DR) and diabetic macular edema (DME) which are the leading causes of blindness in the working-age population. Since levels of miR-126 are significantly lower in T2DM patients than in healthy controls, the aim of this study is to investigate whether hyperglycemia affects expression of miR-126 in a model in vitro of blood retinal barrier.

Materials and methods: We used commercially available human retinal pigment epithelial cells (ARPE-19) and endothelial cells (HECV). HECV cells were seeded in transwell inserts, let adhere for 24 hours and then co-cultured for 24 hours with ARPE-19 cells in DMEM normal glucose (5.5 mmol/L; CTR) or DMEM high glucose (25 mmol/L; HG) supplemented with 10% FBS. Total RNA was extracted from HECV cells and levels of miR-126 were detected using quantitative real-time PCR. Then mRNA expression of the miR-126 targets VEGF-A and HIF-1 α was evaluated by quantitative real-time PCR. Another set of cells was lysed in RIPA buffer and HIF-1 α protein expression was evaluated by Western blot.

Results: Levels of miR-126 were strongly decreased in HECV cells cultured with HG compare to CTR ($-62.5\% \pm 10.61\%$, $p < 0.001$ vs CTR). Lowered levels of miR-126 in HG condition are associated with increased mRNA expression of VEGF-A and HIF-1 α (respectively $+30\% \pm 11.79\%$, $p < 0.05$ vs CTR; and $+33.3\% \pm 10.26\%$, $p < 0.01$ vs CTR). In addition HIF-1 α protein levels was up-regulated in HECV cells cultured under hyperglycemic condition ($+51.7\% \pm 8.622\%$, $p < 0.001$ vs CTR).

Conclusion: Here we show evidence that hyperglycemia directly lowers levels of miR-126 in endothelial cells. These results suggest that HG enhanced VEGF-A and HIF-1 α mRNA expression by down-regulating miR-126. Furthermore the increased expression of VEGF-A induced by HG may be due to the synergic effect of miR-126 down-regulation and HIF-1 α protein stabilization. These findings suggest that hyperglycemia may contribute to microvascular complication of diabetes by impairing levels of miR-126.

miR-126 is downregulated in pericytes following exposure to mesenchymal stem cell-derived extracellular vesicles obtained in diabetic-like conditions

A. Mazzeo, E. Beltramo, A. Iavello, S. Grimaldi, A. Carpanetto, M. Porta; Dept of Medical Sciences, University of Turin, Italy.

Background and aims: Loss of pericytes in the early phases of diabetic retinopathy (DR) may disrupt their stable association with endothelial cells (EC), leading to EC proliferation and, eventually, angiogenesis. We have recently shown that extracellular vesicles (EV) derived from mesenchymal stem cells (MSC) in diabetic-like conditions may play a role in vessel destabilization by interfering with the strict EC/pericyte/extracellular matrix interactions. Thus they might contribute to angiogenesis through paracrine signalling; in particular, a role for MMP-2 has been described. MicroRNAs (miR) are short RNA sequences acting as gene

modulators and playing important roles in angiogenesis and inflammation. MiR-126 is secreted mostly by the endothelium and controls vascular integrity and regeneration after injury. A down-regulation of miR-126 was observed in experimental models of DR, in diabetic retina extracts and in chorioretinal EC in hypoxic conditions, correlating with an increase in VEGF and MMP. Our aim in this study was therefore to investigate miR-126 expression in pericytes and the possible influence of EV derived by MSC cultured in diabetic-like conditions.

Materials and methods: Pericytes (HRP) were cultured in physiological (NG), stable high (HG) and intermittent high (intHG) glucose conditions for 8 days. In other experiments, EV were extracted from the supernatant of MSC cultured in hypoxic (hypo) and/or HG conditions and added to HRP cultured in NG for 6, 24 and 48 hrs. Real-Time PCR for miR-126 was performed on RNA extracts.

Results: HRP express miR-126 and this expression is down-regulated by 20% in intHG. miR-126 expression is not significantly modified by 6 and 24 hr exposure of HRP to EV. After 48 hrs, miR-126 is up-regulated by exposure to NG-EV ($+62\%$ vs ctrl). HG-EV and NG-hypo-EV do not influence significantly miR-126 expression, while EV obtained by MSC cultured in HG + hypoxia (HG-hypo) down-regulate miR-126 (-41% vs ctrl and -64% vs NG-EV, $p < 0.05$).

Conclusion: We show for the first time in our knowledge that HRP express miR-126 and that its expression is down-regulated in diabetic-like conditions. Moreover, exposure of HRP to EV obtained in diabetic conditions is able to decrease miR-126 expression, consistently with previous observations of its involvement in DR and providing further insights for our findings of EV contribution to vessel destabilization.

PS 107 Diabetic retinopathy screening

1088

Retinopathy in children with diabetes: When should they be screened?

I.M. Stratton, S.J. Aldington, P.H. Scanlon;

Gloucestershire Diabetic Retinopathy Research Group, Gloucestershire Hospitals, Cheltenham, UK.

Background and aims: Current advice in the UK is to commence screening for diabetic retinopathy with digital retinal photography at twelve years of age. Here we report on the relationships between age at diagnosis of diabetes, age at diabetic eye screening and severity of Diabetic Retinopathy (DR) in children aged 12 or 13.

Materials and methods: Data were extracted from 6 UK screening programmes. Time from diagnosis of diabetes to first screening and age at diagnosis were calculated.

Results: Data were available for 2125 children screened for the first time at age 12 or 13 and diagnosed with diabetes before the age of 13. The proportion with any retinopathy decreased monotonically from 20% in those diagnosed at age of 2 years or below to 8% in those diagnosed at 12 ($p < 0.0001$). The proportion with mild non-proliferative retinopathy in both eyes decreased from 11% in those diagnosed at 2 or below and 2% those diagnosed at 12. Only 3 children (aged 8, 10 and 11 respectively at time of diagnosis of diabetes) had images graded with referable retinopathy and of these 2 had non-referable DR at all subsequent screenings. Of 1703 children with subsequent images 25 were graded with referable DR over a mean follow-up of 3 years, incidence rate of 5 per 1,000 per year. Those with longer duration of diabetes at age 12 were at higher risk of progression to referable DR with hazard ratio of 1.3 per year (95% CI 1.18 to 1.50)

Conclusion: Although the rate of retinopathy in children below the age of 13 at first screening in the UK is significantly higher in those diagnosed with diabetes in early childhood, the rate is low and few children progress to referable DR. In this large cohort there is no evidence to suggest that earlier screening or more frequent screening is needed in this age group.

Retinopathy level at first screen at age 12 or 13

1089

Automated screening of diabetic retinopathy is safe and effective: a large-scale study on 55,074 diabetic patients

K.M. Solanki, M. Bhaskaranand, S.K. Bhat, C. Ramachandra; Eyenuk, Inc., Woodland Hills, USA.

Background and aims: Diabetic retinopathy (DR) is the leading cause of new-onset blindness in working-age adults in the industrialized world today. Fully-automated screening solutions are indispensable to screen

the large and ever-increasing number of diabetic patients for preventable vision loss due to DR. EyeArt is a computerized, high diagnostic efficacy, cloud-based DR screening system that can screen thousands of patient images in just a few hours and thus enables seamless, large-scale screening deployment to aid triage of DR patients in most need of eye-care. The aim of this study is to validate EyeArt for detecting referable DR defined to be moderate non-proliferative DR (NPDR) or higher on the International Clinical Diabetic Retinopathy (ICDR) severity scale and assess its ability to reduce the workload of retina experts.

Materials and methods: A total of 440,072 color retinal fundus images of 55,074 diabetic patient visits or encounters were obtained from the EyePACS database without any patient identification data. Each of these encounters had 2-24 images including external lens-shots. These deidentified images were captured between April 2006 and December 2013 at various DR screening centers that use the EyePACS professional image grading services. The DR severity on the ICDR scale provided by human graders at EyePACS were also made available and considered to be the gold standard. The images were analyzed by EyeArt. External lens-shots and images of inadequate quality that were ungradable due to factors like poor focus or poor illumination were automatically flagged by the EyeArt system and were not further analyzed for detecting referable DR. A “refer” recommendation was provided for patients with apparent signs of moderate NPDR or higher on the ICDR scale and a “no refer” recommendation was provided for patients with no apparent signs of DR or signs of mild DR. EyeArt’s referral recommendation performance was evaluated by using sensitivity, specificity, and area under the receiver operating characteristic curve (AUROC).

Results: Among the 55,074 encounters, prevalence of encounters with moderate NPDR or higher was 14.7% and prevalence of encounters with potentially treatable DR (severe NPDR or proliferative DR) was 3.5%. EyeArt’s screening sensitivity was 90% (95% CI: 89.3% - 90.6%) and specificity was 47.5% (95% CI: 47.1% - 48.0%). This corresponds to 31,926 “refer” recommendations and 809 false negatives out of which 766 did not meet the general treatment criteria (i.e. had moderate NPDR). The AUROC was 0.847 (95% CI: 0.842 - 0.852). EyeArt’s sensitivity for detecting potentially treatable DR was 97.8% (1878/1921 encounters). If the 23,148 encounters with “no refer” recommendations and 4,512 encounters with confident “refer” recommendations (operating point at 98% specificity) are not seen by graders, the graders need to grade only 49.8% of the total encounters with EyeArt. Therefore, in this mode of operation, EyeArt can help reduce the workload of graders by a factor of about 2.

Conclusion: EyeArt has high sensitivity and specificity for identifying patients with referable DR, making it safe and effective for integration into DR screening workflow. It can help save costs by greatly reducing the workload of image graders.

Stratification of screening intervals for diabetic retinopathy based on one versus two consecutive negative screening events

R.L. Thomas¹, S.D. Luzio¹, A. Crowder², R. McPherson², D.R. Owens¹; ¹Diabetes Research Unit, Cymru, Swansea University, ²Cardiff and Vale University Health Board, Diabetic Retinopathy Screening Service for Wales, Cardiff, UK.

Background and aims: There is ongoing debate about the appropriate interval for diabetic retinopathy (DR) screening. It has been proposed that persons with diabetes without evidence of DR at two consecutive negative screening events are at low risk of developing referable DR (RDR) and can safely be screened bi or triennially. The question remains whether one screening event with no evidence of DR is adequate to similarly extend the screening interval. The aim of this study was to compare the incidence of RDR in persons without evidence of DR at either one or two prior consecutive screening events.

Materials and methods: The diabetic retinopathy screening service for Wales (DRSSW) screens annually all persons with diabetes within Wales over the age of 12 years. The service utilises standardised image capture i.e. 2×45 degree digital retinal per eye using Canon DgI cameras and grading according to a nationally agreed protocol (DRSSW protocol). All persons included in the analysis were identified as having no DR, background DR or referable DR (RDR) i.e. pre-proliferative, proliferative DR or exudative maculopathy. Kaplan Meier survival estimates were obtained for the population undergoing screening and the incidence rates of RDR over 5 years were compared between those with one or two prior consecutive negative screening events for type 1 and type 2 diabetes separately.

Results: 1,338 persons with type 1 diabetes and 48,908 type 2 diabetes without evidence of DR at their first screening event between 2000 and 2013 were included in the analysis. There were 39 and 506 new cases of RDR over 5 years in those with type 1 and type 2 diabetes, respectively, with the 5 years cumulative incidence of RDR being 3.7% and 1.3% respectively. Of those with no DR at first screening 879 (65.7%) persons with type 1 diabetes and 37,958 (77.6%) persons with type 2 diabetes remained without DR at their second screening event which occurred at a mean of 606.7 (304.4) days and 574.8 (267.2) days respectively after the initial screening event. There were 10 and 146 new cases of RDR respectively within this group at 5 years, with the cumulative incidence of RDR being 5.1% and 1.3% respectively. The 1-5 year cumulative incidence of RDR for persons with type 1 diabetes was 0, 0.5, 0.7, 1.9 and 3.7% for those with 1 negative screening event and 0, 0.2, 1.2, 2.7 and 5.1% for those with 2 consecutive negative screening events without DR. The 1-5 year cumulative incidence of RDR for persons with type 2 diabetes was 0, 0.2, 0.5, 0.8 and 1.3% for those with 1 negative screening event without DR and 0, 0, 0.3, 0.7 and 1.3% for those with 2 negative consecutive screening events without DR.

Conclusion: There appears to be little added benefit of needing 2 consecutive annual negative screening events in order to safely extend the interval of screening to biennial in those persons considered to be at low risk as the incidence of RDR was 0% with 1 or two subsequent screening events. If screening intervals were extended to triennial then the incidence of RDR was slightly lower in those persons with 2 prior consecutive negative screening events at 0.2% compared to 0.5% for type 1 diabetes with 1 screening event and 0% compared to 0.2% respectively for type 2 diabetes.

1091

Diabetic retinopathy severity grading using digital image processing algorithms

C. Valverde¹, M. Garcia², R. Hornero², M.I. López^{3,1};

¹Universidad de Valladolid, ²Biomedical Engineering Group, Department TSCIT, ETS. Ingenieros de Telecomunicación, Universidad de Valladolid, ³Hospital Clinico Universitario de Valladolid, Spain.

Background and aims: Diabetic retinopathy (DR) is an important cause of visual impairment. To ensure early detection and treatment, patients should undergo periodic eye examinations. In them, retinal images of the patient are usually captured using digital fundus cameras. Ophthalmologists further review these images to determine the degree of DR and establish the follow-up period accordingly. However, with the growing incidence of diabetes, the number of images to be examined can be prohibitively large. For this reason, automatic methods to detect DR severity level could be helpful to reduce the workload of ophthalmologists.

Materials and methods: We analysed 249 images from 18 diabetic patients without DR and 35 diabetic patients with different degrees of DR. Images were divided in a training set with 81 images and a test set of 168 images (96 without DR lesions and 72 with DR lesions). An ophthalmologist manually marked the location of hard exudates (EXs) and red lesions (RLs) in these images and classified the severity of DR for each patient. Besides, an automatic method for the location of EXs and RLs in

the images was developed using digital image processing algorithms based on neural-networks (NNs). Three different types of NNs were analysed: multilayer perceptron (MLP), radial basis function (RBF) networks and support vector machine (SVM). The level of DR severity for a patient was subsequently established according to the number of lesions located in each image of the patient.

Results: The best results on the location of EXs and RLs were obtained with MLP. Using a lesion-based criterion, we achieved a mean sensitivity (SEI) of 60.0% and a mean positive predictive value (PPV1) of 50.0% for EXs. For RLs we obtained SEI =51.9% and PPV1 =50.5%. With an image-based criterion, a mean sensitivity (SEi) of 76.4%, a mean specificity (SPi) of 55.2% and a mean accuracy (ACi) of 62.9% were obtained for EXs. For RLs we achieved SEi =71.2%, SPi =50.0% and ACi =58.5%. In a second phase, we assessed the usefulness of the proposed method for DR severity grading according to the detected lesions. Our results show that we were able to detect the correct DR severity grade in 65.7% of the patients. In 97.1% of the incorrectly classified cases, the automatic method provided the grade immediately above that given by the ophthalmologist. Besides, we reached an accuracy of 77.1% in distinguishing referable DR from non-referable DR.

Conclusion: Automatic methods for DR lesion detection and DR severity grading could be an important aid for ophthalmologists in the screening and evaluation of DR. Our results show that, in most cases, the frequency of revisions given by the automatic method would be equal or lower than that indicated by the ophthalmologist. However, further efforts should be directed to improve our results in the location of DR lesions and classification of DR severity grade, by improving the different stages of the algorithm and revising the definition of DR grades for automatic methods.

1092

Validation of an algorithm to predict the risk of sight threatening retinopathy in a multi-ethnic patient group treated in a Dutch hospital

K.M. Holtzer-Goor^{1,2}, A.A. van der Heijden^{2,3}, M. Jonker¹, E. Stolk¹, G. Nijpels^{2,3};

¹iBMG/iMTA, Erasmus University Rotterdam, ²EMGO Institute for Health and Care Research, ³Department of General Practice and Elderly Care Medicine, VU University Medical Center, Amsterdam, Netherlands.

Background and aims: The majority of guidelines recommend a biennial funduscopy to monitor retinopathy for all persons with type 2 diabetes mellitus (T2DM) free of elevated risk factors, and an annual funduscopy for all other persons with T2DM. Only a minority of this population develops sight threatening retinopathy (STR). Recent studies indicate that it is possible to estimate STR risk based on individual patient characteristics and calculate a screening interval accordingly. In persons with a low STR risk, the screening frequency could be reduced, where it could be increased in the small high risk group. This personalized screening method would probably reduce the total number of funduscopies, which would contribute to issues of the high and rising costs of T2DM care, the increasing demand for health care, and the limited eye care capacity. The algorithm developed in Iceland proved to predict the STR risk quit well in a mainly Caucasian population treated in a Primary Care Diabetes centre. However, it is yet unknown how the algorithm acts in a multi-ethnic patient group treated in secondary care, which was the aim of this study.

Materials and methods: Data of 888 persons with T2DM, treated in a hospital in the Netherlands were analysed. Using the Icelandic model, STR risk and an accompanying screening interval ranging from 6 to 60 months were calculated for each person based on gender, diabetes duration, HbA1c, systolic blood pressure and presence of retinopathy. In patients who developed STR during follow-up, we checked whether STR occurred before or after the model-recommended time of screening. Outcomes of omitted fundus photographs according to the model and potentially missed cases of STR were checked.

Results: The persons in this study had a Caucasian (n=403 (45.4%)), Hindustan-Surinam (n=178 (20.0%)), Negroid (n=33 (3.7%)), unknown (n=246 (27.7%)), or other background. During the average follow-up duration of 40 months, 47 patients (5.3%) developed STR, of which 15 (31.9%) in the Hindustan-Surinam group. In 7 patients (15.2%) STR had developed before the recommended date of screening. Of these, 4 patients (57.1%) had a Caucasian background, 1 patient (14.3%) had a Hindustan-Surinam background and 2 patients (28.6%) had an unknown ethnic background. Using the algorithm, 50% of the fundoscopies would be omitted.

Conclusion: The model was less accurate in a multi-ethnic population of T2DM patients treated in secondary care. It remains to be determined whether this lower accuracy is caused by the multi-ethnic background of the population or the secondary care setting. Nevertheless, the number of missed cases of STR suggests that there is room for improvement of the current model for this multi-ethnic population treated in secondary care.

Ethnic background	# patients	# fundoscopies	# fundoscopies saved (%)	# STR (%)	Missed cases of STR (%)
Negroid	33	63	30 48%	1 3.0%	0 0%
Hindustani	178	391	213 54%	15 8.4%	1 7%
Indians	16	43	27 63%	2 12.5%	0 0%
Non-Hindustani Surinams	12	27	15 56%	1 8.3%	0 0%
Unknown	246	483	237 49%	9 3.7%	2 22%
White	403	776	373 48%	19 4.7%	4 21%
TOTAL	888	1783	895 50%	47 5.3%	7 15%

Screening for diabetic retinopathy: a collaborative model in Italy
M. Porta¹, F. Boscia², P. Lanzetta³, E. Mannucci⁴, U. Menchini⁵, F. Simonelli⁶;

¹Medical Sciences, University of Turin, ²Department of surgical, micro-surgical and medical sciences, University of Sassari, ³Department of Medical and Biological Sciences – Ophthalmology, University of Udine, ⁴Diabetology, Careggi Hospital, Florence, Italy, ⁵Ophthalmology, University of Florence, ⁶Department of Medical, Surgical and Dental Sciences - Eye Clinic, 2nd University of Naples, Italy.

Background and aims: Systematic screening for diabetic retinopathy (DR) is not centrally organized in Italy, where screening is performed mostly on an opportunistic basis. The REaD (REtina and Diabetes) programme was launched in April 2013 to establish a network of screening centres where diabetes and eye specialists work in the same settings. This paper reports on the results obtained up to December 2014.

Materials and methods: Screening was conducted in 33 diabetes clinics by non-mydiatic digital fundus cameras (DRS, Centervue, Padua, Italy) connected to ophthalmology units within the same health structures in Italy. Two partially overlapping non-stereoscopic 45 degree fields (central and nasal) of each eye were obtained by trained operators and sent via web to partnering eye units. Images were then evaluated by an ophthalmologist to assess the presence of diabetic retinopathy (DR) and/or macular oedema (DMO) according to a severity scale with standardized referral guidelines.

Results: In total, 16,275 patients were screened, of which 53.0% were male; 51.3% were ≤64 years old and 48.7% were ≥65 years old. Out of 77,309 images collected, 22 centres collected approximately 2,000 each and 11 collected more than 2000. In total, 87.2% of patients could be properly assessed. The percentage of ungradable images decreased from 14% (November 2013) to 9.5% (December 2014). Most ungradable images (57% of those obtained with mydriasis and 62% without mydriasis) were observed in patients aged 61 to 80. Of the 14,185 patients with gradable images, 3,260 (23%) had diabetic retinopathy and were referred for further assessment and treatment.

Conclusion: The REaD programme is the largest screening campaign conducted in Italy in a setting where screening is mostly performed on an opportunistic basis. Non-mydiatic digital fundus cameras may be a cost-containing screening tool for DR. The number of ungradable images was a main limitation, at its maximum when the programme started,

possibly due to operator-related factors, then stabilized around 10%. It appeared mainly related to patient age and non-induction of mydriasis. Systematic screening for DR with non-mydiatic digital cameras allows diabetes specialists to obtain a basic fundus evaluation directly in their units and to promptly organize referrals to ophthalmic centers in case of abnormal findings.

1094

Regional differences in macular thickness in the early stages of diabetic retinopathy in type 2 diabetes

K.M. Gooding¹, A.C. Shore¹, R. Ling², F. Casanova¹, H.C. Looker³, E. Agardh⁴;

¹Diabetes and Vascular Medicine, University of Exeter Medical School, ²West of England Eye Unit, Royal Devon and Exeter NHS Foundation Trust, ³Medical Research Institute, University of Dundee, UK, ⁴Department of Clinical Sciences, Ophthalmology, Lund University, Malmö, Sweden.

Background and aims: Following the advent of optical coherence tomography (OCT) for the measurement of macular thickness there has been interest in the relationship between macular thickness and diabetic retinopathy (DR). Research to date has focussed on fovea thickness with conflicting results. The variations in the observations may reflect different grading systems utilised to assess retinopathy status. As part of the SUMMIT consortium this study aims to examine the relationship between early stages of DR and macular thickness in all subdivision of the OCT ETDRS grid.

Materials and methods: 780 participants with type 2 diabetes (461, 162 and 157 with no, microaneurysms only or mild background DR respectively) were recruited across two centres. DR was graded from two-field retinal photography. Macular thickness (inner limiting membrane to the mid-point of the retinal pigment epithelium) was measured in both eyes using a standard OCT 512×128 scanning protocol. Participant characteristics were recorded. The eye with the worse retinopathy and its corresponding OCT data were utilised in the analysis. If retinopathy was the same in both eyes the data from the right eye was utilised. The relationship between retinal thicknesses in each ETDRS region with DR (entered as no DR, microaneurysms only and mild background DR) was investigated using regression analysis, adjusting for age, gender and centre.

Results: There was no relationship between the thickness of the fovea or inner quadrants with DR. In the outer quadrants there was a significant positive association between thickness in the temporal region and DR (unstandardised β (standard error): 1.639(0.648) μm ; standardised $\beta=0.092$, $p=0.012$). This association remained when further adjusted for glycaemic control (HbA1c) and duration of diabetes (unstandardised β (standard error): 1.655(0.709) μm ; standardised $\beta=0.093$, $p=0.020$). This association was not present in the nasal, superior or inferior outer quadrants.

Conclusion: This study suggests that there are small differences in the net thickness in the outer temporal region in the early stages of DR. An attractive explanation is that in the early stages of DR there is thinning of the retinal nerve fibre layer (RNFL) accompanied by thickening of another retinal layer, resulting in no net change in thickness in the majority of the ETDRS grid. As the outer temporal region has minimal RNFL there is net thickening in this region.

Cataract associated with diabetes and diabetic retinopathy in type 2 diabetes

M. Tomić, R. Vrabec, Ž. Rogulja Pepeonik, S. Ljubić, T. Bulum, K. Blaslov, L. Duvnjak;
Vuk Vrhovac University Clinic for Diabetes, Endocrinology and Metabolic Diseases, Merkur University Hospital, Zagreb, Croatia.

Background and aims: Cataract is the commonest cause of preventable blindness worldwide. In patients with diabetes, cataract occurs at a younger age and progresses more rapidly than senile cataract, resulting in higher rates of cataract surgery at a quite young age and poorer vision outcomes especially in operated eyes with active proliferative retinopathy and/or preexisting macular edema. The exact pathogenesis that leads to lens opacification in diabetes is still insufficiently understood and presumed to involve diabetic complications risk factors. The aim of this study was to investigate the role of diabetes duration, metabolic risk factors, diabetic retinopathy (DR) and nephropathy in cataract development in type 2 diabetes.

Materials and methods: This was a cross-sectional study including 107 type 2 diabetic patients (67 male / 40 female, mean age 66.74±8.01 years, mean diabetes duration 15.05±5.69 years). Metabolic risk factors: glycated hemoglobin (HbA1c), total cholesterol, HDL cholesterol, LDL cholesterol and triglycerides were determined using routine laboratory methods. Blood pressure was measured with a mercury sphygmomanometer after a 10-minute resting period. Serum creatinine, creatinine clearance and albumin/creatinine (A/C) ratio were used to determine the presence of nephropathy. Ophthalmologic examination included best corrected visual acuity (BCVA), biomicroscopy of the lens, binocular indirect slit lamp funduscopy and color fundus photography of two fields (macular field, disc/nasal field) of both eyes according to the EURODIAB retinal photography methodology. Lens opacity was graded according to the Lens Opacity Classification System version III (LOCSIII).

Results: According to the 4 grading scales of the LOCSIII patients were divided into three groups: group 1 - patients with clear crystalline lens (n=16), group 2 - patients with initial cataract (NO1-NO2, NC1-NC2, C1-C2, P1-P2; n=74), and group 3 - patients with immature cataract (NO3-NO4, NC3-NC4, C3-C4, P3-P4; n=17). The three groups did not differ in age, gender, diabetes treatment, SBP and DBP, total cholesterol, HDL, LDL and triglycerides. Group 3 had significantly longer diabetes duration (17.12±6.38 years vs. 10.81±4.09 years; p<0.001) and marginally higher HbA1c (7.11±1.06 vs. 6.38±0.82; p=0.052) than group 1. DR was significantly more severe (35/29/36% vs. 82/6/12%; p=0.047) and creatinine clearance significantly lower (1.53±0.25 vs. 1.90±0.72; p=0.017) in group 3 than in group 1. Cataract was positively correlated with DBP (p=0.002), DR (p=0.009) and A/C ratio (p=0.004). DR was positively correlated with HbA1c (p=0.018), triglycerides (p=0.041) and A/C ratio (p=0.007). Multiple regression analysis showed that diabetes duration (β coefficient=0.365; p<0.001), SBP (β coefficient=0.379; p=0.003), DBP (β coefficient=0.503; p<0.001) and DR (β coefficient=0.243; p=0.013) were the main predictors of cataract development in type 2 diabetic patients.

Conclusion: This study showed that diabetes duration, poor glycemic control, blood pressure, retinopathy and nephropathy play an important role in the cataract development in type 2 diabetes. These findings point to the need for even more reducing risk factors as a means of preventing not only retinopathy but also cataract in order to improve the quality of life of diabetics and reduce the economic burden due to disability and surgery related to cataract.

PS 108 Diabetic nephropathy: pathogenesis and predictors

1096

Genetic exploration of a causal role of dyslipidaemia on diabetic nephropathy in type 1 diabetes

E.H. Dahlström^{1,2}, J. Todd^{3,4}, N. Sandholm^{1,2}, R. Salem^{3,4}, C. Forsblom^{1,2}, N. Tolonen^{1,2}, V. Harjutsalo^{1,2}, J. Hirschorn^{3,4}, J.C. Florez^{5,6}, P.-H. Groop^{1,2};

¹Folkhälsan Institute of Genetics, ²Abdominal Center Nephrology, Helsinki, Finland, ³Division of Endocrinology, Boston Children's Hospital, ⁴Department of Pediatrics, Harvard Medical School, ⁵Program in Medical and Population Genetics, Broad Institute, ⁶Department of Medicine, Center for Human Genetic Research and Diabetes Unit, Massachusetts General Hospital, USA.

Background and aims: Dyslipidemia has been suggested as a risk factor for diabetic nephropathy (DN), but epidemiologic studies do not reveal whether these associations are causal. Genome-wide association studies have uncovered a number of single nucleotide polymorphisms (SNPs) affecting plasma lipid fractions. In three cohorts participating in the Genetics of Nephropathy-An International Effort (GeNIE) cohort, we tested if genetic risk scores (GRS) for LDL cholesterol, HDL cholesterol, total cholesterol and triglycerides were associated with DN in 6126 adult patients with type 1 diabetes.

Materials and methods: We created weighted GRS constructed from established variants for HDL cholesterol (71 SNPs), LDL cholesterol (58 SNPs), triglycerides (40 SNPs) and total cholesterol (74 SNPs) weighting each risk allele by its published effect size, in each of 3 cohorts. DN was defined as having macroalbuminuria or end-stage renal disease (ESRD). Controls with normal albumin excretion rate were required to have a diabetes duration of more than 15 years. Association results from each cohort were combined in a meta-analysis using a fixed effect model.

Results: Genetic risk scores for lipid fractions (LDL cholesterol, HDL cholesterol, triglycerides, and total cholesterol) were not significantly associated with DN in meta-analyses. However, there was a trend towards increased odds of DN with a higher LDL cholesterol GRS (OR=1.048 per 1 SD of GRS [95% CI, 0.994-1.105], P=0.085) and a trend towards decreased odds of DN with a higher HDL cholesterol GRS (OR=0.954 per 1 SD of GRS [95% CI, 0.904-1.006], P=0.080). We also investigated the impact of GRS lipid fractions on DN subtypes; macroalbuminuria and ESRD. We found that a higher HDL cholesterol GRS was significantly associated with decreased odds of macroalbuminuria (OR=0.936 per 1 SD of GRS [95% CI, 0.879-0.996], P=0.036) and a higher triglyceride GRS with increased odds of macroalbuminuria (OR=1.069 per 1 SD of GRS [95% CI, 1.005-1.138], P=0.034). None of the GRS lipid fractions were significantly associated with ESRD.

Conclusion: In conclusion, genetic factors associated with increased HDL and TG are associated with macroalbuminuria in patients with T1D suggesting that these lipids have a causal role on development of diabetic nephropathy. Further research is needed to verify these findings.

Long-term high level of LDL cholesterol associated with a new onset of chronic kidney disease in patients with type 2 diabetes mellitus

T.-S. Lim¹, J.-S. Yun¹, S.-A. Cha¹, S.-D. Moon², H. Seok³, S.-H. Ko¹, Y.-B. Ahn¹;

¹Internal Medicine, The Catholic University of Korea, St. Vincent's hospital, Suwon, ²Internal Medicine, The Catholic University of Korea, Incheon St. Mary's Hospital, ³Internal Medicine, The Catholic University of Korea, Uijeongbu St. Mary's Hospital, Republic of Korea.

Background and aims: We investigated factors that might influence the development of chronic kidney disease (CKD) in patients with type 2 diabetes.

Materials and methods: From January 2003 to December 2004, a total of 861 patients with type 2 diabetes without CKD (estimated glomerular filtration rate [GFR] ≥ 60 ml/min/1.73 m²) were consecutively enrolled. The blood lipid concentrations for total cholesterol, triglycerides, high-density lipoprotein (HDL) cholesterol, low-density lipoprotein (LDL) cholesterol, and the estimated GFR were measured annually and mean LDL cholesterol level was calculated from annual LDL cholesterol data during the study. The new onset CKD was defined as estimated GFR < 60 ml/min/1.73 m² using a Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation. We used a Cox proportional hazard regression analysis to test the associations between new onset CKD and potential explanatory variables.

Results: Of the 861 patients enrolled in this study, 582 (67.6%) completed the follow-up evaluation. The median follow-up time was 10.1 years. The mean age was 55.0 \pm 10.0 years, and the duration of diabetes was 8.0 \pm 6.6 years. The baseline estimated GFR was 95.2 \pm 15.1 ml/min/1.73 m². The patients who developed a new onset of CKD had higher level of mean LDL level (2.67 \pm 0.56 vs 2.85 \pm 0.58 mmol/l; $p=0.004$) than those who did not develop CKD. During the follow-up period, 184 patients (31.6%) progressed to chronic kidney disease. The hazard ratio of CKD development was 1.61 (95% CI 1.14–2.26; p for trend = 0.006) per 1.0 mmol/l mean LDL cholesterol level increase after adjusting for sex, age, diabetic duration, mean HbA_{1c}, albuminuria, treatment of insulin, ACE inhibitor/angiotensin receptor blocker and lipid lowering agents.

Conclusion: The development of CKD was independently associated with serum LDL cholesterol level in patients with type 2 diabetes. Thus, in addition to strict glycemic control, constant long term management of dyslipidemia is important to prevent development of CKD.

1098

Association of monocyte-to-HDL-cholesterol ratio with microalbuminuria in patients with type 2 diabetes mellitus

R. Emral, A.G. Canpolat, Ç. Keskin, S. Canlar, Ö. Demir, D. Çorapçioğlu;
Endocrinology and Metabolic Diseases, Ankara University Faculty of Medicine, Turkey.

Background and aims: Chronic kidney disease (CKD) due to diabetes mellitus is a growing health problem worldwide. Chronic proinflammatory state exists in adults with CKD. Previous studies have demonstrated that monocyte count to high density lipoprotein cholesterol (HDL-C) ratio (MHR) is one of the indicators of oxidative stress and systemic inflammation and showed that renal dysfunction was associated with both a reduction in serum HDL-C level and increased circulating monocyte count. Thus, we aimed to evaluate the relationship

Materials and methods: Between June 2014 and January 2015 a total of 80 patients with type 2 DM ($n=34$ with microalbuminuria and $n=46$ without microalbuminuria) who admitted to our outpatient clinic were enrolled. 24-h urine analysis for microalbuminuria, calculation of MHR and serum C-reactive protein (CRP) were performed for each patient. Patients with malignancy or acute/chronic infectious/inflammatory state were excluded.

Results: Patients with microalbuminuria were older, with higher glycosylated hemoglobin levels (HbA_{1c}). The MHR and CRP levels were also significantly higher in patients with microalbuminuria ($p=0.002$ and $p<0.001$, respectively). There was a positive correlation between MHR and serum CRP ($r=0.462$, $p<0.001$). In multivariate logistic regression analysis, MHR was found as independent predictor for the presence of microalbuminuria in patients with diabetes (OR: 1.44, $p<0.001$).

Conclusion: Higher MHR which indicates an enhanced inflammation and oxidative stress was significantly and independently associated with the presence of microalbuminuria in patients with diabetes. Besides, MHR was positively correlated with serum CRP level as a conventional marker for systemic inflammation.

1099

Functional polymorphisms in the promoter region of heme oxygenase-1 and susceptibility to diabetic nephropathy in type 2 diabetes

H. Won¹, Y. Lee², E. Lee³, B. Kim², C. Nam⁴, B. Lee², E. Kang², B. Cha², H. Lee²;

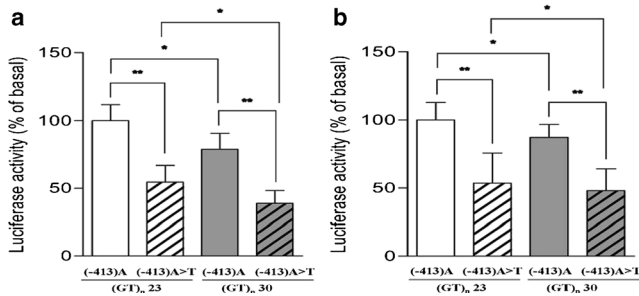

¹Department of Internal medicine, Konyang University College of Medicine, Daejeon, ²Department of Internal medicine, Yonsei University College of Medicine, ³Department of Internal medicine, The Catholic University of Korea, ⁴Department of Preventive Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.

Background and aims: Heme oxygenase (HO)-1 is a key enzyme in cytoprotective mechanisms against oxidative stress in the cardiovascular-renal system. The T(-413)A single nucleotide polymorphism (SNP) and (GT)_n microsatellite polymorphism in the HO-1 gene promoter modulate the HO-1 gene transcriptional activity and these polymorphisms are associated with various human diseases. We investigated the association between HO-1 promoter polymorphisms and nephropathy in type 2 diabetes and assessed the effect of SNP on promoter activity in kidney cell-lines in vitro.

Materials and methods: We sequenced the T(-413)A SNP and (GT)_n repeat segments of the HO-1 gene promoter in 536 patients with type 2 diabetes. (GT)_n alleles were divided into 2 groups: short (S, ≤ 25 GT repeats) and long (L, >25 GT repeats) alleles. Diabetic nephropathy was defined as follows: urinary albumin/creatinine ratio ≥ 30 mg/mg or albumin excretion ≥ 30 mg/day in a 24 h urine analysis. The regulatory effects of SNPs in the HO-1 promoter were explored in two kidney cell-lines using luciferase assay after site-specific mutagenesis of HO-1 promoter.

Results: Patients with the TT genotype in the T(-413)A SNP were significantly more susceptible to diabetic nephropathy than those carrying the A allele, with an odds ratio (OR) of 1.577 (95% confidence interval, 1.088–2.285; $P=0.016$). Subgroup analysis showed that patients carrying the TT genotype with long duration of diabetes (≥ 20 years, OR = 3.325, $P<0.05$), poor glycemic control (HbA_{1c} $>7.4\%$, OR = 1.780, $P<0.05$), and male gender (OR = 2.043, $P<0.05$) had higher odds ratios for the development of diabetic nephropathy. Regarding to the (GT)_n repeats, the LL genotype showed a higher odds ratio for the development of diabetic nephropathy only in patients with hypertension when compared to the S allele. In vitro experiments, promoter activity of the T(-413)A SNP was higher with A allele than T allele in human embryonic kidney cells and mesangial cells.

Conclusion: In conclusion, the T(-413)A SNP in the HO-1 promoter is significantly associated with diabetic nephropathy development in type 2 diabetes patients, especially with longer duration and poor glycemic control.

T-cadherin gene (*CDH13*) polymorphisms and nephropathy in subjects with type 1 diabetes

A. Nicolas^{1,2}, K. Mohammadi³, N. Bellili-Muñoz¹, R. Roussel^{1,3}, S. Hadjadj⁴, M. Marre^{1,3}, G. Velho¹, F. Fumeron^{1,3},
¹Inserm UMR51138, ²Université Pierre et Marie Curie, Sorbonne Universités, ³Diabetology, Endocrinology and Nutrition, Bichat Hospital, APHP, Paris, ⁴Diabetology and Endocrinology, University Hospital of Poitiers, ⁵Université Paris Diderot, Sorbonne Paris Cité, France.

Background and aims: T-cadherin is a receptor for the active forms of adiponectin, and variants in the T-cadherin gene (*CDH13*) have been associated with adiponectin levels. Plasma adiponectin levels are associated with diabetic nephropathy (DN). We investigated associations of *CDH13* allelic variations with kidney complications in subjects with type 1 diabetes.

Materials and methods: Three *CDH13* polymorphisms (rs11646213, rs3865188, rs4783244) were genotyped in 1297 Caucasian type 1 diabetic patients from SURGENE (n=340), GENESIS (n=501) and GENEDIAB (n=456) studies. Follow-up data were available for all SURGENE participants and for 462 GENESIS and 283 GENEDIAB participants. Duration of follow-up was 10, 9 and 5 years, respectively. Renal events were defined as new cases of DN or progression to a more severe stage of DN. We used ANCOVA to compare means of clinical and biological parameters between genotypes. Odds-ratios (OR) and hazard-ratios (HR) were estimated for the prevalence and incidence of DN using logistic regression and Cox model analyses, respectively. GENEDIAB and GENESIS data were pooled for the analyses. All analyses were adjusted for sex, age, duration of diabetes, body mass index, retinopathy stages and cohort membership (when adequate).

Results: In the SURGENE study, the variants rs11646213 (HR 1.69; CI 95% 1.01-2.71; p=0.04) and rs3865188 (HR 0.74; CI 95% 0.55-0.99; p=0.04) were associated with the incidence of renal events during follow-up. At the end of the study, these variants were associated with the prevalence of DN (OR 3.30; CI 95% 1.28-8.38; p=0.01 for rs11646213 and OR 0.54; CI 95% 0.30-0.93; p=0.03 for rs3865188). In the pooled analysis of GENEDIAB and GENESIS studies, the AA genotype of rs11646213 was associated with the prevalence of established/advanced DN (OR 1.47; CI 95% 1.18-1.85; p=0.0009), with higher urinary albumin excretion (p=0.01) and diastolic blood pressure (p=0.01). The same genotype was associated with higher incidence of end-stage renal disease (ESRD) during follow-up (HR 1.96; CI 95% 1.06-3.51; p=0.03). Furthermore, the minor alleles A and T of rs3865188 and rs4783244, respectively, were also associated with the prevalence of established/advanced DN (OR 0.71; CI 95% 0.57-0.90; p=0.004 for rs3865188 and OR 0.79; CI 95% 0.63-0.99; p=0.05 for rs4783244) and the incidence of ESRD (HR 0.47; CI 95% 0.27-0.84; p=0.01 for rs3865188 and HR 0.44; CI 95% 0.25-0.79; p=0.006 for rs4783244).

Conclusion: In subjects with type 1 diabetes, *CDH13* polymorphisms were associated with the prevalence of established and advanced diabetic nephropathy, as well as with the incidence of renal events and ESRD. The genotypes at risk have been previously associated with lower plasma adiponectin levels. Further investigations are needed to determine whether the variations in plasma adiponectin and/or t-cadherin levels can explain these associations.

Markers of chronic kidney disease - albuminuria and glomerular filtration rate encoded by different genetic determinants in type 2 diabetes

A.V. Zheleznyakova¹, O.K. Vikulova¹, V.V. Nosikov², M.V. Shestakova¹;

¹Endocrinology research centre, ²National Research Center “GosNIIGenetika”, Moscow, Russian Federation.

Background and aims: The major markers of chronic kidney disease (CKD) - albuminuria (AU) and glomerular filtration rate (GFR) have the different clinical pattern due to diabetes type: in type 1 diabetes AU is a predictor of subsequent GFR decrease, in type 2 diabetes (T2D) it might develop in parallel or after GFR decrease may be due to different genetic determinants. The aim of our study was to assess the association of candidate genes polymorphisms encoding the key mediators of kidney damage with AU and GFR in T2D patients.

Materials and methods: We enrolled 262 patients with T2D divided into groups due to the rate of AU > / < 30 mg/per 24H (AU+/-, n=128/134) and GFR ≥ / < 60 ml/min/1.73 m² estimated by MDRD (CKD+/CKD-, n=86/176) and analyzed a complex of 6 pm in genes involved in coding of major mediators of kidney injury: endothelial dysfunction [nitric oxide synthase-3 (ecNOS4a/4b in NOS3), angiotensin I-converting enzyme (I/D in ACE)]; lipids metabolism [apolipoprotein B (I/D in APOB), apolipoprotein E (e2/e3/e4 in APOE)]; insulin secretion and sensitivity (rs5219 in KCNJ11 coding protein Kir6.2 subunits of potassium inwardly-rectifying channel, rs7903146 in TCF7L2 coding transcriptional factor 7-like 2). Statistic analysis was assessed by χ², OR, p < 0.05. The study was approved by local ethical committee; informed concern was obtained from all the patients.

Results: Significant association with AU showed one of the studied pm: 4a/4b in NOS3 gene: we observed excess of 4a allele and 4a/4a genotype in group with AU did as risk factors [4a: OR=1.7; 95%CI 1,1-2,5, 4aa: OR=9.89; 95%CI 2,05-47,72]. Significant association with GFR decrease showed pm in 4 genes. NOS3 gene: the prevalence of 4b/4bb in CKD- group [OR=0.45/0.45; 95%CI 0,2-0,7/0,26-0,77, respectively]; while allele 4a and genotype 4a/4a did as risk factors [OR=2,2/9,9; 95%CI 1,4-3,6/2,1-47,7, respectively]. APOB gene: genotype DD protected from CKD [OR=0,2; 95%CI 0,05-0,8, p=0,04] in dominant inheritance model compared with carriers of II and ID genotypes that did as risk factors [OR=5,00; 95%CI 1,1-21, p=0,02]. KCNJ11 gene: an excess of allele T facilitate to CKD existence [OR=2,4 95%CI 1,4-4,1], allele C/genotype CC were protective [OR=0,52/0,44, 95%CI 0,3-0,8/0,2-0,8 respectively]. TCF7L2 gene: genotype TT [OR=0,12, 95%CI 0,03-0,53] had a protective role. We didn't find a variant association of pm's in ACE and APOE with CKD. CKD risk highly depended on the amount and combination of risk/protective genotypes (r=0,971, p<0,05). The absence of any risk genotypes protected from CKD [RR=0], if one of risk genotypes detected RR=0,86, if any 2 of them RR=1,7, any 3 risk genotypes increased CKD risk with RR=2,2 and RR=3,27 was the highest in carriers of 4 predisposing variants of studied pm.

Conclusion: The CKD development might have genetic susceptibility with different genetic determinants for AU and GFR in T2D patients. Risk of AU is associated with polymorphism of NOS3 gene; risk of GFR decline - with pm in NOS3, APOB, KCNJ11 and TCF7L2 genes. CKD risk was highly depended on the amount of risk genotypes with highest risk in carriers of 4 predisposing variants. The data obtained allow offering these pm as diagnostic panel for allocation of high-risk patients, which require more frequent screening and active prevention for this complication.

1102

Uric acid contributes to the faster progression of diabetic kidney disease and higher incidence of major cardiovascular event in type 2 diabetic patients

L. Pacal¹, V. Bartakova¹, K. Kuricova¹, Z. Nova¹, V. Dvorakova¹, M. Svrckova¹, D. Maluskova², J. Rehorova³, J. Svojanovsky⁴, J. Olsovsky⁴, J. Belobradkova³, D. Krusova⁴, K. Kankova¹;

¹Department of Pathophysiology, ²Institute of Biostatistics and analyses, Faculty of Medicine, Masaryk University, ³Clinic of Internal Medicine - Gastroenterology, University Hospital, ⁴Clinic of Internal Medicine, Diabetes and Nephrology Centres, St. Anne's University Hospital, Brno, Czech Republic.

Background and aims: Recent evidence suggests that increased serum uric acid (SUA) is associated with increased risk of diabetic kidney disease (DKD) development in patients with type 1 diabetes. Data on the role of SUA in the progression of DKD in type 2 diabetes (T2DM) are lacking. Polymorphisms in genes encoding for uric acid transporters in the kidney (SLC2A9, ABCG2) and gut (ABCG2) affect SUA and were associated with hyperuricaemia and gout but were not studied with respect to DKD yet. The aims of the study were to assess (i) the prognostic value of baseline SUA and (ii) variability in selected genes involved in the regulation of uric acid metabolism for DKD progression in T2DM.

Materials and methods: 422 patients with T2DM and different stage of DKD (defined as macroalbuminuria or ESRD and/or CKD III and higher) at baseline were included in the prospective study. Median follow-up was 47 [IQR 27-79] months. Hyperuricaemia was defined as initial SUA \geq 420 μ mol/l in men and \geq 360 μ mol/l in women or as a treatment with allopurinol at the inception in the study. Following endpoints were defined: 1) DKD progression (i.e. the decline of GFR <60 ml/min per 1.73 m² during the follow-up period for those with GFR \geq 60 ml/min per 1.73 m² at baseline or achieving ESRD, or the development of overt proteinuria in normo- and microalbuminuric subjects at baseline or the progression of CKD by at least stage for those with CKD III and IV at baseline) with all-cause mortality as a competing risk and 2) major cardiovascular event (MACE - i.e. fatal or non-fatal myocardial infarction or cerebrovascular event, limb amputation, revascularization) with non-CVD death as a competing risk. Using PCR-based methodology we detected 5 SNPs in the genes formerly associated with hyperuricaemia/gout (4 in SLC2A9 and 1 in ABCG2). Statistical analysis involved survival analysis, competing risk analysis and Cox regression.

Results: Cumulative incidence of DKD progression was 54.4%, MACE 32.2% and total mortality 43.8%. Initial hyperuricaemia was confirmed as a significant risk factor for both DKD progression and MACE ($P < 0.00001$ and $P = 0.0021$, log-rank test). Allopurinol treatment did not have protective effect with respect to DKD progression. Patients with and without initial hyperuricaemia did not differ in the frequency of risk genotype in any of studied SNPs. Allele T of SLC2A9 rs16890979 was marginally associated with faster DKD progression ($P = 0.05$, Kaplan-Meier).

Conclusion: Our results suggest that hyperuricaemia significantly contributes to the progression of DKD and to the higher incidence of MACE in patients with T2DM. The effect of studied genetic variants appears to be minor.

Uric acid associated with decline of GFR in diabetic nephropathy

S. Pilemann-Lyberg^{1,2}, M. Lindhardt¹, F. Persson¹, S. Andersen³, P. Rossing^{1,4};

¹Diabetes complications research, Steno Diabetes Center, Gentofte, ²Danish Diabetes Academy and Aarhus University, Aarhus, ³Department of Cardiology, Endocrinology and Nephrology, Nordsjællands Hospital, Hillerød, ⁴Aarhus University, Denmark.

Background and aims: Diabetes is the major cause of chronic kidney disease (CKD). Evidence from epidemiological and prospective studies indicates that serum uric acid (UA) is a risk factor for development and progression of CKD and loss of kidney function. We evaluated the effect of serum UA on change in GFR in patients with type 1 diabetes (T1DM) in a previous conducted clinical trial.

Materials and methods: Post hoc analysis of a prospective, double-blinded, clinical intervention trial of the long-term renoprotective effect of AT1 receptor blockade (losartan 100 mg) on progression of diabetic nephropathy in T1DM homozygous for the I (n=26) or D (n=27) allele of the ACE/ID polymorphisms. Mean follow-up time was 3 years (range 1.5 - 3.5). Serum UA was measured at baseline. Primary end-point was GFR measured with Cr51-clearance every 6 month. Effect of UA was tested in a linear regression model with and without adjustment for known progression factors (Gender, HbA1c, systolic blood pressure, cholesterol, baseline GFR and baseline urinary albumin excretion rate (UAER)).

Results: Mean baseline UA was 0.339 mmol/L (SD \pm 0.1), GFR 87 ml/min/ 1.73 m² (SD \pm 23), Geometric mean of UAER 1023 mg/ 24 h (IQR, 631 - 1995). Similar association between UA and change in GFR was present for the two ACE/ID polymorphisms. In an unadjusted linear model UA was positively associated with decline in GFR ($r^2 = 0.06$, $p = 0.09$). After adjustment for known progression factors the association increased to a significant level ($r^2 = 0.35$, $p = 0.011$). In the backward elimination UA remained in the model, together with baseline UAER and baseline GFR ($r^2 = 0.26$, $p = 0.0031$).

Conclusion: Uric acid was positively associated with decline in GFR in type 1 diabetic patients with nephropathy. UA was a significant predictor together with UAER and baseline GFR. The clinical significance of UA is currently investigated in a multicenter clinical trial (PERL Study).

The effect of sensor augmented insulin pump treatment versus multiple daily injections on albuminuria: a one year randomised controlled study

S. Rosenlund¹, T.W. Hansen¹, P. Rossing¹, S. Andersen²;

¹Steno Diabetes Center, Gentofte, ²Nordsjællands Hospital, Hilleroed, Denmark.

Background and aims: The effect of tight glycaemic control on persisting albuminuria remains unclear. Insulin delivery method may play an important part by affecting HbA1c and/or glucose variability. We investigated the effect of 1 year sensor augmented insulin pump treatment (SAP) versus multiple daily injections (MDI) on albuminuria in type 1 diabetes patients with a history of elevated urinary albumin excretion.

Materials and methods: In a randomized controlled open-label parallel trial 60 type 1 diabetes patients were randomized to 1 year SAP or MDI treatment. At screening patients had urinary albumin creatinine ratio (UACR) ≥ 10 mg/g in 2 out of 3 morning urines. All were on stable RAS inhibition 4 weeks prior to screening and throughout the study. UACR was measured in 3 morning urines at all visits. Glucose variability (CGM) and glomerular filtration rate (51Cr-EDTA GFR) was measured at beginning and end of study. Changes in UACR between treatment groups were analysed using a mixed linear model including all measurements during the study and adjustment for HbA1c.

Results: 57 patients (SAP: n=28; MDI: n=29) completed the study. At baseline 86% had UACR ≥ 30 mg/g. Age was (mean \pm SD) 51 \pm 10 years, duration of diabetes was 33 \pm 12 years. UACR was (geometric mean, IQR) 99 (37–235) mg/g. GFR: 94 \pm 22 ml/min/1.73 m², HbA1c: 75 \pm 12 mmol/mol, glucose variability (given as SD): 4.0 \pm 1.0 mmol/mol and systolic blood pressure (SBP): 143 \pm 17 mmHg; no difference between groups ($P \geq 0.08$ for all). After 1 year, HbA1c decreased 14 \pm 11 vs. 6 \pm 11 mmol/mol ($P=0.013$), glucose variability decreased 0.9 \pm 1.1 vs. 0.3 \pm 1.0 mmol/mol ($P=0.037$), GFR declined 5.6 \pm 9.6 vs. 3.4 \pm 13 ml/min/1.73 m² ($P=0.50$), SBP decreased 1.6 \pm 17 vs. 3.6 \pm 17 mmHg ($P=0.68$) in SAP vs. MDI treatment, respectively. UACR (mean(95%CI)) decreased 13 (-39–22)% with SAP vs. 30 (-12–92)% increase on MDI (unadjusted: $P=0.052$; adjusted for HbA1c: $P=0.042$). In the subgroup of patients with UACR ≥ 30 mg/g at baseline (n=48) UACR decreased 18 (-44–20)% in the SAP treatment group (n=24) while MDI treated patients (n=24) had an increase of 38 (-11–71)% (unadjusted: $P=0.01$; adjusted for HbA1c: $P=0.01$).

Conclusion: In conclusion, sensor augmented insulin pump treatment tended to reduce UACR in a randomized controlled trial in type 1 diabetes patients with a history of albuminuria on stable RAS inhibition. Significance was reached after adjustment for HbA1c. In the subgroup with albuminuria at baseline, SAP treatment reduced UACR significantly. SAP treatment reduced glucose variability and HbA1c and might have a beneficial effect on diabetic nephropathy.

1105

Effect of different types of insulin therapy on transplant state, metabolic and haemodynamic factors control in patients with type 1 diabetes after kidney transplantation

A. Glazunova¹, M. Arutyunova¹, E. Tarasov¹, G. Musaeva², M. Shestakova^{1,2}, Y. Moysyuk³;

¹Research Centre of Endocrinology, ²I.M. Sechenov First Moscow State Medical University, ³Academician V.I. Shumakov federal research center of transplantology and artificial organs, Moscow, Russian Federation.

Background and aims: To evaluate the impact of different types of insulin therapy (continuous subcutaneous insulin infusion (CSII) using insulin pump or multiple insulin injections (MII)) on carbohydrate metabolism, the state of the transplant, cardiovascular system, calcium and phosphorus metabolism in patients with type 1 diabetes (DM1) after kidney transplantation (KT).

Materials and methods: The study included two groups of patients with DM1 after transplantation: 1) 17 patients treated with CSII 2) 10 with MII. Mean duration of diabetes in the first group was 25 years [20;5;34, 5], the second group - 24,5 years [20;30]. Posttransplantation period in both groups was comparable - 8,0 [7,0;36,0] and 7,5 [7,0;19,0] months.

Results: The mean level of glycated hemoglobin (HbA1c) in groups before the study did not differ: 9.0% [8,0;9,6] and 9.0% [8,7; 9,8], respectively. When patients were transfer into CSII - HbA1c was significantly lower in this group after 3–6–9 months -7,4% [7,4; 8,6] ($p < 0,0005$), while in the MII group - 8,1% [7,5;8,7] ($p < 0,026$). Recurrent diabetic nephropathy at the stage of microalbuminuria was diagnosed in 2 patient (20%) in the MII group with continuing poor glycemic control (the level of albuminuria was 35–65 mg/l, reanalysis - 68–85 mg/l). All patients, treated CSII had normal albuminuria. Glomerular filtration rate (GFR) (CKD-EPI) in both groups was comparable: 67 ml/min/1,73 m² [65,86] and 65 ml/min/1,73 m² [60,0;75,0], respectively. Stabilization of diabetic retinopathy (proliferative stage mainly) was observed in all patients after repeated laser photocoagulation. Positive of hemoglobin, parathyroid hormone, calcium phosphorus product and blood pressure dynamics did not differ in the groups after KT.

Conclusion: The CSII using insulin pump allows to reach target values faster and more efficiently, CSII seems to be more effective than MII in reducing glycemic variability (tab1), and this improving the control of complications and overall prognosis in patients with DM1 after KT.

Tab1.1 Glycemic variability in patients with DM1 after KT, using different types of insulin therapy

The effects of vildagliptin added-on insulin therapy in well-controlled type 2 diabetic patients on markers of glomerular and tubular kidney injuryV. Bayrasheva^{1,2}, A. Babenko¹, S. Chefu¹, Y. Dmitriev¹, I. Shatalov³, E. Grineva¹;¹Institute of Endocrinology, Federal North-West Medical Research Centre, ²Pavlov First Saint Petersburg State Medical University, ³St.Petersburg national research University of Information, Technologies, Mechanics and Optics, Saint-Petersburg, Russian Federation.**Background and aims:** Several recent experimental studies have demonstrated beneficial effects of dipeptidyl peptidase 4 inhibitor vildagliptin on certain processes associated with reduced renal function in diabetes, but its renal effects in patients with type 2 diabetes (T2D) have still remained unclear. The study aimed to assess the effects of vildagliptin added-on insulin therapy on kidney dysfunction markers in type 2 diabetic patients.**Materials and methods:** The study aimed to assess the effects of vildagliptin added-on insulin therapy on kidney dysfunction markers in type 2 diabetic patients. In a single-center, unblinded, randomized comparative clinical study we investigated the dynamic of serum (estimate GFR using creatinine (eGFRcr) and cystatin C (eGFRcys)) and twice-measured urinary markers of renal dysfunction, based on a first morning urine spot (indicators of glomerular injury - albuminuria, and excretion of collagen type IV; proximal tubular (neutrophil gelatinase-associated lipocalin (NGAL)), and distal tubular (liver fatty acid-binding protein (L-FABP)) damage markers in forty three well-controlled insulin-treated patients with T2D randomized either to continue insulinotherapy (insulin-treated group (IG), n=22), or to receive 6-month vildagliptin treatment in daily dose 50 mg added-on insulin (vildagliptin/insulin-treated group (VIG), n=21). Non-inclusion criteria were severe micro- and macrovascular diabetic complication, uncontrolled hypertension, inflammatory and oncological conditions, nephrotoxic drugs using, and renal disease other than diabetic nephropathy.**Results:** Studying groups were comparable on the basis of sex and age (from 54 to 67 years), and duration of T2D ranged from 5 to 17 years. At baseline, in VIG eGFRcr was 76,7±7,8 ml/min/1.73 m², eGFRcys 84,2±10,2 ml/min/1.73 m², albuminuria 37±11,4 mg/l, excretion of collagen type IV 3,98±1,16 µg/l, urinary NGAL 46,7±16,8 ng/ml, and urinary L-FABP was 848±87,8 ng/ml, and these parameters didn't statistically differ compared to IG. Although there were no comparable changes in eGFRcr, albuminuria, and NGAL in both studying groups, eGFRcys, and excretions of collagen type IV were significantly improved in VIG after 6-month vildagliptin treatment (89,6±8,7 ml/min/1.73 m², 3,46±1,1 µg/l, respectively, p≤0,5). Also the tendency to lowering urinary L-FABP was observed (805,6±66,8 ng/ml, P=0,052).**Conclusion:** The results of the study showed that 6-month vildagliptin treatment in daily dose 50 mg added-on insulin therapy in well-controlled type 2 diabetic patients could result in amelioration of glomerular dysfunction.

1107

Urinary albumin excretion with sitagliptin compared to sulfonylurea as add-on to metformin in patients with type 2 diabetes and albuminuria: a real-world evidence studyH.L. Katzeff¹, I. Goldshtein², K. Tunceli¹, G. Chodik², L. Radican¹, V. Shalev², N. Gadir¹, S. Yu¹, S.S. Engel¹, E.S. Ommen¹, O. Sharon¹, A. Karasik³;¹Merck & Co., Inc., Kenilworth, USA, ²Maccabi Healthcare Services, Tel Aviv, ³Sheba Medical Center, Tel Hashomer, Israel.**Background and aims:** We compared the change in urinary albumin to creatinine ratio (UACR) in patients with type 2 diabetes (T2DM) and albuminuria who initiate sitagliptin to those who initiate sulfonylurea (SU) as add-on to metformin monotherapy.**Materials and methods:** A cohort of T2DM patients with albuminuria (UACR >30 mg/g), who initiated sitagliptin or SU as add-on therapy to metformin from 2008-2014, was extracted from the computerized medical records of a large managed care organization in Israel. Patients with available UACR measurements at treatment initiation and 120-365 days afterwards were included. A propensity score matching with a 1:1 ratio and 17 matching factors including demographic, comorbidities, baseline levels of HbA1c, UACR, BMI, eGFR, and ACE/ARB use, was implemented. The changes in UACR were compared between the matched pairs using generalized estimating equations.**Results:** A total of 282 eligible pairs were identified. During a mean follow-up of 9 months, median UACR changes were -35% (IQR=-73% to 5%) and -31% (IQR=-72% to 21%) in the sitagliptin and SU groups, respectively. Mean absolute HbA1c reductions among sitagliptin and SU groups were 0.9% and 1.0%, respectively. The magnitude of UACR reduction generally increased with greater magnitude of HbA1c reduction in both treatment groups. After controlling for HbA1c reduction and the interaction between HbA1c reduction and UACR reduction, sitagliptin users demonstrated a trend toward a greater reduction in UACR compared to SU users (odds ratio=1.20; 95% confidence interval: 0.99-1.47, P=0.063).**Conclusion:** Our results suggest that both sitagliptin and SU reduce albuminuria as an add-on therapy to metformin, but sitagliptin may provide greater reductions in albuminuria per improvement in glycemic control when compared to SU. We could not rule out chance in our study, however, and a larger population study is required to explore this further.

Glucagon-like peptide-1 receptor agonists decreases albuminuria in overweight patients with type 2 diabetes

T. Bulum, K. Blaslov, M. Tomić, L. Duvnjak;

Vuk Vrhovac Clinic for Diabetes, Endocrinology and Metabolic Diseases, University Hospital Merkur, Zagreb, Croatia.

Background and aims: Glucagon-like peptide-1 (GLP-1) is a gut incretin hormone that stimulates insulin secretion from pancreatic β-cell in a glucose-dependent manner. In kidney, the GLP-1 receptors are expressed in glomerular capillary and vascular walls. Oxidative stress produced by chronic hyperglycemia has a central role in the development and progression of diabetic nephropathy. Activation of GLP-1 receptor stimulates the production of cAMP and subsequent activation of protein kinase A (PKA) and contributes to various physiological actions including insulin secretion and antioxidative effects that protect various tissues from oxidative injury. GLP-1 receptor agonists exenatide and liraglutide have structural similarity and bind to the GLP-1 receptor displaying a similar broad range of activities relevant to improving glycemic control and antioxidative effects. The aim of this study was to investigate the effects of GLP-1 receptor agonists exenatide and liraglutide on metabolic and renal function parameters in overweight patients with type 2 diabetes (T2DM).**Materials and methods:** A total of 75 overweight T2DM with normal or mildly decreased (estimated GFR≥60 mlmin-1.73 m²) renal function were included in this study and followed for 17 months (age 58±8 years, 33 M/42 F, body mass index (BMI) 39±5 kg/m², weight 112±20 kg, HbA1c 8.4±1.2%, duration of diabetes 12±6 years, serum creatinine 73±20 µmol/L, estimated GFR 89±16 mlmin-1.73 m², urinary albumin excretion rate (UAE) 184.8±560.1 mg/24 h, exenatide/liraglutide group 36/39 patients). UAE was measured from at least two 24-h urine samples. Estimated GFR was calculated using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula. Microalbumin was measured spectrophotometrically by turbidimetric immuno-inhibition. Liraglutide was started as 0.6 mg once daily dose and increased up to 1.8 mg once daily. Exenatide was started as 5 µg twice daily dose and increased to 10 µg twice daily.

Results: Treatment with GLP-1 receptor agonists caused a significant decrease in HbA1c from 8.4 ± 1.2 to $8.0 \pm 1.3\%$ ($p=0.03$), BMI from 39 ± 5 to 36 ± 5 kg/m² ($p<0.001$), and weight from 112 ± 20 to 103 ± 20 kg ($p<0.001$). However, the 17-months administration of GLP-1 receptor agonists caused a significant decrease in UAE from 184.8 ± 560.1 to 82.8 ± 268.9 mg/24 h ($p=0.04$), while serum creatinine (from 73 ± 20 to 73 ± 22 umol/L ($p=0.4$)) and estimated GFR (from 89 ± 16 to 89 ± 19 ml/min/1.73 m² ($p=0.4$)) did not significantly changed. The effects of GLP-1 receptor agonists on metabolic and renal function parameters were similar in both exenatide/liraglutide groups (data not shown) and were not significantly different compared to presented combination results.

Conclusion: The results of our study suggest that therapy with GLP-1 receptor agonists liraglutide and exenatide may significantly reduce UAE in overweight T2DM. It has been suggested that GLP-1 receptor agonists has a crucial role in protection against increased renal oxidative stress under chronic hyperglycemia via inhibition of NAD(P)H oxidase and PKA activation which resulted in reduced albuminuria and mesangial expansion.

Primary prevention of albuminuria using renin-angiotensin system inhibitors in patients with type 2 diabetes: a systematic review

F. Persson¹, B. Hemmingsen², M.K. Lindhardt¹, P. Rossing^{1,3}, H.-H. Parving^{4,5},

¹Steno Diabetes Center, Gentofte, ²Cardiology, Nephrology and Endocrinology, Nordsjællands University Hospital, Hillerød, ³NNF Center for Basic and Metabolic Research, ⁴Medical Endocrinology, Rigshospitalet, Copenhagen, ⁵Health, Aarhus University, Denmark.

Background and aims: Early prevention of diabetic nephropathy by way of blocking the renin angiotensin system (RAS) in patients with normoalbuminuria seems rational, but trials have so far shown conflicting results. The present meta-analysis was undertaken to investigate if such treatment can prevent development of microalbuminuria and to assess whether available trials can provide sufficient information for such conclusions.

Materials and methods: We searched MEDLINE, EMBASE and the Cochrane Library for double-blinded randomised controlled trials, with a population of patients with type 2 diabetes and normoalbuminuria, comparing angiotensin enzyme inhibitors (ACEi) or angiotensin receptor blockers (ARB) to placebo. At least one year of follow-up was required, and trials had to have at least 50 participants in each arm. Random effects and fixed effect models were performed as well as trial sequential analysis.

Results: Six trials (Ravid et al, BENEDICT, MICRO-HOPE, ADVANCE, DIRECT, ROADMAP) were identified and included in the analysis ($n=16921$). Overall risk of bias was low. In a fixed effects model analysis ACE or ARB treatment was superior to placebo in relation to development of microalbuminuria, relative risk 0.84 (95% CI 0.79, 0.88) $p<0.001$, I² 23%, risk difference -4% (-5%, -3%), $p=0.001$. Similar results were seen with the random effects model. Trial sequential analysis confirmed a 16% RRR for development of microalbuminuria suggesting sufficient trial data are available to draw a conclusion.

Conclusion: Sufficient trial data are available for the meta-analysis to conclude that in patients with type 2 diabetes and normoalbuminuria, ACEinhibitors or ARBs reduces the risk for development of microalbuminuria.

Patiromer lowers serum potassium in patients with elevated potassium and diabetes and advanced CKD on RAAS inhibitors: Results from OPAL-HK and AMETHYST-DN

M. Weir¹, D. Bushinsky², M. Mayo³, D. Garza³, Y. Stasiv³, S. Arthur³, B. Schreiber³, L. Berman³, G. Bakris⁴,

¹University of Maryland, Baltimore, ²University of Rochester, ³Relypsa, Inc., Redwood City, ⁴University of Chicago, USA.

Background and aims: Albuminuria and decreased glomerular filtration rate (GFR) are associated with increased risk of end stage renal disease and cardiovascular events in patients (pts) with diabetes (DM). Guidelines recommend renin-angiotensin-aldosterone system inhibitors (RAASi) for the management of micro- and macro-vascular complications of DM and advanced chronic kidney disease (CKD), however such pts are at high risk for development of hyperkalemia, which may limit or prevent RAASi use. We evaluated the effect of patiromer, a novel investigational potassium (K⁺)-binder, on serum K⁺ in DM pts with advanced CKD on RAASi.

Materials and methods: OPAL-HK was a 12-week, 2-part (Part A, treatment phase; Part B, randomized withdrawal phase), single-blind study ($n=243$); AMETHYST-DN was a 52-week, randomized, open-label study ($n=304$). Eligible pts had estimated GFR (eGFR) 15-59 mL/min/1.73 m², were on ≥ 1 RAASi and, in AMETHYST-DN, had Type 2 (T2) DM. Entry serum K⁺ was $5.1-<6.5$ mEq/L (OPAL-HK) and $>5.0-<6.0$ mEq/L (AMETHYST-DN). In a post-hoc subgroup analysis, efficacy data were pooled to determine the change from baseline in serum K⁺ during the first 4 weeks of patiromer treatment (primary endpoint in both studies) in pts with hyperkalemia, T2DM and eGFR <60 mL/min/1.73 m². Pts were stratified by baseline serum K⁺: $>5.0-5.5$ (mild) and $>5.5-<6.0$ mEq/L (moderate) in AMETHYST-DN; $5.1-<5.5$ (mild) and $5.5-<6.5$ mEq/L (moderate-severe) in OPAL-HK.

Results: The pooled analysis includes 386 pts with T2DM and advanced CKD and hyperkalemia on stable doses of ≥ 1 RAASi, who then received patiromer at a starting dose of 4.2 or 8.4 g twice daily, respectively, for mild or moderate-severe hyperkalemia for 4 weeks. For pts with mild and moderate-severe hyperkalemia, respectively, mean (SD) time since T2DM diagnosis was 13 ± 8 and 14 ± 9 yr, mean (SD) eGFR was 38 ± 12 and 32 ± 12 mL/min/1.73 m², and mean (SE) serum K⁺ was 5.2 ± 0.02 mEq/L and 5.7 ± 0.03 mEq/L at baseline (Day 1). With patiromer mean serum K⁺ was reduced to <5.0 mEq/L by the first post-baseline visit (Day 3, approx. 48 hr after first dose) in mild hyperkalemia pts and by Week 1 in moderate-severe hyperkalemia pts and continued to improve (Fig). By week 4, mean (95% CI) serum K⁺ change from baseline was -0.58 mEq/L ($-0.65, -0.51$) in mild hyperkalemia and -1.12 mEq/L ($-1.20, -1.04$) in moderate-severe hyperkalemia pts (both $p<0.001$). Adverse events in these pts were predominately mild-to-moderate gastrointestinal complaints. Adverse events led to patiromer discontinuation in 10.5% of pts over 52 weeks in AMETHYST-DN and in 5.0% of pts in Part A (first 4 weeks) and 0% in Part B (weeks 5-12) in OPAL-HK.

Conclusion: Patiromer significantly reduced serum K^+ in hyperkalemic pts with T2DM and advanced CKD over 4 weeks. Patiromer may be an option for hyperkalemia treatment in pts with T2DM and advanced CKD.

Death, cardiovascular and renal events in type 2 diabetic patients with proteinuria followed by nephrologists: results of the 2-year ALICE PROTECT study

B. Fiquet¹, J.-M. Halimi², G. Choukroun³, C. Combe⁴, B. Dussol⁵, J.-P. Fauvel⁶, S. Quéré⁷, D. Joly⁸,

¹Medical affairs, Novartis Pharma SAS, Rueil-Malmaison, ²Nephrology unit, CHU Université François Rabelais, Tours, ³Nephrology unit, CHU Université Picardie Jules Verne, Amiens, ⁴Nephrology unit, CHU Université Bordeaux Segalen, ⁵Nephrology unit, CHU Aix-Marseille université, ⁶Nephrology hypertension unit, CHU Université Claude Bernard, Lyon, ⁷Biostatistic, Novartis Pharma SAS, Rueil-Malmaison, ⁸Nephrology unit, Hôpital Necker Université Paris-Descartes, Paris, France.

Background and aims: Type 2 diabetes (T2DM) is the leading cause of chronic kidney disease (CKD) in western countries. The combination of T2DM and CKD increases the risk of end stage renal disease (ESRD), cardiovascular events and all-cause mortality. UKPDS study showed that the risk of death was higher than the risk of renal disease progression. Early control of blood pressure (BP) and proteinuria (Pu) is crucial to slow down the progression of the CKD and prevent cardiovascular events and mortality.

Materials and methods: Prospective, multicenter, observational study conducted from 2010 to 2013. Overall, 153 French nephrologists included 986 T2DM patients with Pu (≥ 0.5 g/day) and an eGFR > 15 ml/min/1.73 m². Data from 729 patients were available after a 2-year follow-up. The primary objective was to assess the proportion of patients reaching the BP ($< 140/90$ mmHg) and Pu targets (< 0.5 g/day) at the end of the study. We also looked at renal (doubling of plasma creatinine and/or ESRD) and cardiovascular events.

Results: At baseline, 74% of the patients were male, mean age was 70 years. The mean T2DM duration was 17 years with a mean HbA1c of 7.4%. All were treated for hypertension and 33% had a controlled BP; 81% had dyslipidemia and LDLc was < 1 g/L for 54%; 44% had retinopathy, 40% macrovascular complications and 12% heart failure. Mean Pu was 2 g/day and eGFR 40 ± 20 ml/min/1.73 m², with 13%, 18%, 32% and 37% of the patients in respectively stage 2, 3a, 3b and 4 CKD. After two years, 21% reached the Pu target and 39% the BP target. The mean eGFR of 40 ± 20.3 ml/min/1.73 m² at baseline dropped to 36.5 ± 20.9 by year one and to 33.9 ± 22.6 ml/min/1.73 m² by year two ($p < 0.001$). This

corresponded to a mean annual eGFR reduction of 3.2 ml/min/1.73 m². 118 patients presented a renal event (16.2%): doubling of serum creatinine for 86 patients (11.8%) and start of dialysis for 72 (9.9%); 176 patients (24.1%) developed at least one cardiovascular complication during the follow-up period, and among these, 50 had also developed renal complications. Overall, 61 patients (8.4%) had a coronary event, 25 patients had a stroke (3.4%), 32 patients underwent a lower limb revascularisation procedure (4.4%), 17 patients required amputation (2.3%) and 80 patients were hospitalised with heart failure (11%). Sixty patients died, i.e. 8.2%, 26 patients from cardiovascular causes.

Conclusion: Our study highlights that achieving BP and Pu targets remains a major challenge in patients with T2DM and nephropathy, even in a nephrology environment. In contrast to older studies, renal failure is more frequent than death.

PS 110 Diabetic nephropathy: identification and quantification

1112

Triglyceride variation and renal function in type 2 diabetes

R. Fonseca, C. Tavares Bello, C. Barreiros, C. Moniz, C. Limbert, J. Sequeira Duarte, M. Oliveira, J. Azinheira, C. Vasconcelos; Endocrinology, Hospital de Egas Moniz, Lisboa, Portugal.

Background and aims: Diabetic nephropathy progression is linked to glycemic and blood pressure control. The effect of lipid metabolism is not totally understood. Hypertriglyceridemia is thought to be a risk factor to renal failure progression. The author's objective was to investigate the association between triglyceride variation (Δ TG), renal function and metabolic control in type 2 diabetic patients (T2D).

Materials and methods: Retrospective cohort observational study of T2D patients, followed between 2005 and 2014, for at least two years. Secondary forms of diabetes, children and renal transplant patients were excluded. Δ TG was determined by calculating the mean of yearly standard deviation of triglyceride levels per patient and compared to eGFR (obtained by CKD-EPI formula), glycemic control, blood pressure and drugs. We used descriptive statistical methods, Pearson's correlation, student t-test and ANOVA for continuous and chi-square for categorical variables.

Results: There were 2322 patients (38% males) with a median follow-up time of 6.9 \pm 4.9 years. Initial median GFR_e was 71 (7-138)ml/min/1.73 m² and the final 63 ml/min/1.73 m². Δ TG was strongly correlation with GFR_e worsening ($p=0,002$). Higher fasting plasma glucose, HbA_{1c}, albuminuria and uric acid were also associated to TG variation ($p<0,001$). A modest correlation was obtained between Δ TG and weight ($p=0,045$), but not significantly with BMI. There was not an impact of Δ TG in inflammatory markers, hepatic function and systolic blood pressure.

Conclusion: Triglyceride variation was significantly associated with renal function worsening, but also with worse glycemic control (higher fast plasma glucose and HbA_{1c}) and hyperuricemia. Hypertriglyceridemia control may be an important factor to slow the diabetic nephropathy progression.

1113

Evolution of albuminuria depending on HbA_{1c} in diabetes mellitus type 1 patients. 20-year follow-up study

L.L. Bolotskaya¹, M.Y. Kutuzova¹, M.S. Shamkhalova¹, M.V. Shestakova²;

¹Diabetic Nephropathy, ²Diabetology, FSBU Endocrinology Research Center, Moscow, Russian Federation.

Background and aims: To investigate the rate of albuminuria (AU) according to changes of glycated hemoglobin (HbA_{1c}) in patients with debut of diabetes mellitus type 1 (DMT1) in their childhood during 20 year observational period.

Materials and methods: 256 patients with DMT1 (girls-143, boys-113) took part in the follow-up study from 1994 to 2014. Average age of DMT1 manifestation was 9.95 \pm 3.01 years. HbA_{1c} was measured 4 times a year. Complications screening was done at least once a year.

Results: AU was diagnosed in 44 patients (17.2%) at the age of 15.53 \pm 3.93 years after 5.6 \pm 2.76 years from beginning of DMT1 in accordance with categories A2 (30-300 mg/L) and A3 (>300 mg/L) with average level of HbA_{1c} 9.57 \pm 2.32%. Correlation between changes in the rate of AU and annual fluctuation of HbA_{1c} level was established in 37 patients (84%). All measurements of HbA_{1c} were conditionally divided into 2 groups: 1) HbA_{1c}<9%; 2) HbA_{1c} \geq 9%. We determined annual crucial changes of HbA_{1c} level, which were associated with

manifestation of AU or its progression: in the group of HbA_{1c}<9% average yearly fluctuation of HbA_{1c} was -1.92 \pm 1.08 \div 1.59 \pm 1.09; in the group of HbA_{1c} \geq 9% - -1.39 \pm 1.4 \div 1.41 \pm 1.3. The difference between negative average values of the HbA_{1c} crucial interval in two groups was statistically significant ($p<0.01$). The safe interval of annual HbA_{1c} level changes leading to AU reduction or even regression to the category A1 (<30 mg/L) was established: in the group of HbA_{1c}<9% - -0.78 \pm 0.78 \div 0.76 \pm 0.74; in the group of HbA_{1c} \geq 9% - -0.98 \pm 0.88 \div 0.94 \pm 0.94. The divergence between negative average values of HbA_{1c} changes in both groups was estimated with $p=0.05$.

Conclusion: In our study the correlation between AU and HbA_{1c} fluctuation rates was established. We also determined safe HbA_{1c} fluctuation rate interval as renal dysfunction risk factor in patients with DMT1 debut in childhood.

1114

The association between glycaemia, blood pressure, and lipidaemia control and the risk of renal function progression in type 2 diabetes patients

P.-Y. Chang¹, L.-N. Chien², Y.-W. Chang³, Y.-F. Lin⁴, K.-X. Ho⁵, W.-T. Chiu⁶, H.-Y. Chiou¹;

¹School of Public Health, ²School of Health Care Administration, Taipei Medical University, Taiwan, ³Department of Information Management, China Jiliang University, Hangzhou, China, ⁴Graduate Institute of Clinical Medicine, Taipei Medical University, Taipei, ⁵Department of Nursing, Hsin Sheng College of Medical Care and Management, Taoyuan, ⁶Graduate Institute of Injury Prevention and Control, Taipei Medical University, Taiwan.

Background and aims: Studies have demonstrated that the intensive control of glycemia, blood pressure, or lipidemia can slow progression of kidney outcomes. In addition to glycemia control of patients with diabetes, blood pressure and hyperlipidemia should also be managed. However, there is no study to discuss the association between simultaneous control of diabetes mellitus, hypertension, and hyperlipidemia and renal function. Thus, this study was to examine the interactive effects of the intensive control of three diseases on rapid progression of renal function.

Materials and methods: This prospective cohort study enrolled 2768 adult patients with type 2 diabetes from eight hospitals in Taiwan in October, 2008 to September, 2014. Demographic characteristics was collected using structured questionnaires. Clinical examination was obtained using medical chart reviews. Rapid progression of renal function was defined as a continued decline in eGFR of more than 5 ml/min/1.73 m²-2/year. The poor control of diabetes mellitus, hypertension and hyperlipidemia was defined as if a patient had a HbA_{1c} \geq 7%, MAP >100 mmHg, and total cholesterol \geq 200 mg/dl and triglyceride \geq 150 mg/dl, respectively. Cox proportional hazard regression models were used to study the associated between interactive effects of diabetes, hypertension and hyperlipidemia controls and the rapid progression of renal function. Covariates included age, sex, stroke, CVD, anemia, CKD, BMI, baseline eGFR, BUN, smoking, alcohol, and Chinese herb drug.

Results: A total of 27.1% (751/2768) had rapid progression of renal function during a mean follow-up of 2.4 years (SD: \pm 1.16). The mean age of the cohort was 62.9 \pm 11.5 years, and male gender accounted for 53.6%.

When considered the single effect of the control of diabetes, hypertension and hyperlipidemia, the poor control of glycemia had the highest risk of the increase risk of rapid progression of renal function, with an adjusted HR of 1.41 (95% CI: 1.22-1.64). The poor control of hypertension and hyperlipidemia was also associated the increase risk of rapid progression of renal function, with an adjusted HR of 1.27 (95% CI: 1.03-1.56) and 1.25 (95% CI: 1.01-1.56), respectively. When considered the interactive effect of the poor control of all three diseases, we treated the patients with an intensive control of all three disease as the reference group. Compared

to the reference group, the poor control of all three diseases had the highest risk of rapid progression of renal function, with an adjusted HR of 2.84 (95% CI, 1.80–4.47). Even if the patients with an intensive control of glycemia, the result showed the poor control of both hypertension and hyperlipidemia was associated with the increased risk of rapid progression of renal function, with adjusted HR of 1.92 (95% CI of 1.11–3.29) than the reference group.

Conclusion: A poor control of glycemia, blood pressure, and lipidemia were found to be associated with the increased risk of declining renal function.

Decline in renal function was not associated with steatosis evaluated by proton-spectroscopy in a population of people with type 2 diabetes
J.-M. Petit, C. Fourmont, B. Guiu, B. Bouillet, M.-C. Brindisi, E. Crevisy, P. Buffier, S. Baillot-Rudoni, J. Cercueil, B. Verges; diabetologie, CHU du Bocage, Dijon, France.

Background and aims: Data regarding the link between hepatic steatosis and renal function in people with type 2 diabetes are controversial. Liver fat content was associated with the development of diabetic nephropathy in cross-sectional studies but not in one longitudinal study. We aimed to determine whether liver fat content was associated with a decline in renal function in patients with type 2 diabetes.

Materials and methods: Two hundred and twenty-three patients with type 2 diabetes were included in the study. Liver fat content was measured by proton spectroscopy at inclusion. Steatosis was defined by liver fat content greater than 5.5%. The decline in renal function was assessed by changes in the estimated glomerular filtration rate (eGFR), (MDRD formula) over time. Diabetic nephropathy at inclusion was defined by the presence of microalbuminuria or macroproteinuria.

Results: One hundred and thirty-four (60.1%) patients had steatosis. Those with steatosis had higher BMI ($p=0.0003$), lower diabetes duration ($p=0.005$) and a lower frequency of diabetic nephropathy at inclusion (12.6% vs 24.7%, $p=0.03$). Age, HbA1c and eGFR at inclusion were not statistically different between groups. The median follow up was 4.4 years. Hepatic steatosis was not associated with the rate of decline in renal function calculated by year, but the difference was borderline significant (Patients with steatosis had a lower annual renal decline than those without steatosis (+0.48 vs. -0.98 ml/min per year, $p=0.06$). In multivariate analysis, steatosis was associated with BMI, but not with age, diabetes duration, diabetic nephropathy at inclusion, eGFR at inclusion, renal decline per year or gender.

Conclusion: When we used an accurate method to evaluate liver fat content, the presence of steatosis was not associated with the decline in renal function in our cohort of patients with type 2 diabetes. Our study suggests that early identification of hepatic steatosis in people with type 2 diabetes may not be useful to identify people at the highest risk of renal decline.

1116

The risk of incident chronic kidney disease in a Korean metabolically healthy obese population

C. Jung¹, Y. Kang¹, K.-U. Lee^{1,2}, J. Jang^{1,2}, I.-K. Lee³, M. Rhee⁴;
¹Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, ²Metabolism Reserch Unit, Asan Institute for Life Sciences, Seoul, ³Department of Internal Medicine, Kyungpook National University School of Medicine, Daegu, ⁴Department of Internal Medicine, Division of Endocrinology and Metabolism, Department of Internal Medicine, Korea University, Seoul, Republic of Korea.

Background and aims: Obesity is considered to be an important risk factor for chronic kidney disease (CKD). The metabolically healthy obese (MHO) phenotype refers to obese individuals with a favorable metabolic profile. Its prognostic value remains controversial and may depend on the health outcome being investigated. We examined the risk of MHO phenotype with incident CKD in a Korean population.

Materials and methods: The study population comprised 40,579 Koreans without CKD. Participants were stratified by body mass index (BMI) (cut-off value, 25.0 kg/m²) and metabolic health state (assessed using Adult Treatment Panel-III criteria). Incident CKD was assessed by the Modification of Diet in Renal Disease (MDRD) study equation and defined by a glomerular filtration rate (GFR) less than 60 ml/min/1.73 m² during the follow-up period.

Results: Over the median follow-up period of 39.0 months (range, 4.8–83.8 months), 315 of the 40,579 individuals (0.8%) developed incident CKD. Compared with the metabolically healthy nonobese (MHNO) group, the MHO group showed increased risk of incident CKD with a multivariate-adjusted hazard ratio (HR) of 1.52 (95% confidence interval [CI], 1.10–2.11). Nonobese but metabolically unhealthy individuals were at an increased risk of incident CKD (multivariate-adjusted HR, 1.44 [95% CI, 1.01–2.00]) than the MHNO group.

Conclusion: Metabolically unhealthy obese individuals were at the highest risk of incident CKD. A healthy metabolic profile does not protect obese adults from incident CKD. Thus, it is important to consider metabolic health and obesity when evaluating CKD risk.

1117

The prevalence of diabetic nephropathy in patients with type 2 diabetes mellitus in Slovakia: the NEFRITI Study

E. Martinka¹, P. Pontuch²;
¹Diabetes, National Institute of Endocrinology and Diabetology, Lubochna, ²4th Department of Internal Medicine, St. Cyril and Methodius Hospital, Bratislava, Slovakia.

Background and aims: To assess: 1) the prevalence of diabetic nephropathy (DNeF), 2) proportion of patients with complications and accompanying diseases, according to the stage of chronic kidney disease (CKD) and albuminuria, and 3) the proportion of patients with GFR < 60 ml/min/1.73 m² with normal creatinine values.

Materials and methods: Randomized, multicentric, epidemiological survey in cohort of 1831 patients with type 2 diabetes mellitus. Urinary albumin was determined by turbidimetric method, GFR was calculated by CKD-EPI formula.

Results: Male 46,5%, age 63,85±9,48 years (y), duration of diabetes 9, 29±7,21 y, HbA1c 7,5±1,6 median 7,2% (DCCT), BMI 31,5±5,6 kg.m⁻², hypertension 82,1%, dyslipidemia 76,8%, serum creatinine 80,3±44,0 umol/l, GFR 87,2±27,7 ml/min/1,73 m², UACR 8,1±36,0 median 1, 41 mg/mmol. Proportions of patients with normoalbuminuria (nA) resp. microalbuminuria (miA) resp. macroalbuminuria (maA) were 67,7% resp. 25,2% resp. 5,01%. Proportion of patients with CKD stage 1 (CKD1) 42,9% CKD2 42,8%, CKD3a 9,4% CKD3b 3,3%, CKD4 1, 2% CKD5 0,39%. The prevalence of DNeF based on a presence of maA or miA, eGFR > 30 ml/min/1,73 m² and diabetic retinopathy was 12,7%. The prevalence of DNeF was increasing with duration of diabetes:

less than 5y / 5-10y / 10-15y / 15y and more was 4,8 / 9,9 / 15,9 / 26,8%. Chronic renal failure (CKD5 and/or dialysis) was found in 0,45%. The proportion of patients with complications of diabetes and accompanying diseases were rapidly increasing with both increasing stage of CKD and albuminuria (Tab. 1).

Conclusion: The prevalence of DNeF in patients with Type 2 diabetes in Slovakia was 12,3%. Both, increase in stage of CKD and albuminuria were associated with increase in all complications of diabetes and accompanying diseases. Normal serum creatinine values were found in 35,4% of patients with eGFR <60 ml/min/1,73 m². Namely in elderly women. The study has been reviewed by the Local Ethics Committee and therefore it been performed in accordance with the ethical standards laid down in the Helsinki Declaration.

Table 1. The proportion of patients with complications of diabetes and accompanying diseases according to the stage of CKD and albuminuria

	NeuP	NPDR	PDR	DF	Amp1	Amp2	CAD	ACS	HF	Stroke	Canc
CKD1 (n=763)	37,33	15,99	2,6	1,11	0,99	0	23,73	5,07	2,23	4,21	4,82
CKD2 (n=762)	39,58	18,49	2,78	1,71	1,19	0,53	33,38	4,76	3,96	1,59	8,3

CKD – chronic kidney disease, NeuP – diabetic neuropathy, NPDR – non proliferative diabetic retinopathy, PDR – proliferative diabetic retinopathy, DF – diabetic foot with ulcer, Amp1 – amputation under ankle, Amp2 – amputation over ankle, CAD – coronary artery disease, ACS – acute coronary syndrome, HF – heart failure, Stroke – stroke, Canc – Cancer

1118

Frailty and the relationship between albuminuria and renal function in elderly patients with type 2 diabetes (ZODIAC)

K.J.J. van Hateren, L.C. Hartog, G.W.D. Landman, K.H. Groenier, H.J.G. Bilou, N. Kleefstra;
Diabetes Centre, Zwolle, Netherlands.

Background and aims: In elderly patients with type 2 diabetes mellitus (T2DM), a moderate reduced renal function (eGFR between 45 and 60 ml/min) is not related to mortality. Other cardiovascular risk factors, such as blood pressure, also have different consequences in old age. Previous studies showed that frailty influences the relationship between several risk factors, e.g. blood pressure, and mortality in old age. We hypothesized that the relationship between renal function and mortality may also be influenced by the level of frailty.

Materials and methods: Patients with T2DM participating in a prospective observational cohort study (ZODIAC) in the Netherlands were included. Patients aged 60 years and older were selected from this cohort of primary care treated patients. Frailty was defined as a score less than 80 on the subscale ‘physical functioning’ of the RAND-36 questionnaire. After median follow-up for 14 years, multivariate Cox regression analyses were performed to evaluate the association between albuminuria/renal function and (cardiovascular) mortality. Analyses were performed in strata according to the frailty level (‘physical functioning’ score 80). We adjusted for age, gender, BMI, duration of diabetes, systolic blood pressure, serum creatinine level (for model with albuminuria), total cholesterol-HDL ratio, HbA_{1c}, macrovascular complications, albuminuria (for model with eGFR), lipid lowering drugs and the use of antihypertensive drugs. Renal function was estimated by the Modification of Diet in Renal Disease equation (MDRD).

Results: Approximately 60% of our study population was female. Median age (interquartile range) was 72 (67-77) years and median diabetes duration was 6 (3-12) years. Frailty was highly prevalent in our study population; 629 out of 858 patients (73%) fulfilled the criterion. Albuminuria was related to increased all-cause and cardiovascular mortality in both frail and non-frail patients (table 1). Every 10 ml/min decrease in eGFR was related to a 41% (95% confidence interval (CI): 12-76%) and 18% (95% CI: 8-27%) higher cardiovascular mortality risk in non-frail and frail patients, respectively. No significant associations were observed between eGFR and all-cause mortality.

Conclusion: The presence of albuminuria and decreased eGFR were related to cardiovascular mortality in both frail and non-frail elderly patients with T2DM. However, the associations were the strongest for non-frail patients. Therefore, we conclude that frailty seems to attenuate the relationship between renal function and cardiovascular mortality, but not for all-cause mortality.

	All-cause mortality	CVD mortality
Non-frail subjects		
Albuminuria	1.50 (1.00-2.25)	1.98 (1.01-3.86)
eGFR (per 10ml/min decrease)	1.14 (0.99-1.31)	1.41 (1.12-1.76)
Frail subjects		
Albuminuria	1.55 (1.26-1.90)	1.50 (1.09-2.06)
eGFR (per 10ml/min decrease)	1.03 (0.98-1.08)	1.18 (1.08-1.27)

Table 1. Hazard ratios and their 95% confidence intervals of albuminuria and eGFR for all-cause and cardiovascular disease (CVD) mortality. Analyses were stratified according to frailty.

1119

Albumin- and haemoglobin- corrected HbA_{1c} detects uncontrolled diabetic patients on haemodialysis better than glycated serum protein: a continuous glucose monitoring study

F. Iliadis¹, M. Divani¹, T. Didangelos¹, C. Margaritidis¹, A. Makedou², V. Liakopoulos³, A. Hatzitolios¹, D. Grekas¹;

¹First Propedeutic Department of Internal Medicine, ²Laboratory of Lipids, 2nd Paediatric Department, ³First Department of Internal Medicine, AXEPA Hospital, Aristotle University of Thessaloniki, Greece.

Background and aims: It is reported that HbA_{1c} is unreliable in hemodialysis patients, underestimating the level of glycemic control. Anemia and administration of erythropoietin are the primary factors that influence its validity. Alternatively the glycated serum protein (GSP) has been proposed as a more reliable marker of glycemic control in these patients. The aim of the study was to compare these two markers of glucose control estimation in hemodialysis patients with diabetes.

Materials and methods: We studied 38 hemodialysis patients with diabetes (36 type 2), sex: 22 male, age: 62.8 (16.2) years, BMI: 27.0 (3.9) Kg/m², serum albumin (Alb): 4.0 (0.3) g/dl, hemoglobin (Hb): 10.9 (1.4) g/dl, HbA_{1c}: 6.5 (1.3)% and GSP: 622.8 (184.3) μmol/L. A 7-day continuous glucose monitoring system was used (iPro2 CGM) in order to measure the average glucose (mAG: 162.5±35.3 mg/dl) and the standard deviation of mAG (mSDG: 49.1±17.0 mg/dl). The predicted HbA_{1c} (preHbA_{1c}) according to mAG was calculated, based on equation: preHbA_{1c}=mAG+46.7 / 28.7. Moreover we estimated the AG according to HbA_{1c}, based on equation for patients in hemodialysis: eAG=104.8+(29.7 X HbA_{1c}) - (18.4 X Alb) - (4.7 X Hb) and thereafter we estimated the corrected HbA_{1c} (corHbA_{1c}=eAG+46.7 / 28.7). ROC analysis was performed to determine which of the three markers (HbA_{1c}, corHbA_{1c} and GSP) could predict better mAG≥184 mg/dl, which in patients with normal renal function corresponds to HbA_{1c}≥8% and detects the uncontrolled diabetic patients in hemodialysis. Statistical analysis was performed with SPSS 18.0. P value<0.05 was considered statistically significant.

Results: preHbA_{1c} and corHbA_{1c} were 7.3 (1.2)% and 7.6 (1.4)% respectively. There was a significant difference between HbA_{1c}, preHbA_{1c} and corHbA_{1c} (p=0.001). HbA_{1c} was statistically significantly lower compared to preHbA_{1c} (p=0.033) and to corHbA_{1c} (p=0.001). There was no statistically significant difference between preHbA_{1c} and corHbA_{1c} (p=0.509). The mAG and the mSDAG were significantly correlated with HbA_{1c}, corHbA_{1c} and GSP (p>0.001). The area under receiver-operating characteristic curve (AUC) for HbA_{1c}, corHbA_{1c} and GSP to detect mAG≥184 mg/dl was 0.786 (0.623-0.902), 0.771 (0.606-0.891) and 0.694 (0.523-0.832) respectively. There was no significant statistical difference between the AUCs. The sensitivity of HbA_{1c}≥8%, corHbA_{1c}≥8% and GSP≥650.0 μmol/L to detect mAG≥184 mg/dl was 36.4%, 72.7% and 81,8% respectively. The specificity of HbA_{1c}≥8%, corHbA_{1c}≥8% and GSP≥650.0 μmol/L to detect mAG≥184 mg/dl was 85.2%, 85.2% and 63.0% respectively. In total, the false negative and

false positive values of HbA_{1c}≥8%, corHbA_{1c}≥8% and GSP≥650.0 μmol/L to detect mAG≥184 mg/dl were 11 (28.9%), 7 (18.4%) and 12 (31.5%) respectively.

Conclusion: In hemodialysis diabetic patients, HbA_{1c} should be corrected according to serum albumin and hemoglobin. The albumin- and hemoglobin- corrected HbA_{1c} seems to detect uncontrolled diabetic patients on hemodialysis better than glycated serum protein.

PS 111 Diabetic nephropathy: mechanisms

1120

High glucose induces membrane-bound transcription factor peptidase site1 via carbohydrate response element binding protein to modulate ER stress in mesangial cells

Y. Makino, K.K. Atageldiyeva, H. Kitsunai, K. Mizumoto, T. Yanagimachi, Y. Fujita, A. Abiko, Y. Takiyama, M. Haneda;
Department of Medicine, Asahikawa Medical University, Japan.

Background and aims: High glucose (HG) evokes a variety of gene expressions in mesangial cells (MC) that alter cellular functions responsible for the development of diabetic glomerulopathy. We previously reported that HG activates hypoxia-inducible factor-1 α and its target genes expression in MC, leading to an extracellular matrix expansion in diabetic glomeruli. A glucose responsive transcription factor, carbohydrate response element binding protein (ChREBP), plays a pivotal role in such derangement of gene regulation. To provide more insight into glucose-mediated gene regulation at genome-wide level, we performed chromatin immunoprecipitation with anti-ChREBP antibodies followed by DNA microarray analysis (ChIP-chip) and identified membrane-bound transcription factor peptidase site1 (MBTPS1) as a novel target gene of ChREBP in MC. MBTPS1 proteolytically activates a class of transmembrane transcription factors at the endoplasmic reticulum (ER) and participates in the regulation of cellular events such as response to ER stress; however the role of MBTPS1 in MC under diabetic circumstances is largely unknown. In the present study, we examined the mechanism by which MBTPS1 is induced by HG in MC, and the role of MBTPS1 in the regulation of cellular function.

Materials and methods: Cultured human MC were incubated in HG (25 mM glucose) and normal glucose (NG; 5.6 mM glucose), and the gene and protein expression were analyzed. Gene expressions in the kidney of diabetic model mice were determined by real time PCR.

Results: ChIP-chip assay revealed binding of ChREBP to MBTPS1 gene at 2.5 kb in 3'-flanking region. In validation analyses, exposure to HG for 24 h enhanced MBTPS1 mRNA expression in cultured MC (2.4±0.43 fold, compared to NG). Knock-down of ChREBP abrogated this induction response. MBTPS1 is known for the proteolytic activation of activating transcription factor-6 (ATF6), which is involved in the adoptive response to ER stress. In support of these issues, HG induced the activation of ATF6 in MC and the inhibitor of MBTPS1 cancelled this activation. Interestingly, the target genes of ATF6 were not universally induced by HG; C/EBP homologous protein, a critical determinant of ER stress-induced apoptosis, was induced by 4.8±1.1 fold ($p<0.05$), whereas X-box-binding protein 1 was induced by 1.8±0.2 fold ($p<0.05$) and glucose-regulated protein-78 was not induced, indicating that MBTPS1 may participate in the control of the fate of MC exposed to HG. Moreover, the expression of MBTPS1 mRNA was upregulated in the kidney of streptozotocin-induced diabetic model mice compared to control mice (1.36 fold).

Conclusion: HG-mediated induction of MBTPS1 via ChREBP operates in response to ER stress in MC, which may provide novel insights into the pathogenesis and therapeutic intervention of diabetic nephropathy.

1121

Advanced Glycation End products (AGEs) increase human renal tubular foam cell formation by endoplasmic reticulum stress

Y. Yuan, H. Sun, Z. Sun;

Department of Endocrinology, ZhongDa Hospital, SouthEast University, Nanjing, China.

Background and aims: Diabetic nephropathy caused by advanced glycation end products (AGEs) is associated with lipid accumulation in renal tubule. This study was designed to investigate whether Nε-(carboxymethyl) lysine (CML) (one of AGEs family) increase lipid accumulation in human renal tubular epithelial cell line (HK-2) via increasing cholesterol synthesis and uptake, reducing cholesterol efflux through endoplasmic reticulum stress (ERS).

Materials and methods: HK-2 were incubated with CML. Cell viability was evaluated through the CCK-8 assay, and cell apoptosis was evaluated by Annexin V-FITC Kit. Intracellular cholesterol content was assessed by Oil Red O staining and cholesterol enzymatic assay. Expression of mRNA and protein of molecules controlling cholesterol homeostasis in the treated cells was examined by real-time quantitative PCR and western blotting, respectively.

Results: CML reduced the cell viability and increased the cell apoptosis of HK-2 cells, which could be inhibited by anti-RAGE (RAGE, receptor of AGEs). CML increased cholesterol accumulation in HK-2 cells, however anti-RAGE reduced the lipid content. Exposure to CML increased expression of 78-kDa glucose-regulated protein (GRP78) and C/EBP homologous protein (CHOP), which up-regulated transcription factor SREBP-2 to the Golgi for activation by cleavage enhanced gene transcription of HMGCoA reductase and LDL receptor, down-regulated adenosine triphosphate-binding cassette transporter A1 (ABCA1) and Liver X receptor (LXR), which were reversed by anti-RAGE. The effects of CML were blocked by 4-PBA (4-PBA was used to inhibit ERS).

Conclusion: CML increased HMG-CoAR-mediated cholesterol synthesis and LDL-mediated cholesterol uptake, reduced ABCA1-mediated cholesterol efflux through ERS, ultimately, caused lipid accumulation in HK-2 cells. These data imply that inhibiting ERS might have a potential renal protective role in prevention of renal tubular foam cell formation.

1122

Effects of high free fatty acids on human kidney epithelial cells

G. Li¹, X.-F. Khew¹, S. Meng¹, C.-S. Yap¹, M.-M. Tong¹, Y.-M. Bee²;
¹Clinical Research, ²Endocrinology, Singapore General Hospital, Singapore.

Background and aims: Diabetes is an epidemic metabolic syndrome, becoming one of the most common causes of kidney diseases leading to the end stage renal failure and dialysis requirement. Several factors including hyperglycemia and dyslipidemia have been identified as risk factors for diabetic nephropathy. Also, an elevation of free fatty acids (FFA) level is commonly observed in diabetic patients. This study examined potential adverse effects of high FFA on kidney epithelial cells and investigated relevant signaling pathways.

Materials and methods: RC124 cells (a human kidney epithelial cell line) were treated with high concentrations (0.5 and 1 mM) of the saturated palmitic acid (PA) alone, or a mixture of equal amount of PA and the monounsaturated oleic acid (OA), for 12, 24 or 48 hours, followed by assessments of cell viability and various signaling pathways using immuno-blotting and assay kits run on Muse Cell Analyzer.

Results: Morphological changes occurred after kidney epithelial cells were exposure to high FFA, displaying coarse surface and membrane blebbing. When OA was present, cell confluence was higher than that by high PA treatment alone. High PA treatment reduced (up to by 80%) viability of kidney epithelial cells in both time- and dose- dependent manner. By contrast, co-treatment with equal amount of OA was able to block such adverse effects by PA to a large degree. The underlying

mechanisms for high FFA effects on renal cell viability were studied by examining related signaling events. High PA treatment activated caspase-3 and induced apoptotic cell death at 24 h. In addition, PA treatment evoked endoplasmic reticulum (ER) stress (as indicated by increased phosphorylation of eIF2 α) and induction of autophagy (assessed by detection of LC3-II) in renal cells. Both high PA-induced ER stress and autophagy occurred at 12 h, a time point prior to apoptosis occurrence, suggesting their possible causative relationship in the course of injuring cells. On the other hand, co-treatment with OA abolished such PA-induced ER stress, autophagy and apoptosis of renal cells.

Conclusion: High PA may exert lipotoxicity effects on kidney epithelial cells via induction of ER stress, autophagy and apoptosis, which may contribute to the development of renal diseases in diabetes. OA appears capable of antagonizing high PA's adverse action and potential for development of targeting drugs.

The function of ELMO1 in renal development under diabetic conditions within zebrafish and in human diabetic nephropathy

K.R. Sharma¹, K. Heckler¹, S.J. Stoll¹, J.-L. Hillebrands², J. Kroll¹;

¹Department of Vascular Biology and Tumor Angiogenesis, Center for Biomedicine and Medical Technology Mannheim (CBTM), Germany, ²Department of Pathology and Medical Biology, University Medical Center Groningen, Netherlands.

Background and aims: Although the engulfment and cell motility 1 (ELMO1) protein functions as a guanine exchange factor for Rac1, regulating cell migration and early vascular development within the zebrafish (ZF); recently, it was found to protect endothelial cells from apoptosis via activation of the Rac1/PAK/AKT signalling cascade in vitro and in vivo. GWAS data suggests that polymorphisms in different regions of human ELMO1 acts as a potential contributing factor for the development of diabetic nephropathy (DN). However, the function and altered expression of ELMO1 remains unclear with respect to the development of DN and this study thus aims to illustrate the role played by ELMO1 in renal development in ZF, under diabetic conditions, and DN patients.

Materials and methods: ELMO1 expression within the Wt1B:GFP transgenic zebrafish line was knocked out using the CRISPR:Cas9 technology. The renal system in Wt1B:GFP fish line is tagged with GFP and hence was used to observe developmental changes within the pronephron. ZF embryos were rendered diabetic via the knockdown of PDX1 using specific splice blocking morpholinos. Nephron functional assays were carried out with the help of TexasRed labelled Dextran to observe leakage via the pronephron. TUNEL assay was used to measure increase in apoptosis within the ZF embryos. Lastly, human kidney paraffin sections from controls and DN human patients suffering from Type 1 and Type 2 DM were stained to observe and compare ELMO1 expression within the glomeruli.

Results: It was observed that a knockout of ELMO1 within ZF embryos leads to pathophysiological changes within the pronephron, adversely affecting pronephric structure and appropriate ultrafiltration. Subsequently, renal structure and function is restored in rendered diabetic ZF embryos upon over-expression of ELMO1. ZF embryos upon loss of ELMO1 showed a significant increase of apoptosis within the ZF pronephron, which consequently lead to the renal pathophysiological effects. Lastly, expression of ELMO1 within kidney samples of human patients suffering from Type 1 and Type 2 DM was greatly reduced as compared to control samples.

Conclusion: Collectively, the results indicate that ELMO1 is extremely important for glomerular protection and renal cell survival via decreasing apoptosis, especially within the diabetic diseased renal conditions.

1124

Defining the role of pyroptosis and apoptosis in diabetic nephropathy
K. Shahzad¹, F. Bock^{1,2}, M. Al-DABET¹, H. Wang¹, I. Gadi¹, S. Kohli¹,
 J. Wolter¹, M. Thati¹, B. isermann¹;

¹Uniklinikum Magdeburg, Institute for Clinical Chemistry and, ²Department of Internal Medicine I and Clinical Chemistry, University of Heidelberg, Germany.

Background and aims: Cell death and inflammation are both associated with the progression of diabetic nephropathy (dNP). Glomerular cell apoptosis is thought to contribute to diabetic nephropathy. However, direct experimental evidence supporting a causative role of apoptosis is lacking. Of note, common cell death assays like TUNEL fail to distinguish apoptosis from other cell death forms, leaving the question open, whether apoptosis has a prevailing role for establishing dNP. To evaluate the role of apoptosis for experimental diabetic nephropathy we used various pharmacological and genetic approaches.

Materials and methods: Murine models of type 2 (db/db mice) and type 1 (Streptozotocin [STZ] -uninephrectomized mice) diabetes were analyzed. dNP was quantified based on albuminuria and histological changes. Expression levels of cleaved caspase-1 (Casp1), Casp3, and IL1 β were determined by immunoblotting and immunohistochemistry. A subset of mice was injected with M-920 (a pan caspases inhibitor targeting Casp1, 3, 4, 5, 6, 7) and CIX (an inhibitor of Casp3, 6, 7, 8, 10). Furthermore, Casp3 and Casp1 deficient mice were used to distinguish the role of apoptosis and pyroptosis.

Results: Of the two pharmacological approaches used in db/db mice only one (M-920, targeting also Casp1) efficiently ameliorated diabetic nephropathy. Furthermore, Casp1 inhibitor, but not CIX, prevented glucose induced Nlpr3 expression as well as IL-1 β and caspase-1 cleavage in podocyte in vitro and in vivo. Importantly, while Casp1 deficient mice with STZ induced persistent hyperglycemia were protected from diabetic nephropathy, Casp3 deficient mice were not. Hence, manifestation of dNP is independent of caspase-3, but requires caspase-1 in mice.

Conclusion: Taken together, these studies question the role of Casp3 dependent cell death while emphasizing the role of inflammasome and Casp1 activation and potentially of pyroptosis for diabetic nephropathy. Therefore, we propose that inflammasome inhibition is a more feasible therapeutic approach to successfully target dNP than apoptosis inhibition.

The antifibrotic microRNA crosstalk in the action of N-acetyl-seryl-aspartyl-lysyl-proline on kidney fibrosis in diabetes

D. Koya, S.P. Srivastava, M. Kanasaki, T. Nagai, S. Shi, K. Kanasaki;
 Endocrinology & Metabolism, Kanazawa Medical University,
 Kahokugun, Ishikawa, Japan.

Background and aims: N-acetyl-seryl-aspartyl-lysyl-proline (AcSDKP) is an endogenous peptide and provides renal-protective effects by inhibiting renal fibrosis.

Materials and methods: We found that the suppression of AcSDKP and concomitant induction of dipeptidyl peptidase-4 (DPP-4) were connected with insufficient levels of antifibrotic microRNAs in the kidney of streptozotocin (STZ)-induced diabetic CD-1 mice, considering the possible collaborations among these molecular defects in the onset of kidney fibrosis of diabetes.

Results: By the comparative studies using streptozotocin (STZ)-induced diabetic non-fibrotic (129Sv) kidneys, we found that diabetic CD-1 mice with fibrotic kidney was differentiated from non-fibrotic diabetic 129SV mice by the suppression of AcSDKP, prominent induction of DPP-4 protein expression/activity, endothelial to mesenchymal transition (EndMT), and the suppression of anti-fibrotic microRNAs (miRs) such as miR-29 s and miR-let-7 s. These alterations in diabetic CD-1 mice were all reversed by AcSDKP treatment. Transfection studies in human

microvascular endothelial cells revealed that miR-29 s and miR-let-7 s are bidirectionally regulated each other against EndMT program, and such regulation of miR-29 s and miR-let-7 s played an essential role in maintaining the antifibrotic program in AcSDKP action. The suppressed level of AcSDKP in diabetic CD-1 mice also induced inflammatory responses by enhancing both IFN- γ and TGF- β signaling, resulting in inhibition of antifibrotic miRs crosstalk.

Conclusion: In conclusion, the present study provides new insight into the physiologically relevant antifibrotic actions of AcSDKP via restoration of antifibrotic miRs, and such anti-fibrotic programs mediated by AcSDKP would have potential utility in combating diabetic nephropathy.

High levels of fasting plasma pro-enkephalin predict deterioration of kidney function and incidence of chronic kidney disease

C.-A. Schulz¹, U. Ericson¹, G. Hindy¹, P. Almgren¹, A. Bergman², O. Melander¹, M. Orho-Melander¹;
¹Lund University, Malmö, Sweden, ²SphingoTec GmbH, Hohen Neuendorf, Germany.

Background and aims: Recently, high levels of pro-enkephalin A (p-ENK) have been associated with decreased estimated glomerular filtration rate (eGFR) in an acute setting. Here we examined, if plasma levels of p-ENK may predict chronic kidney disease (CKD), a decline of eGFR or increase of cystatin C, and analyzed the genetic determinants of p-ENK using a genome-wide association study (GWAS).

Materials and methods: The study included 2568 individuals, aged 46–68 years, without CKD (eGFR ≥ 60 ml/min/m²), and with measured fasting plasma p-ENK at baseline (1991–1994). Incidence of CKD was defined as \leq eGFR 60 ml/min/m² at follow-up re-examination (2007–2012). Logistic regression was used to calculate the odds ratio (OR) of CKD according to tertiles of fasting plasma concentrations of p-ENK adjusting for sex, age, eGFR, fasting glucose, systolic blood pressure, anti-hypertensive medication, BMI at baseline and follow-up time. Further, we conducted a GWAS for p-ENK levels in 4150 participants and tested if the genetic markers identified genome wide significantly associated with p-ENK may prospectively predict incidence of CKD from baseline to follow-up re-examination.

Results: During a mean follow-up time of 16.6 years we observed a CKD incidence rate of 32%. Among participants in the highest tertile of p-ENK concentration at baseline the OR for CKD was increased to 1.51 (95% CI 1.18–1.94) compared to participants within the lowest p-ENK tertile. The yearly mean decline of eGFR was significantly higher ($P=0.0002$) among participants with high levels of p-ENK and likewise did cystatin C ($P=0.005$) and creatinine ($P=0.000003$) increase in individuals with high p-ENK concentrations. In GWAS we identified 19 SNPs up- and 5 SNPs down-stream of the PENK locus that altered p-ENK concentration on a GWAS significant level. Per copy of the p-ENK increasing minor alleles of the lead SNP rs1012178 ($P: 4.666\text{--}21$) the risk for incidence of CKD was significantly increased (OR: 1.19; 95% CI 1.02–1.38). The mean decline of eGFR per year was significantly higher ($P=0.0007$) and creatinine ($P=0.002$) and cystatin C ($P=0.031$) levels increased more compared to homozygote major allele carriers.

Conclusion: Our large prospective study suggest circulating p-ENK as a potential biomarker to predict incidence of CKD. GWAS followed by analyses for the lead SNP provided evidence for that increased risk for CKD observed in participants with high p-ENK concentrations may be partially genetically determined.

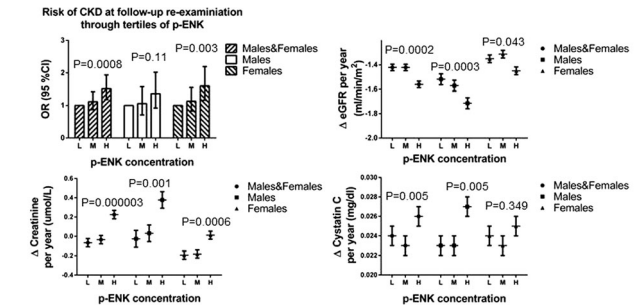

Figure 1: a) Risk for CKD at follow-up re-examination in relation to baseline p-ENK concentration in 2568 participants of MDC-CC. The logistic regression model was adjusted for sex, age, eGFR, fasting glucose, systolic blood pressure, anti-hypertensive medication, BMI at baseline and follow-up time. Changes per year in b) eGFR (estimated Glomerular Filtration Rate CKD-EPI 2012 based on Inker et al.), c) creatinine and d) Cystatin C through levels of fasting plasma p-ENK in a linear model adjusted for age, (sex), and baseline levels. P= P-trend.

Increased copeptin in plasma predicts mortality and renal outcome in patients with type 1 diabetes

S. Theilade¹, S. Rosenlund¹, T.W. Hansen¹, J. Gøtzte^{2,3}, F. Persson^{1,4}, P. Rossing^{1,4},
¹520, Steno Diabetes Center, Gentofte, ²Rigshospitalet, Copenhagen, ³Aarhus University, ⁴University of Copenhagen, Denmark.

Background and aims: Copeptin is a surrogate marker for vasopressin in plasma and associated with cardiovascular disease (CVD) and renal disease in patients with type 2 diabetes. Here, we examined the association between copeptin concentrations and cardiorenal disease in patients with type 1 diabetes.

Materials and methods: Baseline complications were defined as albuminuria ($n=358$) (urinary albumin excretion rate (UAER) ≥ 30 mg/24 h) and CVD ($n=143$) (myocardial infarction, revascularisation, stroke or peripheral arterial disease). Adjustments in the regression model included gender, age, diabetes duration, eGFR, UAER, HbA_{1c}, cholesterol, systolic blood pressure, insulin dose, sodium excretion, BMI, smoking and antihypertensive treatment. During follow up we assessed 1) the development of a combined endpoint including end stage renal disease (ESRD) (dialysis, renal transplantation), doubling of baseline creatinine and all-cause mortality, and 2) annual change in eGFR.

Results: In 665 patients with type 1 diabetes (age (mean \pm SD) 55 ± 13 years, 301(45%) females), the median (interquartile range) copeptin concentration was 5.5 (3.3–10.9) pmol/L. In multivariate analysis, copeptin concentrations were higher in males and correlated positively with UAER and HbA_{1c} and, inversely with eGFR and systolic blood pressure ($p \leq 0.008$). Moreover, copeptin concentrations were higher in patients with albuminuria than in patients without (8.0 (3.8–16.0) vs. 4.4 (2.8–6.8) pmol/L; adjusted $p=0.035$). During a follow up of median [interquartile range] 3.9 [0.16–5.0] years, the mean \pm SD, annual eGFR decline was 0.30 ± 4.1 ml/min/1.73 m². Increased copeptin concentrations predicted the combined endpoint ($n=47$) with a hazard ratio of 3.5 (1.6–7.7) (per doubling in ln-copeptin; $p=0.002$) adjusted for gender, age, systolic blood pressure, eGFR and previous CVD, and was associated with a larger annual decline in eGFR (adjusted $p=0.02$). **Conclusion:**

Increased copeptin concentrations were associated with impaired renal function and larger decline in eGFR. Moreover, increased copeptin concentration independently predicted the combined endpoint. Copeptin may thus be a useful cardiorenal risk marker in patients with type 1 diabetes. *Clinical Trial Registration Number: NCT01171248*

Serum adiponectin and glomerular filtration rate in patients with type 2 diabetes

L. Ortega Moreno¹, O. Lamacchia², L. Salvemini¹, S. De Cosmo³, M. Cignarelli⁴, V. Trischitta⁵, C. Menzaghi¹;

¹Research Unit of Endocrinology, IRCCS, San Giovanni Rotondo, ²University of Foggia, ³IRCCS, San Giovanni Rotondo, ⁴University of Foggia, San Giovanni Rotondo, ⁵Sapienza University, Rome, Italy.

Background and aims: High serum adiponectin has been associated with decreased renal function in the general population. Only sparse and conflicting results, all derived from small studies mainly carried out in non-European populations, have been reported in patients with type 2 diabetes (T2D), a subgroup of individuals who are at high risk of renal dysfunction. The aim of this study was to fill up this gap of knowledge by investigating such association among diabetic patients of European ancestry.

Materials and methods: The association between serum adiponectin levels and estimated glomerular filtration rate (eGFR by Modification of Diet in Renal Disease equation) was investigated in 1,212 patients with T2D from two different Italian samples: 847 patients from San Giovanni Rotondo (SGR) and 365 patients from Foggia.

Results: Serum adiponectin was inversely associated with eGFR in SGR [β (SE) for 1 SD of adiponectin = -2.53 (0.69), $p=2.0 \times 10^{-4}$] and in Foggia [β (SE) = -5.63 (1.66), $p=0.001$] samples, as well as in the two studies combined [β (SE) = -3.46 (0.69), $p=6.0 \times 10^{-7}$]. The association was somehow reduced but still significant after adjusting for sex, smoking habits, BMI, diabetes duration, HbA1c, anti-diabetic, anti-hypertensive and anti-dyslipidemic treatments [β (SE) = -1.79 (0.73), $p=0.015$]. For each adiponectin SD increment, the odds of having eGFR < 60 ml/min/1.73 m² increased by 46% (OR = 1.46; 95% CI 1.24–1.71; $p=3.2 \times 10^{-6}$) in SGR sample, 52% (OR = 1.52; 95% CI 1.19–1.94; $p=0.001$) in Foggia sample, and 47% (OR = 1.47; 95% CI 1.29–1.68; $p=8.7 \times 10^{-9}$) in the two studies considered together. Further adjustment for the above mentioned covariates did not change the observed association (OR = 1.36; 95% CI 1.16–1.59; $p=9.6 \times 10^{-5}$).

Conclusion: This is the first report of an association between high serum adiponectin and low eGFR in a large study of patients with T2D of European ancestry. Such counterintuitive, paradoxical association deserve further attempts to be deeper understood.

1129

Associations of serum N-glycans with glycaemic control and albuminuria in type 1 diabetes

M. Colombo¹, F. Vučković², M. Pučić Baković², H.C. Looker³, F. Agakov⁴, G. Lauc², P.M. McKeigue¹, H.M. Colhoun³, on behalf of the SDRN Type 1 Bioresource Investigators;

¹Usher Institute of Population Health Science and Informatics, University of Edinburgh, UK, ²Genos Glycoscience Research Laboratory, Zagreb, Croatia, ³Population Health Sciences, University of Dundee, ⁴Pharmatics Ltd, Edinburgh, UK.

Background and aims: Higher glycaemia levels leading to altered flux through the hexosamine pathway is considered to be a pivotal pathway in diabetic complications, as this produces UDP-N-acetylglucosamine (UDP-GlcNAc), the substrate for N-linked glycosylation. The N-glycan profile reflects oligosaccharide modifications on secreted proteins resulting from N-linked glycosylation. We tested whether in people with type 1 diabetes the N-glycans profile in serum differs by glycaemic control and albuminuria status.

Materials and methods: Study participants comprised 744 people with T1D recruited from diabetes clinics and primary care into the Scottish Diabetes Research Network Type 1 Bioresource. The N-glycan profile in non-fasting serum samples were analysed using hydrophilic interaction ultra performance liquid chromatography (HILIC-UPLC) and divided into 39 glycan groups (GP1–GP39). We investigated associations with HbA1c adjusted for age and sex, through linear regression where the relative quantity of each N-glycan was evaluated independently and then further adjusted for diabetes duration. We also examined associations with 14 summary variables reflecting the ratios of different branching patterns and levels of sialylation and galactosylation. We used a Bonferroni adjusted p-value to consider significance of associations. We used a cross-validated forward selection to define a set of N-glycans associated with HbA1c and used it to compute an N-glycan-based score for glycaemia and tested it for association with albuminuria status adjusted for age, sex, diabetes, duration and HbA1c.

Results: At baseline median (inter-quartile range) for age was 43.6 (31.4, 54.8) years, duration 20.6 (11.0, 30.2) years, HbA1c 75.7 (63.0, 85.9) mmol/mol, eGFR 108.1 (66.6, 135.6) ml/min/1.73 m², 23.7% of the subjects had micro- or macroalbuminuria (13.2% and 10.5% respectively). Of the 39 N-glycans and 14 summary measures, 16 showed strong associations in either direction with HbA1c at $p < 0.0001$ (Fig 1). The proportion of N-glycans that were tri-antennary glycans was higher with poorer glycaemic control and the level of non-sialylated glycans was decreased. Further adjustment for diabetes duration did not alter these associations. The N-glycan-based score was associated with albuminuria status adjusted for age, sex, diabetes duration and HbA1c (regression coefficient = 0.06, 95% CI: (0.02, 3.52), $p=0.0005$).

Conclusion: In type 1 diabetes the serum N-glycan profile shows strong associations with glycaemic control in a pattern consistent with increased hexosamine flux. Further studies are needed to evaluate whether the cross sectional association with albuminuria is found in prospective studies.

Arterial stiffness is an independent predictor of renal function decline and stroke in patients with type 2 diabetes with preserved renal function

N. Fountoulakis, K. Patel, C. Thakrar, A. Smith, G. Viberti, L. Gnudi, J. Karalliedde;
Diabetes, King's College London, UK.

Background and aims: Aortic pulse wave velocity (Ao-PWV) the gold standard measure of arterial stiffness is an independent predictor of cardiovascular disease (CVD) in T2DM patients with advanced renal disease. The role of Ao-PWV as a predictor of glomerular filtration rate (GFR) decline in T2DM patients with relatively preserved renal function is unclear.

Materials and methods: In a prospective, observational study of 119 T2DM consecutive patients (81 males) attending a diabetes clinic in a university hospital, we evaluated if Ao-PWV measured (by applanation tonometry (AtCor Medical, Sydney, NSW, Australia) at baseline, was a predictor of renal function decline, CVD or cerebrovascular events (CVA). Patients were followed at least annually with standardized clinical and laboratory assessments. CVD and CVA events were obtained from hospital records.

Results: Median duration of follow up was 9 yrs (range 3-11). At baseline mean age was 60 yrs (range 34 to 80), duration of diabetes 9 yrs (range 4-28), mean \pm SD estimated GFR (Modification of Diet in Renal Disease equation) 85 ± 24 ml/min, Ao-PWV 10.1 ± 2.6 m/s, urine albumin to creatinine ratio (median 1.3 mg/mmol, interquartile range 0.6-4.7) and HbA1c $7.9 \pm 1.5\%$. Patients were divided into two groups above ($n=72$) or below ($n=47$) 60 yrs of age. Patients below 60 yrs reaching an eGFR value below the median for this group at the end of the observation period had a higher Ao-PWV value at baseline (9.2 vs. 7.9 m/s, mean difference 1.3 m/s 95% CI 0.2-2.4 $p=0.02$) and a higher rate of GFR decline (-3.3 ml/min/yr, 95% CI -5.0 to -1.5 $p=0.001$). Ao-PWV was an independent risk factor for decline of renal function after adjustment for age, pulse pressure, gender, baseline eGFR, and albuminuria. In those above 60 yrs baseline Ao-PWV was similar (11.6 vs. 11.1 m/s) in patients above or below final median eGFR for this group. During the follow up there were 4 (3.3%) CVA events and 17 (14%) CVD events. Ao-PWV was an independent predictor of CVA events ($p=0.015$, odds ratio=2.5) but not CVD after adjustment for conventional risk factors.

Conclusion: In 'younger' T2DM subjects with preserved renal function Ao-PWV is an independent predictor of renal function decline. In the whole cohort, Ao-PWV predicted CVA independent of traditional risk factors. Treatments that target Ao-PWV reduction may delay the progression of renal function decline in T2DM.

1131

Microalbuminuria, but not mildly reduced eGFR, predicts cardiovascular outcomes in patients with type 2 diabetes

P. Sjöblom^{1,2}, F.H. Nystrom¹, T. Länne¹, J. Engvall^{1,3}, C.J. Östgren¹;
¹Department of Medical and Health Sciences, Linköping University, ²Department of Local Care Finspång, County Council of Östergötland, ³Department of Endocrinology and Metabolism, Linköping University Hospital, Sweden.

Background and aims: A growing body of evidence emphasizes the importance of albuminuria as a predictor for cardiovascular disease and mortality in patients with type 2 diabetes. However, it is still a matter of controversy if mild renal impairment is an independent risk factor for macrovascular complications. Thus, the aim of this study was to explore the impact from microalbuminuria and mild renal impairment on cardiovascular events in patients with type 2 diabetes.

Materials and methods: Data were analyzed from 706 patients from baseline in the Cardiovascular Risk factors in Patients with Diabetes - a Prospective study in Primary care (CARDIPP). The participants were

consecutively recruited 2005-2008, at an age of 55-65 years from 22 primary health care centers in Sweden. The mean age of the patients was 60.7 years. At baseline, urine and blood samples for standardized laboratory analyses were taken in the morning following at least 10 hours fasting. Presence of microalbuminuria was defined as a u-albumin/creatinine ratio (uACR) ≥ 3.0 mg/mmol. Estimated Glomerular Filtration Rate (eGFR) was calculated by use of the MDRD formula and reduced renal function was defined as level of eGFR < 60 ml/min/1.73 m². Cardiovascular disease and death data were retrieved from the hospital discharge register and the cause of death register in Sweden until 31st December 2012. The primary endpoint was a composite endpoint of the first non-fatal or fatal event of hospitalization for acute myocardial infarction or stroke or cardiovascular mortality diagnosed according to ICD-10, I00-99. The relations of microalbuminuria and renal impairment to risk of the outcomes were investigated using Cox proportional hazard models.

Results: When uACR was used as a continuous variable, covariates in the final model were age, sex, smoking status, previous MI, LDL-cholesterol, triglycerides, HbA1c, mean 24-h systolic blood pressure and use of ACE inhibitors, ARB, beta-blockers and statins in Cox proportional hazard models. There was a strong association between uACR and the endpoint, $P=0.001$ HR: 1.03; CI 1.01-1.04. When uACR was replaced by eGFR in the analysis there were no significant association between eGFR and the primary endpoint crude or in any model of adjustments of covariates. The association between uACR and eGFR and the primary endpoint are further illustrated in the Figure by Kaplan-Meier curves with uACR dichotomized at ≥ 3.0 mg/mmol and eGFR < 60 ml/min/1.73 m².

Conclusion: Our study confirms that microalbuminuria defined as uACR, but not renal impairment defined by eGFR, predicts cardiovascular complications in middle-aged patients with type 2 diabetes.

Figure

Kaplan-Meier estimates above shows significance for uACR, $p=0.035$ (log-rank test).

For comparison of survival with eGFR higher or lower than 60 ml/min/1.73m² there was no statistical significance, $p=0.326$.

Albuminuria is positively associated with elevated numbers of circulating endothelial pre- and mature cells, but inversely associated with circulating fibrocytes

A. Rosendahl¹, B. von Scholten², R. Bergholdt³, P. Rossing², T. Hansen²;

¹BiopharmQC New Haemophilia, Novo Nordisk A/S, ²Steno Diabetes Center, ³Diabetes Complications Biology, Novo Nordisk A/S, Gentofte, Denmark.

Background and aims: Diabetic nephropathy is characterized as a microvascular disease with enhanced vascular leakiness in the diabetic

kidney together with aberrant tissue remodelling. Abnormal number and function of endothelial cells, stem cells and activation of leukocytes is considered as contributing mechanisms to the “kidney-micro”-vascular leaky syndrome. We aim to determine if circulating endothelial pre- and mature cells, fibrocytes or monocyte sub-populations are abnormally regulated in type 2 diabetic patients with albuminuria.

Materials and methods: Cross-sectional study of 37 type 2 diabetic patients, 18 with normoalbuminuria (<30 mg/24 h) and 19 with albuminuria (≥30 mg/24 h) randomly selected from our outpatient clinic. 8-color flow cytometry (FACS analysis) of peripheral blood was performed. Analysis of covariance compared -expression of cell markers as well as absolute number of specific cell populations in patients with normoalbuminuria vs. albuminuria. Adjustment included age, sex, body mass index, total cholesterol, 24 h systolic blood pressure, smoking, HbA1c and eGFR.

Results: The cohort included 30% women, mean ± SD age was 62.4 ± 9.4 years, and median (interquartile range) UACR was 61.5 (10–234) mg/24 h. Expression of VEGFR2 was significantly enhanced in patients with albuminuria compared to normoalbuminuria (p=0.009). Also, the total number of circulating mature endothelial cells (CEC) was significantly enhanced in patients with albuminuria (p<0.001). Moreover, the circulating fibrocyte number and collagen-1 expression was inversely associated with presence of albuminuria (p≤0.037 for both). The TGFβ2 stabilizing and M2-associated galectin-3 expression on M1 and M0-M2 macrophages was positively associated with presence of albuminuria (p≤0.029 for all). In contrast, the expression of the M1-like marker CD11c (p=0.042) was inversely associated with presence of albuminuria on all macrophages and particularly on the M0-like macrophages (p=0.014).

Conclusion: The enhanced number of CEC together with elevated expression of VEGFR2 may indicate an aberrant function of the CEC with reduced capacity to heal the kidney microvascular disease. The imbalanced M2-polarization of macrophages may favour improper repair leading to excessive tissue fibrosis. Hence therapeutic approaches addressing migratory pattern of CEC, providing adjuvant activating signals and restoring immune balance might provide novel individualized treatment regimes.

1133

Systemic inflammation and glucose variability in type 2 diabetic patients with and without chronic kidney disease

V.V. Klimontov, N.E. Myakina, N.V. Tyan;

Scientific Institute of Clinical and Experimental Lymphology, Novosibirsk, Russian Federation.

Background and aims: A growing body of evidence indicates that chronic macrophage-mediated inflammation is involved in the pathogenesis of diabetic kidney disease. Furthermore, it was demonstrated that increased glucose variability (GV) can enhance the systemic inflammatory response in diabetes. The aim of our study was to assess the relationship between acute-phase and macrophage-related inflammatory markers and GV parameters in type 2 diabetic patients with and without chronic kidney disease (CKD).

Materials and methods: We observed 211 insulin-treated patients, 47 M/164 F, 43–70 years of age, HbA1c 8.4, 7.2–9.6% (median, 25th–75th percentile). Sixty four patients had estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m². The serum levels of high-sensitivity C-reactive protein (hsCRP), alpha1-acid glycoprotein (AGP), macrophage colony stimulating factor (M-CSF), macrophage inflammatory protein 1alpha (MIP-1alpha), macrophage migration inhibiting factor (MIF), as well as urinary albumin and type IV collagen were determined by ELISA and compared to control (30 healthy subjects). The parameters of GV were derived from the blinded continuous glucose monitoring (CGM) recordings. The values of nine GV indices were estimated, including lability index, M-value, J-index, continuous overlapping net glycaemic action, mean absolute glucose,

high blood glucose index, low blood glucose index, mean amplitude of glucose excursions and average daily risk range.

Results: The increased serum levels of hsCRP, AGP, M-CSF, MIP-1alpha and MIF were found in observed diabetic patients as compared to control (p<0.0001, p<0.0001, p<0.0001, p=0.03 and p=0.0006 respectively). The concentration of hsCRP correlated positively with AGP and M-CSF (r=0.44 and r=0.37, both p<0.01), AGP demonstrated correlations with M-CSF and MIP-1alpha (r=0.51 and r=0.4, both p<0.01). Concentrations of hsCRP, M-CSF and MIP-1alpha, as well as urinary type IV collagen, were higher in patients with reduced eGFR as compared to those without (p=0.04, p=0.02, p=0.02 and p=0.01 respectively). Serum AGP and M-CSF correlated positively with urinary albumin/creatinine ratio (r=0.39 and r=0.37 respectively, p<0.0001), meanwhile hsCRP, M-CSF and MIP-1alpha demonstrated weak relationships with type IV collagen excretion (r=0.31, r=0.37, r=0.4, all p<0.01). Subjects with reduced GFR did not differ from those without by mean monitored glucose and all investigated GV parameters. No relationships were found between concentrations of inflammatory markers and GV indices.

Conclusion: The serum levels of acute-phase and macrophage-related inflammatory proteins are associated with CKD in type 2 diabetic patients. The parameters of GV seem to be not related to inflammatory markers in these patients.

Type 2 diabetes is associated with greater carotid stiffness and greater pressure-dependency of carotid stiffness: The Maastricht Study

M.G.J. Veugen, R.M.A. Henry, T.T. van Sloten, E. Hermeling, H.-P. Brunner-La Rocca, M.T. Schram, P.C. Dagnelie, C.D.A. Stehouwer, K.D. Reesink; on behalf of The Maastricht Study group; Cardiovascular Research Institute Maastricht (CaRIM); MUMC+, Netherlands.

Background and aims: Arterial remodeling is considered an adaptive process aimed at maintaining mechanical arterial integrity under altered arterial environmental conditions, e.g. hypertension and hyperglycemia. This process has been shown operative in both impaired glucose metabolism and type 2 diabetes, but eventually may even become maladaptive leading to excessive arterial stiffening. A specific marker of arterial remodeling, hypothesized to be closely linked to structural alterations of the arterial wall itself, we propose is the pressure-dependency of arterial stiffness. The pressure-dependency of arterial stiffness is quantified as the systolic-diastolic difference in pulse wave velocity (δ PWV), with greater δ PWV signifying greater pressure dependency. Thus far, the relationship between arterial stiffness pressure dependency with deteriorating glucose metabolism status (GMS) has not been investigated. Therefore, we investigated in The Maastricht Study the associations of carotid arterial stiffness (cPWV) and the pressure-dependency of carotid arterial stiffness (δ PWV) with deteriorating GMS. Additionally, we investigated the interdependency of cPWV and δ PWV to evaluate whether arterial remodeling may act differentially upon cPWV and δ PWV.

Materials and methods: The study population consisted of 746 individuals (415 normal glucose metabolism [NGM], 126 impaired glucose metabolism [IGM] and 205 type 2 diabetes [T2D]). Each participant underwent carotid ultrasonography and tonometry to determine cPWV and δ PWV. Linear regression analyses were used to investigate the associations of cPWV and δ PWV with deteriorating GMS (NGM as reference category). Models were adjusted for age, sex, mean arterial pressure (MAP), anti-hypertensive medication, prior cardiovascular disease, eGFR, BMI and smoking and δ PWV or cPWV as appropriate.

Results: After adjustment for age, sex and MAP, T2D was associated with greater cPWV (β (95% CI; 0.377 (0.124; 0.629) and δ PWV (0.311 (0.027; 0.595)). Further adjustments did not change these associations materially. After additional adjustment for δ PWV or cPWV the associations of T2D with cPWV and δ PWV were attenuated (0.292 (0.051; 0.534) and 0.182 (-0.090; 0.454), respectively). IGM was not associated with either cPWV or δ PWV.

Conclusion: In T2D, but not in IGM, both cPWV and δ PWV were increased. These associations were only partially interdependent which suggests that the process of arterial remodeling may act differentially on carotid arterial stiffness and the pressure dependency of carotid arterial stiffness. This study hereby provides a pathophysiological framework to understand how arterial remodeling may shift from being adaptive to maladaptive with deteriorating GMS.

Hypertension among urban and rural type 2 diabetic subjects in Bangladesh

P.C. Banik¹, M. Moniruzzaman², F. Zaman³, L. Ali¹;

¹Noncommunicable Diseases, Bangladesh University of Health Sciences (BUHS), ²Injury Prevention and Disability, Country Office for Bangladesh, World Health Organization, ³Epidemiology, Bangladesh University of Health Sciences (BUHS), Dhaka, Bangladesh.

Background and aims: Hypertension is known to be more common among people with type 2 diabetes mellitus (T2DM), but the prevalence

and risk factors of the comorbidity vary from population to population. The present study was undertaken to estimate the proportion of hypertension among urban and rural Bangladeshi Type 2 diabetic subjects.

Materials and methods: An analytical cross-sectional study was conducted among 640 urban (M/F, 244/396; age in years, 52.23 \pm 11.8; BMI, 25.95 \pm 3.9 Kg/m²) and 560 rural (M/F, 244/396; age in years, 50.89 \pm 11.9; BMI, 24.13 \pm 4.6) subjects, selected purposively from various health care facilities in Dhaka and Northern Districts of Bangladesh. The World Bank criteria were followed for the selection of the urban and rural areas. Diagnosis of T2DM and hypertension was done by WHO Study Group Criteria (following a 2-sample OGTT) and WHO/ISH Guideline respectively. Data were collected by face-to-face interview and by physical examinations through interviewer administered pretested semi-structured questionnaire and check-list. Data were analyzed by univariate, bivariate and multivariate statistics as appropriate.

Results: Hypertension was present among 45.5% urban (95% CI, 41.6–49.4) and 43.6% rural (CI, 39.5–47.7) subjects. There was no significant difference in the proportion of hypertension between the two demographic locations. Males and females did not differ in the proportion of hypertension either in the urban or in the rural region. The trend in the proportion did not vary when the data were analyzed for systolic and diastolic hypertension separately. Urban hypertensive subjects had higher age compared to their normotensive counterparts (age in years, 53.85 \pm 10.5 vs 50.88 \pm 12.7; p <0.001). The rural hypertensive subjects showed similar difference in age (54.69 \pm 11.4 vs 47.95 \pm 11.5; p <0.001). The BMI of the hypertensive subjects (25.56 \pm 4.1 Kg/m²) was higher compared to normotensive (24.73 \pm 4.4 Kg/m²) and the difference was significant (p <0.001). The waist circumference (WC) of the hypertensive subjects (90.11 \pm 13.1 cm) was similarly higher compared to normotensive subjects (86.30 \pm 14.2 cm) and difference was significant (p <0.001). Physical activity was significantly less in hypertensive compared to the normotensive subjects (p =0.032). On Pearson correlation analysis hypertension correlated positively with WC (r =0.092, p <0.001), and duration of DM (r =0.122, p <0.001). On multiple regression analysis higher age (p <0.001, OR=1.036, CI, 1.025–1.048), greater WC (p <0.001, OR=1.014, CI, 1.004–1.025) and less physical activity (p <0.001, OR=1.396, CI, 1.098–1.775) were found as the main predictors of hypertension.

Conclusion: A large proportion of Type 2 diabetic subjects in Bangladesh, both males and females, irrespective of urban or rural origin, suffer from hypertension. Higher age, central obesity and reduced physical activity are the major predictors of hypertension in this population. Only an appropriate lifestyle intervention can minimize the risk of hypertension among T2DM subjects.

1136

Diastolic but not systolic orthostatic hypotension is associated with organ damage and with increased risk for cardiovascular complications in type 2 diabetes

M. Wijkman¹, T. Lindström², T. Länne², C. Östgren², F.H. Nystrom²;

¹Department of Internal Medicine and Department of Medical and Health Sciences, Linköping University, Norrköping, ²Department of Medical and Health Sciences, Linköping University, Linköping, Sweden.

Background and aims: Orthostatic hypotension (OH) is a marker for increased cardiovascular risk, and is common in patients with diabetes. It is likely that the diastolic and systolic components of OH represent two different clinical entities, but their respective impacts on cardiovascular prognosis have not been compared in patients with diabetes. The aim of this study was to determine the association between diastolic and systolic OH, respectively, with markers of macrovascular atherosclerosis and with subsequent cardiovascular prognosis, in a cohort of patients with type 2 diabetes.

Materials and methods: Office blood pressures were measured in the sitting and in the standing position in 749 patients with type 2 diabetes, as part of the baseline examination of the observational cohort study

CARDIPP (Cardiovascular Risk factors in Patients with Diabetes - a Prospective study in Primary care). Systolic OH was defined as a systolic blood pressure drop ≥ 20 mmHg, and diastolic OH was defined as a diastolic blood pressure drop ≥ 10 mmHg when rising from sitting to standing. Aortic pulse wave velocity (PWV) and carotid intima media thickness (IMT) measurements were performed at baseline. Patients were treated in usual care at their primary health care centers, and were followed until any of the primary endpoint events (fatal or non-fatal myocardial infarction or stroke, or cardiovascular death) occurred or until 31 December 2012.

Results: Among the 749 study participants, 18 had systolic OH only, 25 had diastolic OH only, and 6 had combined systolic and diastolic OH. Patients with diastolic OH had significantly higher PWV than patients without diastolic OH (11.3 m/s vs. 10.3 m/s, $P=0.030$), but there was no significant difference between patients with systolic OH and patients without systolic OH (11.0 m/s vs. 10.4 m/s, $P=0.145$). Likewise, carotid IMT was significantly higher in patients with diastolic OH than in patients without diastolic OH (0.83 mm vs. 0.73 mm; $P=0.002$), but did not differ significantly between patients with systolic OH and patients without systolic OH (0.74 mm vs. 0.79 mm, $P=0.138$). During a median follow-up time of 5.9 years, there were 48 primary endpoint events. The presence of diastolic OH was a significant predictor of cardiovascular complications (crude hazard ratio: 3.321; 95% CI: 1.412 - 7.815; $P=0.006$), but the presence of systolic OH was not (crude hazard ratio: 0.636; 95% CI: 0.088 - 4.609, $P=0.654$). When treated as a continuous variable, diastolic blood pressure drop from sitting to standing was significantly associated with increased risk for cardiovascular complications (crude hazard ratio per 1 mmHg: 1.048; 95% CI: 1.007 - 1.091; $P=0.020$), but systolic blood pressure drop was not (crude hazard ratio per 1 mmHg: 1.002; 95% CI: 0.976 - 1.028; $P=0.894$).

Conclusion: In patients with type 2 diabetes, diastolic OH is associated with more severe atherosclerosis, and with an increased risk for macrovascular diabetes complications. On the contrary, we found no significant associations between systolic OH and degree of atherosclerosis or prognosis. Diastolic OH is easily diagnosed in the usual clinical setting, and our data suggest that it is a useful marker to detect patients at higher risk for macrovascular diabetes complications.

Clinical Trial Registration Number: NCT01049737

1137

Baroreceptor stimulation enhanced vessel sensitivity to nitric oxide-mediated vasodilation, implications for treatment of diabetes and the metabolic syndrome

J. Gmitrov;

National Institute of Public Health, Tokyo, Japan. Pro Vitae and Krompachy Hospital Agel SK Inc., Gelnica, Slovakia.

Background and aims: Increasing evidence suggests endothelial nitric oxide (NO) deficit and baroreflex dysfunction to be characteristic for diabetic and cardiovascular conditions ranging from arterial hypertension to stroke and coronary heart disease with deleterious impact on morbidity and mortality. To test the hypothesis that arterial baroreflex has a modulatory effect on NO-dependent vasodilation the magnitude of the cutaneous vasodilator response to sodium nitroprusside (SNP), a spontaneous NO donor, was determined in relation to increase in baroreflex sensitivity (BRS) generated by carotid baroreceptor magnetic activation and potential implementation in NO deficiency states.

Materials and methods: Mean femoral artery blood pressure (MAP), heart rate (HR) and ear lobe skin microcirculatory blood flow, measured by microphotoelectric plethysmogram (MPPG), were simultaneously recorded in conscious rabbits before and after 40-min sinocarotid baroreceptor exposure to 350 mT static magnetic field (SMF), generated by Nd-Fe-B alloy ($n=8$) or sham magnets ($n=8$, controls). Arterial baroreflex sensitivity (BRS) was measured by changes in HR and MAP ($\Delta HR / \Delta MAP$) after intravenous bolus injections of SNP and phenylephrine.

Results: SMF sinocarotid baroreceptor exposure significantly increased BRS, HR variability and decreased phenylephrine MAP ramps. The vasodilatory effect of SNP was markedly enhanced after SMF exposure (MPPGbeforeSMF: 2.57 ± 0.81 V vs. MPPGafterSMF: 7.82 ± 1.61 V, $p < 0.0001$), Figure 1, and positively correlated with increase in BRS ($r=0.51$, $p=0.01$).

Conclusion: The important and novel findings demonstrated in this study are that arterial baroreflex modulates NO-mediated vasodilation and that sinocarotid baroreceptor magnetic stimulation improved vessel sensitivity to NO vasodilatory effect. These may synergistically reinforce the reciprocal cross-talk relationship between insulin resistance and NO deficit arguing for baroreceptor stimulation in cardiometabolic conditions such as diabetes and the metabolic syndrome where unresponsiveness of vascular smooth muscle cells to NO amplifies deleterious consequences of the reduced endothelial NO availability importantly contributing to autonomic dysfunction, arterial hypertension and the non-lipid residual cardiovascular risk.

BARORECEPTOR STIMULATION ENHANCED SODIUM NITROPRUSSIDE (NITRIC OXIDE - DONOR) VASODILATOR RESPONSIVENESS

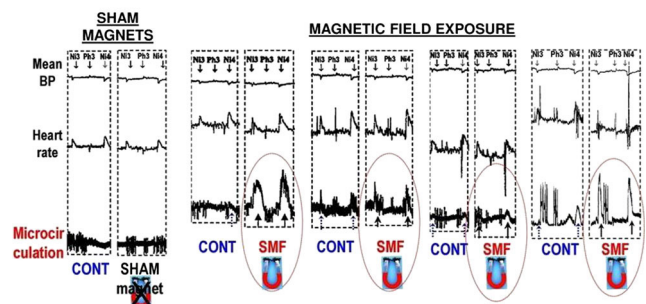

Figure 1. Segments of five experimental recordings after local exposure of sham magnets (SHAM, control experiment) or static magnetic field (SMF) to sinocarotid baroreceptors. (Ni3, 10.0; Ni4, 30.0) and (Ph3, 3.0), doses of sodium nitroprusside and phenylephrine ($\mu\text{g}/\text{kg}$), respectively, given by intravenous bolus injections for BRS testing. CONT, initial readings.

A notable increase of the vasodilation in response to same dose sodium nitroprusside after sinocarotid baroreceptor magnetic stimulation is obvious.

1138

LEADER-4: blood pressure control in patients with type 2 diabetes and high cardiovascular risk: baseline data from the trial

J.R. Petrie, on behalf of the LEADER investigators; University of Glasgow, UK.

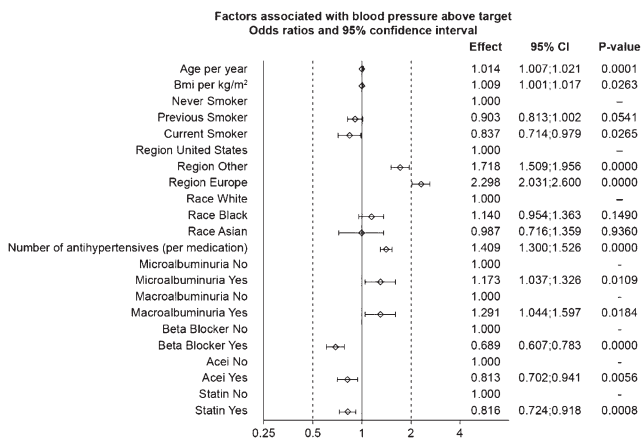

Background and aims: Blood pressure (BP) control is a key strategy for reducing cardiovascular (CV) and renal complications in patients with type 2 diabetes mellitus (T2DM). As a result, treatment guidelines include disease-specific targets but these can be difficult to achieve even with multiple antihypertensive agents. For patients with T2DM who are also obese, there is limited knowledge about the percentage whose BP reaches target and the factors associated with non-achievement of target.

Materials and methods: We collected data on BP control at baseline (2010-2012) and demographic/anthropometric characteristics from the Liraglutide Effect and Action in Diabetes; Evaluation in Cardiovascular outcomes Results (LEADER) trial. LEADER is an ongoing Phase 3B randomized, double-blind, placebo-controlled CV outcome trial examining the safety and efficacy of the GLP-1 receptor agonist liraglutide in 9340 people with T2DM from 32 countries (including USA, Europe, Asia and other countries). Mean (\pm SD) age was 64 ± 7.2 years; BMI 32.5 ± 6.3 kg/m^2 ; duration of diabetes 12.7 ± 8.0 years; 81% had suffered

a previous CV event. We analysed factors associated with BP control using multiple logistic regression models in order to assess the association between dichotomized 'off-target' hypertension endpoints and predefined explanatory factors.

Results: 91% of participants had a history of hypertension but only 51% were treated to a target BP of <140/85 mmHg [European Society of Hypertension (ESH)/ European Society of Cardiology (ESC) 2013] and only 26% to the predefined BP target of <130/80 mmHg (ESH/ ESC guideline 2007). This was despite prescription of multiple antihypertensive agents: 61% of patients were on two or more agents and 19% on three or more. Those with a previous CV event had lower BP than those without ($137\pm 18.8/78\pm 10.6$ mmHg vs. $140\pm 17.7/80\pm 9.9$ mmHg; $p < 0.001$) and were prescribed more antihypertensive agents ($p < 0.001$). BP control was better in the US than Europe with a higher proportion achieving a BP target of 140/85 mmHg (63% vs. 42%, $p < 0.0001$) and a BP target of <130/80 mmHg (37% vs. 20%, $p < 0.0001$); this was not readily explained by baseline demographics or the intensity of antihypertensive therapy. In multifactorially adjusted logistic regression analyses, principal characteristics associated with poorer BP control were: region of residence, smoking status, and number of antihypertensive agents (Figure).

Conclusion: These data confirm that even with modern antihypertensive agents, BP is frequently poorly controlled in individuals with long-standing T2DM, including individuals who are also obese. The LEADER trial will provide important information on the effects of the GLP-1 receptor agonist liraglutide on BP and other CV risk factors in relation to CV safety and outcomes in this patient population.

Remodelling of the aorta and kidney in L-NAME-induced hypertension in rats: comparison of the protective effect of ivabradine with captopril and melatonin

F. Simko, K. Repova, K. Krajcovicova, S. Aziriova, L. Paulis, T. Baka; Institute of Pathophysiology, School of Medicine, Comenius University, Bratislava, Slovakia.

Background and aims: Ivabradine was recently proven to reduce morbidity and mortality in patients with heart failure. It is supposed that its benefit is achieved through the reduction of heart rate via blockade of the If-channel in sinoatrial node. Besides the heart rate reduction, ivabradine seems to reduce afterload potentially through its antiproliferative effect on the aorta. The aim of our experiment was to show the effect of ivabradine on morphometry of the aorta and kidney and to compare ivabradine with well established protectives - angiotensin converting enzyme (ACE) inhibitor captopril and melatonin.

Materials and methods: 72 male Wistar rats were divided into 6 groups: controls (C), ivabradine (10 mg/kg/day) (Iv), N ω -Nitro-L-arginine methyl ester (40 mg/kg/day) (L-NAME), L-NAME+ivabradine (L-NAME+Iv), L-NAME+captopril (100 mg/kg/day) (L-NAME+Cap), L-NAME+melatonin (10 mg/kg/day) (L-NAME+Mel). Drugs were administered in drinking water for 4 weeks. Systolic blood pressure (SBP) and heart rate (HR) were measured (by tail-cuff method) once a week. After 4 weeks of the therapy rats were killed and organs (heart, aorta, kidney) were removed and processed for morphometric and biochemical investigation. One-way analysis of variance (ANOVA) and the Bonferroni test were used for statistical analysis. Differences were considered significant if the p value <0.05.

Results: Ivabradine significantly ($p < 0.05$) reduced SBP in Iv (by 21%) and in L-NAME (by 19%) and markedly reduced HR in both Iv and L-NAME (by 26% and 21%, respectively). Ivabradine did not affect the wall thickness (WT) and cross-sectional area (CSA) of the aorta in neither controls nor in L-NAME. Captopril reduced SBP and WT in L-NAME but HR and CSA remained unchanged. Melatonin reduced both SBP (by 14%) and HR (by 10%) without any effects on WT or CSA. Enhancement of glomerular tuft area (AG) in L-NAME was decreased by ivabradine (by 8%) and captopril (by 7%). Density of glomeruli was decreased by ivabradine (16%), captopril (19%) and melatonin (14%).

Conclusion: Ivabradine reduced HR, SBP and modified kidney remodelling in L-NAME-induced hypertension, without influencing the remodelling of the aorta.

Sitagliptin and risk of hypertension in patients with type 2 diabetes mellitus: meta-analysis of randomised trials

B. Zhang, Z. Lu;

Department of Neurology, the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

Background and aims: Recent reports of sitagliptin use have raised questions about whether the sitagliptin have beneficial effect on blood pressure of type 2 diabetes mellitus (T2DM) patients. The aim of this meta-analysis was to evaluate the effect of sitagliptin on hypertension.

Materials and methods: We searched PubMed, MEDLINE, EMBASE, the Cochrane Central Register of Controlled Trials, and product information sheets for randomized controlled trials, systematic reviews, and meta-analyses published through December 2012. Studies were included if they were randomized controlled trials of sitagliptin vs placebo or active comparator for T2DM patients also monitored hypertension. Relative risks of hypertension events were estimated using a fixed-effects meta-analysis.

Results: We analyzed 8 randomized controlled trials. Compared with placebo therapy and control therapy, sitagliptin had no significant increase in risk of hypertension ($n=46/2381$ vs $39/2224$; RR 0.99; 95% CI, 0.65 - 1.52; $P=0.97$). The risk of hypertension was slightly lower in the sitagliptin group than in the placebo group, but the difference was not statistically significant ($n=27/1459$ vs $19/694$; RR 0.72; 95% CI, 0.40 - 1.29; $P=0.27$). Conversely, the risk of hypertension was slightly higher in the sitagliptin group than in the control therapy group, but the difference was not statistically significant ($n=19/922$ vs $20/1530$; RR 1.48; 95% CI, 0.76 - 2.86; $P=0.25$). There was no evidence of substantial heterogeneity among the trials ($I^2=41%$, $I^2=28%$, and $I^2=46%$, respectively).

Conclusion: Sitagliptin has no beneficial or harmful effect on hypertension in the treatment of T2DM.

PS 114 Diabetic complications: beyond the vasculature

1141

The changes of the mitochondria in the lung parenchyma in streptozotocin-induced diabetes

O. Pivovaro¹, E. Rozova², B. Mankovsky³;

¹Kyiv Medical University of UAFM, ²Bogomoletz Institute of Physiology, ³P.L. Shupyk National Medical Academy of Postgraduate Education, Kyiv, Ukraine.

Background and aims: There is growing body of evidence that lungs represent another target for diabetic complications. However, the pathogenetic mechanisms of lung damage in diabetes mellitus remain not fully understood. The damage of mitochondria can be one of the underlying mechanisms of the development of this complication. Therefore, the aim of this study was to investigate ultrastructural features of mitochondria in pulmonary tissue in the streptozotocin (STZ)-induced diabetes.

Materials and methods: The study was performed on 47 STZ-induced diabetic and 43 control male Wistar rats. Diabetes was induced by single intraperitoneal injection of STZ 60 mg/kg in 0.1 M citrate buffer, pH-4.5. The tissue for the further evaluation was collected after 18 weeks of diabetes. The diabetic rats were not treated with insulin. The morphometric assessment was performed using the electron microscope PEM-125 K and the data were analyzed using the software Image Tool Version 3 (USA).

Results: We found swelling and clarification of the mitochondrial matrix, the intercrystalline intervals enlargement without change of the space between the internal and external membranes which corresponded to a reduced generation of adenosine triphosphate, fragmentation and decondensation of the mitochondrial membrane in the lung tissue in STZ-induced diabetic rats compared to non-diabetic rats. The total number of mitochondria in the lung tissue was not significantly different in STZ-induced diabetic rats compared to control group - $10,1 \pm 0,4$ U/ μm^2 and $9,6 \pm 0,3$ U/ μm^2 , respectively, $p > 0,05$. However, it was found an increased number of structurally damaged mitochondria per μm^2 of the lung parenchyma - $15,3 \pm 0,8\%$ and $4,6 \pm 0,4\%$, in STZ-induced diabetic rats and control group respectively, $p < 0,001$. There were no signs of morphogenesis activation. Also, it was an increase of the average diameter of the mitochondria in the diabetic rats compared to controls - $0,64 \pm 0,05$ μm and $0,39 \pm 0,04$ μm , respectively, $p < 0,01$.

Conclusion: Experimental STZ-induced diabetes mellitus leads to the morphological changes of mitochondria in the lung parenchyma. The revealed mitochondrial dysfunction could be one of the possible mechanisms of the lung damage observed in diabetes mellitus.

1142

Carbon monoxide in exhaled air and the development of vascular complications in type 2 diabetes

V.I. Tkachenko;

Department of Family Medicine, Shupyk National Medical Academy of Postgraduate Education, Kiev, Ukraine.

Background and aims: Decompensated diabetes leads to high levels of glycosylated hemoglobin (HbA1c), which forms close bond with oxygen and cause tissue hypoxia. On the other hand the catabolism of heme-containing compounds and proteins, lipid peroxidation, cetogenesis and other metabolic transformations lead to formation of endogen carbon monoxide (CO) that form carboxyhemoglobin and exacerbates tissue hypoxia and development of angiopathy in diabetes. The aim of our research is to study the level of CO in exhaled air and the development of vascular complications in patients with type 2 diabetes.

Materials and methods: We examined 53 patients with type 2 diabetes (age 57.5 ± 1.18 years, 39 women and 14 men, diabetes duration 6.1 ± 2.1 years) and 26 patients without diabetes (age 59.5 ± 2.18 years, 18 women and 8 men) who did not smoke and have no respiratory or blood diseases. All patients underwent clinical and laboratory examination: HbA1c levels, lipid profile, C-reactive protein, urinary albumin/creatinine ratio. CO in exhaled air was performed using Smokelyzer Bedfont Scientific Micro +. Doppler of carotid arteries was done to register diabetes complications. Statistical analysis - using Excell 2007, SPSS.

Results: The patients with type 2 diabetes had significantly higher fasting glucose (9.4 ± 0.5 mmol/l, $p < 0.01$) and HbA1c ($7.6 \pm 0.4\%$, $p < 0.05$) in contrast to comparison group (glucose = 5.3 ± 0.4 mmol/l, HbA1c = $5.5 \pm 0.1\%$). Violation of lipid metabolism was also confirmed by significant differences in triglyceride levels (1.08 ± 0.07 mmol/l) and levels of very low-density lipoproteins (VLDL = 0.5 ± 0.03 mmol/l) in patients with diabetes, in contrast to comparison group (triglyceride = 0.8 ± 0.1 mmol/l, VLDL = 0.4 ± 0.03 mmol/l, $p < 0.01$). The level of urinary albumin/creatinine ratio was significantly higher in diabetes patients (2.9 ± 0.6 mg/mmol), in contrast to comparison group (1.1 ± 0.2 mg/mmol, $p < 0.05$) that shows endothelial dysfunction, the initial glomerular and vascular changes, and is known marker of atherosclerosis and cardiovascular events. In this situation, patients with diabetes had significantly higher CO levels in exhaled air (1.9 ± 0.2 ppm, $p < 0.05$), in contrast to comparison group (1.5 ± 0.1 ppm), which had significantly direct correlation with urinary albumin/creatinine ratio ($p < 0.01$), HbA1c ($p < 0.05$) and confirms direct relationship of hyperglycemia, endothelial dysfunction and CO levels in exhaled air. Significant thickening of intima/media in patients with type 2 diabetes was determined by Doppler of carotid artery, which has direct correlation with total cholesterol ($p < 0.05$), LDL ($p < 0.05$), HbA1c ($p < 0.05$) and was inversely related to HDL level ($p < 0.01$); atherosclerotic plaques with restriction of blood flow were identified in 21% of diabetes patients. Our data confirm the significant relationship between glucose metabolism, endothelial dysfunction, microvascular and macrovascular complications, atherosclerosis and level of CO in exhaled air.

Conclusion: Defined in patients with type 2 diabetes significantly higher glucose levels, HbA1c level, urinary albumin/creatinine ratio, which correlated with significantly higher CO levels in exhaled air, suggests a direct relationship between hyperglycemia, endothelial dysfunction and CO levels in exhaled air. Determination of CO in exhaled air is composed of non-invasive method and can be used to analyze the development angiopathy and cardiovascular complications in general practice.

1143

Prevalence, associates and prognostic significance of abnormal pulmonary function in type 2 diabetes: the Fremantle Diabetes Study Phase II

T.M.E. Davis, J. Drinkwater, W.A. Davis;

School of Medicine and Pharmacology, University of Western Australia, Fremantle, Australia.

Background and aims: We found previously that type 2 diabetes (T2DM) was associated with reduced pulmonary function in the community-based observational Fremantle Diabetes Study Phase I (FDS1) in patients recruited between 1993 and 1996. Since clinical management, complications and methods of spirometric data assessment have changed over the last two decades, we re-examined the prevalence, associates and prognostic significance of abnormal pulmonary function in a larger, contemporary sample of community-based patients with T2DM from the same geographical area as FDS1.

Materials and methods: We used baseline data including spirometry from the FDS Phase II (FDS2) collected between 2008 and 2011. Mortality data were available through validated health service linkage to end-June 2013. The highest forced expiratory volume in the first second

(FEV1) and forced vital capacity (FVC) from three recordings/patient were used in analyses. Predicted values and lower limits of normal (LLN; z-score < -1.96) were determined using Quanjer Global Lungs Initiative 2012 reference equations which are based on sex, age, height and ethnicity. Multivariable linear regression was used to assess independent associates of lung function measures. Cox proportional hazard modelling was used to determine whether FEV1 and FVC predicted mortality.

Results: Of 1,551 participants, 1,393 (89.8%) performed acceptable lung function tests. Of these patients, 109 (7.8%) died during a mean \pm SD of 3.7 ± 1.0 years (5,106 patient-years) of follow-up. The mean \pm SD FEV1 and FVC as percentage predicted were $82.6 \pm 18.9\%$ and $85.7 \pm 17.4\%$, respectively, and 294 (21.1%) and 238 (17.1%), respectively, had FEV1 and FVC values below the LLN. After adjusting for other variables including a history of respiratory disease, body mass index and smoking, the diabetes-related independent inverse predictors of both FEV1 and FVC were diabetes duration, HbA1c, ln(urinary albumin:creatinine), self-reported ischaemic heart disease, and peripheral arterial disease (ankle:brachial index ≤ 0.90) ($P \leq 0.037$ in each case). Although FEV1 and FVC as percentages of predicted were bivariate associated with mortality ($P \leq 0.001$), neither variable was an independent predictor of death in a fully adjusted model.

Conclusion: These spirometric data, derived from contemporary validated predictive equations, confirm that T2DM is associated with a restrictive lung defect, especially in those patients with long duration of disease, poor glycaemic control, and both micro- and macrovascular complications of diabetes. Abnormal pulmonary function is not an independent predictor of short-term mortality in T2DM.

Metformin protects against homocysteine-induced apoptosis of osteocytic MLO-Y4 cells by activation of AMP-activated protein kinase

I. Kanazawa, A. Takeno, K.-I. Tanaka, M. Notsu, M. Yokomoto, T. Yamaguchi, T. Sugimoto;

Internal Medicine 1, Shimane University Faculty of Medicine, Izumo, Japan.

Background and aims: Homocysteine (Hcy) is a sulfur-containing amino acid formed by the demethylation of methionine. Hcy is reported to be significantly increased in patients with diabetes mellitus, and it is an emerging risk factor for diabetic complications such as diabetic nephropathy and cardiovascular disease. On the other hand, accumulating evidence has shown that the risk of osteoporotic fractures is increased in type 2 diabetes mellitus. Previous studies have shown that elevated plasma Hcy level is associated with the risk of osteoporotic fracture. Osteocytes are the most abundant cells in the bone, and they play important roles in coordinating the functions of osteoblasts and osteoclasts. However, to our best knowledge, no study has described the effects of Hcy on osteocytes. While Hcy increases oxidative stress, AMP-activated protein kinase (AMPK) activation ameliorates it, suggesting that an AMPK activator, metformin, may rescue the adverse effects of Hcy on osteocytes. This study aimed to investigate whether Hcy induces apoptosis of osteocytes through regulating expressions of oxidant and anti-oxidant enzymes and determine the effects of AMPK activation by metformin and 5-aminoimidazole-4-carboxamide-1- β -D-ribofuranoside (AICAR) on the Hcy-induced apoptosis of the cells.

Materials and methods: MLO-Y4, a murine long bone-derived osteocytic cell line, was used. DNA fragment ELISA and TUNEL staining assays were performed to detect the apoptosis of the cells. Real-time PCR and western blot analysis were performed to examine the expression of NADPH (Nox) oxidase and superoxide dismutase (SOD).

Results: DNA fragment ELISA and TUNEL staining assays showed that Hcy treatments (0.1–5.0 mM) induced apoptosis of MLO-Y4 cells in a

dose-dependent manner. The detrimental effect of Hcy was partly but significantly reversed by an antioxidant (N-acetylcysteine) and NADPH oxidase (Nox) inhibitors (apocynin and diphenyleneiodonium). In addition, metformin (10–100 μ M) and treatment with AICAR (0.05–0.1 mM) ameliorated Hcy-induced apoptosis of the cells. The favorable effect of metformin on Hcy-induced apoptosis was completely cancelled by an AMPK inhibitor Ara-A. Hcy increased the expression levels of Nox1 and Nox2, while it had no effects on the expressions of Nox4 or the anti-oxidant enzymes, SOD1 and SOD2. Hcy-induced increases in the expressions of Nox1 and Nox2 decreased significantly by treatments with AICAR.

Conclusion: These findings suggest that Hcy induces apoptosis of osteocytes by increasing the expression of Nox1 and Nox2, and metformin effectively prevents the detrimental reactions via AMPK activation.

1145

Wnt/b-catenin pathway downregulation, indicated by increased dickkopf-1 in type 1 diabetes, is probably associated with lower bone mineral density

K. Karavanaki¹, C. Tsentidis¹, L. Kossiva¹, A. Marmarinos², A. Doulgeraki³, D. Gourgiotis²;

¹Diabetic clinic, 2nd dept. of paediatrics, ²Biochemistry Laboratory, 2nd dept. of paediatrics, Athens University, ³Department of Bone and Mineral Metabolism, Institute of Child Health, Athens, Greece.

Background and aims: Diabetes Mellitus disrupts many bone metabolic pathways, predisposing to reduced bone mass. Increased fracture risk and elevated Dickkopf-1 and sclerostin levels, which are inhibitors of Wnt/ β -catenin pathway, have been documented in adult patients with T2DM; however no relevant data exist on childhood T1DM. We aimed to study plasma Dickkopf-1 and sclerostin concentrations in children and adolescents with T1DM and controls and to correlate them with metabolic bone markers and bone mineral density (BMD).

Materials and methods: We evaluated 40 children and adolescents with T1DM (mean \pm SD age:13.04 \pm 3.53 years, T1DM duration:5.15 \pm 3.33 years), along with 40 healthy matched controls (age 12.99 \pm 3.3 years). Dickkopf-1, Sclerostin, Receptor Activator of Nuclear factor-KappaB Ligand(s-RANKL), Osteoprotegerin, Osteocalcin, C-telopeptide crosslinks-CTX, electrolytes, PTH, total 25(OH)D were measured and lumbar spine and total body BMD were evaluated.

Results: BMD was found lower and Dickkopf-1 levels were found higher (13.56 \pm 5.34 vs 11.35 \pm 3.76 pmol/L, $p=0.0194$) in T1DM patients than controls. A trend for lower values was found in girls (13.36 \pm 4.04 vs 11.72 \pm 5.14 pmol/L, $p=0.06$) and in pubertal children (13.61 \pm 4.87 vs 11.83 \pm 4.56 pmol/L, $p=0.054$). Dickkopf-1 correlated with Sclerostin and L1-L4 BMD z-score only in controls and with Osteoprotegerin and i-Phosphorus only in patients, while in both groups a significant correlation with log(CTX) and \sqrt ALP was documented. A significant correlation of Dickkopf-1 with IGF-1 and insulin dose was also found in patients.

Conclusion: Higher levels of Dickkopf-1 were found in T1DM children and adolescents, indicating a downregulated Wnt signaling system and possible lower osteoblast activation that could be associated with T1DM osteopathy.

1146

FGF-23 in type 1 diabetes: the potential role of mineral metabolism in arterial stiffness

G. Llauro^{1,2}, A. Megia^{3,2}, A. Cano⁴, O. Giménez-Palop⁴, I. Simón^{3,2}, M. González-Sastre⁵, E. Berlanga⁶, J. Vendrell^{3,2}, J.-M. González-Clemente^{4,2};

Corporació Sanitària i Universitària Parc Taulí (Universitat Autònoma de Barcelona), Sabadell, Spain.

Background and aims: Existing evidence suggests that an abnormal mineral metabolism, and particularly vitamin D deficiency, may promote atherosclerosis. However, the discovery of fibroblast growth factor 23 (FGF-23) has introduced a new perspective linking vitamin D metabolism and cardiovascular (CV) disease. FGF-23 is an endocrine peptide that regulates mineral metabolism and is directly associated with adverse CV outcomes. Our aim was to investigate the likely relationship between FGF-23 and vitamin D with arterial stiffness (AS), as an early sign of atherosclerosis, in a group of subjects with type 1 diabetes (T1DM) without previous clinical cardiovascular disease.

Materials and methods: 68 T1DM patients and 68 age- and sex-matched controls were evaluated for: 1) age, sex, diabetes duration, physical activity, smoking, alcohol intake, BMI, BP, fasting plasma glucose, HbA_{1c}, estimated glomerular filtration rate (eGFR) and lipid profile, 2) microvascular complications, 3) concentrations of FGF-23 and mineral metabolism parameters (calcium, phosphate, parathyroid hormone (PTH) and 25-hydroxy-vitamin D (25(OH)D)), 4) AS, assessed as aortic pulse wave velocity (aPWV), and 5) low-grade inflammation (hsCRP, IL-6, sTNF α R1, sTNF α R2) and endothelial dysfunction (ED) markers (ICAM-1, VCAM-1, E-Selectin).

Results: Subjects with T1DM had higher aPWV compared with healthy controls (6.8(6.0-7.9)m/s vs. 6.1(5.5-6.7)m/s; $p<0.001$), but they did not present differences in 25(OH)D (28.3(23.9-33.3)ng/mL vs. 28.1(20.2-34.5)ng/mL; $p=0.462$) and in FGF-23 plasma concentrations (70.1(38.4-151.9)RU/ml vs. 77.6(51.8-113.9)RU/ml; $p=0.329$). In patients with T1DM, higher concentrations of FGF-23 were positively associated with aPWV after adjusting for eGFR and classical cardiovascular risk factors (model 1: $\beta=0.202$, $p=0.026$), other mineral metabolism parameters (model 2: $\beta=0.214$, $p=0.015$), microvascular complications, low-grade inflammation and ED markers (model 3: $\beta=0.170$, $p=0.045$). Lower 25(OH)D concentrations were also associated with higher aPWV after adjusting for FGF-23 and all the above-mentioned factors (model 3: $\beta=-0.241$, $p=0.015$).

Conclusion: We conclude that both FGF-23 plasma concentrations (positively) and 25(OH)D serum concentrations (negatively) are associated with AS in subjects with T1DM and no previous clinical cardiovascular disease.

Impaired balance ability, particularly one-leg stand evaluation, is associated with diabetic complications even in younger adults with type 2 diabetes

D. Kukidome¹, M. Sato¹, S. Shimoda¹, T. Nishikawa^{1,2}, E. Araki¹;
¹METABOLIC MEDICINE, FACULTY OF LIFE SCIENCES, ²Community medicine, KUMAMOTO UNIVERSITY SCHOOL OF MEDICINE, Kumamoto, Japan.

Background and aims: Elderly individuals with diabetes were at greater falls risk, but probability for falls among younger adults with diabetes is unknown. Several clinical balance tests have been reported to be a useful predictor of falls among older adults. Our aims of this study are 1) to characterize the balance ability of subjects aged 30 and older with type 2 diabetes (T2D) compared with non-diabetic control subjects, 2) to investigate the relevance between the balance ability and diabetic complications among subjects with T2D.

Materials and methods: Two static balance tests, one-leg stand (OLS) and outer area of postural sway while standing (OAPS), and two dynamic balance tests, timed up and go test (TUG) and functional reach test (FR), were measured in 115 T2D subjects and 51 non-diabetic subjects. All subjects were interviewed for a history of falls, and were divided into six groups with age: younger (60 years) T2D (n=55), or older control (n=15). In comparison of balance ability among the different groups, Mann-Whitney test or Kruskal-Wallis test were used.

Results: T2D subjects had significantly lower balance ability compared with non-diabetic subjects in all four balance measures (OLS; 44.8 vs 60.0 sec, OAPS; 1.83 vs 1.25 cm², TUG: 7.3 vs 5.8 sec, FR 0.189 vs 0.230, all P<0.01). In subjects with T2D, the balance ability assessed by measuring OLS and OAPS decreased gradually with retinopathy progression (OLS; 52.9, 42.8, 10.3 sec, P<0.01, OAPS; 1.67, 1.94, 3.08 cm², P<0.01 in no retinopathy, simple retinopathy, or either preproliferative or proliferative retinopathy, respectively). Subjects with diabetic neuropathy showed a lower balance ability assessed by OLS (30.0 vs 57.5 sec, P<0.01), OAPS (1.65 vs 2.11 cm², P<0.05) and TUG (6.7 vs 7.5 sec, P<0.05) compared with those without diabetic neuropathy. Furthermore, T2D subjects with a falls history (n=9) had a longer duration of diabetes (18.3 vs 9.7 years, P<0.05), a shorter time of OLS (6.1 vs 46.6 sec, P<0.01) and a longer time of TUG (9.7 vs 7.2 sec, P<0.01) compared with those without a falls history. Even in younger and middle-aged T2D subjects, the OLS, TUG and FR evaluation showed lower balance ability, compared with those of age-matched non-diabetic subjects (in younger OLS; 52.7 vs 60.0 sec, TUG; 6.8 vs 5.3 sec, FR; 0.197 vs 0.240, in middle-aged OLS; 57.5 vs 58.1 sec, TUG; 6.9 vs 5.8 sec, FR; 0.192 vs 0.238, all P<0.01, respectively).

Conclusion: Subjects with T2D, even in younger adults, had impaired balance ability. OLS was closely associated with the severity of diabetic neuropathy and retinopathy in every aged group, and the previous falls history. Therefore OLS may be the most suitable clinical measurement for evaluating balance ability and falls risks among subjects with T2D.

Severe vertebral fracture and low osteocalcin level increase the mortality in postmenopausal women with type 2 diabetes mellitus

H. Miyake, I. Kanazawa, T. Sugimoto;
 Internal Medicine 1, Shimane University Faculty of Medicine, Izumo, Japan.

Background and aims: Accumulating evidence has shown that patients with type 2 diabetes mellitus (T2DM) have an increased risk of osteoporotic fracture independently of bone mineral density. Although osteoporotic fractures such as hip fracture and vertebral fracture (VF) are known to increase mortality in general population, there are no studies

investigating whether the fractures influence the mortality of patients with T2DM. On the other hand, previous studies have shown that osteocalcin, which is secreted from osteoblasts, has a hormonal function improving glucose tolerance by increasing insulin secretion and sensitivity. Because serum osteocalcin levels are decreased in diabetic patients, we hypothesized that serum osteocalcin may be associated with the mortality. Therefore, the aim of this study was to examine whether the presence of VF and bone turnover markers including osteocalcin were associated with the mortality in postmenopausal women with T2DM.

Materials and methods: This is a historical cohort study with the endpoint of all-cause mortality in postmenopausal women with type 2 diabetes. We recruited 190 postmenopausal women with T2DM who previously underwent lateral X-ray examination of thoracic and lumbar spine to check VF from 1993 to 2009 at Shimane University Hospital. A VF was diagnosed if at least one of three height measurements along the length of the same vertebrae had decreased by >20% compared to the height of the nearest uncompressed vertebral body. VFs were classified as follows; grade 1 (G1), a reduction of 20-25%; G2, 25-40%; G3, more than 40%. The participants were observed up to 7 years, and the association between VF and bone turnover markers versus all-cause mortality was explored using Kaplan-Meier method, logrank test, and Cox regression analysis.

Results: At the entry of this study, mean age and duration of diabetes were 67.5 and 12.3 years, respectively. Mean serum osteocalcin level was 6.9 ng/mL, and 54 patients (28.4%) had vertebral fractures. Of 190 subjects, 19 patients died during the observation period. Logrank tests showed that lower serum osteocalcin (<6.5 ng/mL), multiple and G3 VFs were associated with higher mortality compared to higher osteocalcin (≥6.5 ng/mL) or non VFs, respectively (at least p<0.01). Moreover, age-adjusted Cox regression analyses showed that G3 VF was significantly associated with the mortality [relative risk (RR)=3.7, 95% confidence interval (CI)=1.1-13.0, p=0.04] and multiple VFs were marginally with it (RR=2.8, 95%CI=0.9-8.7, p=0.08) compared to non VFs, and that serum osteocalcin was significantly associated with age-adjusted mortality (Hazard ratio (HR)=0.36, 95%CI=0.16-0.80 per SD increase, p=0.012). Moreover, the association of osteocalcin and mortality was still significant even after additional adjustment for duration of diabetes mellitus, body mass index, HbA1c, and serum creatinine (HR=0.30, 95%CI=0.11-0.80 per SD increase, p=0.02).

Conclusion: The present study for the first time showed that severe VF and low serum osteocalcin were associated with all-cause mortality in postmenopausal women with T2DM.

Relation of 25OHD3 availability to VDR expression and NF- κ B-dependent proinflammatory signalling pathway in diabetes-induced liver failure

D. Labudzynski¹, I. Shymanskyi¹, S. Savosko², V. Dosenko³, M. Veliky¹;

¹Laboratory of Medicine biochemistry, Palladin Institute of Biochemistry of NAS of Ukraine, ²Department of Histology and Embryology, O.O. Bogomolets Kiev National Medical university, ³General and Molecular Patophysiology, Bogomoletz Institute of Physiology of NAS of Ukraine, Kyiv, Ukraine.

Background and aims: Diabetes is known to be characterized with upregulation of pro-inflammatory factors in various tissues. It is known that nuclear factor kappa B (NF- κ B) is a key regulator of inflammatory process and its activation leads to increased expression of inducible nitric oxide synthase (iNOS) and vascular permeability factor (VPF) involved in inflammation. Vitamin D3 (D3) is currently recognized as a potent immunomodulator affecting various inflammatory and autoimmune diseases. Importantly, hormonally active form of vitamin D3 (1,25(OH)₂D₃) binds to vitamin D3 receptors (VDR) functioning as transcription factor to modulate gene expression. However, precise mechanisms of vitamin D3 influence on immune regulation has not been clearly established. We therefore investigated the hepatoprotective role of vitamin D3 in VDR-mediated regulation of pro-inflammatory factors (p65 NF- κ B, VPF, iNOS) expression in diabetic liver.

Materials and methods: Type 1 diabetes was induced in male C57BL/6 mice (24.0±1.6 g) by i.p. injection of high-dose STZ (150 mg/kg b.w.). After 2 weeks of STZ-induced diabetes mice were treated with or without vitamin D3 (15 IU/mouse per os, for 8 weeks). Serum 25OHD3 was assessed by ELISA. The expression of phosphorylated NF- κ B/p65 (Rel A), VPF, iNOS and VDR mRNA were measured by RT-PCR and Western-blot analysis. Histological features were assessed using H&E staining.

Results: Serum level of 25OHD3 was shown to be reduced to 27.4±2.0 in diabetes vs. 41.6±2.9 nmol/L in control, indicative of diabetes-induced D3 deficiency (p<0.05). These changes were accompanied by 1.3-fold overexpression of VDR mRNA, that can be a compensatory mechanism in response to D3 deficiency. It should be noted, that diabetes was associated with 2.4-fold augmentation of RelA expression in hepatic tissue of diabetic mice. NF- κ B overexpression was accompanied by 1.53- and 1.28-fold increase in VPF and iNOS mRNA levels in liver. The results of RT-PCR correlated with results of Western blot analysis that showed a 1.21-, 2.04-, 1.62- and 1.32-fold elevation of liver tissue protein contents of VDR, NF- κ B p65, VPF and iNOS respectively. Diabetes also caused structural lesions in liver, which were characterized by altered blood microcirculation (dilated microvessels), degenerative changes in cytological structure of hepatocytes and their mitotic activity. Full restoration of 25OHD3 content and partial normalization of liver tissue structure were achieved by D3 treatment. Vitamin D3 administration caused a partial normalization of mRNA expression and protein contents of VDR, pNF- κ B/p65, VPF and iNOS in liver tissue. It can be suggested that D3 prevents overexpression of pNF- κ B/p65 and nuclear translocation of phosphorylated p65 in hepatocytes and its effect is mediated through 1, 25(OH)₂D₃ and VDR.

Conclusion: The study confirmed that diabetes-induced liver abnormalities are associated with upregulation of VDR and inflammatory markers NF- κ B/p65, VPF and iNOS expression that correlated with insufficient vitamin D3 availability. Our results can explain protective VDR-mediated effects of vitamin D3 action against diabetes-induced liver cells injury.

Metformin attenuates hepatitis C virus-induced hepatic fibrosis through up-regulation of AMPK and orphan nuclear receptor SHP
J.-H. Jeon¹, G.-S. Jung¹, Y.-K. Choi¹, K.-H. Bae¹, A. Khang¹, M.-K. Kim², E.-H. Kim³, I.-K. Lee¹, K.-G. Park¹;

¹Department of Internal Medicine, Kyungpook National University School of Medicine, ²Department of Internal Medicine, Keimyung University School of Medicine, ³Department of Internal Medicine, Daegu Fatima Hospital, Daegu, Republic of Korea.

Background and aims: Metformin, a commonly prescribed oral hypoglycemic agent, has pleiotropic benefits including lowering cancer development and cancer mortality in patients with type 2 diabetes. Metformin was also independently associated with a reduction in hepatitis C virus (HCV)-induced cirrhosis in patients with type 2 diabetes. Mounting evidence suggests that the potential beneficial effects of metformin are associated with AMPK and SHP activation. However, little is known about the protective effects exerted by metformin induced AMPK and SHP activation against HCV-induced hepatic fibrosis.

Materials and methods: Levels of SHP, p-AMPK and fibrotic markers in HCV-infected human liver and in Huh-7.5 cells infected with HCV genotype 2a (JFH-1) were investigated. The effect of adenovirus-mediated overexpression of SHP (Ad-SHP) and AMPK activation by metformin on fibrotic gene expression was evaluated in HCV-infected cells. Finally, we examined the effect of Ad-SHP and metformin on invasion and activation of LX2 human hepatic stellate cells induced by conditioned media (CM) from HCV-infected hepatocyte.

Results: In human livers infected with HCV and Huh-7.5 cells infected with JFH-1, SHP mRNA and protein levels were diminished compared with control livers and Huh-7.5 cells, respectively, whereas profibrotic factors, including TGF- β , were increased. In addition, levels of phosphorylated p38 mitogen-activated protein kinase, c-Jun N-terminal kinase, and Smad3 were also increased. Metformin-induced AMPK activation recovered HCV-suppressed SHP expression, and Ad-SHP inhibited mRNA and protein levels of profibrotic factors and fibrotic genes. SHP overexpression also inhibited HCV-stimulated nuclear factor-kappa B activation, which led to decreased TGF- β production. CytoSelect invasion assay revealed that increased activity and invasiveness of HSCs induced by CM from HCV-infected Huh-7.5 cells were attenuated by treatment with metformin or Ad-SHP.

Conclusion: These results demonstrate that metformin-induced activation of AMPK and SHP reverses profibrogenic features of HCV-infected cells by overcoming HCV-induced diminution of AMPK and SHP expression, and concomitantly decreasing TGF- β and fibrotic gene expression. These findings provide a rationale for metformin as a possible therapeutic agent against HCV-induced hepatic fibrosis, especially when accompanied by type 2 diabetes.

Non-alcoholic fatty liver disease is associated with vascular inflammation: analysis by 18 F-fluorodeoxyglucose positron emission tomography

R. Min Jung¹, H. Choi¹, J. Ryu¹, H. Hong¹, H. Yoo¹, J. Seo², N. Kim³, H. Kim³, S. Kim³, N. Kim², S. Baik¹, D. Choi³, K. Choi¹;

¹Division of Endocrinology and Metabolism, Department of Internal Medicine, Korea University Guro Hospital, ²Department of Internal Medicine, Korea University Ansan Hospital, ³Department of Internal Medicine, Korea University Anam Hospital, Seoul, Republic of Korea.

Background and aims: Growing evidence suggests that non-alcoholic fatty liver disease (NAFLD) is associated with cardiovascular disease as well as metabolic syndrome. FDG-PET is a novel imaging technique that detects vascular inflammation, which may reflect rupture-prone vulnerable atherosclerotic plaques.

Materials and methods: Vascular inflammation was measured as the maximum target-to-background ratio (maxTBR), along with various cardiometabolic risk factors in 51 subjects with NAFLD, and compared them with 100 age- and gender-matched subjects without NAFLD. The liver attenuation index (LAI), which was measured using computed tomography, was used as a parameter for the diagnosis of NAFLD.

Results: After adjusting for age and sex, both maxTBR and LAI values were associated with several cardiometabolic risk parameters. Furthermore, there was a significant inter-relationship between LAI and maxTBR values ($r=-0.227$, $P=0.005$). Individuals with NAFLD had higher maxTBR values than those without NAFLD ($P=0.026$), although their carotid intima-media thickness values did not differ. The proportion of subjects with NAFLD showed a step-wise increment following the tertiles of maxTBR values (P for trend=0.015). In multiple logistic regression analysis, maxTBR tertiles were independently associated with NAFLD after adjusting for age, gender, systolic blood pressure, triglycerides, HDL-cholesterol, glucose, BUN, creatinine and homeostasis model assessment of insulin resistance (HOMA-IR) ($P=0.030$). However, their relationship was attenuated after further adjustment for waist circumference, LDL-cholesterol or high sensitive C-reactive protein.

Conclusion: The present study first shows that patients with NAFLD have an increased risk for vascular inflammation as measured via FDG-PET/CT.

The hepatic protective effect of hepassocin on hyperglycaemic crisis
H.-Y. Ou¹, H.-T. Wu², C.-H. Lin¹, Y.-F. Du¹, F.-H. Lu³, J.-S. Wu³, H.-C. Hung¹, Y.-C. Yang³, C.-J. Chang³;

¹Department of Internal Medicine, ²Research Center of Herbal Medicine, New Drugs, and Nutritional Supplements, ³Department of Family Medicine, National Cheng-Kung University, Tainan, Taiwan.

Background and aims: Hyperglycemic crisis is a metabolic emergency associated with uncontrolled diabetes that may result in morbidity. Although it is known that reactive oxygen species (ROS) production by hyperglycemia leads to hepatic dysfunction, only a mild increase of aspartate aminotransferase (AST) and/or alanine aminotransferase (ALT) level is observed in patients with hyperglycemic crisis, and the exact mechanisms were still undefined. Hepassocin is a hepatokine that plays as a mitogen for hepatocytes and exerts a hepatic protection action against chemical-induced liver injury. However, the effect of hepassocin in hyperglycemia-induced hepatic dysfunction remains obscure. Thus, the aim of this study is to investigate the role of hepassocin in hyperglycemia-induced hepatic dysfunction.

Materials and methods: Thirty patients with hyperglycemic crisis, including diabetic ketoacidosis and hyperosmolar hyperglycemic state, without obvious infection were enrolled at our university hospital. Standard treatment of hyperglycemic crisis including insulin, hydration, and correction of electrolyte imbalance were given. After resolution of hyperglycemia, the blood samples were collected to examine hepassocin concentrations by enzyme-linked immunosorbent assay. In addition, streptozotocin-induced hyperglycemic mice and HepG2 cell models were used to evaluate the role of hepassocin in hyperglycemic crisis.

Results: The serum concentrations of hepassocin were significantly increased in patients with hyperglycemic crisis. After treatment to relieve hyperglycemic status, hepassocin levels were significantly reduced ($P<0.01$). In addition, we found a dose-dependent increase in the hepassocin expression of HepG2 cells exposed to high glucose condition. In streptozotocin-induced hyperglycemic mice, treatment with hepassocin significantly decreased the levels of AST and ALT without affecting the concentrations of blood glucose and insulin in circulation ($P<0.001$). In addition, the hepatic SOD1 expression was increased after the hepassocin

treatment. Furthermore, we found that hepassocin increased the activity of ERK1/2, Nf-E2 related factor-2 (NRF2) translocation to nuclear, as well as SOD1 expression. Blockade of ERK1/2 by U0126 inhibited NRF2 translocation and SOD1 expression, indicating hepassocin increased SOD1 through an ERK1/2-NRF2-SOD1 dependent pathway. As a result of increased SOD1 expression, HepG2 hepatocytes were protected by hepassocin from ketone body (acetoacetate)-induced ROS production and cell death.

Conclusion: Hepassocin plays a protective role in hyperglycemia-induced hepatic dysfunction by regulating ERK1/2 activity. Hepassocin induced SOD1 expression through an ERK1/2-NRF2-SOD1 dependent pathway, and this effect further decreased ROS production and protects hepatocytes from hyperglycemia-induced hepatocyte injury.

Liver proteome and microRNAs in insulin receptor knockout mice reveal novel molecules involved in the diabetes pathophysiology

B. Capuani¹, D. Della Morte¹, S. Caratelli², D. Pastore¹, A. Coppola¹, F. Pacifici¹, R. Arriga¹, A. Bellia¹, M. Federici¹, P. Sbraccia¹, M. Romano³, A. Galli³, G. Donadel¹, G. Sconocchia², D. Lauro¹;

¹Systems Medicine, University of Rome, ²Institute of Translational Pharmacology Council National Research, ³Unit of Endocrinology, Diabetology and Metabolic Diseases, University Hospital Fondazione Policlinico Tor Vergata, Rome, Italy.

Background and aims: Type 2 Diabetes Mellitus (T2DM) is a disease characterized by alteration of insulin signaling in specific target tissues, such as skeletal muscle, adipose tissue, and liver. Dysfunction and later failure of insulin-producing pancreatic beta cells (β -cells) and peripheral insulin resistance induce hyperglycemia in pre-diabetes conditions. Fundamental is discovering early biomarkers to delay or prevent onset of T2DM. Recently, some studies are seeking for biomarkers through proteomic and microRNA (miRNA) approaches, but none identified specific hepatic proteins which trigger early stages of T2DM. Therefore we are reaching the goal to reveal new proteins involved in the onset of diabetes and/or its relative complications.

Materials and methods: miRNAs were extracted from ten mice for each genotype (IR+/+, IR+/-, and IR-/-) its integrity assayed on Nano Chip and Small Chip Agilent, and then hybridised with miRNA Microarray System with miRNA Complete Labeling and Hyb kit (Agilent) for expression profiling. Expression levels of specific miRNAs were validated by qRT-PCR using TaqMan assay. We used miR-Walk algorithm to determine miRNA targets and mRNAs expression were validated by qRT-PCR. Different protein profiles of IR+/+, IR+/-, and IR-/- were analyzed by 2D PAGE and nLC MS/MS analysis. HMGB1 acetylation and SIRT1 expression were analyzed by Immunoprecipitation and Western Blot, while HMGB1 secretion was studied by ELISA kit (Shino Test), and immunofluorescence microscopy.

Results: We analyzed protein and miRNA patterns by proteomic and miRNA arrays in insulin receptor knockout (IR-/-) and heterozygous (IR+/-) mice as a murine model of liver metabolic dysfunction associated with diabetic ketoacidosis and insulin resistance. We evaluated protein expressions by using protein 2-DE MALDI-TOF/TOF and peptic nLC-MS/MS shotgun profiling. Twenty-eight proteins identified by 2-DE analysis and 24 identified by nLC-MS/MS shotgun, were differentially expressed among the 3 genotypes. Bioinformatic analysis revealed a central role of High Mobility Group Box 1/2 and hantiglin (HTT) never reported to be associated with metabolic and related liver disease. MiRNAs array identified only 4 miRNA differently expressed between IR+/+, IR+/- and IR-/- miR-376b, miR-154, miR-543, and miR-199b. Quantitative Real time polymerase reaction (qRT-PCR) confirmed these results, and bioinformatic analysis reveals interesting mRNA targets involved in metabolic pathways linked with proteomic analysis. Among these targets, the most interesting is SIRT1, a deacetylase involved in

HMGB1 translocation, and then, in the activation of inflammatory state mediated by HMGB1.

Conclusion: These results provide new insight into pathophysiology of T2DM and non alcoholic fatty liver disease, and should be useful to be confirmed as novel biomarkers to predict risk for diabetes and its complications.

1154

Tissue-specific effects on mitochondrial dysfunction in type 1 and 2 diabetic mouse models

N. Volk, T.H. Fleming, E. Kliemank, P.P. Nawroth;
Department of Medicine I and Clinical Chemistry, University of Heidelberg, Germany.

Background and aims: During diabetes, increased hyperglycemic flux is considered to raise the production of reactive oxygen species (ROS). However, it remains under debate whether this increase is due to or causing functional changes of the mitochondria. Several studies have been published to determine the effect of diabetes on the function of the mitochondria. Yet, the results are contradictory. Here, we present a screen analyzing the effects of diabetes on the mitochondria of heart, kidney and liver using low-dose streptozotocin (STZ)-induced wild-type mice as a model for type 1 diabetes (T1D) and db/db mice as a model for type 2 diabetes (T2D).

Materials and methods: Mitochondria were isolated by differential centrifugation and purity was determined using FACS. Functionality of the mitochondria was analyzed using fluorescence-photometric and spectrophotometric assays. Gene expression profiles were analyzed using quantitative PCR. Data was expressed as fold change to control (mean \pm SD) and statistical significance was calculated using students t-test.

Results: After 3 months of diabetes (3 M) oxygen consumption was decreased (0.11 \pm 0.09, P-value<0.001) and ATP production showed a tendency to decrease in heart-derived mitochondria of T1D mice. In T2D oxygen consumption (0.68 \pm 0.07, P-value<0.01), ATP (0.71 \pm 0.20, P-value=0.03) and superoxide (0.78 \pm 0.01, P-value=0.02) production were decreased in cardiac mitochondria. In the mitochondrial fraction of T1D kidneys increased ATP production (1.25 \pm 0.15, P-value<0.01) and a tendency of increased oxygen consumption was measured. In T2D oxygen consumption (0.31 \pm 0.23, P-value<0.01) was decreased whereas ATP and superoxide production remained unchanged. In T1D increased superoxide production (1.31 \pm 0.28, P-value=0.04) and a tendency of increased oxygen consumption and ATP production was measured in the liver. In T2D superoxide production (1.48 \pm 0.17, P-value<0.01) was increased in the same extent as in T1D. However, ATP and oxygen consumption (10.29 \pm 5.40, P-value=0.02) increased to a higher extent in T2D. Besides the comparison of T1D and T2D, mitochondrial changes were also analyzed during the progression of diabetes using the T1D model. 6 months after the induction of diabetes (6 M) ATP and superoxide production were unchanged compared to 3 M. In the heart- and liver-derived mitochondria oxygen consumption remained unchanged as well. However, oxygen consumption in the kidney increased in 6 M compared to 3 M. Gene expression analysis showed a decrease in mitochondrial complexes and antioxidative enzymes in the diabetic kidney in 3 M and 6 M. In the heart and liver changes in the expression were first detected in 6 M and less pronounced than in the kidney.

Conclusion: In this study it was found that the effect of diabetes on mitochondrial dysfunction depends on the tissue and model studied and that results obtained from one organ and model cannot be applied to another. Furthermore, the kidney was found to be the organ which was affected first and most severe in T1D, suggesting that tissues which are highly susceptible to chronic hyperglycaemia are likely to be the most affected with respect to mitochondrial properties.

Long-term clinical outcomes in patients with acute coronary syndrome and dysglycaemia

J. Kuhl, G. Jöreskog, M. Bengtsson, P. Lundman, M. Kalani;
Department of Clinical Sciences, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Diabetes and impaired glucose tolerance (IGT) are major risk factors for atherosclerosis including coronary artery disease (CAD). The aim of the present study was to investigate the importance of glucose tolerance for long term clinical outcome in patients with acute coronary syndrome (ACS).

Materials and methods: 1062 consecutive patients, 781 men and 281 women, aged 32-80 years, admitted to the coronary care unit at a University Hospital, for ACS from year 2006 to 2008. At discharge, the patients were categorized according to an OGTT as having normal glucose tolerance (NGT); n=295 (28%), impaired glucose tolerance (IFG) and impaired glucose tolerance (IGT); n=299 (28%), diabetes discovered by OGTT; n=156 (15%) or known diabetes at admission to the hospital; n=312 (29%). Mortality and reinfarction rates were studied during a mean follow-up time of 4.0 (\pm 0.8) years. Clinical outcome data were obtained from the Swedish Coronary Angiography and Angioplasty Registry and the Swedish National Registry.

Results: Patients with known diabetes at admission had compared to patients with dysglycaemia discovered by OGTT and NGT a significant increase (p<0.001) in death within 14 days (2.9% vs 0.2% and 0%), 30 days (4.8% vs 0.2% and 0%), 6 month (9% vs 1% and 0%), 1 year (12% vs 2% and 0%) and 3 years (25% vs 5% and 3%). During the follow-up, reinfarction was significantly higher (p<0.001) in patients with known diabetes compared to patients with dysglycaemia discovered by OGTT and NGT (28% vs 17% and 12%). The composite endpoint of mortality and reinfarction was significantly higher (p<0.001) in patients with known diabetes compared to patients with dysglycaemia discovered by OGTT and NGT (44% vs 22% and 15%). Furthermore, it was also a significant difference (p<0.001) between patients with dysglycaemia discovered by OGTT as compared to patients with NGT.

Conclusion: A majority of patients admitted for ACS have disturbed glucose metabolism including diabetes with high prevalence of previously undiagnosed dysglycaemia. Both known diabetes and dysglycaemia discovered by OGTT are associated with poor clinical prognosis in these patients.

Figure 1: Kaplan-Meier curves showing cumulative death within 3 years

HbA_{1c} and risk of stroke in 33,414 type 1 diabetes patients compared to 166,097 controls from the general population

A. Rosengren¹, C.H. Stahl¹, S. Gudbjornsdottir², A.-M. Svensson², M. Kosiborod³, M. Clements⁴, M. Lind⁵;

¹Molecular and Clinical Medicine, Institute of Medicine, University of Gothenburg, ²Center of Registers in Region Västra Götaland, Gothenburg University, Sweden, ³Saint Luke's Mid America Heart Institute, University of Missouri–Kansas City School of Medicine, ⁴University of Missouri–Kansas City School of Medicine and Children's Mercy Hospital, the University of Kansas School of Medicine, Kansas City, USA, ⁵Department of Medicine, NU-Hospital Organization, University of Gothenburg, Uddevalla, Sweden.

Background and aims: Earlier studies have found patients with type 1 diabetes at increased risk of stroke compared to the general population. In this study we estimated the risk of stroke among individuals with type 1 diabetes according to HbA_{1c} level, and compared it to the risk in the general population.

Materials and methods: We included 33,414 individuals with type 1 diabetes, aged 18 years or older (mean 35.5 years), registered in the Swedish National Diabetes Register 1998 to 2011 and 166,097 age, sex and county matched controls from the general population. The endpoints all stroke, ischemic stroke and hemorrhagic stroke were captured using ICD-10 codes I61, I62.9, I63, I64 and I67.9 from the Swedish Inpatient and Cause of Death Registers. The risk of stroke for patients with type 1 diabetes were estimated in 5 different HbA_{1c} categories by Cox hazard regression analysis adjusted for age, sex, diabetes duration, born in Sweden, highest education level and baseline comorbidities with controls from the general population as reference.

Results: Medium follow-up was 8.6 years and 9.0 years for patients with type 1 diabetes and controls respectively. Among patients with type 1 diabetes 759 (2.3%) received a non-fatal or fatal stroke diagnosis compared to 1425 (0.9%) among the controls. Unadjusted incidence values of all stroke expressed as cases per 1000 person years were 2.86 (2.66 - 3.08) for patients with type 1 diabetes and 1.04 (0.99 - 1.10) for controls. The risk for all and ischemic stroke was significantly increased for patients with type 1 diabetes in all HbA_{1c} categories. The risk rose gradually by

each HbA_{1c} category from a HR of 1.56 (95% CI 1.21 - 2.01) for all stroke in the lowest category ($\leq 6.9\%$ (≤ 52 mmol/mol)) to a more than 7 times increased risk for patients with type 1 diabetes in the highest HbA_{1c} category (HR for all stroke 7.52 (95% CI 6.10 - 9.26) in HbA_{1c} category $\geq 9.7\%$ (≥ 83 mmol/mol)). For hemorrhagic stroke the risk for patients with type 1 diabetes was increased in all but the lowest HbA_{1c} category compared to the controls. After a gradual increase in risk over the HbA_{1c} categories, patients with type 1 diabetes in the highest HbA_{1c} category $\geq 9.7\%$ (≥ 83 mmol/mol) had a HR of 7.74 (4.74 - 12.62) for hemorrhagic stroke.

Conclusion: Individuals with type 1 diabetes experience a considerably higher risk for stroke compared to the general population. The risk increases gradually with worse glycemic control from a 50% higher risk in the lowest HbA_{1c} category to more than 700% higher risk in the highest HbA_{1c} category.

Blood pressure and stroke risk in 408,076 type 2 diabetes patients compared to 1,913,507 controls from the general population

C.H. Stahl¹, M. Lind², S. Gudbjornsdottir³, A.-M. Svensson³, M. Kosiborod⁴, M. Clements⁵, A. Rosengren¹;

¹Molecular and Clinical Medicine, Gothenburg University, ²NU-Hospital Organization, Gothenburg University, Uddevalla, ³Center of Registers in Region Västra Götaland, Gothenburg University, Göteborg, Sweden, ⁴University of Missouri, Saint Luke's Mid America Heart Institute, ⁵the University of Kansas School of Medicine, Kansas City School of Medicine and Children's Mercy Hospital, Kansas City, USA.

Background and aims: Patients with type 2 diabetes have an elevated risk of stroke. In this study we estimated the risk of stroke among patients with type 2 diabetes at different blood pressure levels compared to the risk in the general population in Sweden.

Materials and methods: This case-control study was based on 408,076 individuals with type 2 diabetes, 18 years or older, registered in the Swedish National Diabetes Register 1998-2011 and 1,913,507 age- and sex matched controls from the general population. Stroke diagnoses were retrieved by ICD-10 codes I61, I62.9, I63, I64 and I67.9 from the Swedish Inpatient and Cause of Death Registers. Cox hazard ratios (HRs) and 95% confidence intervals (CIs) adjusted for age, sex, diabetes duration, born in Sweden, highest education level and baseline comorbidities were estimated at 6 different blood pressure levels (<110/<65, 110-119/65-69, 120-129/70-79, 130-139/80-89, 140-159/90-99, >160/>100 mm Hg)

Results: During a median follow up of 4.0 years for patients with type 2 diabetes and 4.1 years for controls, 19,548 (4.8%) patients with type 2 diabetes and 61,690 (3.2%) controls were diagnosed with non-fatal or fatal stroke. Corresponding unadjusted incidence values for any stroke as cases per 1000 person years were 10.63 (10.48-10.78) for patients with type 2 diabetes and 6.80 (6.75-6.86) for controls. Multivariable adjusted Cox regression analysis, using controls as reference, yielded a significantly increased risk of any stroke for patients with type 2 diabetes in blood pressure categories above 130-139/80-89 mm Hg (hazard ratio HR of 1.11 (95% CI 1.07-1.15)), with gradually increasing HR to 1.80 (95% CI 1.73-1.86) in the highest blood pressure category (>160/>100 mm Hg). A similar pattern was observed for ischemic stroke. The association was more complex for hemorrhagic stroke with a significant reduced risk for patients with type 2 diabetes compared to controls in lower blood pressure categories and significantly increased only in blood pressure category >160/>100 mmHg (HR 1.49 (95% CI 1.33-1.68)).

Conclusion: Individuals with type 2 diabetes and blood pressure below 130/80 mm Hg have a risk of all stroke and ischemic stroke comparable to that of the general population.

Remnant cholesterol predicts cardiovascular event risk in patients with type 2 diabetes independently from the baseline coronary artery disease state

H. Drexel^{1,2}, C.H. Saely^{3,1}, D. Zanolin⁴, P. Rein¹, A. Vonbank¹, A. Leiberer⁴, A. Muendlein⁴;

¹Academic Teaching Hospital Feldkirch, Austria, ²Drexel University, Philadelphia, USA, ³Private University of the Principality of Liechtenstein, Triesen, Liechtenstein, ⁴VIVIT Institute, Feldkirch, Austria.

Background and aims: Remnant cholesterol, which is calculated as total cholesterol minus LDL cholesterol minus HDL cholesterol recently has attracted interest as a marker of cardiovascular event risk. We aimed at investigating the power of remnant cholesterol to predict cardiovascular events in patients with type 2 diabetes (T2DM) as well as in non-diabetic patients in whom the baseline coronary artery disease (CAD) state was verified angiographically.

Materials and methods: We enrolled 1774 consecutive patients undergoing coronary angiography for the evaluation of established or suspected stable CAD. Prospectively, cardiovascular events were recorded over a mean follow-up period of 7.5±2.9 years. Diabetes was diagnosed according to ADA criteria.

Results: During follow-up, 32.5% of our patients suffered cardiovascular events; the event rate was significantly higher in patients with T2DM (n=513) than in nondiabetic subjects (40.5 vs. 29.3%; p<0.001). Remnant cholesterol significantly predicted cardiovascular events in the total study population, among patients with T2DM, as well as among non-diabetic subjects both univariately (HR 1.18 [1.10-1.27], p<0.001, 1.20 [1.05-1.38], p=0.008 and 1.19 [1.09-1.30], p<0.001, respectively) and after multivariate adjustment including presence as well as extent of baseline CAD (HR 1.15 [1.07-1.24], p<0.001, 1.21 [1.05-1.39], p=0.009 and 1.15 [1.05-1.25], p=0.002, respectively).

Conclusion: From our data we conclude that remnant cholesterol predicts cardiovascular event risk in patients with type 2 diabetes as well as in non-diabetic patients independently from the baseline CAD state.

1159

Contrasting eight cardiovascular risk equations for use in type 2 diabetes cohorts using the CORE Diabetes Model

M. Lamotte¹, V. Foos², P. McEwan³;

¹IMS Health, Vilvoorde, Belgium, ²IMS Health, Basel, Switzerland, ³Health Economics & Outcomes Research Ltd, Cardiff, UK.

Background and aims: Within health economic evaluations concern persists regarding the generalizability of cardiovascular (CV) risk equations (REs) and their impact upon cost-effectiveness predictions. The IMS CORE Diabetes Model (CDM) is a widely published and validated decision support tool that has been recently updated to include eight sets of CV risk equations derived from European, American, Asian and Global cohorts. The objective of this study was to compare and contrast cardiovascular incidence and predicted quality adjusted life expectancy (QALE) across these REs.

Materials and methods: Lifetime analyses comparing outcomes for metformin+ sulphonylurea (M+S) versus metformin + DPP-4 (M+D) were undertaken using the CDM with basal insulin rescue therapy applied to both arms at an HbA1c threshold level of 7.5%. Baseline characteristics and treatments effects from the published EDGE study were utilised: mean age 57.8 years, duration diabetes 5.5 years, 54.8% male, HbA1c 8.2% and BMI 29 kg/m². HbA1c reductions applied were -0.99% and -1.19% for M+S and M+D respectively with a -0.3 kg and -1.6 kg change in body weight for M+S and M+D respectively. A comparison of cumulative incidence (CI) of myocardial infarction (MI) and stroke, QALE and incremental cost effectiveness ratio (ICER) was made for the following risk equations Swedish-National Diabetes Registry (S-NDR); UKPDS 68 (UK); UKPDS 82 (UK); ADVANCE (Global); FREMANTLE

(Australian); ARIC (US); HONG KONG (Asia) and PROCAM (European). UK 2013 costs were applied; costs and health benefits were discounted at 3.5%.

Results: Across all REs, overall mean (standard error [SE]) predicted CI of MI and stroke were 23.9% (4.1) and 35.7% (4.6) respectively. Averaged across treatment arms, the Swedish-NDR RE predicted highest CI of stroke (58.3%) and ARIC the lowest (4.3%); PROCAM the highest CI of MI (69.7%) and ARIC lowest (9.8%). Mean (SE) predicted QALE across all RE was 9.2 (0.2) with the highest (10.4) from ARIC and lowest (7.8) from PROCAM. The overall mean (SE) ICER across all RE was £8,569 (£280) with the lowest (£6,980) from UKPDS 68 and highest (£10,964) from PROCAM (range £3,984).

Conclusion: There was a noteworthy difference in predicted CI of CV events across the eight RE and therefore economic assessments should utilise RE from the most representative population. Importantly, estimated QALE and ICERs were relatively stable. Nevertheless, choice of RE may have a significant impact on cost-effectiveness evaluations, particularly where results lie close to the willingness-to-pay threshold.

Testosterone in patients with acute myocardial infarction and glucose abnormalities and in matched controls: a report from the GAMI study

A. Wang¹, S. Arver², J. Flanagan², L.G. Mellbin¹, V. Gyberg¹, K. Malmberg¹, A. Norhammar¹, P. Näsman³, V. Ritsinger¹, L. Rydén¹;

¹Cardiology Unit, Department of Medicine Solna, Karolinska Institutet, Stockholm, ²Center for Andrology and Sexual Medicine, Department of Medicine, Karolinska University Hospital, Huddinge, ³Center for Safety Research, KTH Royal Institute of Technology, Stockholm, Sweden.

Background and aims: Low levels of testosterone are prevalent in men with diabetes and have been associated with impaired cardiovascular health. A potential relationship between testosterone, diabetes and cardiovascular disease needs to be further elucidated. The present aims were to investigate the prevalence of low testosterone (<350 ng/dl) and the dynamic of levels over time in patients with acute myocardial infarction (AMI) with or without newly detected glucose abnormalities and in controls. Further, the study explored the relation between testosterone and cardiovascular prognosis.

Materials and methods: The material comprises male patients with AMI without known diabetes (n=123) and age-matched controls without AMI (n=124). Testosterone levels were measured at baseline for controls and at the first morning after admission, at discharge, and 3 and 12 months post-discharge for patients. Study participants were categorized as having normal or abnormal glucose tolerance (NGT or AGT=diabetes or impaired glucose tolerance) by means of an oral glucose tolerance test. The prognostic impact of testosterone was studied by Cox regression hazard analyses (by +1 SD) with major cardiovascular events (cardiovascular death, non-fatal MI, non-fatal stroke or severe heart failure) as primary endpoint during 11 years follow-up.

Results: At the first morning after admission, 76% of the patients had low testosterone (vs. 43% in controls) and their median testosterone levels were significantly lower than among controls (Table 1). Testosterone was lower in patients with AGT than NGT during hospitalization. The prevalence of low testosterone was 83% in AGT vs. 65% in NGT patients, and 57% in AGT vs. 34% in NGT controls. Testosterone did not predict cardiovascular events in patients (events=50) or controls (events=27). Subgroups analyses were not performed due to limited number of events.

Conclusion: Low testosterone levels are common in patients with AMI, especially in combination with AGT. Over time, the difference in testosterone levels between patients with or without glucose abnormalities diminished. The results raise questions on the proposed causal relationship between testosterone and glucose abnormalities. Also, it indicates that testosterone substitution should not be instituted based on samples taken during hospitalization for AMI.

Table 1. Testosterone levels (ng/dl) in patients and controls presented as median and interquartile range (IQR) for the total cohort and with regards to glucose categorization.

	Patients				Controls
	Day after admission (n=123)	Discharge (n=115)	3 months (n=101)	12 months (n=87)	Baseline (n=124)
Total	243 (184-346)	310 (204-426)	345 (265-429)	357 (270-485)	380 (276-476)
NGT	308 (199-387) (n=43)*	286 (112-429)	299 (44-417)	308 (121-445)	386 (315-481) (n=77)*
AGT	230 (178-301) (n=75)*	201 (20-360)	285 (26-394)	264 (30-382)	341 (266-441) (n=47)*
p[†]	0.04	0.03	0.55	0.14	0.15

*Individuals with glucose categorization available.
†p-value for group wise comparison of AGT vs. NGT.

0.05), and so was the increase in p21 protein levels ($p < 0.05$). Increased Akt and p42/p44 MAPK phosphorylation ($p < 0.05$) was observed in CPC exposed to myo-inositol or D-chiro-inositol for up to 30 min.

Conclusion: Palmitate increases both autophagy and senescence in human CPC. Both myo-inositol and D-chiro-inositol activate survival kinases and counteract the effects of palmitate. Inositols may thus protect the myocardium from lipotoxic damage by preserving the CPC pool in type 2 diabetic and/or obese subjects with elevated free fatty acid levels.

Myo-inositol and d-chiro-inositol prevent palmitate-induced autophagy and senescence in human cardiac progenitor cells

R. D'Oria¹, L. Laviola¹, A. Leonardini¹, M. Incalza¹, C. Caccioppoli¹, P. Nigro¹, M. Scioscia², A. Natalicchio¹, S. Perrini¹, F. Giorgino¹;
¹Endocrinology & Metabolic Diseases, University of Bari, ²Obstetrics and Gynecology, Sacro Cuore Don Calabria, Verona, Italy.

Background and aims: Supplementation with myo-inositol and D-chiro-inositol has been shown to induce insulin-mimetic effects in humans and to improve cardiac performance in experimental heart failure. The aim of this study was to evaluate the effects of myo-inositol and D-chiro-inositol on lipotoxicity-induced autophagy and senescence in human cardiac progenitor cells (CPC).

Materials and methods: Human CPC were isolated from right auricle biopsies of patients undergoing elective heart surgery and exposed to palmitate (0.25 mM up to 16 h). Autophagy was evidenced by monodansylcadaverine and autophagolysosome labeling, and by immunoblotting of microtubule-associated protein 1 light chain 3 (LC3)-II and beclin1. Cellular senescence was detected by evaluation of senescence-associated β -galactosidase activity, p21(WAF1/Cip1) and p16(Ink4a) gene and protein expression. Protein expression and phosphorylation were detected by immunoblotting.

Results: Incubation of CPC with 0.25 mmol/L palmitate for 16 h increased cell autophagy, evidenced by monodansylcadaverine staining and confirmed by increased levels of LC3-II and beclin-1, respectively ($p < 0.05$). Palmitate also induced cellular senescence, demonstrated by increased senescence-associated β -galactosidase activity. Cellular senescence was confirmed by the detection of increased p21(WAF1/Cip1) gene and protein expression ($p < 0.05$), whereas the p16(Ink4a) pathway appeared to be unaffected. Chemical inhibition of autophagy with 3-methyladenine resulted in reduced β -galactosidase staining, suggesting that increased autophagy mediates palmitate-induced cellular senescence in human CPC. When cells were pretreated with myo-inositol or D-chiro-inositol (1-1000 micromol/L), both the palmitate-induced autophagosome formation and increase in LC3-II were abrogated ($p <$

PS 117 Adverse consequences of glycation

1162

ApoA-I glycation; linking diabetes and CVD

J. Domingo-Espin¹, J. Dalla-Riva¹, K. Bernfur², O. Wolanin¹, M. Lindahl¹, J. Lagerstedt¹;

¹Department of Experimental Medical Science, ²Department of Biochemistry and Structural Biology, Lund University, Lund, Sweden.

Background and aims: Diabetic patients have an increased risk of suffering from atherosclerosis. Apolipoprotein A-I (ApoA-I) function and metabolism in high-density lipoprotein (HDL) is closely linked to diabetes. Recognized positive qualities of ApoA-I in HDL include removal of cholesterol from macrophage-derived foam cells at the vascular wall in the reverse cholesterol transport pathway, as well as anti-inflammatory and anti-thrombotic functions, all leading to reduced development of atherosclerosis and cardiovascular disease. Importantly, novel features of this lipoprotein have recently emerged describing ApoA-I/HDL as regulator of glucose homeostasis (insulin secretion and glucose disposal in target tissues), thus suggesting dysfunctional ApoA-I/HDL as a contributing factor to the development of type 2 diabetes. In support of this, our recent *in vivo* data show massive impact (increase) on glucose disposal capacity following acute ApoA-I injections. Intensive glycemic control management reduces CVD events with the most significant reduction related to HbA1c. Hyperglycemia results in increased non-enzymatic reaction of sugars with proteins to form advanced glycation end products (AGEs). Taking all this information into account we hypothesize that the glycation of ApoA-I structurally and functionally modifies the protein and it has an important impact in the impairment of its ability to control glucose homeostasis and cholesterol efflux thus leading to the increase of diabetes and CVD complications. The aim of this study is to elucidate the role of hyperglycemia/glycation of ApoA-I/HDL in its loss of functionality, especially related to its impact on glucose homeostasis.

Materials and methods: Recombinant ApoA-I is *in vitro* glycated with glycolaldehyde (GA) or methylglyoxal (MG) and modifications of the protein are determined by mass spectrometry analysis. Functional modification of the protein are tested by acute injections of ApoA-I (modified and non-modified) in diet-induced obese (DIO) and insulin resistant mice followed by a glucose tolerance test (GTT) and insulin concentration determination (ELISA), lipid clearance assay (LCA), HDL formation assay and finally cholesterol efflux experiments.

Results: Glucose clearance in a glucose tolerance test is markedly improved by the injection of non-modified ApoA-I. When the protein is glycated by MG, a less efficient glucose clearance can be observed, especially in the first 15 minutes of the test ($n=15$, $p<0,05$). The capacity of ApoA-I to form HDL particles is clearly reduced when it is modified as seen by the LCA and also, cholesterol efflux from macrophages is reduced. Mass spectrometry studies reveal a different modification pattern for each of the reactive carbonyls used (GA or MG).

Conclusion: Non-enzymatic glycation of ApoA-I partially impairs the capacity of the protein to form HDL particles leading to reduced glucose clearance in DIO mice. Different reactive carbonyls lead to different profiles in glucose clearance suggesting that there are specific residues in the protein implicated in the glucose homeostasis functions.

Glycation as an atherogenic modification of lipoproteins, and the contribution of copper

J.D. Schofield^{1,2}, Y. Liu¹, T. Siahmansur¹, M.W. France³, P.N. Durrington¹, G.J. Cooper⁴, H. Soran^{1,2};

¹Lipoprotein Research Group, University of Manchester, ²University Department of Medicine, Central Manchester University Hospitals NHS Trust, ³Department of Clinical Biochemistry, Central Manchester University Hospitals NHS Trust, ⁴Centre for Advanced Discovery & Experimental Therapeutics, University of Manchester, UK.

Background and aims: Cardiovascular disease is the leading cause of death and disability in diabetes. Low-density lipoprotein (LDL) is the permissive factor in the development of atherosclerosis. LDL must undergo oxidation and / or glycation to participate in atherogenesis. Glycated LDL is present in the circulation under physiological conditions and at higher concentrations in diabetes and in those destined to experience myocardial infarction, but LDL glycation *in vitro* requires supraphysiological glucose concentrations. Protection against glycation is a recognised function of high-density lipoprotein (HDL). The role of copper in promoting *in vitro* glycation requires further investigation as it may be possible to manipulate this process therapeutically with a copper chelating agent to protect lipoproteins against glycation.

Materials and methods: LDL (1.019-1.063 g/ml) and HDL (1.063-1.21 g/ml) were isolated from human serum using sequential preparative ultracentrifugation before incubation of LDL at a concentration of 1 mg/ml with glucose and copper at physiological concentrations (5-25 mMol/l and 1.25-5 μ mol/l respectively) for 3 days. The ability of HDL and the divalent copper-selective chelator triethylenetetramine to protect against glycation were also assessed. Glycated lipoproteins were separated from non-glycated lipoproteins using *m*-aminophenylboronate affinity chromatography. Apolipoprotein B (apoB) was measured immunoturbidimetrically and glycated apoB by a validated in-house high-sensitivity ELISA. Lipid hydroperoxide (LPO) formed during glycation was measured by a cholesterol oxidase colorimetric assay. The cholesterol efflux capacity of HDL *in vitro* was determined by a previously validated assay.

Results: *In vitro* glycation occurs more readily in the presence of physiological concentrations of copper. Incubation with 10mMol/l glucose and 1.25 μ mol/l and 2.5 μ mol/l copper sulphate for 3 days significantly increased the proportion of glycated apoB ($P=0.003$ and 0.01 respectively). Similar effects were observed in the presence of copper chloride ($P=0.05$) but not copper-histidine complex ($P=0.28$) or ferrous sulphate ($P=0.18$). Addition of HDL prevented glycation of apoB ($P=0.02$). We also for the first time report a potential therapeutic role for copper-selective chelation in the protection of lipoproteins against glycation. Glycation also appears to impair the capacity of HDL to promote cholesterol efflux ($P=0.36$), with a further reduction in the presence of 1.25 μ mol/l copper sulphate ($P=0.21$).

Conclusion: This work offers insight into HDL functionality in diabetes and supporting evidence for the emerging link between copper dysregulation and the accumulation of advanced glycation end-products, and a potential role for copper in lipoprotein glycation.

Unravelling the methylglyoxal effect on the angiogenic process

C. Nigro¹, A. Leone¹, F. Fiory¹, P. Mirra¹, I. Prevenzano¹, T.H. Fleming², P.P. Nawroth², T. Procopio¹, A. Volpe¹, R. Falco¹, F. Beguinot¹, C. Miele¹;

¹DiSMet & IEOS-CNR, Federico II University of Naples, Italy, ²Department of Medicine I and Clinical Chemistry, University Hospital Heidelberg, Germany.

Background and aims: Much of the morbidity and mortality associated with diabetes mellitus (DM) reflects its deleterious effects on micro and macrocirculation. DM impairs physiological angiogenesis by molecular mechanisms that are not fully understood. Generation of Advanced Glycation End-products (AGEs) has an important role in the development of hyperglycaemia-induced endothelial damage. The highly reactive dicarbonyl methylglyoxal (MG) is the most reactive AGE precursor in endothelial cells. It is a potent dicarbonyl glycation agent formed from glycolysis intermediates of in cells and degraded by the glyoxalase system (Glo). Glo1 activity prevents the accumulation of MG, thereby suppressing dicarbonyl-mediated glycation reactions and cellular damage. The concentration of MG is increased 2 to 5-fold in plasma of diabetic patients. Recent experimental evidence indicate that MG is implicated in the pathogenesis of diabetic complications, however, the mechanisms by which MG accumulation leads to endothelial dysfunction and possibly to the vascular complications associated with DM need to be clarified. Homeobox (Hox) genes and miRNAs-mediated epigenetic regulation have a crucial role in the neovascularization both in physiological and pathological conditions. This work aims at elucidating the MG effect on the angiogenic ability of endothelial cells and the molecular mechanisms involved.

Materials and methods: Proliferation and migration were evaluated by cell-growth curves, scratch and transwell migration assays on mouse aortic endothelial cells isolated from heterozygous mice for glo1 deletion (Glo1-/+ MAEC) and their wild type littermates (WT MAEC). Glo1, HoxA5 and miRNAs expression levels were measured by Real-time PCR and MG intracellular concentrations by HPLC.

Results: Glo1-/+ MAEC show a 50% reduction of Glo1 mRNA levels and a 5-fold increase of MG intracellular concentrations compared to WT MAEC (p=0.0001). Cell-growth curves reveal that Glo1-/+ MAEC grow slower than WT MAEC (Glo1-/+ MAEC 106833±15610 vs WT MAEC 202733±62699 cells at 24 h, p=0.002). Preliminary data indicate that Glo1-/+ MAEC have a delayed wound healing upon VEGF stimulation even when the proliferation is inhibited by mitomycin C (Glo1-/+ MAEC 55.1±13% vs WT MAEC 100% of wound closure at 12 h) and an impaired migration capacity (Glo1-/+ MAEC 0.062±0.008 vs WT MAEC 0.09±0.024 OD) compared to WT MAEC. To investigate the molecular mechanisms by which angiogenic function may be compromised by MG in MAEC, HoxA5 and vascular function-related miRNAs expression has been evaluated. mRNA levels of the anti-angiogenic gene HoxA5 are 2-fold increased in Glo1-/+ MAEC compared to WT MAEC (Glo1-/+ MAEC 1.98±0.48 vs WT MAEC 1 REU, p=0.01). Moreover, miRNA126 and miRNA503 levels are 0.5-fold reduced and 2-fold increased, respectively, in Glo1-/+ MAEC compared to WT MAEC.

Conclusion: These results suggest that MG accumulation impairs the angiogenic ability of Glo1-/+ MAEC. This effect is associated to the overexpression of the anti-angiogenic HoxA5 and the altered levels of miRNA-126 and miRNA-503, found to be modified in vascular dysfunction. A better understanding of the molecular mechanisms by which MG alters the angiogenic process may allow to identify novel approaches in the prevention and treatment of diabetes vascular disease.

Fructose-derived advanced glycation end-products induce a negative crosstalk between lipogenesis and muscle reprogramming in mice through SREBP-1c

R. Mastrocola¹, M. Collino², D. Nigro¹, C. Medana³, F. Dal Bello³, F. Chiazza², G. Boccuzzi⁴, M. Aragno¹;

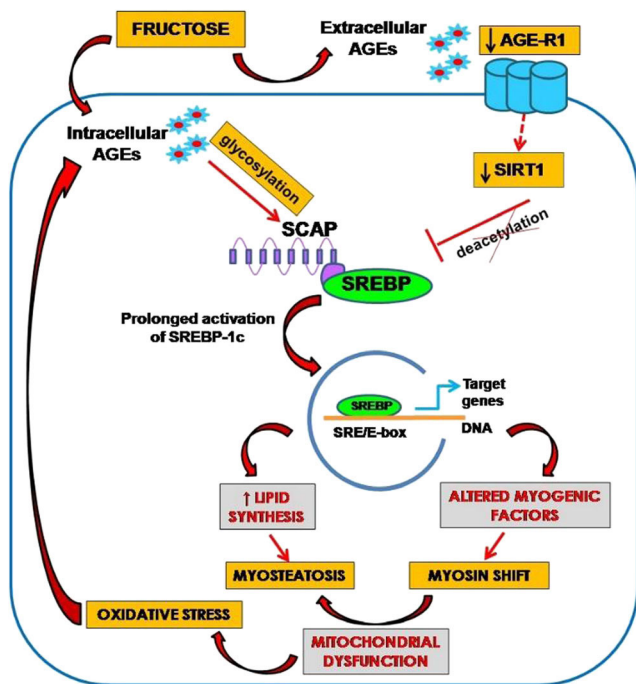

¹Clinical and Biological Sciences, ²Drug Science and Technology, ³Molecular Biotechnology and Health Sciences, ⁴Medical Sciences, University of Turin, Italy.

Background and aims: Advanced Glycation End-Products (AGEs) have been recently linked to the onset of obesity, adiposity, and insulin-resistance. AGEs can endogenously be formed by dietary sugars, in particular fructose, which is widely used as added sweetener in foods and drinks. We previously reported that chronic fructose exposure generates AGEs in mice plasma and liver at higher level than glucose. Recently we documented that AGEs accumulate in gastrocnemius muscle in obese mice and that this is associated to activation of the SCAP/SREBP-1c lipogenic pathway. We have now investigated whether mice skeletal muscle structure and metabolism can be affected by chronic exposure to a high-fructose diet and we have better characterized the causal role of fructose-derived AGEs by using the glycation inhibitor pyridoxamine.

Materials and methods: C57Bl/6J mice were fed a standard diet (SD) or a 60% fructose diet (HFRT) for 12 weeks. Two subgroups of SD and HFRT mice received the anti-glycative compound pyridoxamine (120 mg/kg/day) in the drinking water.

Results: At the end of protocol HFRT mice showed increased plasma glucose (P<0.05 vs SD), insulin (P<0.05 vs SD), triglycerides (P<0.05 vs SD) and cholesterol (P<0.001 vs SD), and impaired OGTT curve. Very high levels of AGEs were detected both in plasma and gastrocnemius muscle (P<0.001 vs SD). We found that AGEs enhanced the activation of SREBP-1c through either downregulation of the SREBP-inhibiting enzyme SIRT-1 and increased glycation of the SREBP-activating protein SCAP. Interestingly, the AGEs-induced SREBP-1c activation also had dramatic repercussions on myogenic regulatory factors and myosin heavy chain isoforms expression, paralleled by depletion of muscle strength (P<0.05 vs SD) and increased fatigability (P<0.05 vs SD). This could be related to the impaired individual oxidative activity of myofibers, and oxidative stress increase. The use of pyridoxamine almost completely counteracted not only AGEs generation, but all the fructose-induced muscle alterations.

Conclusion: The present data indicate for the first time that fructose-derived AGEs exert a multiple interference on SREBP-1c activity which in turn enhances fatty acids synthesis and impairs muscle proteins expression, leading to a negative crosstalk between lipogenesis and muscle reprogramming. Thus, these findings revealed an unsuspected involvement of AGEs in muscle derangements that could contribute to further progression of insulin resistance and obesity.

Lens autofluorescence relates to skin autofluorescence but poorly to glycated haemoglobin in patients with diabetes

J. Skrha jr., J. Soupal, M. Prazny, J. Skrha;

Third Department of Medicine, First Faculty of Medicine, Charles University in Prague, General University Hospital, Czech Republic.

Background and aims: Advanced glycation endproducts (AGEs) play an essential role in the pathophysiology of diabetes and its complications. Their accumulation in the lens reflects the intensity of glycation process and it is demonstrated by specific lens autofluorescence. Recently, a new confocal biomicroscope ClearPath DS-120 easily measuring lens autofluorescence (LAF) has been developed. The aim of this study was to compare lens autofluorescence (LAF) in diabetic and non-diabetic subjects with their skin autofluorescence (SAF) and parameters of glucose control.

Materials and methods: LAF was measured in the left eye in 126 diabetic patients (55 Type 1 /T1DM/ aged 42 ± 14 yrs, 71 Type 2 /T2DM/ aged 61 ± 10 yrs) and 59 healthy controls (aged 47 ± 13 yrs) by ClearPath DS-120 (Freedom Meditech, US). SAF was measured on forearm by AGE-Reader (Diagnoptics BV, Netherlands) in subgroup with 116 subjects (32 T1DM, 35 T2DM and 49 controls). Results were expressed in arbitrary units (AU) and compared with age, anthropometrical data, current glycated hemoglobin HbA1c (in IFCC units) and mean HbA1c in the last 2 years, renal function (using MDRD formula) and albuminuria.

Results: In both T1DM and T2DM LAF was significantly higher as compared to healthy controls (0.26 ± 0.09 , 0.23 ± 0.06 vs 0.17 ± 0.04 AU, $p < 0.0001$). Similar results were found in SAF (2.01 ± 0.45 , 2.28 ± 0.57 vs 1.78 ± 0.33 AU, $p < 0.0001$). Significantly higher mean current HbA1c

found in T1DM and T2DM as compared to controls (65 ± 16 ; 58 ± 18 vs 34 ± 5 mmol/mol, $p < 0.0001$) was related to LAF only in T2DM (T1DM: $r = 0.19$, NS; T2DM: $r = 0.37$, $p < 0.01$; controls: $r = 0.28$, NS). The same was true for the two-year HbA1c. LAF was inversely related to glomerular filtration in T1DM ($r = -0.34$, $p < 0.05$) and controls ($r = -0.29$, $p < 0.05$), but not in T2DM ($r = -0.10$, NS). No significant difference of LAF was observed in diabetic patients with or without positive albuminuria (0.27 ± 0.08 vs 0.24 ± 0.07 AU, NS). Significant relationship of LAF and SAF was found in all groups (T1DM: $r = 0.53$, $p < 0.005$, T2DM: $r = 0.36$, $p < 0.05$; controls: $r = 0.30$, $p < 0.05$).

Conclusion: Our study demonstrates significant association of lens and skin autofluorescence in subjects with or without diabetes. It confirms similar effect of non-enzymatic glycation in two different tissues. LAF is elevated in diabetes, but is not entirely related to current or average two-year HbA1c, since LAF is likely a very-long-term glycation marker independent on HbA1c variability. On the other hand, LAF does not reflect more advanced changes as it was not significantly different in patients with or without albuminuria or with normal or decreased MDRD. A follow-up study will be necessary to evaluate the usefulness of LAF in clinical practice.

Synergistic effects of transplanted endothelial progenitor cells and RWJ67657 in diabetic ischaemic stroke models

Y.-Y. Bai;

Jiangsu Key Laboratory of Molecular and Functional Imaging, Department of Radiology, Zhongda Hospital, Nanjing, China.

Background and aims: An immature vascular phenotype in diabetes may cause more severe vascular damage and poorer functional outcomes after stroke, and it would be feasible to repair damaged functional vessels using endothelial progenitor cell (EPC) transplantation. However, high glucose induces p38 mitogen-activated protein kinase (MAPK) activation, which can accelerate the senescence and apoptosis of EPCs. The aim of this study was to investigate the combined effects of EPC transplantation and p38 MAPK inhibitor administration on diabetic stroke outcomes.

Materials and methods: Bone marrow-derived EPCs, labeled with a multi-functional nanoprobe modified with paramagnetic chelators and fluorophores, were injected intra-arterially into wild-type and db/db mice after ischemic stroke induction. RWJ 67657 (RWJ), a p38 MAPK inhibitor, was administered orally into db/db mice for 7 consecutive days, with the first dose given 30 min before stroke induction.

Results: The signal on magnetic resonance (MR) and optical imaging of diabetic stroke models was significantly lower than that of wild-type controls ($P < 0.001$, $n = 4$ to 6 per group). However, the signal intensity of diabetic stroke models significantly increased after oral administration of RWJ ($P < 0.05$, $n = 4$ or 5 per group), indicating that more transplanted EPCs migrated to the ischemic brain. Neither EPC transplantation nor RWJ administration alone significantly improved diabetic stroke outcome, although RWJ displayed a potent anti-inflammatory effect. By both improving the functioning of EPCs and reducing inflammation, EPC transplantation plus RWJ administration in vivo synergistically promoted angiogenesis ($P < 0.05$, $n = 4$ per group) and neurogenesis ($P < 0.05$, $n = 6$ or 7 per group) after diabetic stroke. In addition, fractional anisotropy value and number of fibers in the ipsilateral internal capsule derived from MR diffusion tensor imaging (MR-DTI), together with myelin basic protein-positive cells were significantly increased in the combination group, indicating more white matter remodeling. Furthermore, behavioral scores, infarct volume reduction, and expressions of VEGF and BDNF were significantly increased in diabetic mice treated with both EPCs and RWJ.

Conclusion: The dual-modal imaging strategy suggested that diabetes reduced the number of transplanted EPCs homing to the ischemic area, while consecutive intragastric administration of RWJ could protect EPC from being damaged in diabetic mice. The combination of EPC

transplantation and RWJ administration accelerated recovery from diabetic stroke, which might have been caused by increased levels of pro-angiogenic and neurotrophic factors.

A novel role for the Krüppel-like factor 14, *klf14*, on macrophage inflammatory response and atherosclerosis development

Y. Jia^{1,2}, L. Li^{1,2}, G. Yang³;

¹Key Laboratory of Diagnostic Medicine (Ministry of Education) & Department of Clinical Biochemistry, ²College of Laboratory Medicine, ³Department of Endocrinology, the Second Affiliated Hospital, Chongqing Medical University, China.

Background and aims: Genome-wide association studies have shown that Krüppel-like factor 14 (KLF14) is associated with both Type 2 diabetes mellitus (T2DM) and lipid metabolism. However, its role in chronic inflammatory responses and the pathogenesis of atherosclerosis remains unknown. The present study was designed to investigate in both vivo and vitro the impact of KLF14 on chronic inflammatory responses and atherosclerosis.

Materials and methods: In vivo, KLF14-knockdown ApoE KO mice by an adenovirus-mediated RNAi was used to assess the effects of KLF14 knockdown on metabolic parameters and the formation of atherosclerosis on a high fat diet. Atherosclerotic lesions in the aorta were analyzed by en face analysis of the spread total aorta and analysis of cross sections of the aortic sinus with oil red O staining. The circulating levels of pro-inflammatory cytokine in ApoE KO mice were detected by ELISA. In vitro, Both the effects of up-regulation and down-regulation of KLF14 on the ac-LDL-induced cholesterol accumulation in macrophage were evaluated. Effects of KLF14 on the expressions of cytokines and the activities of mitogen-activated protein kinases (MAPKs) were detected by real time-PCR and western blot, respectively. The specific inhibitors of MAPKs were used to analyze the mechanisms by which KLF14 regulates the accumulation of cholesterol and cholesterol ester.

Results: Here, we have shown that in ApoE KO mice, a well established animal model of atherosclerosis, fed with both high fat diet (HFD) and standard chow diet (SCD), expression of KLF14 in aorta tissues was higher than in C57BL/6J mice. Consistent with this, adenovirus-mediated KLF14 knockdown markedly reduced the circulating levels of pro-inflammatory cytokine and the formation of atherosclerotic lesions in HFD-fed ApoE KO mice. In RAW264.7 macrophages, KLF14 overexpression significantly increased ac-LDL induced expressions of inflammatory cytokine and further strengthened ac-LDL-induced increase in total cholesterol (TC), cholesteryl ester (CE) and the ratios of CE to TC. Conversely, KLF14 knockdown in these cells remarkably attenuated ac-LDL-induced increase in TC, CE and the ratios of CE to TC and the expressions of inflammatory cytokine. KLF14 overexpression remarkably elevated the phosphorylation levels of p38 MAPK and ERK1/2 in ac-LDL-stimulated RAW264.7 macrophages. Importantly, treatment with a p38 MAPK (PD098059) and ERK1/2 inhibitors (SB203580) significantly nullified the ability of KLF14 to promote inflammatory cytokine expressions in these cells.

Conclusion: These data demonstrate an important role for KLF14 expression in atherosclerotic lesion formation. Thus, KLF14 may be a potential target for therapy of atherosclerosis.

Increased infiltration of inflammatory immune-cells in sciatic nerves but not in dorsal root ganglions in late diabetic neuropathy in the murine STZ model of diabetes

A.S. Hidmark, T.H. Fleming, S. Vitas, P.P. Nawroth;

Innere Medizin I und klinische Chemie, Heidelberg, Germany.

Background and aims: The diabetic condition is associated with a pro-inflammatory phenotype of immune-cells infiltrating into different organs

where inflammatory macrophages contribute to the pathogenesis of the disease and impair tissue re-generation. Infiltrating immune-cells into the peripheral nervous system during DN, in absence of an injury, has not yet been demonstrated in the streptozotocin (STZ) mouse model of diabetes. The aim of this study is to investigate changes to immune-cell population in sciatic nerve (SN) and dorsal root ganglion (DRG) in late diabetic neuropathy.

Materials and methods: Diabetes was induced in WT C56BL/6, mice or in mice lacking T-cells (RAG2^{-/-}) by STZ (50 mg/kg/day i.p. for 5 days). At 6 months, thermal hypoalgesia was assessed by hotplate and Hargreave's and neuronal blood flow of SN by laser-doppler. Peritoneal cavity lavage was collected and SN and DRGs were digested and stained with antibodies against CD45, CD68 and CD206. The cells were analyzed by flow cytometry. Statistical significance was tested with two-tailed student's T-test.

Results: At 6 months of STZ-induced diabetes, WT mice showed significant hypoalgesia, as compared to the age-matched WT controls; hotplate response times were increased by 6.5 secs on average ($p < 0.002$) and 2.8 secs by Hargreave's ($p < 0.0001$). SN blood-flow was significantly reduced in WT diabetic mice (74% as compared to controls, $p < 0.01$, $n = 5$). In contrast, the diabetic RAG2^{-/-} mice showed no significant differences either in measurements of thermal hypoalgesia or SN-blood flow. In the SN of the WT diabetic mice, a 2-fold increase of infiltrating CD45⁺ leukocytes was observed by flow cytometry (from 4.5% of all nucleated cells to 9.3%, $p < 0.001$, $n = 11$), but no significant increase in infiltration was observed in the DRGs. These findings were confirmed by immunohistochemistry stainings of SN and DRGs cryosections. No increase in infiltrating leukocytes was observed in the SN of the RAG2^{-/-} diabetic mice, as compared to the control RAG2^{-/-} mice. In SN of both the control and diabetic WT mice, 50–70% of the infiltrating CD45⁺ cells expressed the macrophage marker CD68. However, fewer of the SN CD68⁺ macrophages in the WT diabetic mice expressed the M2 marker, CD206 (reduced from 70% of macrophages in control to 58% in diabetic mice, $p < 0.01$). The proportion of macrophages in peritoneal cavity lavage expressing CD206 was reduced from 10% in WT control mice to 4% in WT diabetic mice ($p < 0.05$).

Conclusion: Late diabetic neuropathy is associated with increased infiltration of leukocytes in SN but not DRG of STZ-induced diabetic mice. Leukocyte infiltration into SN and neuropathic symptoms, such as thermal hypoalgesia and reduced SN blood-flow, were reduced in mice lacking T and B cells. We conclude that late diabetic neuropathy is associated with changes of macrophage populations in peripheral nerves, which require the adaptive immune system.

New insights for an old marker: TGF-beta, diabetic nephropathy and metabolic memory

A.A.F. Oliveira¹, L.L. Bobadilla¹, T.F. Oliveira¹, M.H.G. Medeiros², P. Di Mascio², A.M. Loureiro¹;

¹Department of Clinical and Toxicological Analysis, ²Department of Biochemistry, University of São Paulo, Brazil.

Background and aims: Metabolic memory has been pointed out as an important phenomenon to explain the increasing incidence of diabetic nephropathy (DN) and other diabetes complications even by patients under intensive glycemic control. TGF- β is thought to play a key role in mediating major kidney alterations due to diabetes, such as hypertrophy and fibrosis. Although the mechanisms by which TGF- β causes renal fibrosis are well characterized, the relationship between TGF- β and metabolic memory remains unexplored, which is the purpose of this study.

Materials and methods: Male Wistar rats were made diabetic by a single injection of streptozotocin. After 4 or 12 weeks of diabetes induction, animals were kept under intensive glycemic control for the same period, until 8 or 24 weeks, respectively. Treatments were performed with insulin alone or combined with metformin (100 mg/kg). For the 24 weeks study, a group treated with insulin plus N-acetylcysteine (NAC, 750 mg/kg) was included. Control groups consisted of non-diabetic and diabetic animals after 8, 12 and 24 weeks. Body weight and blood glucose were monitored weekly, while HbA1c and renal function were assessed at different time points along the study. Renal expression of TGF- β was analyzed by western blotting, and intracellular metabolites related to glycolytic pathway and tricarboxylic acid cycle were quantified in kidney tissue by reverse phase ion pair HPLC-ESI-MS/MS.

Results: High levels of HbA1c were detected after 4 weeks of diabetes, but the decline of renal function started just after 8 weeks, as evidenced by increased proteinuria, albuminuria and kidney/body weight ratio. This impairment on renal function occurred in parallel to the raise of TGF- β expression ($p = 0.0018$), ATP ($p = 0.0039$), and fumarate ($p = 0.0103$) levels, compared to non-diabetic animals. Treatments with either insulin alone or combined with metformin recovered all of these early alterations. After 12 weeks of diabetes, the decline of renal function was more pronounced, including tubular injury, assessed by KIM-1 quantification in urine ($p = 0.0003$). TGF- β expression remained elevated ($p = 0.0040$), as well as glutamine ($p = 0.0024$) and glutamate ($p = 0.0043$), in comparison to non-diabetic rats. At the end of 24 weeks, when diabetic animals presented a clear impairment of glomerular and tubular function, renal expression of TGF- β was even higher ($p = 0.0198$) and none of the treatment strategies were able to normalize it. Concomitantly, greater levels of pyruvate ($p = 0.001$), lactate ($p = 0.0002$), malate ($p = 0.0464$), succinate ($p = 0.0166$), glutamine ($p = 0.0051$), and glutamate ($p = 0.0211$) were detected in diabetic kidneys, suggesting the occurrence of tricarboxylic acid cycle changes.

Conclusion: Increased TGF- β expression is an early alteration related to DN, which is just normalized by early, but not late, glycemic control, even though renal function is re-established. This uncontrolled TGF- β expression may lead to mitochondrial damage and mediate other long-term modifications related to the occurrence of metabolic memory, which deserves more investigation.

Impaired cytokine responses from circulating monocytes in type 2 diabetes mellitus

F. Kousathana¹, M. Georgitsi², V. Lambadiari³, E.J. Giamarellos-Bourboulis², G. Dimitriadis³, M. Mouktaroudi²;

¹2nd Department of Internal Medicine, Research Unit and Diabetes Center, University of Athens, Medical School, Attikon University Hospital, ²4th Department of Internal Medicine, University of Athens, Medical School, ³2nd Department of Internal Medicine, Research Unit and Diabetes Center, University of Athens, Medical School, Attikon University Hospital, Greece.

Background and aims: Although type 2 diabetes mellitus (T2DM) is associated with predisposition to infection, the mechanism is poorly studied. We explored the impairment of innate immune responses to microbial antigens as part of the mechanism underlying infection predisposition.

Materials and methods: Peripheral blood mononuclear cells were isolated from 20 healthy controls and 34 treatment-naïve patients (HbA1c 9.64±1.48%) and stimulated with each of the following six stimuli: a) the purified Toll-like receptor (TLR)-4 ligand lipopolysaccharide (LPS) of *Escherichia coli* O55:B5; b) the TLR2 ligand Pam3Cys; c) the lymphocyte mitogen phytohemagglutinin (PHA); and d) heat-killed isolates of *Pseudomonas aeruginosa* (PA), *Staphylococcus aureus* (SA) and *Candida albicans* (CA). TNF α and IL-1 β were measured in cell supernatants. Stimulations were repeated after 3 and 6 months of treatment and related with the level of glycemic control. Any less than 5-fold increase of cytokine production to at least four stimuli compared to medium-treated cells was considered appropriate response. HbA1c below 7% was considered proper glycemic control.

Results: All healthy controls (100%) had appropriate cytokine responses compared to only 18 (52.9%) of T2DM patients ($p < 0.0001$). This was predominantly shown for IL-1 β after stimulation with LPS, PA and CA (Figure). In treatment month 3, IL-1 β produced after LPS stimulation of cells of patients with proper glycemic control was 5277.6±1262.0 pg/ml compared with 1235.8±488.8 pg/ml of cells of patients with improper glycemic control ($p < 0.0001$).

Conclusion: T2DM is characterized by impaired cytokine production from circulating monocytes. This is pronounced for LPS that is a ligand of the cell wall of Gram-negative bacteria and it is partly restored after proper glycemic control. Results provide insight into the mechanism of predisposition for Gram-negative infections in T2DM and of the importance of proper glycemic control for prevention.

IL-1beta, a novel predictive factor of cardiovascular disease in patient with newly diagnosed, drug-naïve type 2 diabetes mellitus

K. Joung, H. Kim, B. Ku;

Internal Medicine, Endocrinology, Chungnam National University, Daejeon, Republic of Korea.

Background and aims: Cardiovascular disease (CVD) is a major cause of death in patients with type 2 diabetes mellitus (T2DM). So development of markers to detect earlier and prevent CVD in patients with T2DM is very important. Chronic activation of innate immune system through the nucleotide binding and oligomerization domain-like receptor family pyrin domain-containing 3 (NLRP3) inflammasome leads to the maturation and secretion of proinflammatory cytokines such as IL-1beta and 18 and plays an essential role in the pathogenic mechanism of T2DM and CVD. In our previous study, NLRP3 inflammasome activation is elevated in myeloid cells from drug-naïve, newly diagnosed type 2 diabetic patients and antidiabetic treatment with metformin contributes to modulation of inflammasome activation. However, the study whether the NLRP3 inflammasome activation and its products in diabetic patients can predict the risk of CVD has not been reported. Therefore, we examined the association of CVD risk using the Framingham risk equation with the NLRP3 inflammasome activation in two groups; patients with newly diagnosed, drug-naïve T2DM (New-DM) vs with patients taking anti-diabetic drug over one year (Old-DM).

Materials and methods: We used the serum, cultured monocyte-derived macrophages (MDMs) and their supernatants for measuring the mRNA expression and secreted maturation form of IL-1beta in New-DM (n=44) and Old-DM (n=16). Statistical analyses were completed using unpaired t-test, Pearson correlation, and one-way ANOVA.

Results: Although the mean values of Framingham 10-year CVD risk score were not significantly different between two groups (8.9±7.1 vs 9.3±7.4, $p = 0.863$), the serum value of IL-1beta showed the positive linear correlation with Framingham 10-year CVD risk score only in New-DM ($r = 0.314$, $p = 0.038$), not in Old-DM ($r = -0.083$, $p = 0.760$). To evaluate whether IL-1beta and NLRP3 inflammasome activation were different between the low risk group (10-year CVD risk score < 5%) and the intermediate to high risk group (10-year CVD risk score $\geq 10\%$), we compared the values of mean \pm SD between two groups in New-DM and Old-DM. The serum value of IL-1beta showed the significantly increase in the intermediate to high risk group compared to the low risk group only in New-DM (18.03±15.36 vs 28.41±10.65, $p = 0.046$), not in Old-DM (23.25±13.43 vs 21.47±8.99, $p = 0.960$) as expected. In addition, the intermediate to high risk group compared to the low risk group had significantly elevated levels of IL-1beta in LPS-primed MDMs after treatment with different “danger signal” molecules, such as ATP (349.35±141.32 vs 383.17±157.60, $p = 0.017$), monosodium uric acid crystals (MUS) (262.94±69.98 vs 283.30±82.68, $p = 0.003$) and free fatty acids (FFAs) (384.41±127.11 vs 392.55±141.60, $p = 0.004$) only in New-DM, not in Old-DM.

Conclusion: In conclusion, serum IL-1beta was positively correlated with CVD risk score using Framingham risk equation only in New-DM. The serum value of IL-1beta also increased significantly in the intermediate to high risk group compared to the low risk group only in New-DM. Our study suggests that serum IL-1beta might be used as a marker for prediction of CVD in newly diagnosed type 2 diabetic patients.

Glycaemic variability correlates with 1.5-AHG but not with markers of oxidation, inflammation and endothelial function: baseline results of the CAROLINA® CGM substudy

R. Mazze¹, R. Bergenstal¹, E. Strock¹, X. Min¹, K. Thompson¹, S. Borgman¹, M. Mattheus², K. Hermansson³, H. Woerle⁴, O. Johansen⁵; ¹International Diabetes Center, Minneapolis, USA, ²Global biometrics, Boehringer-Ingelheim, Ingelheim, Germany, ³Boehringer-Ingelheim, Stockholm, Sweden, ⁴Therapeutic area metabolism, Boehringer-Ingelheim, Ingelheim, Germany, ⁵Medical department, Boehringer-Ingelheim, Asker, Norway.

Background and aims: DPP4-inhibitors enhance glucose-induced insulin secretion, decreases glucagon secretion and might effectively reduce blood glucose variability. This is investigated in the CGM substudy of CAROLINA®, an ongoing, cardiovascular outcome trial assessing potential differing impact of linagliptin or glimepiride predominantly when given as second line therapy in patients with relatively early type 2 diabetes (T2D).

Materials and methods: To explore potential relationships between glycaemic variability (assessed with CGM, Dexcom SEVEN PLUS) and circulating markers of glucose variability (1.5 - anhydroglucitol [1.5-AHG]), oxidative stress (8 isoprostane prostaglandin F_{2α}) endothelial function (asymmetric dimethylarginine and Endothelin-1) and systemic inflammation (interleukin-6) we analyzed the baseline glucose excursion patterns and assessed whether glycaemic variability was correlated with five vascular markers. Specifically, we characterized the baseline ambulatory glucose profiles (AGP) with glucose exposure (by total area under the curve), glucose variability (by inter-quartile range) and glucose stability (by the average hourly absolute change) of all CGM readings over a 2-week period. We also calculated the mean amplitude of glycemic excursions (MAGE).

Results: Mean ± SD age of the 44 patients (91% males) with T2D was 66 ± 9 years and HbA1c 7.0 ± 0.4%. Median (min, max) diabetes duration was 11.0 (4.0, 29.0) years and 43% had a history of vascular complications. 79.5% were treated with metformin (66% in monotherapy), 34.1% received a sulfonylurea (34% as monotherapy) and 11.4% did not receive and treatment. As indicated in the table, a modest, significant negative correlation between glycaemic variability and 1.5 AHG was observed, but no significant correlations between the vascular markers and glucose variability were seen.

Conclusion: A modest, significant negative correlation between glycaemic variability and 1.5 AHG was observed indicating a potential applicability of this marker to identify patients with excess glucose perturbations. We found no significant correlations between glycaemic variability and the vascular markers (Table). Future analysis of the prospective CAROLINA® CGM substudy will determine if glimepiride and linagliptin have differing impact on glycaemic excursions patterns.

Table. CGM and biomarker characteristics of the CAROLINA® CGM-substudy population

Markers of glycaemic variability		Correlations between glucose variability and biomarkers	
		Spearman's correlation coefficient	p-value
Glucose variability (mean±SD)	44.2±12.6 mg/dL		
Glucose stability (mean±SD)	8.9±3.3 mg/dL/hr		
Glucose exposure (mean±SD)	3506.1±491.1 mg dL*24hr		
MAGE*	72.5±26.9 mg dL		
Biomarkers*			
1.5 AHG (mean±SD)	12.8±6.2 µg/ml	-0.366	0.0186
IL-6 (median, min, max)	3.0 (1.4, 22.2) pg/ml	0.034	0.8329
TNF-α (median, min, max)≠	2.9 (2.2, 5.6) pg/ml	0.191	0.2963
8-iso PGF _{2α} (median, min, max)	23.4 (17.2, 60.2) pg/ml	0.104	0.5161
ADMA (median, min, max)	0.5 (0.4, 0.7) µmol/l	0.256	0.1063
Endothelin-1 (median, min, max)	1.9 (0.7, 19.9) fmol/ml	-0.08	0.6223

*: n=41, †: n=32 Abbreviations: BP – blood pressure; CRP – c-reactive protein; MAGE – mean amplitude of glycemic excursions; AHG – anhydroglucitol; TNF-α – tumor necrosis factor α; 8-iso PGF_{2α} – 8 isoprostane prostaglandin F_{2α}; ADMA – asymmetric dimethylarginine.

Role of SGK-1 in regulating eNOS activity in human coronary artery endothelial cells

D. Pastore¹, D. Della Morte¹, B. Capuani¹, F. Pacifici¹, A. Coppola¹, R. Arriga¹, A. Bellia¹, A. Galli², M. Romano², P. Sbraccia¹, M. Tesaro¹, G. Sconocchia³, D. Lauro¹;

¹University of Rome Tor Vergata, ²University Hospital 'Fondazione Policlinico di Tor Vergata', ³Institute of Translational Pharmacology, National Research Council, Roma, Italy.

Background and aims: Cardiovascular diseases (CVD) are the leading cause of death globally and especially in patients with diabetes. CVD is a class of diseases that involve the blood vessels, in fact the initial step in development of CVD is the impairment in endothelial homeostasis, which is modulated by nitric oxide (NO) production. Important studies performed in endothelial cells recognized some signaling, such as the activation of PI3K-AKT-1 pathway, that improves endothelial nitric oxide synthase (eNOS) activation as a result of insulin stimulation. While it is known that Akt-1 directly phosphorylates human eNOS at Ser1177 resulting in an increase of eNOS activity, on the contrary the role of Serum and glucocorticoid-inducible kinase (SGK)-1 in modulation of eNOS activity is still sparse. In this study, we analyzed the role of SGK-1 in regulating eNOS activation in a cell model of human coronary artery endothelial cells (HCAEC).

Materials and methods: A retrovirus system was used to infect HCAEC with different constructs such as SGK-1wt, SGK-1Δ60 (lacking of the N-60 amino acids, not ubiquitinated and more active construct), and SGK-1Δ60KD (kinase dead constructs). eNOS phosphorylation at Ser1177 was measured in cells infected with different SGK-1 constructs in diverse experimental conditions: 1. insulin stimulation alone (10⁻⁷ M for 1 h); 2. SGK1 inhibitor (GSK650394, 103 nM, added 30 min before insulin); 3. AKT-1 inhibitor (iAKT, 10 µM, added 18 h before insulin) in presence or absence of insulin.

Results: AKT-1 inhibitor completely inhibited phosphorylation and activation of AKT-1 in Ser473 in all constructs, but inhibited only partially eNOS phosphorylation in Ser1177. In a similar way, SGK-1 inhibitor, inhibited only partially eNOS activity and phosphorylation but this inhibition was significantly less (p<0.05) in SGK-1Δ60 cells than other constructs, probably due to an increased activity of SGK-1 in these cells.

Conclusion: These results demonstrated that SGK-1 and AKT-1 may have a synergistic and compensatory effect in inducing eNOS phosphorylation in Ser1177 modulating NO production in HCAEC cells. Further studies in different cellular systems and in vivo are needed to better define the role of SGK-1 in diabetic cardiovascular diseases.

1175

Previously unknown glucose abnormalities are common in individuals with periodontitis, especially in those with a previous myocardial infarction

A. Norhammar¹, B. Kjellström¹, N. Habib¹, P. Näsman², A. Gustafsson³, L. Rydén¹, for the PAROKRANK Study Group;

¹Karolinska Institute, Department of Medicine, Cardiology Unit, Karolinska University Hospital, ²Royal Institute of Technology (KTH), ³Karolinska Institute, Dental Medicine, Stockholm, Sweden.

Background and aims: Periodontal disease (PD) is more common in diabetes (DM) and is suggested as a risk factor for myocardial infarction (MI) as well as for dysglycaemia. The prevalence of unknown abnormal glucose tolerance (AGT) in people with PD and if this is more common in MI patients with PD has not been investigated. We studied the prevalence of AGT in different grades of PD in patients with a first MI and controls.

Materials and methods: Patients (n=805) <75 years with a first MI in Sweden 2010-2014 and age and gender matched controls (n=805) were examined for risk factors, including an oral glucose tolerance test (OGTT). Dental bone loss was examined by panoramic radiographs

and PD classified as healthy ($\geq 80\%$ remaining bone), mild to moderate (79–66%) or severe ($< 66\%$). Known diabetes was present if reported by the participant. AGT was based on OGTT according to WHO (DM=F-glucose: ≥ 7.0 mmol/l and or F-glucose < 7.0 and 2-h above 11.0 mmol/l, impaired glucose tolerance (IGT); F-glucose < 7.0 and 2-h glucose $\geq 7.8 - 11.0$ mmol/l).

Results: Mean age was 62 ± 8 years (81% males). Previously known DM was present in 10% of patients and 8% of controls, newly detected DM in 9 and 5% ($p=0.002$) and new IGT in 20% and 12% ($p<0.0001$) respectively. AGT (new DM +IGT) was present in 29% of patients and 17% of controls ($p<0.0001$). Among study participants with signs of PD (moderate + severe) 62% of patients and 37% of controls had unknown AGT. Newly detected DM (Figure) was more common in patients with severe PD than in those without PD (18% vs. 9%) and more common than in controls (9% vs. 4%).

Conclusion: Unknown AGT is more common among patients with a first MI than in controls and especially apparent in the presence of PD. Newly detected DM is particularly apparent in patients with severe PD. This indicates that PD may induce a chronic inflammatory condition and provoke glucose abnormalities as well as MI supporting the assumption of a two-way relationship between dysglycaemia and PD.

The relationship between LDL-c reduction during statin therapy and the risk of new-onset diabetes: a meta-analysis

R. Cai¹, Y. Yuan¹, S. Wang¹, X. Ruan²;

¹Affiliated ZhongDa Hospital of Southeast University, Nanjing, China,

²John Moorhead Research Laboratory, Centre for Nephrology, University College London (UCL) Medical School, UK.

Background and aims: Recent studies demonstrated that lower target LDL-c level of statin use is associated with excess risk of diabetes. This study is to investigate under what circumstances we should focus on statin-induced diabetes according to the new ACC-AHA cardiovascular prevention guidelines.

Materials and methods: We searched Pubmed, Embase, and the Cochrane Central Register of Controlled Trials, with no time constraints, for randomized placebo and standard care-controlled endpoint trials of statins. According to the new ACC-AHA cardiovascular prevention guidelines, the included trials were stratified by the relative LDL-c reduction of 10% to 20%; 20% to 30%; 30% to 40%; or 40% to 50%. We calculated an overall odds ratio (OR) with a random-effect model.

Results: Totally, 4559 patients developed diabetes during duration in 14 trials. The risks of incident diabetes elevate by 13% and 29% when relative LDL-c reduction were 30–40% and 40–50%, respectively. However, incident diabetes did not increase when relative LDL-c reduction were $< 20\%$ and between 20–30%. In absolute terms, one additional case of diabetes is diagnosed per 137 patients and per 108 patients whose relative LDL-c reduction were 30–40% and within 40%–50% when taking statin therapy for 4 years.

Conclusion: LDL-c reduction is positive related with new-onset diabetes risk. We should pay close attention to incident diabetes among the "major statin benefit groups", especially when LDL-c reduction more than 30% during the process of lipid lowering.

1177

Effects of lipid drugs on glycaemic control in type 2 diabetesG. Bardini¹, S. Giannini², B. Cresci², L. Pala², C.M. Rotella¹;¹Obesity Agency, ²Diabetology and Endocrinology Unit, University of Florence, Italy.

Background and aims: Several studies showed that statins increase the risk of incident diabetes; however, the relationship between statins and glycaemic control in subjects with established diabetes has not been well characterized. Aim of this study was to evaluate the effect of lipid drugs, statins, ezetimibe and fenofibrate, on glycaemic control in patients with type 2 diabetes (DM2).

Materials and methods: In a retrospective study, a consecutive series of 423 (210 F, 213 M) DM2 clinic outpatients, aged 67.7 ± 8.8 years, were consecutively examined for HbA1c levels before starting lipid drugs and after 6, 12 and 18 months with lipid therapies. All patients studied remained with unchanged diabetes therapies for all the study duration. Subjects with current corticosteroids drugs and chronic kidney disease were excluded. Statins were subdivided by pharmacological potency, based on their low density lipoprotein-cholesterol reduction below 40% (low-potency statins: atorvastatin 10 mg, simvastatin 10 mg, 20 mg and 40 mg, fluvastatin, pravastatin and lovastatin at all doses) and upper 40% (high-potency statins: rosuvastatin all doses, atorvastatin 20 mg and 40 mg and simvastatin+ezetimibe all doses). We compared HbA1c levels modifications during the 18 months of follow-up in subjects with or without lipid drugs.

Results: The patients studied showed HbA1c $7.0 \pm 1.1\%$ (53 ± 12 mmol/mol) with 13.8 ± 7.1 years duration of diabetes. 90.6% patients assumed oral hypoglycaemic agents, 9.4% insulin, and 88.0% lipid drugs. Among these, 96.0% were treated with statins and 4.0% with fenofibrate. Among subjects with statins therapy, 50.8% patients assumed high-potency statins and 49.2% low-potency statins. No statistical difference was found in HbA1c baseline levels between subjects with or without lipid therapies. During the follow-up, we observed a significant increase of HbA1c levels in patients treated with lipid drugs compared to subjects without any lipid therapy: $6.9 \pm 0.9\%$ vs $6.5 \pm 0.8\%$ ($p=0.004$) at 6 months, $6.88 \pm 0.8\%$ vs $6.46 \pm 0.7\%$ ($p=0.003$) at 12 months and $6.9 \pm 0.8\%$ vs $6.4 \pm 0.8\%$ ($p=0.002$) at 18 months. Considering the effects of statins potency on HbA1c variation, we observed an increase of 0.5% at 6 months ($p=0.022$), 0.45% at 12 months ($p=0.003$) and 0.53% ($p=0.001$) at 18 months in HbA1c by high-potency statins. Low-potency statins were associated to an increment of HbA1c levels 0.31% ($p=0.025$) at 6 months, 0.36% ($p=0.03$) at 1 year and 0.48% ($p=0.001$) at 18 months. Fenofibrate showed an increase of HbA1c 0.5% ($p=0.021$) at 6 months, 0.76% ($p=0.002$) at 1 year and 0.78% ($p=0.001$) at 18 months.

Conclusion: In DM2 patients, lipid therapies are associated with a modest, but significant decrease in glycaemic control. This fact should not be relevant in clinical setting in the choice of lipid drugs considering their positive effects on cardiovascular protection.

1178

High adherence to dietary recommendations associates with lower risk of developing high triglycerides and LDL during 16 years of follow-upS. Hellstrand¹, I. Drake², U. Ericson¹, J. Hlebowicz³, B. Gullberg², B. Hedblad⁴, G. Engström⁴, M. Orho-Melander¹, E. Sonestedt¹;¹Diabetes and Cardiovascular Disease - Genetic Epidemiology, Clinical Sciences, ²Nutritional Epidemiology, Clinical Sciences, ³Experimental Cardiovascular Research, Clinical Sciences, ⁴Cardiovascular Epidemiology, Clinical Sciences, Lund University, Malmö, Sweden.

Background and aims: A high diet quality according to the Swedish nutrition recommendations associates with reduced risk of mortality and cardiovascular disease in the Malmö Diet and Cancer cohort. To further clarify this protective association we examined its relation to change in

standard blood lipids during 16 years of follow-up. In addition, because genetic variation could influence the response to certain diets we examined if genetic risk scores composed of 80 validated lipid-associated genetic variants modify this association.

Materials and methods: We included 3,145 individuals from the population-based Malmö Diet and Cancer cohort study that had standard lipid concentrations (triglycerides, HDL and LDL) measured both at baseline examination (1992-1994) and after an average of 16 years of follow-up. Dietary intakes at baseline were measured using a modified diet history method, and a diet quality index was constructed based on adherence to recommended intakes for saturated fat, polyunsaturated fat, sucrose, fiber, fruit and vegetables, and fish.

Results: A high compared with a low diet quality index was associated with higher HDL concentrations at baseline and lower risk of developing high triglycerides and high LDL during follow-up. We found an inverse association between diet quality and HDL change during follow-up only among those with lower genetic risk for low HDL but not among those with higher genetic risk (p -interaction=0.04). Among those with low genetic risk for low HDL, low diet quality was associated with decreased HDL during follow-up.

Conclusion: Individuals with high adherence to the Swedish nutrition recommendation had lower risk of developing high triglycerides and LDL during 16 years of follow-up. We found no strong evidence that genetic risk for dyslipidemia modified the association between diet quality index and change in standard blood lipids.

Rosuvastatin 5 mg improved carotid atherosclerotic changes regardless of LDL cholesterol level in Japanese diabetic patients: a 2-year prospective study

R. Saiki, H. Imai, M. Hashizume, Y. Kigawa, G. Koizumi, R. Tadokoro, S. Sato, F. Otsuka, M. Taniyama;

Endocrinology and Metabolism, Showa University Fujigaoka Hospital, Yokohama, Japan.

Background and aims: A new AHA guideline on the treatment of blood cholesterol recommends moderate-intensity statin therapy (MIST) for diabetic patients regardless of LDL-C levels. In Japan, we set the targeted values for lipid level in detail based on medical conditions. However, the dosage of strong statin is generally less than western countries due to size of physique. Therefore, no enough evidences using MIST exist for Asian people. In this study, we had assessed the effectiveness of rosuvastatin 5 mg as MIST on carotid atherosclerotic changes for Japanese diabetic patients.

Materials and methods: Ninety-nine diabetic outpatients (59.6% male; mean age= 55.8 ± 8.0 years; average diabetic duration= 9.4 ± 6.5 years; mean HbA1c= $7.26 \pm 1.3\%$; 33% statin-naïve) were enrolled who also meet the following requirements; Age ≤ 65 years, with hyper lipidemia, found max carotid intima media thickness (CIMT) ≥ 1 mm or plaques in carotid ultra sound (US). 33 patients had already received statin therapy before the study. Daily oral administration of 5 mg rosuvastatin was started or switched from other statins and the fasting blood samples were collected (including TC, HDL-C, triglyceride and LDL-C was estimated by Friedwald method) every 1 to 3 months, then carotid US had been performed 1 to 2 years later. We had assessed the mean CIMT(mm) including no plaques, max CIMT(mm) and stenosis(%) using ECST measurement method and the course of primary lesion area of max CIMT and stenosis was followed. In addition, we assessed the change of US findings depending on reduced LDL-C levels.

Results: Mean levels of LDL-C were reduced from 100.4 ± 28.4 (mg/dl) to 71.5 ± 23.7 (after 1-2 years). There were no significant changes in HbA1c levels for 2 years (mean HbA1c: $7.26 \rightarrow 7.26 \rightarrow 7.27\%$). The significant improvement was not accepted after 1 year, but accepted after

2 years through the observation of carotid US findings: mean CIMT $0.76 \pm 0.16 \rightarrow 0.72 \pm 0.16$ ($p=0.02$), max CIMT $2.0 \pm 0.9 \rightarrow 1.8 \pm 0.8$ ($p=0.0002$), stenosis $22.9 \pm 9.2 \rightarrow 20.2 \pm 8.3$ ($p<0.0001$) (by using Student's *t* test). Based on the levels of LDL-C after 1-2 years of administration, we divided participants into 2 groups by referring to the ESC/EAS dyslipidemia guideline recommendation for diabetic patients [LDL-C<70 mg/dl=group A ($n=51$; mean age=56.5 years; 63% male; mean LDL-C=55.1 mg/dl; mean HbA1c=7.2%); $70 \leq$ LDL-C=group B ($n=48$; mean age=55.0 years; 56% male; mean LDL-C=89.6 mg/dl; mean HbA1c=7.4%)]. Both groups had significant amelioration of max CIMT (A: $p=0.016$; B: $p=0.001$) and stenosis (A: $p<0.0001$; B: $p=0.002$) but mean IMT was improved only in group A ($p=0.01$) (by using Wilcoxon signed-rank test). There were no significant differences within 2 groups in the result of 2 years changing rate of each US findings (by using Mann-Whitney U test) with no significant differences in age, sex, diabetic duration and HbA1c. Mean changing rates of US findings in each group were as follows: mean CIMT [-5.6 vs -1.1 ($p=0.14$)]; max CIMT [-9.31 vs -3.22 ($p=0.81$)]; stenosis [-6.9 vs -12.9 ($p=0.95$)] (%).

Conclusion: This result shows that rosuvastatin 5 mg (as MIST) administration for Japanese diabetic patients for 2 years improves carotid atherosclerotic change regardless of maintained LDL-C levels without deterioration in HbA1c.

1180

Does diagnosis of diabetes mellitus among patients surviving an ACS event affect lipid control measures? Results from the Dyslipidaemia International Study (DYSIS) II ACS

D. Lautsch¹, A.K. Gitt², J. Ferrieres³, M. Horack⁴, V. Ashton¹, P. Brudi¹, B. Ambegaonkar¹, DYSIS II study investigators;

¹Merck & Co., Inc., Kenilworth, USA, ²Stiftung Institut für Herzinfarktforschung, Herzzentrum Ludwigshafen, Ludwigshafen am Rhein, Germany, ³Toulouse University School of Medicine, Rangueil Hospital, France, ⁴Stiftung Institut für Herzinfarktforschung, Ludwigshafen am Rhein, Germany.

Background and aims: Patients suffering an acute coronary syndrome (ACS) event with concomitant diabetes mellitus (DM) remain at very high risk for future cardiovascular complications. Current ESC guidelines recommend an LDL-C target of <70 mg/dl for very high risk patients. We aimed to determine LDL-C target achievement rates among post-ACS patients with DM and how this differs from patients without DM. We further evaluated lipid management and in those not reaching target, the distance to LDL-C <70 mg/dl.

Materials and methods: DYSIS II ACS, a multicountry observational cross sectional study, enrolled ACS patients from May 2013-October 2014 in 18 countries from Asia-Pacific, Europe, and Middle East/Africa regions. Eligible adult patients were hospitalized for an ACS event, had documented DM (previously diagnosed, fasting plasma glucose ≥ 126 mg/dl, or currently receiving treatment for DM), full lipid profile available within 24 hours of hospital admission, on lipid lowering therapy (LLT) ≥ 3 months or not at all, alive at discharge, and not participating in clinical trials involving medication. Patient follow-up interviews were conducted 4 months after ACS hospital admission date to capture details on recurrent events, current symptoms, laboratory values, LLT, and quality of life.

Results: Among 3855 enrolled ACS patients (mean age 62.3 ± 12.1 years; 76.4% male), 36.9% had DM, with 23.8% of DM patients having an LDL-C <70 mg/dl versus 16.0% of patients without DM ($p<0.0001$). Median distance to LDL-C target at enrollment was 38.0 (16.0,66.0) mg/dl among DM patients and 48.0 (24.0,77.0) mg/dl among patients without DM ($p<0.0001$). Seventy-seven percent of DM patients and 58.5% of patients without DM were currently receiving LLT when admitted to the hospital. Approximately ninety-one percent of ACS patients ($n=3496$) had 4 month follow-up data available, with 37.5% having DM. Lipid results available for 1040 patients at follow-up showed that 38.8% of

DM patients versus 28.1% of patients without DM ($p<0.001$) achieved an LDL-C <70 mg/dl. Median distance to LDL-C target was 21.5 (9.0, 42.0) mg/dl for DM patients and 21.0 (6.0,37.0) mg/dl for patients without DM ($p=0.16$). Differences in LLT management 4 months after an ACS event are shown in Table 1.

Conclusion: LLT was used the same way in both patient groups, with concomitant DM having no influence on the physicians' prescribing behavior. LDL-C was lower in patients with DM indicating towards a different lipid profile containing smaller lipoprotein particles. Additional effective lipid lowering strategies are needed among these very high cardiovascular risk patients in order to further reduce CV events.

Table 1: Lipid-Lowering Therapies 4 months after ACS Event

	DM Patients n=1231	Patients without DM n=2071
Atorvastatin equivalent dose (mg/day) ^a	33 ± 20	32 ± 22
Statin monotherapy ^b	85.5%	87.2%
Statin + ezetimibe ^b	5.0%	5.0%
Statin + other non-statin ^b	4.2%	3.2%
Non-statin monotherapy ^b	0.5%	0.4%
No statin or non-statin treatment ^b	4.8%	4.2%

Target value attainment among treated ACS and CHD patients with concomitant type 2 diabetes mellitus in 21 countries: the Dyslipidaemia International Study (DYSIS) II results

A.K. Gitt¹, J. Ferrieres², D. Lautsch³, M. Horack⁴, V. Ashton³, P. Brudi³, B. Ambegaonkar³, DYSIS II study investigators;

¹Stiftung Institut für Herzinfarktforschung, Herzzentrum Ludwigshafen, Ludwigshafen am Rhein, Germany, ²Toulouse University School of Medicine, Rangueil Hospital, France, ³Merck & Co., Inc., Kenilworth, USA, ⁴Stiftung Institut für Herzinfarktforschung, Ludwigshafen am Rhein, Germany.

Background and aims: ESC guidelines set target LDL-C values for patients suffering from diabetes or CHD at <70 mg/dl. The condition of concomitant CHD and diabetes puts patients at very high risk for cardiovascular events, specifically recurrent infarctions. We aimed to determine target value attainment in 2 cohorts: stable CHD patients and post-acute coronary syndrome (ACS) patients respectively, both with concomitant type 2 diabetes mellitus (T2DM). Further, we evaluated lipid management and in those not reaching the target, the distance to LDL-C <70 mg/dl.

Materials and methods: DYSIS II, a multicountry observational cross sectional study enrolled stable CHD and ACS patients in 21 countries from Asia-Pacific, Europe, and Middle East/Africa regions. Eligible adult patients were hospitalized for an ACS event or had a documented history of CHD, documented T2DM (previously diagnosed, fasting plasma glucose ≥ 126 mg/dl, or currently receiving treatment for diabetes), full lipid profile available within 24 hours of hospital admission for ACS patients and 0-12 months prior to enrollment for CHD patients, on lipid lowering therapy (LLT) ≥ 3 months or not at all, and not participating in clinical trials involving medication.

Results: Overall, 1346 patients with ACS and T2DM were enrolled, with 77.4% ($n=1042$) currently on LLT when admitted to the hospital. Only 28.3% of patients on LLT had an LDL-C <70 mg/dl (mean LDL-C 94.2 ± 40.2 mg/dl), with median distance to LDL-C target being 32.0 (14.0, 57.0) mg/dl. Mean atorvastatin equivalent dose was 23 ± 16 mg/day, with the majority of patients on statin monotherapy (91.4%), followed by 3.6% statin + other non-statin (fibrates or omega 3 fatty acids), 3.2% statin + ezetimibe, and 1.8% non-statin monotherapy when admitted to the hospital. Among 2620 enrolled stable CHD patients with T2DM, 94.6% ($n=2479$) were currently on LLT, with 36.3% achieving an LDL-C <70 mg/dl

(mean LDL-C 82.4 ± 41.0 mg/dl). Median distance to target LDL-C was 21.0 (9.0, 38.0) mg/dl. Mean atorvastatin equivalent dose was 25 ± 18 mg/day, with 81.9% currently on statin monotherapy followed by 10.4% statin + ezetimibe, 6.5% statin + other non-statin (fibrates, nicotinic acid, or omega 3 fatty acids), and 1.2% non-statin monotherapy.

Conclusion: Approximately two-thirds of treated ACS and stable CHD patients with concomitant T2DM were not at the recommended LDL-C target while receiving primarily statin monotherapy. DYSIS II confirms that patients at highest CV risk are treated mainly with moderate statin doses. Switching to higher statin doses, and the addition of ezetimibe, will further reduce the risk of future cardiovascular events.

Table 1: Patient characteristics among treated ACS and CHD patients with concomitant T2DM

	ACS patients n=1042	CHD patients n=2479
Mean age (years)	64.6 ± 10.7	65.9 ± 9.9
Male	69.4 %	74.5 %
Hypercholesterolemia	74.0 %	77.6 %
Hypertension	82.5 %	80.6 %
Body mass index >30 kg/m ²	31.7 %	32.8 %
History of previous myocardial infarction	31.1 %	52.5 %
Family history of CHD	24.6 %	31.1 %
Current smoker	18.1 %	9.3 %

The abruptness of terminating nicotinic acid delivery has a profound effect on free fatty acid and insulin rebound in rats

T. Kroon^{1,2}, J. Gabrielsson², N.D. Oakes¹;

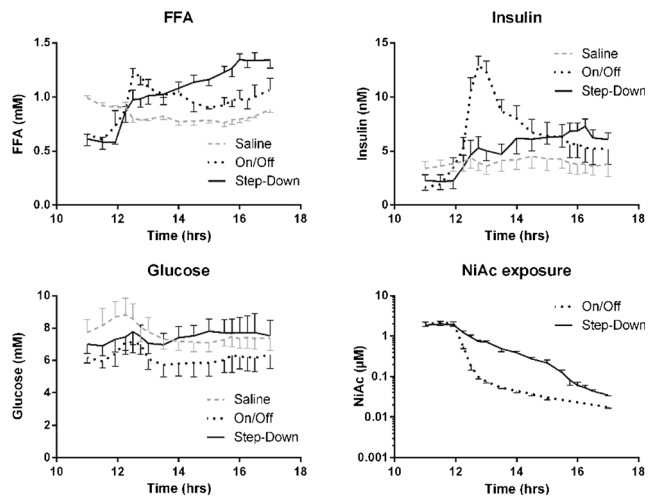

¹iMed CVMD, AstraZeneca, Mölndal, ²Swedish University of Agricultural Sciences (SLU), Uppsala, Sweden.

Background and aims: A major factor thought to drive insulin resistance is ectopic lipid accumulation. Reducing circulating lipids including free fatty acids (FFA) may offer an approach to ameliorate insulin resistance. Acute nicotinic acid (NiAc) infusion results in rapid reduction of plasma FFA concentrations. However, this tends to be offset following infusion cessation, by a FFA rebound, which overshoots pre-treatment levels. One possible explanation is that this is a consequence of the very short plasma NiAc half life (~3 min in the rat). The aim of this study was to determine whether a slow step-down NiAc infusion protocol (Step-Down group) vs. simply turning the infusion off (On/Off group) could attenuate the FFA rebound development and maximize NiAc induced FFA lowering.

Materials and methods: FFA lowering was assessed in obese Zucker rats following a 12 hr constant rate NiAc infusion with corresponding saline infused controls.

Results: It was found that, following a 12 hr constant rate NiAc infusion the On/Off group exhibited a FFA rebound and a remarkable insulin rebound. To our surprise the Step-Down group did not succeed in improving FFA control. In fact the area under the FFA curve during the 5 hr step-down phase was greater than for the corresponding period in the On/Off group (5.70 vs. 4.96 mM hr, $P < 0.05$) despite substantially higher plasma levels of NiAc in the Step-Down group. The higher FFA levels were associated with, and may have been caused by, a markedly blunted insulin rebound in the Step/Down versus On/Off group possibly due to NiAc-induced inhibition of insulin secretion.

Conclusion: In conclusion, these results show that the time dependence of the infusion profile of the anti-lipolytic agent NiAc has a very significant impact on control of plasma FFA levels. Specifically, gradual step-down reduction of NiAc infusion actually degraded the anti-lipolytic effectiveness of NiAc compared to abrupt withdrawal possibly due to a NiAc induced blunting of insulin secretion.

PS 120 Non-glycaemic effects of incretin system

Down-regulation of vascular GLP-1 receptor expression in subjects with obesity

T. Kimura¹, M. Shimoda¹, S. Okauchi¹, A. Obata¹, H. Hirukawa¹, K. Kohara¹, A. Hiraoka², K. Tamura², G. Chikazawa², H. Yoshitaka², I. Shimizu², K. Kaku¹, H. Kaneto¹;

¹Diabetes, Endocrinology and Metabolism, Kawasaki Medical School, Kurashiki, ²Sakakibara Heart Institute, Okayama, Japan.

Background and aims: It is known that incretin signaling improve vascular relaxation response through eNOS expression and/or activity in endothelial cells. In addition, it has been shown that incretin has anti-atherosclerotic effects in vascular smooth muscle cells. On the other hand, although it has been reported that GLP-1 receptor expression in pancreatic β -cells is reduced under diabetic conditions, it remains unknown whether vascular GLP-1 receptor expression is altered under some conditions and which factor could influence vascular GLP-1 receptor expression. The aim of this study was to reveal the alteration of vascular GLP-1 receptor expression and the factors affecting its expression in human artery.

Materials and methods: We examined the subjects having artery surgery. Excised diseased artery was mechanically separated into the intima and tunica. Gene expression of various factors in the intima and tunica was analyzed by real time RT-PCR. Primer pairs encoding genes associated with GLP-1 receptor and factors related to arteriosclerosis were prepared, and real-time RT-PCR with Sybr Green was performed. Each gene expression was semi-quantified by the comparative Ct method with each result in β -actin as a control. Subjects were divided into obesity (BMI ≥ 25 kg/m²) and non-obesity group (BMI < 25 kg/m²) and comparison of the clinical parameters and various gene expression levels in the intima and tunica was performed. The results were expressed as mean \pm SE. A Wilcoxon test was used to test the difference between obesity and non-obesity group with $p < 0.05$ regarded as significant.

Results: Subjects were 36 patients (male / female = 26 / 10, abdominal or thoracic aortic aneurysm / aortic dissection / arteriosclerosis obliterans / other = 11 / 17 / 6 / 2, diabetic / non-diabetic = 11 / 23, age 67.3 \pm 2.3 years old, BMI 23.7 \pm 0.8 kg / m², HbA1C 6.3 \pm 0.3%). BMI in obese and non-obese group was 28.6 \pm 0.7 kg/m² and 20.2 \pm 0.6 kg/m², respectively ($p < 0.05$). Between the obesity and non-obesity group, there was no significant difference in FBG (121.2 \pm 8.9 mg/dl vs 119.6 \pm 6.3 mg/dl). Plasma insulin level in obesity group was higher compared to that in non-obesity group (29.2 \pm 11.0 μ U/ml vs 6.5 \pm 1.3 μ U/ml) ($p < 0.05$). And there was no significant difference in HbA1c (5.9 \pm 0.2% vs 6.6 \pm 0.5%), triglyceride, HDL-cholesterol, LDL-cholesterol between the 2 groups. GLP-1 receptor gene expression in the intima and tunica was significantly lower in obesity group compared to that in non-obesity group ($p < 0.05$). In spearman's rank correlation coefficient test, there was significantly negative correlation between GLP-1 receptor gene expression and BMI, LDL-cholesterol in the intima and tunica.

Conclusion: GLP-1 receptor gene expression in human artery was down-regulated in subjects with obesity. The present results suggest that obesity and hyperinsulinemia down-regulate GLP-1 receptor gene expression in human artery.

Resistance to the GLP-1 effects on platelets in type 2 diabetes mellitus

C. Barale, F. Cavalot, C. Frascaroli, L. Mattiello, A. Guerrasio, I. Russo; Internal Medicine and Metabolic Disease Unit, Department of Clinical and Biological Sciences, San Luigi Gonzaga Hospital, University of Turin, Orbassano, Italy.

Background and aims: Glucagon-like peptide 1 (GLP-1) shows pleiotropic benefits on cardiovascular system: its influence on platelets - deeply involved in the pathogenesis of diabetic vascular diseases - is poorly investigated. The GLP-1 active form is GLP-1 (7-36), rapidly degraded to GLP-1 (9-36). We previously showed that, in platelets, both GLP-1 (7-36) and GLP-1 (9-36) and the analogue Liraglutide similarly increase the sensitivity to the antiaggregating nitric oxide (NO) and decrease the agonist-induced activation of the signalling pathways PI-3Kinase (PI-3 K) and MAP-Kinase (MAPK) and reactive oxygen species (ROS) production. The GLP-1 influence on platelet response in Type 2 Diabetes Mellitus (T2DM) is not known. Aim of this study was to verify whether the GLP-1 effects observed in healthy subjects were preserved in T2DM.

Materials and methods: In platelets from 20 T2DM patients (M/F: 9/11; age 56.1 \pm 1.9 years; BMI: 32.6 \pm 1.1 kg/m²; HbA1C: 8.0 \pm 0.2%) and 12 healthy control subjects (M/F: 6/6; age: 48.2 \pm 3.4 years; BMI: 24.0 \pm 0.7 kg/m²) we evaluated the ability of GLP-1(7-36), GLP-1(9-36) and Liraglutide (100 nmol/l) to influence: the antiaggregating effects of the nitric oxide donor Na-nitroprusside (SNP) (Born's method), the phosphorylation levels of AKT (pAKT) and ERK-1/2 (pERK-1/2) (Western Blot) and ROS synthesis (DCF-DA fluorescence assay) in the presence of the agonists ADP (10 micromol/l), Collagen (4 mg/L) and Na-Arachidonate (NaA) (100 micromol/l).

Results: The effects of GLP-1 (7-36), GLP-1 (9-36) and Liraglutide, were lower in T2DM compared with healthy subjects. In particular, in the presence of GLP-1 (7-36): the percent (%) increases of the antiaggregating effects of SNP were 4.0 \pm 1.8 vs 28.2 \pm 4.8 ($p < 0.0001$) with ADP, and 17.0 \pm 5.2 vs 36.8 \pm 5.1 ($p < 0.02$) with Collagen; the % reductions of pAKT were 3.2 \pm 4.2 vs 43.1 \pm 3.5 ($p < 0.0001$) with Collagen, and 5.4 \pm 5.2 vs 32.1 \pm 6.8 ($p < 0.004$) with NaA; the % reductions of pERK-2 were 3.5 \pm 2.2 vs 25 \pm 8.2 ($p < 0.004$) with Collagen, and 10.5 \pm 8.6 vs 40.2 \pm 9.5 ($p < 0.03$) with NaA; the % reductions of ROS production were 15.1 \pm 5.2 vs 41.2 \pm 7.5 ($p < 0.006$) with NaA. In the presence of GLP-1 (9-36): the % increases of the antiaggregating effects of SNP were 6.1 \pm 1.9 vs 25.6 \pm 3.0 ($p < 0.0001$) with ADP, and 18.5 \pm 3.8 vs 32.7 \pm 4.1 ($p < 0.02$) with Collagen; the % reductions of pAKT were 4.8 \pm 3.1 vs 45.3 \pm 4.6 ($p < 0.0001$) with Collagen, and 6.1 \pm 3.3 vs 35.9 \pm 7.3 ($p < 0.0001$) with NaA; the % reductions of pERK-2 were 4.9 \pm 2.0 vs 28 \pm 9.1 ($p < 0.004$) with Collagen, and 12.6 \pm 8.1 vs 44.0 \pm 9.8 ($p < 0.02$) with NaA; the % reductions of ROS production were 17.1 \pm 8.3 vs 45.9 \pm 7.9 ($p < 0.03$) with NaA. In the presence of Liraglutide: the % increases of the antiaggregating effects of SNP were 5.7 \pm 2.5 vs 30.1 \pm 7.8 ($p < 0.001$) with ADP, and 15.5 \pm 3.5 vs 33.5 \pm 4.4 ($p < 0.003$) with Collagen; the % reductions of pAKT were 15.9 \pm 5.7 vs 39.1 \pm 9.0 ($p < 0.03$) with Collagen, and 20.1 \pm 5.7 vs 36.2 \pm 5.8 (ns) with NaA; the % reductions of pERK-2 were 4.0 \pm 2.5 vs 27.9 \pm 8.8 ($p < 0.003$) with Collagen, and 24.3 \pm 7.7 vs 39.2 \pm 6.8 (ns) with NaA; the % reductions of ROS production were 26.1 \pm 5.4 vs 56.8 \pm 6.3 ($p < 0.001$) with NaA.

Conclusion: T2DM is characterized by a resistance to the effects of the native GLP-1 (7-36), truncated GLP-1 (9-36) and GLP-1 analogue Liraglutide to increase the antiaggregating effects of NO, to reduce platelet activation of signalling pathways PI-3 K and MAPK and oxidative stress stimulated by platelet agonists.

The DPP-4 enzyme correlates with plasma triglycerides in non-obese subjects and mediates palmitate-induced apoptosis in human cardiac progenitor cells

M. Incalza, L. Laviola, C. Caccioppoli, A. Leonardini, R. D'Oria, A. Cignarelli, V. Andrulli Buccheri, A. Natalicchio, S. Perrini, F. Giorgino; Endocrinology & Metabolic Diseases, University of Bari, Italy.

Background and aims: Hypertriglyceridemia is an independent risk factor for cardiovascular disease, and chronic exposure to elevated saturated fatty acids (SFA) leads to cardiomyocyte dysfunction and death, both in vivo and in vitro. Circulating levels of dipeptidyl peptidase-4 (DPP-4) have been shown to correlate with cardiovascular disease in humans. Thus, we investigated the potential link between plasma DPP-4 levels, triglyceridemia and the activation of apoptotic pathways in human cardiac progenitor cells (CPC).

Materials and methods: Plasma DPP-4 levels were determined with an ELISA assay. DPP-4 activity was measured by a colorimetric assay. Human CPC isolated from right auricle biopsies were exposed to 0.25 mM palmitate up to 24 h. Cell apoptosis was detected by caspase-3 cleavage and cytosolic release of oligosomes. Expression and phosphorylation levels of the proteins under investigation were evaluated by immunoblotting techniques.

Results: In 20 non-diabetic subjects (M/F 9/11, age 47 ± 11 y, BMI 33 ± 9 , triglycerides 135 ± 99 mg/dL), plasma DPP-4 levels were found to positively correlate with BMI ($r=0.485$, $p<0.05$). In addition, DPP-4 levels were significantly and positively associated with plasma triglycerides in non-obese ($r=0.847$, $p<0.05$) but not in obese ($r=0.02$) individuals. Then, primary cultures of CPC were obtained from right auricle biopsies of patients undergoing elective heart surgery. When CPC were exposed to the SFA palmitate (0.25 mmol/L, up to 16 h), DPP-4 levels and activity in the culture medium were found to be increased 2- to 4-fold ($p<0.05$), and this was associated with increased phosphorylation of the stress kinase JNK and the JNK substrate c-Jun ($p<0.05$). In addition, exogenous DPP-4 (up to 500 ng/ml) activated the JNK pathway, inducing a 2.5 fold increase in c-Jun phosphorylation ($p<0.05$). Finally, palmitate augmented CPC apoptosis, evaluated by measuring cytoplasmic oligosomes and Caspase-3 cleavage, ($p<0.05$), but DPP-4 silencing with a specific siRNA prevented CPC apoptosis, as well as c-Jun phosphorylation ($p<0.05$).

Conclusion: The DPP-4 enzyme correlates with plasma triglycerides in vivo in non-obese subjects, is released from CPCs in response to palmitate in vitro, and contributes to SFA-triggered stress signals leading to cardiac cell dysfunction and death.

Correlation of SDF-1 α levels and left ventricular diastolic dysfunction in type 2 diabetes patients according to treatment with or without DPP4-inhibitors

S. Iraklianos¹, A. Papazafiropoulou¹, E. Fousteris¹, E. Trikkalinou¹, V. Gkizlis¹, A. Ganotopoulou¹, A. Theodosios-Georgilas², C. Tountas², S. Matsagos³, P. Spyropoulou³, S. Foussas², A. Melidonis¹;

¹Diabetes Center, ²Cardiology Department, ³Blood Bank Service, Tzanio General Hospital of Piraeus, Greece.

Background and aims: Recent studies have shown that stromal derived factor-1 α (SDF-1 α) is a substrate of dipeptidyl-peptidase-4 (DPP-4) inhibitors. SDF-1 α is a small cytokine that belongs to the chemokine family and can stimulate endothelial progenitor cells. It has, also, been shown that SDF-1 α shares antiapoptotic as well as nephroprotective properties and it has a beneficial effect in the cardiovascular system. Therefore, the aim of the present study was to estimate the effect of the treatment with DPP-4 inhibitors to SDF-1 α levels according to the presence of diastolic dysfunction of left ventricle (DDLV) in subjects with type 2 diabetes (T2D)

Materials and methods: 32 participants (16 males) with T2D, mean age (\pm SD) 67.2 ± 8.3 years, HbA1c $6.4 \pm 0.5\%$, body-mass index (BMI) 29.1 ± 4.9 Kg/m², duration of diabetes 8.5 ± 4.0 years receiving antidiabetic treatment with metformin only (17 participants) or metformin plus DPP-4 inhibitors (14 participants) without known cardiovascular disease were enrolled into the study. All study participants underwent fully clinical examination and ultrasound examination of the heart while a blood sample was taken at fasting state for the estimation of SDF-1 α levels.

Results: Study participants receiving metformin plus DPP-4 inhibitors had higher plasma levels of SDF-1 α compared to participants on metformin therapy only (19.6 ± 4.1 versus 6.9 ± 1.3 pg/ml, respectively, $p=0.01$). 14 participants had DDLV, while SDF-1 α levels did not differ according to the presence or not of DDLV (12.0 ± 1.8 versus 9.1 ± 0.1 pg/ml, respectively, $p=0.65$). 61.3% of participants had arterial hypertension, 77.4% dyslipidemia while 12.9% were current smokers. Multivariate regression analysis (backward), after controlling for age, sex, BMI, smoking, history of arterial hypertension and dyslipidemia, DDLV, white blood cells count, C-reactive protein, creatinine clearance, uric acid, LDL-cholesterol and triglycerides, showed that SDF-1 α levels were positive related with treatment with DPP-4 inhibitors ($\beta=0.91$, $p=0.001$), and negative with duration of T2D ($\beta=-0.42$, $p=0.05$), HDL-cholesterol levels ($\beta=-0.46$, $p=0.02$) and HbA1c ($\beta=-0.41$, $p=0.05$).

Conclusion: The results of the present study showed that treatment with DPP-4 inhibitors has a favorable effect to SDF-1 α levels. On the contrary, no statistical significant relation was found between SDF-1 α levels and DDLV. Finally, long duration of diabetes is related with lower levels of SDF-1 α , confirming the detrimental effects of diabetes per se.

LEADER-5: prevalence and cardiometabolic impact of obesity in cardiovascular high-risk patients with type 2 diabetes: baseline data from the trial

L. Masmiquel¹, S.C. Bain², on behalf of the LEADER investigators; ¹University Institute of Health Science Research, Palma de Mallorca, Spain, ²University of Swansea, UK.

Background and aims: The association between anthropometric measures of adiposity and cardiovascular (CV) risk in patients with established type 2 diabetes mellitus (T2DM) and high CV risk has not been well studied. Some longitudinal cohort studies have shown reduced mortality with higher body mass index (BMI) in patients with T2DM and coronary artery disease, suggesting an "obesity paradox". However, this is not well-established and additional data in this patient group are needed.

Materials and methods: We used baseline data from the Liraglutide Effect and Action in Diabetes: Evaluation of cardiovascular outcome Results (LEADER) trial, which enrolled 9340 patients with T2DM, at high-risk for CVD, across 32 countries. We used cross-sectional data to investigate (1) the prevalence of overweight and obesity; (2) the association of cardiometabolic risk factors with measures of adiposity (BMI and waist circumference (WC)); and (3) the cardiometabolic risk factors affecting treatment intensity. Lipids and blood pressure measurements were considered on target according to ADA 2014 criteria. Descriptive statistics and multivariable logistic regression analyses were used.

Results: Mean BMI was 32.5 ± 6.3 kg/m², with only 9.1% of patients having normal weight. The prevalence of normal WC was also low (6.4% according to harmonized criteria). The percentage of patients with LDL-cholesterol <2.6 mmol/L (100 mg/dl), triglycerides (TG) <1.7 mmol/L (150 mg/dl), and blood pressure ($<140/80$ mmHg) at target was generally lower for individuals with a BMI >40 kg/m² compared to individuals with a BMI <25 kg/m² (37.6% vs. 36.9%, 63.1% vs. 45.9%, 44.9% vs. 38.2%, respectively). A similar trend was observed for WC. No differences were detected for HbA1c and LDL-cholesterol. Insulin, statin, and antihypertensive agent use was more frequent at higher BMI and

WC. Multivariable adjusted logistic regression analyses yielded that obesity was mainly associated with female gender ($p < 0.0001$), with not smoking ($p < 0.0001$), race and region of living ($p < 0.0001$ for both) (Table), as well as triglyceride level and hypertension (data not shown).

Conclusion: Overweight and obesity are extremely prevalent in high-risk patients with T2DM. BMI and WC are associated with cardiometabolic risk factors and treatment intensity is higher in patients who are overweight or obese; however, a high percentage of these patients were not at target for HbA1c, BP, and lipids at baseline. The LEADER trial will provide important information on the effects of the GLP-1 receptor agonist liraglutide on CV outcomes in this patient population.

Clinical Trial Registration Number: NCT01179048

Supported by: Novo Nordisk

no observed difference in mean HRQoL utility between treatment arms at planned observation points, an impact of cardiovascular events was observed: mean baseline, month 12, and closeout utilities among those with a cardiovascular event were 0.75, 0.72, and 0.71, respectively. After a cardiovascular event, mean utilities were 0.69, 0.69, and 0.72 (within 3 months, 3-6 months, and 6-12 months after the event, respectively). In the regression analysis adjusting for age, sex, treatment arm, and baseline HRQoL, utility decrements associated with cardiovascular events were -0.059, -0.045, and -0.037 over the same time periods; all coefficients were statistically significant. Utility decrements for specific cardiovascular events (MI, stroke and hHF) will be presented. Among 96 individuals who experienced a hospitalized hypoglycemic event, mean time between the event and next utility elicitation was 175 days; the adjusted utility decrement following the hypoglycemic event was 0.026, although this difference was not statistically significant.

Conclusion: In a large clinical trial T2DM population, no significant impact was observed by treatment arm for HRQoL, consistent with results reported elsewhere for clinical outcomes. However, cardiovascular events were associated with a significant decrease in HRQoL, most substantial in the initial post-event period. These data also suggest a potential relationship between hypoglycemic events and HRQoL; investigating this association would be best addressed by a study designed to include a sufficient number of hypoglycemic events. The temporal relationship observed between major cardiovascular events and utility trajectories highlights the need to elicit utilities proximal to occurrence of events of interest, in order to accurately and comprehensively quantify HRQoL burden.

Clinical Trial Registration Number: NCT01107886

¹University of Glasgow, UK, ²Harvard Medical School, Boston, USA, ³Hadassah Medical Center, Jerusalem, Israel, ⁴ICON Epidemiology, ⁵Redwood Outcomes, Vancouver, Canada, ⁶AstraZeneca, Molndal, Sweden, ⁷Bristol-Myers Squibb, Wallingford, ⁸AstraZeneca, Gaithersburg, USA.

Background and aims: The Saxagliptin Assessment of Vascular Outcomes Recorded in Patients with Diabetes Mellitus (SAVOR) -TIMI 53 trial was a multicenter randomized controlled phase IV trial of clinical and HRQoL outcomes in 16,492 T2DM patients with a previous cardiovascular event, or multiple risk factors for vascular disease. The analysis quantified the impact of major non-fatal clinical events on HRQoL (as measured by EQ5D utilities); and compared utilities over time according to whether patients experienced clinical events of interest.

Materials and methods: During the trial, EQ5D utility values were elicited annually and following a non-fatal clinical event, including hospitalizations for hypoglycemia, heart failure (hHF) and major cardiovascular events (myocardial infarction and stroke). Utilities were analyzed using linear mixed effects regression, adjusting for baseline characteristics (including EQ5D utility) and a time-dependent variable describing prior cardiovascular events.

Results: Most patients completed the EQ5D survey at baseline, 12 months, and closeout; 1,973 also completed the EQ5D after a clinical event. The mean EQ5D utility of the overall sample was 0.78 at baseline and all subsequent time points and did not vary by treatment arm. Despite

Insulin-like factor 5: a novel orexigenic hormone in humans is dysregulated in obesity

I.V. Wagner^{1,2}, G. Flehmig³, K. Scheuermann⁴, D. Löffler⁴, A. Kömer^{4,2}, W. Kiess^{4,2}, M. Stumvoll^{3,2}, A. Dietrich², M. Bluher^{3,2}, N. Klötting^{3,2}, O. Söder¹, K. Svehnikov¹;

¹Womens and Childrens Health, Karolinska Institutet, Stockholm, Sweden, ²Integrated Research and Treatment Center (IFB Adiposity Diseases), ³Division of Endocrinology, Department of Medicine, ⁴University Hospital for Children and Adolescents, Center for Pediatric Research Leipzig, Germany.

Background and aims: Insulin-like factor 5 (INSL5), a member of the insulin superfamily, is expressed in the colorectum and hypothalamus. INSL5 deficient mice display impaired fertility and dysregulated glucose homeostasis. Based on the observation that INSL5 was elevated by prolonged calorie restriction and declined with feeding, it was suggested that INSL5 might be an orexigenic hormone. Our aim was to explore the relationship between circulating levels of INSL5 and different metabolic parameters in lean and obese subjects and to identify possible links between INSL5 and the development of metabolic disorders such as obesity and diabetes.

Materials and methods: INSL5 was measured in serum samples by ELISA (Cloud clone corp.). 20 lean females and males and 20 obese females and males were included. Furthermore 15 morbidly obese patients were tested before and six months after they underwent bariatric surgery. In addition we measured INSL5 levels in 10 lean and obese individuals after an overnight fasting, after a meal and during an oral glucose tolerance test (OGTT). For all groups, correlations between INSL5 concentrations and anthropometric, metabolic and hormonal measures were investigated.

Results: We found gender specific differences in INSL5 after fasting. INSL5 was significantly higher (by 25.5%, $p < 0.05$) in healthy lean females than males but this gender specific difference was not observed in obese subjects. Basal INSL5 was significantly lower in the obese group (by 28.6%, $p < 0.05$). Correlation analysis revealed that INSL5 was negatively correlated to testosterone in both lean and obese males ($p = 0.001$, $r = -0.58$; $p = 0.02$, $r = -0.52$) and to insulin in both genders. Six months after bariatric surgery 15 males lost 25% of their body weight that was associated with significant (by 97%) increase in serum testosterone and marked (by 17.4%) decline in serum INSL5. Obese subjects with type 2 diabetes (T2DM) had lower INSL5 before and after surgery compared to obese persons without T2DM. In patients without T2DM INSL5 levels decreased more (20.7%) compared to T2DM patients (14.8%). After a meal INSL5 decreased by 21.8% and 20.8% in lean females and males, respectively, while interestingly this effect was not observed in obese individuals of both genders. During an OGTT, after a pure sugar load, there was no significant effect in the lean group but a decrease in INSL5 in the obese subjects with insulin resistance.

Conclusion: Altogether, our data indicate that the gender-related difference in INSL5 was observed only in healthy lean but not in obese individuals. Thus suggesting that the regulation of INSL5 is dependent on the metabolic state in humans. Negative influence of insulin resistance and T2DM on serum levels of INSL5 in obese individuals may indicate a link between beta cell function and INSL5 regulation. Our finding that INSL5 levels were restored after weight loss let us to suggest a negative effect of fat tissue on the biosynthesis of this hormone in obesity. Therefore, INSL5 may become an interesting target for the development of new therapeutic agents to treat metabolic disorders in humans.

Secretory products from epicardial adipose tissue from patients with type 2 diabetes impair mitochondrial respiration in cardiac myocytes via upregulation of miR-208a

M. Blumensatt¹, D. Herzfeld de Wiza¹, H. Mueller¹, D.M. Ouwens^{1,2};
¹German Diabetes Center, Institute for Clinical Biochemistry and Pathobiochemistry, Duesseldorf, Germany, ²Ghent University Hospital, Department of Endocrinology, Belgium.

Background and aims: Alterations in cardiac energy substrate metabolism contribute to the development of diabetic cardiomyopathy. We have recently found that secretory products from epicardial adipose tissue (EAT) from patients with type 2 diabetes impair cardiac myocyte function as illustrated by the induction of insulin resistance, contractile dysfunction, and changes in microRNA expression, including miR-208a, a key regulator of energy metabolism. The present study examines whether EAT affects mitochondrial respiration in cardiac myocytes and whether this can be ascribed to the induction of miR-208a by angiotensin II.

Materials and methods: Biopsies from EAT from were collected from patients with and without type 2 diabetes and used to generate conditioned media (CM). Levels of angiotensin II in CM were determined by enzyme-linked immunosorbent assay. Mitochondrial respiration was measured in primary adult rat cardiac myocytes exposed to CM using a Seahorse XF96e analyzer. Gene and miRNA-expression as well as mtDNA copy number were measured by qRT-PCR. The cardiac mouse cell line HL-1 was used for transfection with precursor-miRNAs to investigate the impact of miRNAs on mitochondrial respiration and fatty acid oxidation. Protein expression and phosphorylation was measured by Western blot analysis.

Results: CM from EAT and from patients with type 2 diabetes (CM-EAT-T2D) increased the levels of miR-208a in both primary adult rat (1.8-fold, $p < 0.05$) and primary human cardiac myocytes (1.6-fold, $p < 0.05$) as compared to cells exposed to CM from patients without type 2 diabetes (CM-EAT-ND). The effects of CM-EAT-T2D on miR-208a induction were abolished by the angiotensin II receptor antagonist, losartan. Higher levels of angiotensin II were identified in CM-EAT-T2D compared to CM-EAT-ND (2-fold, $p < 0.05$). Furthermore, CM-EAT-T2D reduced maximal mitochondrial respiration by 20% and spare respiratory capacity by 40% in primary adult rat cardiac myocytes. Accordingly, expression of the precursor for miR-208a reduced maximal mitochondrial respiration by 19% and spare respiratory capacity by 25% in HL-1 cardiac myocytes. Moreover, miR-208a reduced palmitate-induced maximal respiration by 22%. This decrease in mitochondrial function associated with a reduced phosphorylation of the regulatory beta subunit of AMP-activated protein kinase, and its substrate acetyl-CoA carboxylase. Finally, higher levels of miR-208a reduced mtDNA copy number and the expression of carnitine palmitoyltransferase 1, a regulator of mitochondrial β -oxidation.

Conclusion: Secretory products from epicardial adipose tissue from patients with type 2 diabetes impair mitochondrial respiration in cardiac myocytes via upregulation of miR-208a. This miRNA inhibits myocardial energy metabolism via the down-regulation of mitochondrial β -oxidation. Finally, the induction of miR-208a is prevented by the angiotensin II receptor antagonist losartan.

The effect of a fat-rich mixed meal on metabolic and hormonal parameters, postprandial lipaemia as well as endothelial function in women with polycystic ovary syndrome

G. Argyrakopoulou^{1,2}, E. Diamanti-Kandarakis³, K. Makrilakis¹, N. Tentolouris¹, A. Kokkinos¹, D. Perrea⁴, N. Katsilambros^{1,4}, S. Raptis^{5,2},
¹First Department of Propaedeutic and Internal Medicine, Athens University Medical School, ²Athens Medical Center, ³Third Department of Internal Medicine, Endocrine Unit, ⁴Laboratory of Experimental Surgery and Surgical Research, Athens University Medical School, ⁵Hellenic National Center for Research, Prevention and Treatment of Diabetes Mellitus and its Complications, Athens, Greece.

Background and aims: Polycystic ovary syndrome (PCOS) is characterized by hyperandrogenism, chronic anovulation, and metabolic disorders like insulin resistance, glucose intolerance, dyslipidaemia and impaired endothelial function. No studies have yet investigated the metabolic response of these patients in the postprandial state. The aim of this study was to investigate the effect of consumption of a fat-rich mixed meal on metabolic and hormonal parameters as well as endothelial function in women with PCOS and to compare them with healthy controls.

Materials and methods: We studied 55 women with PCOS (age 26.0±6.1 years; BMI 27.6±6.9 kg/m²), and 20 age and BMI matched healthy controls (age 26.5±4.3 years; BMI 25.15±7.76 kg/m²) who consumed a fat-rich mixed meal (783 kcal; 27.5% carbohydrates 52.5% fat, 20% protein). Sex hormones at times 0' and 6 h after the meal as well as glucose, insulin, total cholesterol, HDL, LDL and triglycerides at times 0', 2 h, 4 h and 6 h were measured. Additionally, all patients underwent an oGTT in a separate session, for the detection of insulin resistance using the HOMA, QUICKI, and MATSUUDA indices. A subset of women (nPCOS=46 and nControls=12) underwent an endothelial function test using flow-mediated dilation and assessment of skin microcirculation using laser Doppler flowmetry.

Results: In the postprandial state, PCOS patients showed a significant reduction of Δ4-androstenedione (p<0.001) and a trend for reduction of free testosterone levels (p=0.052), a significant increase of dehydroepiandrosterone sulfate (p=0.016) and a trend for increase of sex hormone-binding globulin levels (p=0.086). We also found a trend for the triglyceride concentrations expressed as area under the curve (AUC) to be higher (464.79±158.55 vs. 587.72±287.81, p=0.073) and the AUC of insulin to be significantly higher (97.06±62.24 vs. 147.08±94.85, p=0.014) in women with PCOS compared to controls. Furthermore, patients with PCOS had worse endothelial function (brachial artery dilation of 8.52±5.80% vs. 4.78±6.42%, p=0.036) while skin microcirculation and insulin resistance indices were not different between the two groups.

Conclusion: In the postprandial state women with PCOS exhibited significant changes in their hormonal profile. In addition, PCOS compared to controls had a trend for higher postprandial lipaemia and worse endothelial function. These findings suggest that young women with PCOS have detrimental hormonal, metabolic and endothelial alterations. Therefore, they seem to be more susceptible to cardiovascular disease.

1192

Microvesicles from activated endothelial cells are decreased by weight loss and correlate with dyslipidaemia and cardiovascular risk in severe obesity

A. Handberg^{1,2}, M.H. Christensen¹, M.H. Nielsen¹, S.B. Thomsen³, H. Vestergaard³,

¹Dept. of Clinical Biochemistry, Aalborg University Hospital, ²Clinical Institute, Aalborg University, ³Center for Basic Metabolic Research, University of Copenhagen, Denmark.

Background and aims: Obesity, elevated triglycerides (TG) and low HDL-cholesterol are all factors related to the metabolic syndrome

(MetSy), a state that includes increased cardiovascular risk. Endothelial CD36 is involved in TG clearance from TG-rich lipoproteins and up-regulated by oxidative stress, both potentially activating endothelial cells. Microvesicles (MVs) may be markers and mediators of endothelial dysfunction having impact on the cardiovascular state during obesity. The aim of this study was to evaluate the effect of weight loss on levels of total MV number, activated endothelial MVs (EMVs), and CD36 positive EMVs, and their correlation to HDL, TG, and MetSy.

Materials and methods: Twenty obese individuals (BMI of 43.0±5.4 kg/m²) were included. Informed consent was obtained and the study was approved by the local ethical committee. Fasting blood samples were collected at baseline and three months after weight loss. Plasma MV profile was analyzed in accordance to a published flow cytometric method by this group that includes the whole MV size range of 100–1000 nm. MVs were stained with Lactadherin-FITC, CD62e-PE, and CD36-APC antibodies. Statistical analysis included the Wilcoxon signed rank test and Spearman's Correlation test.

Results: Gastric bypass reduced BMI with 20% (p<0.001). Total MV number decreased by 39% (p=0.025), total EMV number by 47% (p=0.002), and CD36 positive EMVs by 73% (p=0.004). At baseline, total MV count correlated with TG (rho =0.5, p=0.015) and TG/HDL ratio (rho=0.6, p=0.009). Total EMVs correlated with HDL (rho=-0.6, p=0.005), TG (rho=0.5, p=0.02) and TG/HDL ratio (rho =0.8, 0.001). When data from baseline and after weight loss were pooled, total MV number was increased by 1.7 (p<0.012), total EMV by 1.74 (p<0.067), and CD36+EMV by 3.45 fold (p<0.01) in participants with MetSy.

Conclusion: Significant weight loss in extremely obese individuals leads to a decrease in total MV number. The decrease in EMVs and CD36+EMVs may reflect reduced endothelial dysfunction and lower cardiovascular risk.

Cardiovascular safety of liraglutide: meta-analysis of major adverse cardiovascular events across weight management and type 2 diabetes development programmes

S.C. Bain¹, I.D. Caterson², J.L. Gross³, C.B. Svendsen⁴, C.B. Jensen⁴, S.P. Marso⁵;

¹Department of Medicine, Abertawe Bro Morgannwg University NHS Trust, Swansea, UK, ²University of Sydney, Australia, ³Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, ⁴Novo Nordisk, Søborg, Denmark, ⁵University of Texas Southwestern Medical Center, Dallas, USA.

Background and aims: The cardiovascular safety of liraglutide among overweight/obese individuals and those with type 2 diabetes (T2D) is unknown. We therefore performed a meta-analysis of all available individuals from five phase 2/3 liraglutide weight management trials, including follow-up through a 120-Day Safety Update. A meta-analysis of 21 trials from T2D development programmes, in which liraglutide was used as a treatment, provided further supportive information. The maximum dose of liraglutide investigated in the weight management programme was 3.0 mg, whereas the maximum dose was 1.8 mg in the T2D trials.

Materials and methods: The primary endpoint was first occurrence of adjudicated major adverse cardiovascular events (MACE) (non-fatal myocardial infarction, non-fatal stroke or CV death) on liraglutide (any dose) or pooled comparator (placebo, active) and was analysed using a Cox proportional hazards model stratified by trial. Prospective adjudication (blinded, independent) was implemented in three of the weight management trials; post-hoc adjudication was conducted for all other trials. Individuals who did not experience an event during the treatment period or within 30 days after last dose were censored at last treatment date plus 30 days. Multiple sensitivity analyses were conducted to confirm the robustness of the primary analysis. Across weight management trials

(liraglutide: $n=3,872$; comparator: $n=2,036$), baseline characteristics were: 71% women; history of CV disease, 9%; mean age, 47 years; mean BMI, 38 kg/m^2 . Across T2D trials (liraglutide: $n=5,511$; comparator: $n=2,748$): 43% women; history of CV disease, 13%; mean age, 56 years; mean BMI, 30 kg/m^2 .

Results: In the weight management trials, the overall number of adjudicated MACE was low and numerically lower with liraglutide (any dose: 10 events, frequency 0.2%, 0.2 events/100 patient-years of exposure [PYE]; liraglutide 3.0 mg: 7 events, 0.2%, 0.2 events/100 PYE) than with comparator (total comparator: 10 events, 0.5%, 0.4 events/100 PYE; placebo: 10 events, 0.5%, 0.4 events/100 PYE). Hazard ratios (HR) and 95% confidence intervals (CI) for liraglutide (any dose) vs. total comparator: 0.40 [0.16; 1.01]; liraglutide 3.0 mg vs. placebo: 0.33 [0.12; 0.90]. As expected, higher event rates were observed across T2D trials: (liraglutide [any dose]: 26 events, 0.5%, 0.6 events/100 PYE vs. total comparator: 23 events, 0.8%, 1.3 events/100 PYE vs. total comparator): HR [95% CI]: 0.6 [0.35, 1.15].

Conclusion: Based on these data, there was no indication of an increased risk of MACE with liraglutide up to doses of 3.0 mg once-daily in overweight/obese individuals, or in those with T2D.

Discrepancies in the relationship of BMI and traditional cardiovascular risk factors in subjects with different levels of obesity

S.R. van Mil¹, A. van Huisstede², B. Klop³, G.J.M. van de Geijn⁴, G.J. Braunstahl², E. Birnie⁵, G.H.H. Mannaerts^{1,6}, L.U. Biter¹, M. Castro Cabezas³;

¹Surgery, ²Pulmonology, ³Internal Medicine, ⁴Clinical Chemistry, ⁵Statistics and Education, Sint Franciscus Vlietland Gasthuis, Rotterdam, Netherlands, ⁶Tawam Hospital, Al Ain, United Arab Emirates.

Background and aims: Obesity is related to increased cardiovascular risk. This relationship is based on the negative effects of body weight on several traditional risk factors. It remains unknown whether this association also holds at higher levels of obesity. The purpose of this study was to investigate this relation in a cohort with wide ranges of BMI.

Materials and methods: Lean subjects participating in observational studies in our out-patient clinic and obese subjects scheduled for bariatric surgery were included. Baseline characteristics and laboratory values were collected according to a standard protocol. Both, the group of lean subjects (i.e. $\text{BMI} < 30$) and the group of obese subjects (i.e. $\text{BMI} \geq 30$) were categorized in quintiles according to BMI. The relation between BMI and cardiovascular risk factors were analyzed using ANOVA.

Results: The cohort consisted of 953 subjects (591 women, 362 men; mean age \pm SD, 49.9 ± 14.8 years). The lean group consisted of 377 subjects, with a mean BMI of $25.0 \pm 2.81 \text{ kg/m}^2$. 576 Subjects were included in the obese group, with a mean BMI of $43.8 \pm 7.58 \text{ kg/m}^2$. The obese group included significantly more women, more T2DM, more HT and more smokers than the lean group. Mean values of LDLC, apolipoprotein B, systolic and diastolic blood pressure were significantly higher in the obese group and HDLC was significantly lower in the obese group. Diastolic blood pressure, apolipoprotein B and LDLC showed a significant dose-response relationship with increasing BMI in the lean group ($p=0.002$, $p=0.005$ and $p=0.034$, respectively), but this association was not observed in the obese group. In the lean group, triglycerides increased with increasing BMI ($p=0.001$) but decreased in the obese group ($p=0.009$). HDLC decreased with higher BMI in both groups, but the association was weaker in the obese. Inflammatory markers like CRP, leukocyte count and C3 increased with increasing BMI in the obese group ($p < 0.001$ for all markers). In the lean subjects this association with BMI was also observed for C3 ($p < 0.001$), but not for CRP and leukocytes.

Conclusion: Lipid associated risk factors showed a significant dose-response relationship with increasing BMI especially in lean subjects,

but this association was weaker in obese subjects. The association with inflammatory markers and BMI was strongest in obese subjects. The relationship between cardiovascular risk factors and BMI is lost in higher levels of obesity. In that case, inflammation seems to be clinically more prevalent.

Type 1 diabetes as a coronary disease equivalent: an analysis of 33,886 individuals with type 1 diabetes and 169,223 controls from the Swedish National Diabetes Registry

V. Matuleviciene^{1,2}, A. Rosengren¹, S. Gudbjörnsdottir¹, A.-M. Svensson³, A. Mårtensson⁴, H. Wedel⁵, S. Dahlqvist⁶, M. Kosiborod⁷, M. Lind¹;

¹Department of Molecular and Clinical Medicine, University of Gothenburg, ²Department of Emergency Medicine, Solna, Karolinska University Hospital, Stockholm, ³Center of Registers in Region Västra Götaland, Gothenburg, ⁴Statistiska Konsultgruppen, Gothenburg, ⁵Nordic School of Public Health, Gothenburg, ⁶Department of Medicine, NU Hospital Organization, Uddevalla, Sweden, ⁷Saint Luke's Mid America Heart Institute and University of Missouri, Kansas City, USA.

Background and aims: Few studies have been performed on the contemporary incidence of myocardial infarction (MI) among patients with type 1 diabetes (T1D) in comparison to the general population. Whether diabetes represents a coronary artery disease equivalent remains controversial, and has not been specifically examined in patients with T1D.

Materials and methods: Individuals with T1D registered in the Swedish National Diabetes Register (NDR) after January 1st, 1998 (n=33,886) were included. For each patient registered in the NDR, 5 controls matched according to age, gender, and county were randomly selected from the general population (n=169,223). T1D individuals without history of MI were compared to controls with and without history of MI. Endpoints included MI, cardiovascular death and all-cause mortality. T1D individuals and controls were studied until occurrence of an endpoint or December 31st, 2011, through the Swedish In-hospital and Cause of death Registries. Analyses were performed with Cox regression adjusting for age and gender.

Results: The mean age of individuals with T1D and no history of MI (n=33142) was 35.3 years and 35.6 years in corresponding controls (n=168257). The mean age of controls with history of MI (n=966) was 62.5 years. The mean follow up period in T1D individuals without history of MI was 7.9 years. Mean follow up was 8.2 years and 6.8 years, respectively, in controls with and without history of MI. Hazard ratios (HRs) for MI and cardiovascular death for individuals with T1D and no history of MI versus corresponding controls were 4.6 (95% CI 4.31 to 4.95) and 3.09 (95% CI 2.78 to 3.42), respectively. The HR for all-cause mortality was 2.70 (95% CI 2.56 to 2.86). The corresponding age-adjusted HRs for T1D individuals without history of MI versus controls with history of MI were 1.20 (95% CI 1.02 to 1.42), 0.93 (95% CI 0.75 to 1.14) and 1.29 (95% CI 1.12 to 1.50).

Conclusion: Individuals with T1D without history of MI had greater risk of future MI and all-cause mortality but had similar risk for cardiovascular death compared with controls with history of MI. These results support the notion that T1D is a coronary disease equivalent.

1196

Increased eGFR as a risk factor for heart failure in 13,781 patients with type 1 diabetes

D. Vestberg^{1,2}, A. Rosengren¹, M. Olsson³, S. Gudbjörnsdottir^{1,4}, B. Haraldsson¹, A.-M. Svensson⁴, M. Lind^{1,2};

¹Molecular and Clinical Medicine, Medicine, Sahlgrenska Academy, Gothenburg, ²Medicine, NU-Hospital Organisation, Trollhättan, ³Mathematical Sciences, Chalmers University of Technology, ⁴Centers of Registers in Region Västra Götaland, Gothenburg, Sweden.

Background and aims: Heart failure (HF) is a disease with poor long time prognosis and is more prevalent among patients with type 1 diabetes.

Decreased kidney function is a well-known risk factor in the general population but little is known of its importance in type 1 diabetes. This study investigates the association of eGFR (estimated GFR) and hospitalisation for heart failure in patients with type 1 diabetes

Materials and methods: Data were obtained from the Swedish National Diabetes Registry (NDR), a nationwide quality-assurance instrument for diabetes care, in conjunction with outcomes data from the Swedish hospital discharge and cause-specific death registries. A cohort of patients 18 years or older who had type 1 diabetes mellitus and no known HF and registered with at least one creatine value in the NDR between January 1998 and December 2003 was identified (N=13,718). Three equations were used to calculate eGFR and proportional hazards regression models were constructed to evaluate the association between eGFR and hospitalization for HF.

Results: Among 13,781 patients (mean age 41.1 (SD 13.3) years at baseline), 330 (2.4%) were hospitalised for HF over median follow-up of 7.0 years. Renal function was normal (eGFR >90 mL/min/1.73 m²) in 67% of patients according to the Cockcroft-Gault formula, compared to 51% and 41% according to the Chronic Kidney Disease Epidemiology (CKD-EPI) and Modification of Diet in Renal Disease (MDRD) formulas. For eGFR 45-60 mL/min/1.73 m², hazard ratios (HRs) for hospitalisation (reference >90 mL/min/1.73 m²) were 3.18 (95% CI 2.17;4.65), 2.12 (1.16;3.08), and 2.44 (1.69;3.55) using the Cockcroft-Gault, MDRD, and CKD-EPI formulas. In the group with even worse kidney function (eGFR <30 mL/min/1.73 m²) the HRs (95% CI) were respectively 3.78 (2.15;5.91), 3.44 (2.14;5.51) and 3.51 (2.21;5.58)

Conclusion: In patients with type 1 diabetes, risk of hospitalisation for heart failure was over two times greater at eGFR 45-60 mL/min/1.73 m² and more than 3 times greater at <30 mL/min/1.73 m² when compared to normal eGFR

1197

Incidence of atrial fibrillation in 33442 individuals with type 1 diabetes from the National Diabetes Registry compared to 167930 matched controls in Sweden from 2001-2011

S. Dahlqvist¹, A. Rosengren^{2,3}, S. Gudbjörnsdottir², A.-M. Svensson⁴, A. Mårtensson⁵, H. Wedel⁶, M. Kosiborod^{7,8}, M. Lind^{1,2};

¹Department of Medicine, NU Hospital Group, Uddevalla, ²Department of Molecular and Clinical Medicine, University of Gothenburg, ³Sahlgrenska University Hospital, Gothenburg, ⁴Centre of Registers in Region Västra Götaland, ⁵Statistiska Konsultgruppen, ⁶Nordic School of Public Health, Gothenburg, Sweden, ⁷University of Missouri, ⁸Saint Luke's Mid America Heart Institute, Kansas City, USA.

Background and aims: Atrial fibrillation (AF) is a condition that substantially increases the risk of stroke. Diabetes is a risk factor for many cardiovascular conditions, and studies of type 2 diabetes have shown that diabetes is associated with higher prevalence and incidence of AF. However the relation between type 1 diabetes (T1D) and AF has not been studied. The aim of this study was, therefore, to evaluate the relation between type 1 diabetes and atrial fibrillation.

Materials and methods: Individuals with T1D registered in the Swedish National Diabetes Registry (NDR) after January 1, 1998 were included in the study. For each individual with T1D, 5 controls matched on age, sex and county were randomly selected from the general population at time of registration in NDR. Because the diagnosis of AF was only available in the Outpatient Registry from 2001, evaluations were performed from January 1, 2001, and onwards. At baseline 253 (0.8%) individuals with T1D and 998 (0.6%) controls were excluded from further analysis due to previous AF diagnosis. After these exclusions, 33442 individuals with T1D and 167930 controls were followed using the Inpatient Registry and the Outpatient Registry with regards to AF until December 31, 2011. Mortality was assessed using the Cause of Death Registry.

Results: Mean age at baseline was 36.3 in individuals with T1D and 36.4 in controls, and 45.3% and 45.2% were women, respectively. During an average follow up of 7.37 years in the T1D group and 7.61 years in the control group, 578 (1.7%) individuals with T1D and 2353 (1.4%) controls were diagnosed with AF. The incidence rate per 1000 years was 2.35 and 1.84 in individuals with T1D and controls, respectively. The overall Hazard Ratio (HR) for individuals with T1D versus controls after adjusting for age and sex was 1.43 (95% CI, 1.31 to 1.57). When additionally adjusting for myocardial infarction (MI) and hospitalization for heart failure (HF) at baseline, the HR decreased to 1.29 (95% CI, 1.18 to 1.42). The HRs for individuals with T1D versus controls when adjusting for age was 2.66 (95% CI, 1.94 to 3.65) in women ≤ 50 years old, 1.56 (95% CI, 1.32 to 1.85) in women >50 years old, 1.64 (95% CI, 1.35 to 1.99) in men ≤ 50 years old and 1.13 (95% CI, 0.98 to 1.31) in men >50 years old. Notably, men older than 50 years had similar risk as controls, with no significant difference. The corresponding HRs with respect to age groups and sex when additionally adjusting for MI and HF was 2.66 (95% CI, 1.94 to 3.65), 1.40 (95% CI, 1.18 to 1.68), 1.61 (95% CI, 1.33 to 1.96) and 1.04 (95% CI, 0.90 to 1.20), respectively.

Conclusion: Type 1 diabetes is associated with a higher risk of AF in women all ages and in men 50 years or younger, but not in men older than 50 years. Further research is needed to confirm and explore reasons for this increased risk.

Features of coronary artery disease in 2776 type 1 diabetes patients undergoing coronary angiography

B. Lagerqvist¹, V. Ritsinger^{2,3}, C. Hero⁴, N. Saleh², K. Eeg-Olofsson⁴, A.-M. Svensson⁵, A. Norhammar²;

¹Department of Medical Sciences, Cardiology, Uppsala University Hospital, ²Department of Medicine, Karolinska University Hospital, Karolinska Institute, Stockholm, ³Department of Research and Development, Region Kronoberg, Växjö, ⁴Department of Medicine, Sahlgrenska University Hospital, University of Gothenburg, ⁵The National Diabetes Register, Centre of Registers, Region of Västra Götaland, Gothenburg, Sweden.

Background and aims: Individuals with diabetes have more widespread coronary artery disease (CAD) than those without which partly can explain their increased risk for cardiovascular death. However few studies have addressed type 1 diabetes in this context. The aim of this study was to assess features of coronary artery disease in type 1 diabetes undergoing coronary angiography.

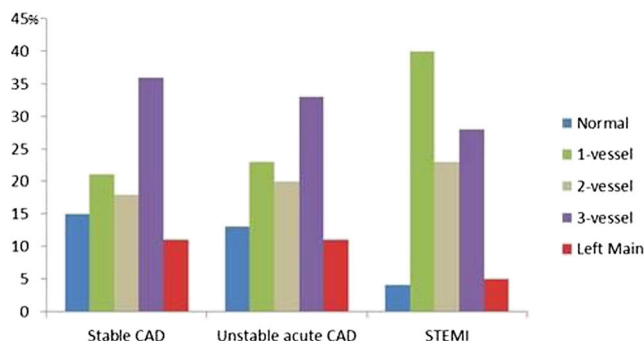

Materials and methods: All patients undergoing coronary angiography during the years 2001–2012 included in the Swedish Coronary Angiography and Angioplasty Registry (SCAAR) as well in the Swedish National Diabetes Registry (NDR) with type 1 diabetes were included and followed for mortality until 31 December 2012. Type 1 diabetes was defined both with an epidemiological definition (onset age before 30 years and insulin treatment alone) and using the clinicians' diagnosis of type 1 diabetes and onset age before 50 years. The coronary angiogram was visually judged by the local coronary interventionist and divided into normal (atheromatosis/stenosis $<50\%$), one-, two-, three- and left main-vessel disease.

Results: Of 2776 individuals with type 1 diabetes (58% male) and complete data on coronary angiogram, mean age was 57 years (SD 11), mean diabetes duration 35 years (SD 14, range 0–76) and mean HbA1c 67 mmol/mol (SD 14). The indications for coronary angiography were stable CAD (31%), unstable acute CAD (38%) and ST-elevation myocardial infarction (STEMI; 10%), heart failure (4%), atypical chest pain (5%), silent ischemia (3%) and other rare reasons. Coronary angiography revealed 21% without significant stenosis, 23% had one-vessel, 18% had

two-vessel and 29% had three-vessel disease. Left main stem disease was present in 9%. Among those with stable CAD 15% had a normal angiography and 21% had one-vessel disease. The corresponding figures for unstable acute CAD were 13% and 23% (Figure).

Conclusion: In patients with type 1 diabetes the coronary angiogram was normal more often than expected or with only one-vessel affected despite a long diabetes duration. These findings might be encouraging for those who are involved in type 1 diabetes care.

Figure: Percentage of coronary artery disease by indication for the coronary angiography

Accelerated decline in brachial distensibility in women with type 1 diabetes: a cross sectional study

P. Ljunggren^{1,2}, P. Johansson^{1,2}, L. Pyle², D. Maahs², R. Sippl², J. Ludvigsson¹, P. Wadwa², J. Snell-Bergeon²;

¹Linköping University, Sweden, ²Barbara Davis Center, Denver, USA.

Background and aims: In patients with type 1 diabetes mellitus (T1D), cardiovascular disease (CVD) events are more common and occur earlier in life than in non-diabetics. Reduced brachial artery distensibility (BrachD), a non-invasive measure of vascular stiffness and early atherosclerosis, is an independent risk factor for development of CVD. A lower BrachD indicates increased arterial stiffness. Our aim was to determine if adults with T1D have lower BrachD compared to adults without diabetes and also to determine how age and gender affect the relationship of BrachD with T1D status. We also investigated the association of BrachD with coronary artery calcium (CAC), a marker of subclinical CVD.

Materials and methods: BrachD was measured using the Dynapulse instrument (PulseMetric, San Diego, CA) in 829 participants (352 with T1D, diabetes duration 29.4 \pm 8.8 years, age 43 \pm 9 years, range 25–63 years; 477 non-diabetics age 47 \pm 9, range 26–62 years) as part of the Coronary Artery Calcification in Type 1 Diabetes (CACTI) Study. CAC was measured twice within 5 minutes and averaged, and CAC volume was square root transformed (CVS) for linear regression analysis. An ANCOVA model was used to test the association of BrachD with age, sex, and T1D, and the significance of an age*sex*T1DM interaction. The correlation of BrachD with CAC was investigated with Spearman correlation coefficients, linear models, and logistic regression.

Results: Mean BrachD was lower in T1D patients vs. controls (6.43 \pm 1.46 vs. 7.16 \pm 1.48% change per mmHg, $p < 0.0001$), indicating higher arterial stiffness. In a model adjusted for age, T1D, and sex, the interaction of age*T1D*sex was significant ($p = 0.0045$). Younger women both with and without T1D had higher BrachD than men with and without T1D, but older women had lower BrachD compared to older men. Women with T1D had a steeper decline than nondiabetic women (Figure 1). BrachD was correlated with CAC score ($r = -0.17$, $p < 0.0001$), but after adjusting for age and sex, neither CAC score nor CVS were associated with BrachD ($p = 0.95$ and $p = 0.23$, respectively).

Conclusion: BrachD is lower in T1D patients indicating increased vascular stiffness. Younger females have higher BrachD than males but the decline with age in BrachD is steeper for women and even greater in women with T1D. This greater change in BrachD with age seen in women with T1D is consistent with the increase in other CVD risk factors in women with T1D. BrachD may be an inexpensive, non-invasive method to ascertain increased CVD risk in this population. CAC was not associated with BrachD after adjusting for age and sex, suggesting that these markers of subclinical atherosclerosis may have different pathophysiological pathways.

Use of statins and risk of cardiovascular disease and death in type 1 diabetes: a report from Swedish NDR

S. Gudbjörnsdóttir^{1,2}, C. Hero², A. Rawshani², A.-M. Svensson¹, S. Franzén¹, B. Eliasson², K. Eeg-Olofsson²;

¹The National Diabetes Register, Gothenburg, ²Department of Medicine, University of Gothenburg, Sweden.

Background and aims: Individuals with type 1 diabetes (T1D) are at higher risk of cardiovascular disease (CVD) and death than the general population. Risk factor control is crucial and statin treatment is advocated by guidelines. Recommendations for persons with T1D proceed largely from extrapolation from other patient populations. The effect of statins in primary prevention among persons with T1D without previous CVD is unknown. Our aim was to examine the effect of statins on major cardiovascular events and death in T1D.

Materials and methods: We used the Swedish National Diabetes Register (NDR) to perform a propensity score based study. A total of 24,230 individuals (included during 2006–2008) with T1D without history of CVD were followed until 31/12/2012; 18,843 (53% male) were untreated and 5387 (57% male) treated with statins. Mean follow-up was 6.0 years with 146,553 person-years of follow-up. A propensity score for treatment with statins was estimated using 32 baseline variables, including socioeconomic factors, and used to balance the covariates in the two groups. Cox regression analysis was performed by stratifying (eight strata) on the propensity score, with and without censoring at cross-over (i.e. switching treatment group by starting or ending medication with statins).

Results: Unadjusted differences were marked at baseline between the groups but the propensity score allowed for balancing of all 32 covariates; there were no differences between treated and untreated after accounting for the propensity score. Figure 1 compares numbers of events and adjusted hazard ratios (HR) with 95% confidence intervals (CI) for CVD death, total death, for fatal/non-fatal acute myocardial infarction (AMI), coronary heart disease (CHD), stroke and CVD in patients with and without statin treatment in the overall cohort and in the cohort with censoring at cross-over.

Conclusion: This large observational study shows that treatment with statins reduces the risk of CVD death and total death as well as stroke in individuals with T1D without history of CVD.

Mortality by affected coronary artery vessels in 2776 patients with type 1 diabetes undergoing coronary angiography

K. Eeg-Olofsson¹, V. Ritsinger^{2,3}, C. Hero¹, N. Saleh², B. Lagerqvist⁴, A.-M. Svensson⁵, A. Norhammar²;

¹Department of Medicine, Sahlgrenska University Hospital, University of Gothenburg, ²Department of Medicine, Karolinska University Hospital, Karolinska Institute, Stockholm, ³Department of Research and Development, Region Kronoberg, Växjö, ⁴Department of Medical Sciences, Uppsala University Hospital, ⁵The National Diabetes Register, Centre of Registers, Region of Västra Götaland, Gothenburg, Sweden.

Background and aims: Individuals with diabetes mellitus have more widespread coronary artery disease (CAD) than those without which partly can explain their increased risk for cardiovascular death. However few studies have addressed type of diabetes in this context and rarely type 1 diabetes. The aim of this study was to assess long-term mortality by affected coronary vessels in type 1 diabetes undergoing coronary angiography.

Materials and methods: All patients undergoing coronary angiography during the years 2001–2012 included in the Swedish Coronary Angiography and Angioplasty Registry (SCAAR) as well as in the Swedish National Diabetes Registry (NDR) with type 1 diabetes were included and followed for mortality until 31 December 2012. Type 1 diabetes was defined both with an epidemiological definition (onset age before 30 years and insulin treatment alone) and using the clinicians’ diagnosis of type 1 diabetes and onset age before 50 years. The coronary angiogram was visually judged by the local coronary interventionist and divided into normal (atheromatosis/stenosis <50%), one-, two-, three- and left main-vessel disease.

Results: Of 2776 individuals with type 1 diabetes (58% male); mean age was 57 years (SD 11), mean diabetes duration 35 years (SD 14, range 0–76) and mean HbA1c 67 mmol/mol (SD 14). Mean follow-up time was 7.2 years (SD 2.2). The most common indications for coronary angiography were stable CAD (31%), unstable acute CAD (38%) and ST-elevation myocardial infarction (STEMI) (10%). Patients with three-vessel compared to one-vessel disease had longer diabetes duration (39 vs. 33 years) and lower onset age of diabetes (21 vs. 23 years) while actual HbA1c did not differ (67.2 vs. 66.8 mmol/mol). Mortality (Figure) was similar in those with normal and one-vessel diseases while those with two-vessel almost had comparable mortality rate to those with three-vessel disease.

Conclusion: In patients with type 1 diabetes admitted for coronary angiography mortality is increased by numbers of affected coronary vessels. Duration of diabetes seems more important than actual HbA1c for

numbers of affected coronary arteries. Figure: Time to mortality by affected coronary vessels after coronary angiography. Log-rank $p < 0.0001$.

Cumulative smoking and the risk of acute myocardial infarction and stroke in patients with type 1 diabetes

M. Feodoroff^{1,2}, V. Harjutsalo^{1,3}, C. Forsblom^{1,2}, P.-H. Groop^{1,2}, FinnDiane Study Group;

¹Folkhälsan Institute of Genetics, ²Abdominal Center Nephrology, ³National Institute for Health and Welfare, Helsinki, Finland.

Background and aims: Previous studies addressing the association between smoking and cardio vascular disease (CVD) in patients with diabetes have mainly been focused on the CVD mortality and only few of them have included patients with type 1 diabetes. Our aim was to study the effect of cumulative smoking in pack-years on the risk of acute myocardial infarction (AMI) and stroke in patients with type 1 diabetes.

Materials and methods: The study included 3,545 patients with type 1 diabetes participating the FinnDiane (Finnish Diabetic Nephropathy) study. The smoking status was based on baseline questionnaires and patients were considered as current, ex- or nonsmokers and the amount of cumulative smoking was calculated in pack-years. The follow-up data for the development of AMI or stroke was based on The Care Register for Health Care and Causes of Death Register until the end of year 2012. The overall follow-up time was 39,481 person years and the median follow-up time was 12.0 (9.2–13.9) years. Cox-regression analyses providing HRs were used to estimate the risk for the development of AMI or stroke per each pack-year as continuous variable. Sex, duration of diabetes, systolic blood pressure, HbA1c and HDL cholesterol were used as covariates. The 14-year cumulative risk of combined AMI and stroke in current, ex- and nonsmokers was estimated with Kaplan-Meier analyses and log-rank test was used for comparison between the groups.

Results: One pack-year increased the risk of incident AMI with a HR of 1.027 (95% CI 1.016–1.037, $p < 0.0001$) in current smokers and 1.032 (1.023–1.041, $p < 0.0001$) in ex-smokers, compared with nonsmokers. In the multivariate model the HR of AMI was 1.011 (0.001–1.022, $p < 0.05$) for current smokers and 1.009 (0.996–1.021, $p = \text{NS}$) for ex-smokers. The results were similar in stroke and the HRs were 1.029 (1.017–1.042, $p < 0.0001$) in current smokers and 1.035 (1.025–1.045, $p < 0.0001$) in ex-smokers compared with nonsmokers in the unadjusted model. In the adjusted model the HRs were 1.015 (1.001–1.028, $p < 0.05$) and 1.019

(1.005–1.032, $p < 0.01$) respectively. The combined 14-year cumulative risk of AMI and stroke was 17.1% (14.7–19.3, $p = 0.011$) in current smokers and 21.4% (18.8–23.9, $p < 0.0001$) in ex-smokers compared with 12.3% (10.9–13.7) in nonsmokers.

Conclusion: Smoking is a significant risk factor for CVD in patients with type 1 diabetes and the risk of developing CVD depends on the cumulative amount of smoked cigarettes. After the adjustments for other CVD riskfactors the risk for AMI in ex-smokers approaches the risk seen in nonsmokers. However, the risk for stroke is the highest in ex-smokers also after the adjustments.

Adipose-specific Dipeptidyl Peptidase 4 (DPP4) knockout mice display improved fasting insulin and smaller adipocytes on High Fat Diet (HFD)

T. Romacho¹, D. Röhrborn¹, I. Indrakusuma¹, T. Jelenik², T.R. Castañeda³, H. Al-Hasani³, M. Roden^{2,4}, H. Sell¹, J. Eckel¹;

¹Paul Langerhans Group for Integrative Physiology, ²Institute for Clinical Diabetology, ³Institute for Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, ⁴Department of Endocrinology and Diabetology, Medical Faculty, Heinrich Heine University, Düsseldorf, Germany.

Background and aims: DPP4 is an important therapeutic target for type 2 diabetes mellitus. Our group has recently characterized this serine protease as a novel adipokine potentially linking obesity to the metabolic syndrome. By using a unique adipose-tissue (AT) specific DPP4 KO mouse model, we aimed to elucidate the role of adipose DPP4 in high fat diet-induced obesity.

Materials and methods: The AT-specific DPP4 KO mouse was generated using a Cre-lox strategy under control of the *aP2* promoter on the C57BL/6J background. Metabolic phenotyping of mice on both chow and HFD (60% kcal fat) over 24 weeks was performed using Phenomaster metabolic cages, MRT, glucose and insulin tolerance tests (ipGTT, ipITT), as well as euglycemic-hyperinsulinemic clamps. DPP4 concentration and DPP4 activity in serum, DPP4 expression in mature adipocytes and stroma-vascular fraction (SVF) as well as plasma levels of glucose, insulin, triglycerides and cholesterol were measured. Adipocyte size was quantified by immunohistochemistry in subcutaneous (sWAT) and epididymal white adipose tissue (eWAT). Furthermore, gene expression was assessed in both depots by qRT-PCR.

Results: DPP4 expression in mature adipocytes from KO mice was reduced up to 65% ($p < 0.01$) with unchanged expression in the SVF. Serum DPP4 was significantly lower in KO animals on both diets. KO mice gained significantly more weight, fat and lean mass on HFD. However, body fat percentage and length remained similar. The genotype exerted no effect on energy expenditure, respiratory quotient and spontaneous physical activity. ipGTT, ipITT and clamps were affected by HFD but not by genotype. On the other hand, fasting insulin and HOMA-IR were significantly lower in KO mice on HFD despite unchanged insulin sensitivity. Cholesterol was reduced in both KO mice on chow and on HFD compared to WT but triglycerides were similar. Within the HFD group, the KO mice showed a marked shift in the adipocyte size distribution towards smaller adipocytes. In both fat depots, differentiation markers remained similar whereas the M2 macrophage markers macrophage mannose receptor 1 and interleukin (IL)-10 were significantly upregulated in KO animals compared to WT under HFD. In eWAT, IL-6 and monocyte chemoattractant protein 1 were significantly increased in KO mice. Serum DPP4 correlated significantly with adipocyte size in both subcutaneous and epididymal AT while negatively with serum adiponectin.

Conclusion: This model proves that AT is an important source of DPP4 in mice. Although KO animals gained more weight and fat mass under HFD challenge, this is not followed by decreased glucose tolerance. Taken into account that KO animals display smaller adipocytes under HFD, these findings point towards a beneficial role for DPP4 deletion in adipose tissue remodeling during HFD. Nevertheless, how DPP4 deletion in adipose tissue translates into impaired metabolic performance in this mouse model must be further clarified.

Spontaneous high fat diet overeating and body weight gain in selectively bred mice for diet-induced glucose intolerance: possible role of leptin

A. Asai, M. Nagao, H. Sugihara, S. Oikawa;

Department of Endocrinology, Diabetes and Metabolism, Nippon Medical School, Tokyo, Japan.

Background and aims: Selective breeding is a powerful approach for studying the polygenic etiology of lifestyle-related diseases, such as type 2 diabetes and obesity. To investigate the pathogenesis of type 2 diabetes under high fat diet (HFD) conditions, we recently established 2 lines of mice with distinctively different susceptibilities to HFD-induced glucose intolerance by selective breeding; designated selectively bred diet-induced glucose intolerance-prone (SDG-P) and -resistant (SDG-R). In addition to the obvious glucose intolerance, SDG-P mice showed greater body weight gain, adiposity, and insulin resistance after HFD feeding as compared to SDG-R mice. Here, we investigated the differences in feeding behavior between the 2 lines of mice and further explored the mechanism underlying the different feeding behavior.

Materials and methods: Male SDG-P and SDG-R mice fed a HFD (32% energy fat) for 5 weeks (5–10 weeks of age). In a pair-feeding experiment, daily food intake of some SDG-P mice (pair-fed SDG-P) was kept the same amount of SDG-R mice during the HFD feeding period. Glucose tolerance was assessed before and after the HFD feeding by OGTT. Plasma leptin concentration was measured by ELISA. Leptin gene expression in epididymal adipose tissue was assessed by quantitative real-time PCR. Data are expressed as mean \pm SEM. Values of $p < 0.05$ were considered statistically different between groups by Student's *t* test or ANOVA with Tukey's multiple comparisons.

Results: At 5 weeks of age (before the HFD feeding), no significant differences were shown in body weight, adipose tissue mass, locomotor activity, and oxygen consumption between SDG-P and SDG-R. In *ad libitum* feeding condition, SDG-P mice showed higher HFD intake and greater body weight gain than SDG-R [SDG-P ($n=14$) vs SDG-R ($n=15$): food intake, 4.3 ± 0.4 vs 3.4 ± 0.2 g/day ($p < 0.001$); body weight after the 5-week HFD feeding, 36.8 ± 4.3 vs 27.3 ± 2.5 g ($p < 0.001$)]. In the pair-feeding experiment, body weight gain of pair-fed SDG-P mice was completely suppressed to the level of SDG-R [27.1 ± 1.5 g ($n=14$, $p=0.991$ vs SDG-R)]. Furthermore, HFD-induced deterioration of glucose intolerance in SDG-P mice was largely abrogated by the pair feeding. Despite the no significant differences in body weight and adipose tissue mass at 5 weeks of age, plasma leptin concentration of SDG-P mice was significantly lower than that of SDG-R mice [SDG-P ($n=12$) vs SDG-R ($n=11$): 1.7 ± 0.7 vs 2.7 ± 1.4 ng/ml ($p=0.039$)]. Leptin gene expression level was also lower in SDG-P mice [$\sim 50\%$ of SDG-R (normalized to *Gapdh*), $p=0.016$]. In addition, exogenous leptin injections (50 μ g/mouse twice daily for 3 days, i.p.) effectively reduced HFD intake in both lines of mice and the body weight gain of SDG-P mice was suppressed to the same level of SDG-R mice by the injections.

Conclusion: The present results demonstrate that the HFD-induced deterioration of glucose intolerance in SDG-P mice is the result of spontaneous overeating. The lower leptin levels before HFD feeding in SDG-P mice suggest a possible role of leptin as a determinant of later overeating, obesity, and the development of type 2 diabetes under HFD conditions.

Methylglyoxal impairs high-fat diet-induced adipose tissue expansion causing systemic dysmetabolism

T. Rodrigues¹, J.P. Almeida¹, J. Sereno², J. Castelhan², C. Neves¹, R. Fonseca¹, S. Gonçalves², L. Gamas¹, M. Castelo-Branco^{2,3}, P. Matafome^{1,4}, R. Seica¹;

¹Laboratory of Physiology, Institute of Biomedical Imaging and Life Sciences (IBILI), Faculty of Medicine, ²Institute for Nuclear Sciences Applied to Health (ICNAS), ³Laboratory of Visual Neuroscience, IBILI, Faculty of Medicine, University of Coimbra, ⁴Coimbra Health School (ESTeSC), Department of Complementary Sciences, Instituto Politécnico de Coimbra, Portugal.

Background and aims: Adipose tissue dysfunction is known to trigger systemic dysmetabolism in obesity and type 2 diabetes. The use of obese models consistently has shown hypoxia in adipose tissue, but previous studies did not fully explore the mechanisms involved. Many of them suggested adipocyte hypertrophy as the cause for hypoxia and dysmetabolism, due to lower oxygen diffusion. However, recent data supported the idea that instead of simple adipocyte hypertrophy, microvascular dysfunction could be the trigger for hypoxia and dysmetabolism. We previously demonstrated that methylglyoxal (MG), a byproduct of glucose metabolism, is able to induce glycation, microvascular dysfunction and inflammation, as well as impaired adaptation to decreased blood supply. This study investigates the role of MG-induced microvascular dysfunction in a context of high-fat diet-induced adipocyte hypertrophy and tissue expansion.

Materials and methods: We used animal models fed a high-fat diet (HFD), with MG-induced glycation (MG) or both (HFDMG) during 4 months, separating both variables in the experimental design, as well as a group of control (Ct) and diabetic Goto-Kakizaki (GK) rats fed a standard diet (n=6/ group). Animals were submitted to functional magnetic resonance imaging (fMRI) in order to assess tissue irrigation. Subsequently, animals were injected i.p. with the hypoxia probe pimonidazole (60 mg/Kg) and epididymal adipose tissue was collected for biochemical analyses.

Results: Rats submitted to MG administration (MG and HFDMG) showed higher accumulation of the MG-derived AGE N(epsilon)-(carboxyethyl) lysine (CEL) in adipose tissue, similarly to diabetic rats. Using fMRI imaging, lower accumulation of the contrast product was observed in high-fat diet-fed (HFD) and GK rats, but mostly in rats treated with MG alone (MG) and in HFD rats supplemented with MG (HFDMG). Moreover, pimonidazole adducts were significantly increased in the epididymal adipose tissue of HFDMG and GK rats, but not HFD or MG. In addition, decreased Perilipin A, a marker of adipocyte dysfunction, was observed in HFDMG rats. Regarding insulin signaling, despite no differences were observed in phosphorylated Akt, the HFD fed rats with MG supplementation (HFDMG) and GK rats, but not the HFD nor the MG groups, showed a significant decrease of the active form of insulin receptor (Tyr1163). These data were in accordance with the i.p. glucose tolerance test (IPGTT), where higher glucose intolerance (higher area under the curve) and hyperinsulinemia were observed in HFDMG rats.

Conclusion: Altogether, our results show that glycation induced by methylglyoxal conduces to microvascular dysfunction that impairs adipose tissue expansibility. In a context of diet-induced hypertrophy and adipose tissue expansion, such events lead to hypoxia, adipocyte dysfunction and insulin resistance, that have systemic repercussions in the glucose metabolism.

Glycation and high-fat diet trigger distinct functional consequences in the heart: an MRI study

P. Matafome^{1,2}, J. Sereno³, J. Castelhan³, T. Rodrigues¹, S. Gonçalves³, C. Neves¹, C. Marques⁴, R. Seica¹, M. Castelo-Branco³;

¹Laboratory of Physiology, Institute of Biomedical Imaging and Life Sciences (IBILI), Faculty of Medicine, University of Coimbra, ²Coimbra Health School (ESTeSC), Department of Complementary Sciences, Instituto Politécnico de Coimbra, ³Institute for Nuclear Sciences Applied to Health (ICNAS), ⁴Center of Ophthalmology, IBILI, Faculty of Medicine, University of Coimbra, Portugal.

Background and aims: Cardiovascular diseases are one of the main consequences of obesity and type 2 diabetes. Among other factors, alterations of lipid metabolism and glucotoxicity are known to be involved in heart disease and decreased ability to adapt to an ischemic event. In the past, we showed that glucose-derived methylglyoxal (MG) is able to decrease the activation of survival pathways during heart ischemia, similarly to diabetic rats. More, we observed that such effects were specifically inhibited by the dicarbonyl scavenger drug pyridoxamine. Moreover, we described that diabetic rats fed a high-fat diet showed impaired response to ischemia. Thus, our goal was to investigate the mechanisms of heart dysfunction in diabetes and obesity, using a magnetic resonance imaging device specially designed for laboratory animals.

Materials and methods: Rats were maintained during 4 months with MG supplementation (100 mg/Kg/day) (MG), a high-fat diet rich in triglycerides (HFD) or both (HFDMG) and compared with controls feeding a standard diet (n=6/ group). The effects of MG-induced glycation and a high-fat diet regimen in several cardiac functional parameters were assessed using magnetic resonance imaging (MRI).

Results: High-fat diet-fed rats (HFD group) showed no significant alterations in heart function parameters, despite a trend to increased end-diastolic volume and end-systolic volume and heart weight was observed. On the other hand, accumulation of glycated products induced by MG supplementation (MG group) resulted in decreased stroke volume and cardiac output, as well as decreased peak filling rate. Interestingly, MG supplementation to high-fat diet-fed rats (HFDMG group) produced many of the functional consequences of MG and further decreased the peak ejection rate.

Conclusion: Using magnetic resonance imaging, our results suggest that moderate ventricular hypertrophy caused by the consumption of a high-fat diet is not associated with impaired heart functional parameters. On the other hand, the accumulation of MG-derived advanced glycation end products impairs filling and ejection rates, conducing to decreased cardiac output and stroke volume. This study sheds light on the mechanisms governing heart failure in obesity and type 2 diabetes, which may conduce to better therapeutic approaches in the future.

PAR2 is upregulated by adipocyte-derived factors and high fat diet in the vascular wall

I. Indrakusuma, T. Romacho, J. Eckel;

Paul Langerhans Group for Integrative Physiology, German Diabetes Center, Düsseldorf, Germany.

Background and aims: Obesity is associated with impaired vascular function. However, the underlying mechanisms linking obesity and cardiovascular diseases are not fully understood. Protease activated receptor-2 (PAR2) is a G protein coupled receptor that can be activated by proteases as well as other activating peptides. Under physiological conditions, PAR2 exerts multiple functions such as controlling vascular tone and coagulation. In pathological conditions, PAR2 is upregulated in atherosclerotic lesions and promotes vasoconstriction. However, little is known about the impact of obesity on PAR2 in the vasculature. Our group has recently proposed that the adipokine soluble DPP4 (sDPP4) acts as an agonist for PAR2 leading to pro-atherogenic effects in human vascular smooth muscle cells (SMC). Thus, we aimed to investigate the impact of adipocyte-derived factors on the expression and function of PAR2 in the context of obesity-related vascular dysfunction.

Materials and methods: SMC were treated with conditioned medium (CM) from in vitro differentiated primary human adipocytes, IL-1 β (10 ng/ml) or YKL-40 (100 ng/ml) for 24 h. Additionally, a time course with CM treatment was performed in SMC. In parallel, human coronary artery endothelial cells (HCAEC) were incubated with CM for 4 h. Protein and mRNA expression were assessed by Western Blot and qRT-PCR, respectively. BrdU incorporation was analyzed to determine SMC proliferation. Furthermore, C57BL/6 mice were fed with either a chow or a 60% high fat diet (HFD) for 24 weeks prior to isolation and subsequent mRNA extraction from aortas. DPP4 activity of serum samples from mice were analyzed with a DPP4 activity kit.

Results: We observed that CM treatment significantly enhanced PAR2 protein expression in both SMC and HCAEC (1.4-, 1.5- fold, respectively). Interestingly, PAR2 mRNA level in SMC showed a peak (1.7 fold) after 1 h of CM exposure. PAR2 protein level was increased in SMC by the adipokines IL-1 β (1.8 fold) or YKL-40 (1.4 fold). Moreover, CM exerted a pro-atherogenic action on SMC since it promoted proliferation at 24 h. This observation was a PAR2-specific effect abrogated in the presence of the PAR2 antagonist GB83 (10 μ M). In vivo, aortas of HFD-fed mice expressed significantly more PAR2 mRNA (1.5 fold) compared to aortas from lean mice. PAR2 upregulation in aortas was in parallel with an increase in the enzymatic activity of DPP4 in the serum of the animals treated with HFD (1.8 fold).

Conclusion: We showed that PAR2 is upregulated in two different vascular cell types in response to CM and in response to specific adipocyte-derived factors, leading to a pro-atherogenic effect. PAR2 expression levels were also elevated by HFD in murine aortas. In conclusion, under obesogenic conditions, where circulating levels of adipokines, such as IL-1 β , YKL40 or sDPP4, are elevated, PAR2 arises as an important player linking obesity-related adipose tissue inflammation with atherogenesis.

Irisin improves endothelial function in obese mice through the AMPK-eNOS pathwayX. Sun¹, F. Han², N. Hou¹;¹Department of Endocrinology, ²Department of Pathology, Affiliated Hospital of Weifang Medical University, China.

Background and aims: Irisin is a novel hormone secreted by myocytes and has been proposed to mediate the beneficial effects of exercise on metabolism. Some studies reported that circulating irisin levels were positively associated with endothelium-dependent vasodilation in obese

subjects and irisin may be involved in the regulation of endothelial function in obesity. Therefore, the objectives of this study were to explore whether irisin could improve endothelial function in obesity.

Materials and methods: C57BL/6 mice were given chow or high fat diet with or without treatment with irisin. Aortic endothelial function was determined by measuring endothelium-dependent vasodilatation (EDV). Nitric oxide (NO) in the aorta was determined. The effect of irisin on the level of phosphorylation of AMP kinase (AMPK), Akt and endothelial nitric-oxide synthase (eNOS) in endothelial cells were determined. Human umbilical vein endothelial cells (HUVECs) were used to study the role of irisin on AMPK-eNOS pathway.

Results: Treatment of obese mice with irisin improved glucose and lipids metabolism (glucose, 88.2 \pm 5.4 mg/dl vs 99.0 \pm 5.4 mg/dl; triglycerides, 83.54 \pm 12.60 mg/dl vs 124.54 \pm 16.83 mg/dl; NEFA 0.73 \pm 0.26 mmol/L vs 1.09 \pm 0.22 mmol/L; P<0.01), reduced serum levels of TNF- α (20.34 \pm 4.24 pg/ml vs 32.45 \pm 5.84 pg/ml, P<0.01), high sensitivity C-reactive protein (1.47 \pm 0.55 vs 2.84 \pm 0.83 mg/L, P<0.01), malondialdehyde (3.16 \pm 0.45 μ mol/L vs 5.33 \pm 0.72 μ mol/L, P<0.01) and increased serum adiponectin levels (16.65 \pm 1.13 μ g/ml vs 14.35 \pm 1.16 μ g/ml, P<0.01). Acetylcholine-stimulated EDV was significantly lower in obese mice compared with control mice (maximum vasodilatation rate, 39.01% \pm 7.96% vs 82.31% \pm 5.18%, P<0.05). Treatment of obese mice with irisin significantly enhanced EDV and improved endothelial function (63.23% \pm 7.97% vs 39.01% \pm 7.96%, P<0.05). This beneficial effect of irisin was partly attenuated in the presence of compound C (AMPK inhibitor), API-2/triciribine (Akt inhibitor) and L-NAME (eNOS inhibitor). Treatment of obese mice with irisin enhanced NO production (19.40 \pm 3.20 μ mol/L vs 10.24 \pm 2.30 μ mol/mg, P<0.01), phosphorylation of AMPK, Akt and eNOS in endothelial cells (P<0.05). Incubation of the HUVECs with irisin induced NO production in a dose- dependent and time-dependent manner (P<0.05) and also enhanced phosphorylation of AMPK, Akt and eNOS (P<0.05). Treatment with L-NAME abolished irisin-induced NO production (P<0.05). Suppression of AMPK expression by siRNA blocked irisin-induced Akt and eNOS phosphorylation and abolished irisin-induced NO production (92.40 \pm 12.30 μ mol/L vs 162.3 \pm 13.20 μ mol/L, P<0.01).

Conclusion: We have provided the first evidence that irisin improved endothelial function in aortas of high-fat diet induced obese mice. The mechanism for this protective effect is related to the activation of the AMPK-eNOS signaling pathway.

Olfactory-bulbar prokineticin-2 is involved in the regulation of food intake and energy homeostasis, and proceeds through a GLP-1R dependent mechanismM. Mortreux¹, N. Kassis¹, R. Burcelin², D.J. Drucker³, C. Magnan¹, S. Migrenne-Li¹;¹University Paris Diderot CNRS UMR 8251, ²INSERM UMR 1048, Toulouse, France, ³Mount Sinai Hospital Lunenfeld-Tanenbaum Research Institute, Toronto, Canada.

Background and aims: Food intake is influenced by olfactory cues and metabolic status can affect the olfactory function of animals and regulate feeding behavior. Prokineticin-2 (PK2) is a hypothalamic anorectic neuropeptide that is also highly expressed in the olfactory bulb (OB) as well as GLP-1 receptor (GLP-1R). Our study was aimed to assess the role of olfactory-bulbar PK2 in regulation of food intake and energetic homeostasis, in relation with GLP-1R signaling pathway.

Materials and methods: To that end, expression of both PK2 and GLP-1R mRNA was measured in fed or fasted mice either under control diet (CD) or high fat diet (HFD). In another serial, spontaneous food intake was measured in fasted mice injected with recombinant PK2 (rPK2) +/- Exendin9 (Ex9) in the OB. Energetic homeostasis was assessed after 5 weeks of down-regulation of OB-PK2 using a specific shRNA.

Results: We first evidenced that PK2 mRNA levels in the OB of C57Bl/6j mice depend on both the nutritional (fed vs fasted) and the metabolic (lean vs obese) status of the animal. Indeed, fasting resulted in a decrease of PK2 mRNA in lean mice and a significant increase of PK2 mRNA in obese mice. Moreover, we confirmed that GLP-1R mRNA was present within the OB and increased by fasting. Injection of rPK2 in the OB significantly decreased food intake during 24 h post-surgery compared to control animals, in both mice fed with CD or HFD. Inhibitory effect of rPK2 injected in the OB was lost when Ex9 was co-infused. Additionally, we injected rPK2 in the OB of GLP-1R-KO mice and could not detect any anorectic effect. Moreover, a chronic down-regulation of OB-PK2 led to variations of GLP-1R mRNAs in both the OB and the HT, and also altered energy homeostasis of animals.

Conclusion: We conclude that olfactory-bulbar PK2 reduces food intake through a GLP-1R dependent mechanism.
