Abstract. In order to create the simulation model of Above-ground Organs Morphogenesis of Flue-cured Tobacco, the dynamic model of organ morphology in different growing step of tobacco was built with potting experimental methods with which the biomass of tobacco organ in different growth period can be systematically determined. As simulation of organ morphology of tobacco measured in 2007 shows that the correlation coefficient between the simulated value and the measured value of above-ground organ of tobacco in different growth cycle is 0.735 to 0.9997 at significant level which proved that the dynamic of above-ground organ morphogenesis of tobacco can be predicted well by the model. The regulation of growth of tobacco morphology can be reflected well by the model of above-ground organ morphogenesis; furthermore, the model can also be a theoretical basis for virtual growth of tobacco.

Keywords: Flue-cured Tobacco, above-ground organ, morphogenesis, model of simulation.

With the dynamic development of information technology on agriculture, more and more researches on virtual plant have been taking. The morphogenesis model, a key technology in virtual plants, has aroused our attention. Ulam [1] and Cohen [2] were the pioneers on research to models of plant branches. These were followed by Lindermayer and his L-system [3], basing on the analysis to the plant organ growth, Hunt [4] produced a plant organ-growing model. Besides, de Reffye, a France man, and his assistants developed a plant-growth system, named AMAP [5, 6]. Combining the L-system and computer graphics, A.R. Smith and Prusinkiewicz made the visualization of plant morphology come true [7-10]. Considering the environment model (e.g. Light and disease and pest injury) and measured data from tri-dimension plant on the L-system, virtual plant model was built in the research center CPAI, Australia [11]. The virtual plant system GROGRA2.4 (Growth grammar Interceptor), which was basing on the L-system, was created by Kurth [12].

As a function-structure model, GREENLAB played an important role in the plant structure area [13-15]; it is brief and honest to mechanization. By building Recurrence

relations among several Mathematical formulas, the feedback relationship was parallel simulated. It only needed a few certain parameters to simulate the growth of plants like trees. Virtual structure model of plant, like cotton, maize, wheat etc, was produced by de Reffye [16], Zhan Zhigang etc [17], and GREENLAB. Technology frame on shape simulation and tri-demission visualization of corn, basing on growth model, was produced by Zhao Chunjiang etc [19], and it created a new idea and method. After researching the static model on maize canopy structure, Ivanov [20] and Fournier [21] rebuilt the tri-dimension canopy and analyzed the way how the light is used by canopy with the help of oriented-object program, Jin Mingxian [22] built the tri-dimension model for root -growth of maize. Besides, maize- visualization model, produced by Guo Yan and Li Baoguo [23-24], can be used to analyze tri-dimension structure character of maize canopy and the maize canopy space distribution under the effect of morphology. These researches above show that plant simulation has been developing fast in all the areas which it refers.

Tobacco is one of the very important cash crops. Researches about its under-ground organ such as root have been done. Ma Xinming [25-26] once described the dynamic relation between growth of root system and surrounding environment and built a mathematic model on morphological development of tobacco roots. However, researches on above-ground organs of tobacco are rare. Taking the existed researches [27-29] as references, basing on the measured data for building tobacco morphology, researching the dynamic relationship between tobacco morphogenesis regulation and the environment, visualization model about tobacco morphogenesis was built, with the help of morphology module produced by Song Youhong etc [18]. A purpose of this paper is to offer a theory for improving the quality of tobacco and increasing of production.

1 Material and Methods

1.1 Designing of Experiment and Materials in Use

This experiment was made in the scientific and educational experimental area of Henan Agricultural University during 2006-2007. All the tobacco seeds, seeds K326 in this experiment, were cultivated in the pots, diameter 40cm, depth 45cm, filled with sandy and tidal soil. Content of nutrient in the soil were listed as Table1:

Table 1. Content of Nutrient in the Sandy and Tidal Soil

Index of Soil	Organic Matter(g.kg ⁻¹)	Available N(mg.kg ⁻¹)	Available P(mg.kg ⁻¹)	Available K(mg.kg ⁻¹)	pH
Content	7.8	35	9.86	80	7.6

The weight of soil which should be air-dried and sifted before being used in each pot was 25kg. Chemical fertilizers used in this soil were AR (NH₄)₂SO₄, KNO₃ and KH₂PO₄ and all of these chemical fertilizers should be scattered off as base fertilizer at the first time. The content of fertilizer N in every kilogram soil was 0.2 gram, and N:

P₂O₅: K₂O=1:1.5:3. Seeding growing with the float system was cultivated in artificial climatic box in the lab. Sixty days later, they were transplanted into the pot, laid in the soil under the shelter. In this way, the environment where they grow in can be similar with that of farmland. The amount of necessary water in different period of growing for tobacco is varied. The supply of water can be controlled with the help of time-domain reflector (TDR) whose type model is TRIME-FM and shelter should also be open in the raining day to prevent the rainwater in. The management of tobacco, planted in row spacing 1.1m, plant spacing 0.6m in this experiment, has noting different with that of farmland except entering rosette stage in their 30th day and pinching in 57th day after being transplanted.

1.2 Measured Items and Measuring Methods

1.2.1 Measured Items for Internodes: Fresh Weight, Length and Diameter

Three typical plants from the experimental area should be taken every 10 days after seeding restitution stage. Then, cut them apart by internodes. Fresh weight of internodes can be measured on milli electronic balance. Length of internodes can be measured by ruler which is correct to 0.1cm. Diameter can be measured by vernier caliper within the accuracy of 0.001cm.

1.2.2 The Length, Width and Area of Leaf

The maximal width on the middle of leaf (Abb. W) and leaf length (Abb. L) can be measured with ruler, and the fresh weight of leaf can be measured with electronic balance. Then, the leaf area (Abb. LA) can be figured out with this formula:

$$LA=L \times W \times 0.6345 \tag{1}$$

Besides, meteorological data can be achieved from meteorological bureau.

1.3 Model Testing

The dynamic model for above-ground organs of tobacco while growing can be built with data measured in 2006 and be tested with the data measured in 2007. The conformity between analog value and observed value can be made a statistical analysis with root mean square error (Abb. RMSE) and 1:1 graphing method. The RMSE can be counted in this equation:

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (OBS_i - SIM_i)^2}{n}} \tag{2}$$

OBS_i: Observed value;

SIM_i: Analog value;

n: Sample size

1.4 Description on Tobacco Models

1.4.1 Model on Growth Cycle of Tobacco

Growth cycle (Abb. GC) was defined as a time span caused by two adjacent me tamers which including internodes, node and leaf growing from the node. It has been proved that the topological structure of plant is obviously affected by cumulative effect which is caused by temperature change of environment [17]. For that growing period of tobacco in field last for 120~130 days which is a pretty long time, the GC was defined as a time unit while modeling. Growing process can be predicted with the following formula (3) which reflect the relationship between tobacco growth and accumulated temperature.

$$NGC = DR \cdot SumT + 7 \quad (3)$$

NGC: Number of Growth Cycle

DR ($^{\circ}\text{C}^{-1}$) : Developing ratio

SumT ($^{\circ}\text{C}$): Accumulated temperature which equals to the sum of temperature after being transplanted

The number 7 in formula (3) represented the number of unrolled leaf when the tobacco plant being transplanted, in other words, 7 Growth Cycles has been finished when being transplanted.

1.4.2 Internodes Morphology of Tobacco

Growing of tobacco stem can be described in two aspects including prolonging and thickening. Internodes morphology in different position should be built in different way. Leaf 1 to leaf 8, counted from the bottom of stem, are too short to measure when being transplanted. So, they were ignored in this experiment. Only internodes whose position was higher than that of the 8th internode were considered while building morphology.

As the shape of tobacco internode is like a cylinder, volume (V_e) of the internode can be figured out with formula (4):

$$Ve(j,i) = \frac{q_e(j,i)}{\rho_e(j,i)} = l_e(j,i) \cdot s_e(j,i) \quad (4)$$

i: Growth cycle (Abb. GC)

j: Position of internodes

$q_e(j,i)$: Accumulated biomass of the *j*th internode in its GC (g).

$\rho_e(j,i)$: The internode density (g/cm^3)

$l_e(j,i)$: The internode length (cm)

$s_e(j,i)$: Cross-sectional area (cm^2)

The length and cross-sectional area of the tobacco internode change with the intercalary growth and primary thickening growth of the internode. Analyzing the experimental data, changing relationship can be built as following:

$$l_e(j, i) = k_e \cdot s_e(j, i)^\alpha \tag{5}$$

k_e, α : Fitting index which is possible to change with the change of the internode position

If defining the morphology index of the internode β and b_e as following:

$$s_b(j, i) = \frac{q_b(j, i)}{\xi_b} \tag{6}$$

Computational formula on length and cross-sectional area of tobacco internodes can be figured out with formulas (4), (5) and (6). It turns out to be formula (7):

$$\begin{cases} \beta = \frac{\alpha - 1}{\alpha + 1} \\ b_e = K_e^{1 - \beta} \end{cases} \tag{7}$$

Value of the length and the cross-sectional area could be figured out in formula (7), only if knowing the biomass of internodes in a certain growing stage when morphology parameters of the internode β, b_e and density ρ_e were given. Then, simulation of internodes morphology can be carried out with biomass.

1.4.3 Morphology of Tobacco Leaf

What we need from tobacco is leaf. The leaf is not only a place for photosynthesis but also a place to store all kinds of chemical substances which directly decide the quality of tobacco. The area of leaf j, S_b , in i^{th} can be figured out in formula (8) with its biomass q_b .

$$\begin{cases} l_e(j, i) = \sqrt{b_e} \left[\frac{q_e(j, i)}{\rho_e(j, i)} \right]^{\frac{1+\beta}{2}} \\ s_e(j, i) = \sqrt{\frac{1}{b_e}} \left[\frac{q_e(j, i)}{\rho_e(j, i)} \right]^{\frac{1-\beta}{2}} \end{cases} \tag{8}$$

ξ_b : Specific leaf weight, in other words, value of dividing leaf area into leaf fresh weight (g/cm^2).

Showing from experimental data, the relationship between leaf length l_b (cm) and its fresh weight q_b (g) can be expressed with formula (9):

$$l_b(j, i) = k_i \cdot q_b(j, i)^r \quad (9)$$

k_i and r in formula (9) are fitting indexes. For that leaf area is always figured out through multiplying a certain parameter λ with the product of leaf length and the maximum width of leaf in agronomy, the maximum width of leaf, w_b (cm), can be figured out after the leaf area and leaf length being simulated with the following formula:

$$w_b(j, i) = \frac{s_b(j, i)}{\lambda \cdot l_b(j, i)} \quad (10)$$

So, the leaf area (Abb. LA), length and the maximum width of this plant can be figured out after the accumulated biomass of leaf in a certain time being simulated if parameters ξ_b, k_i, r and λ were given.

1.4.4 Ascertaining Parameters

Parameter in models can be divided into three kinds: parameters being used to describe the growing process of plant, parameters being used to build the internode model and parameters being used in morphology model. Value of Parameters like growing speed, accumulated biomass, cross-sectional area of the internode, the internode length, leaf area, fresh weight of leaf, leaf width, and specific leaf weight can get from experimental data. However, coefficients like fitting index k_e and α of the internode morphology, morphology index β and b_e of the internode, fitting index k_i and r of leaf are implicit parameters. Parameters of model are listed as following table 2.

Table 2. List of model parameters

	Parameter categories	Unit
Development parameters of tobacco	<i>DR</i> : Developing ratio	°C ⁻¹
	<i>SumT</i> : Accumulated temperature	°C
Morphology parameter of the internode	<i>j</i> : Position of the internode	---
	<i>i</i> : Growth cycle	---
	<i>q_e(j, i)</i> : Accumulated biomass of the <i>j</i> th internode in <i>i</i> th GC(g)	g
	<i>ρ_e(j, i)</i> : The internode density	g/cm ³
	<i>l_e(j, i)</i> : The internode length	cm
	<i>S_e(j, i)</i> : Cross-sectional area	cm ²
	<i>k_e, α</i> : Fitting index of internode	---
	<i>β, b_e</i> : Morphology index	---
Leaf morphology parameter	<i>S_b(j, i)</i> : Leaf area	cm ²
	<i>q_b(j, i)</i> : Fresh weight of leaf	g
	<i>ε_b</i> : Specific leaf weight	g/cm ²
	<i>l_b(j, i), w_b(j, i)</i> : Leaf length and leaf width	cm
	<i>k_{i, r}</i> : Fitting index of leaf	---
	<i>λ</i> : Leaf area index	---

The following Figure 1 is a relation graph between the measured number of tobacco metamer which was defined to be 7 when being transplanted and the accumulated temperature starting from seeding restitution stage.

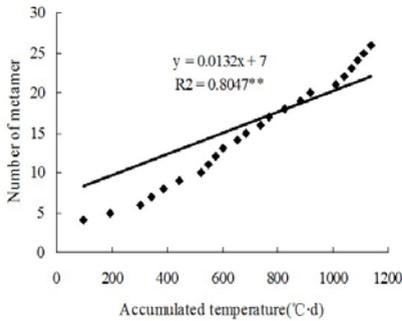

Fig. 1. The relationship between number of tobacco and sum of temperature

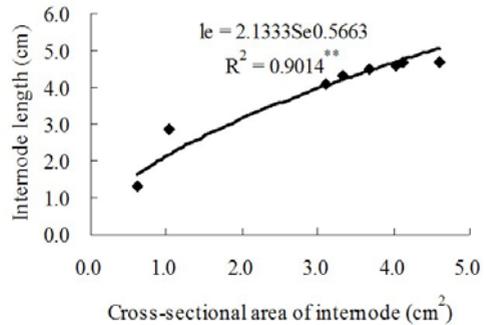

Fig. 2. Relationship between length and cross-sectional area during its elongation (9th internode)

As shown in Fig 1, the simulated number of metamer matches the measured number well. The number of GC equals that of metamer, in other words, one metamer could be produced in one GC. Slope in this model is the developing speed of tobacco,

represented with $DR(^{\circ}C^{-1})$. Meanwhile, a necessary accumulated temperature which is $75.76(^{\circ}C^{-1})$ in this model in a GC is represented with the reciprocal of slope. Real length of time in each GC is 2 or 3 days, changing with daily temperature.

Using experimental data, Fitting coefficients k_e , α can be figured out with formula (4) and the internode morphology coefficients β and b_e can also be figured out with formula (5), showed in Fig 3. As shown in fig 3, two peak values of b_e appeared in the 5th internode and the 14th internode with the rising of the internode position. The value of β grows with the growing of the internode position. For that morphology coefficient in different position of internodes differ, so, the value of β and b_e in different position should be considered while building the internode morphology model.

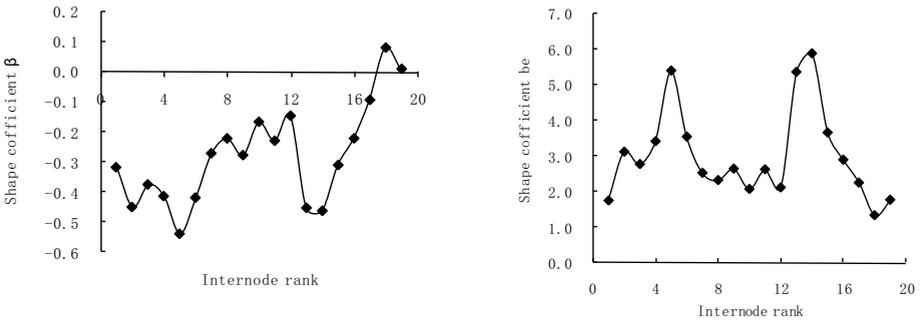

Fig. 3. Internode shape coefficient b_e and β varying with the internode position

The Internode density, showing in fig 4, equals the value that dividing internode volume into measured internode fresh heavy. The internode volume can be acquired by making internode diameter multiply its length. As shown in figure 4, the changing trend of the internode density is different with the position of internode in one GC. The peak value of the third internode density and the 8th internode density come in 12th GC. The internode density grows with rising of the internode position in 16th GC and 20th GC. The internode density should be selected according to different growing step while simulating the internode morphology for that, in general, the internode density is reducing with the growing of GC.

Through fitting analysis on the leaf fresh weight and its leaf area in different leaf position in different growth period measured in 2006, it appears that specific leaf weight \mathcal{E}_b :

$\mathcal{E}_b = 0.045(r=0.869^{**}, n=134)$ as shown in figure 5. Leaf length in different position in different GC and its fresh weight can be fitted in formula (9) (Fig. 6). Leaf area of tobacco used to be figured out through multiplying among leaf length, leaf width and leaf area index. Leaf area index λ in formula (10) is settled as 0.6345.

2 Results and Analysis

In purpose of testing the simulation precision of model on metamer number of tobacco, the predicted results of model was tested with experimental data measured in 2007. The number of metamer was predicted with the help of formula (2) and the accumulated temperature which was measured after being transplanted in 2007. As shown in figure 7, correlation coefficient between the simulated value and actual value reached to 0.992(n=23) which comes up to a significant leave. Meanwhile, *RMSE* between simulated value and actual value is 1.857 which proves them a good uniformity. All tests above prove that it is feasible to simulate the metamer number of tobacco with model.

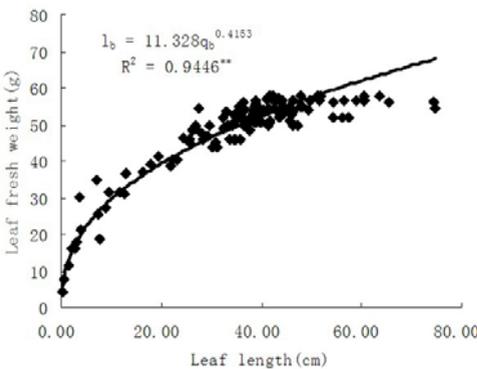

Fig. 6. Relationship between leaf length and its fresh weight

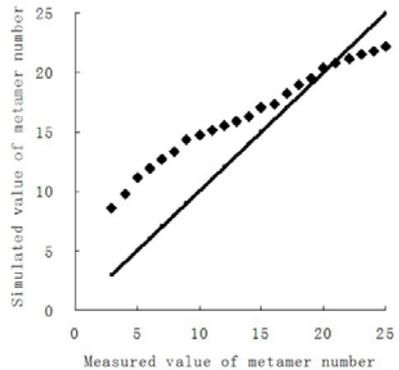

Fig. 7. Comparison between simulated value and measured value of metamer number

Predicted results with models can be tested with experimental data measured in 2007. Taking the 12th and 20th GC for example, in the 12th GC, correlation coefficients between measured values and simulated values of the internode diameter, the internode length, leaf area and leaf length are 0.997, 0.931, 0.997, 0.992, all of which come up to a very significant leave(n=10). *RMSE* between simulated value and measured value of them are 0.045 cm, 2.213 cm, 20.570 cm², 1.828 cm. In the 20th GC, correlation coefficients between measured values and simulated values of the internode diameter, the internode length, leaf area and leaf length are 0.994, 0.735, 0.990, 0.949, all of which come up to a very significant leave(n=19). *RMSE* between simulated value and measured value of them are 0.040 cm, 4.828 cm, 40.141 cm² and 4.039 cm. 1:1 relation schema (Fig8 & Fig9) between measured value and simulated value of the internode diameter, the internode length, leaf area, leaf length in 12th and 20th GC show that simulated value from the dynamic model of tobacco growth matches the measured value well.

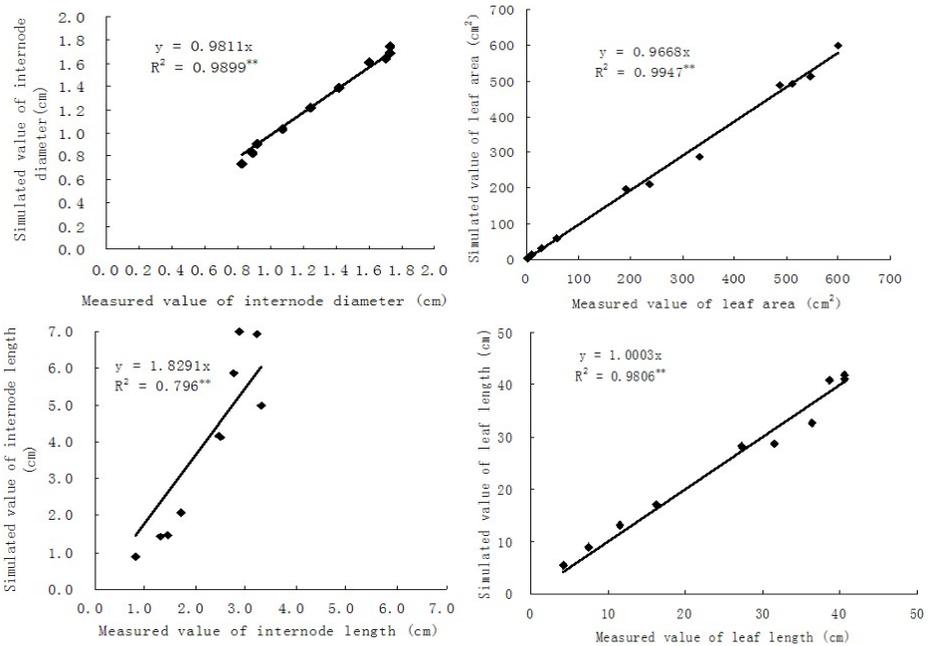

Fig. 8. Comparison between simulated value and measured value in the 12th GC

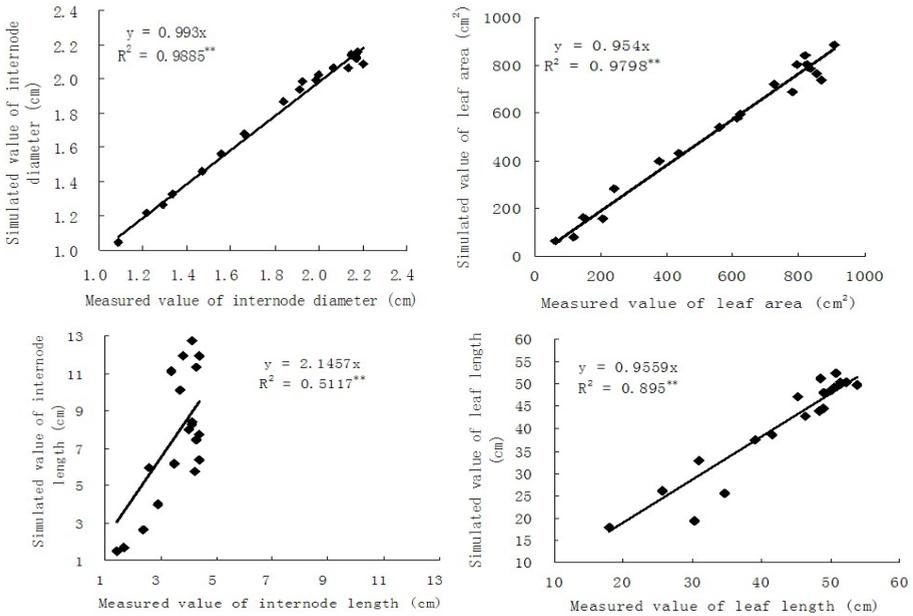

Fig. 9. Comparison between simulated value and measured value in the 20th GC

3 Conclusions and Discussion

The essential basis while building digital plant will be plant growing, structure simulation of plant morphology and union of the both. Interrelation between changing of above-ground organ morphology and GC during the growing process of tobacco was generally researched in this paper. Besides, basing on biomass-morphology relationship of tobacco organ, dynamic model on organ morphology was also built in this paper. It turns out that the model can express biological method well and that there is a high degree of uniformity between simulated results and measured values. They have made the model usable.

Growth period model of tobacco is a factorial index model which is using Rice Clock Model for reference and basing on mechanism of tobacco growing and to express growth process of tobacco [30]. Virtual growth system of tobacco, coupled with dynamic organ model and growth period model, will be a new research direction in the next step. The system is necessary while digitizing the tobacco growth. Information on tobacco growth in different stage can be obtained from the system only if the agriculture technician input few certain parameters of growing environment. With that information, cultivating and control technology, fertilizer rate in necessary and so on will be guided well.

Preparing for building the morphology model of above-ground organ of tobacco, the simulation model which based on the model of physiological and ecological process of tobacco, under the control of outside environment, like temperature, was created in this paper. Taking the spatial angle change during the period of tobacco growth into

consideration while researching and analyzing the dynamic change of tobacco morphology can comprehensively display the dynamic change information of tobacco, and this will be a research direction in the future. At last, that the simulation of the plant internodes morphology is not precise enough, caused by a low sampling rate, should be improved and perfected.
