## Abstract

**Aims/hypothesis** The aim of this work was to investigate whether tetraspanin 7 autoantibodies (TSPAN7A) are valuable in predicting poor beta cell function in individuals with latent autoimmune diabetes in adults (LADA).

**Methods** The cross-sectional study involved participants with LADA ( $n = 173$ ), type 1 diabetes ( $n = 158$ ), type 2 diabetes ( $n = 204$ ) and healthy control participants ( $n = 170$ ). The longitudinal study involved 53 participants with LADA, with a 3-year follow-up. In both cohorts, TSPAN7A in the sera were measured by a luciferase immunoprecipitation system assay, and physical and clinical characteristics were recorded.

**Results** The prevalence of TSPAN7A in LADA, type 1 diabetes, type 2 diabetes and healthy control participants was 21.4% (37/173), 26% (41/158), 0.5% (1/204) and 1.2% (2/170), respectively. Importantly, measurement of TSPAN7A significantly increased the number of individuals with LADA found to be positive for multiple antibodies (32.4% vs 22%;  $p < 0.001$ ). Further logistic regression analysis demonstrated that positivity for TSPAN7A (OR 2.87,  $p = 0.034$ ), disease duration (OR 1.83,  $p = 0.019$ ) and GAD antibody titre (OR 2.67,  $p = 0.009$ ) were risk factors for beta cell function in LADA, while BMI (OR 0.34,  $p = 0.001$ ) was a protective factor. In the prospective study in individuals with LADA, the median annual decrease in rates of fasting C-peptide and 2 h postprandial C-peptide in individuals who were positive for TSPAN7A was significantly higher when compared with the decrease in those who were negative for TSPAN7A (34.6% vs 7.9%,  $p = 0.043$  and 33.2% vs 11%,  $p = 0.041$ , respectively).

**Conclusions/interpretation** TSPAN7A are valid islet autoantibodies for use in East Asian populations with autoimmune diabetes and can discriminate individuals with LADA who have lower beta cell function after disease progression.

## Abbreviations

FCP	Fasting C-peptide
FPG	Fasting plasma glucose
GADA	GAD autoantibodies
IAA	Insulin autoantibodies
IA-2A	Protein tyrosine phosphatase autoantibodies
ICA	Islet cell auto antibodies
LADA	Latent autoimmune diabetes in adults
LIPS	Luciferase immunoprecipitation system assay
PPG	2 h Postprandial plasma glucose
PCP	2 h Postprandial C-peptide
TSPAN7	Tetraspanin 7
TSPAN7A	Tetraspanin 7 autoantibodies
ZnT8A	Zinc transporter 8 autoantibodies

## Research in context

### What is already known about this subject?

- Islet autoantibodies are key markers for the diagnosis of autoimmune diabetes
- Tetraspanin 7 autoantibodies (TSPAN7A) are islet autoantibodies that are present in 19–43% of white people with type 1 diabetes
- Information regarding the association of TSPAN7A with beta cell function is currently lacking

### What is the key question?

- Is the measurement of TSPAN7A also valid in East Asian populations with autoimmune diabetes, and can this autoantibody discriminate individuals with LADA who have lower beta cell function after disease progression?

### What are the new findings?

- TSPAN7A are valid for use in East Asian populations with autoimmune diabetes
- Measurement of TSPAN7A can significantly increase the number of individuals with LADA found to be positive for multiple antibodies
- TSPAN7A can predict progressive decline of beta cell function in individuals with LADA

### How might this impact on clinical practice in the foreseeable future?

- These results show that it is useful to test for TSPAN7A in individuals with LADA to identify multiple-antibody-positive individuals and predict their beta cell function

## Introduction

Latent autoimmune diabetes in adults (LADA) is type 1 diabetes with an onset in adulthood and a slow progression. In LADA, beta cell failure occurs slowly and insulin treatment is not required within at least 6 months of diagnosis [1–3]. Islet autoantibodies are key markers of islet autoimmunity in LADA and type 1 diabetes [4]. Five major autoantibody types have been identified in autoimmune diabetes—*islet cell autoantibodies (ICA)*, *GAD autoantibodies (GADA)*, *insulin autoantibodies (IAA)*, *protein tyrosine phosphatase autoantibodies (IA-2A)* and *zinc transporter 8 autoantibodies (ZnT8A)*. A sixth type, *tetraspanin 7 autoantibodies (TSPAN7A)*, has been identified only recently [5, 6].

Tetraspanin 7 (TSPAN7) is a member of the transmembrane 4 superfamily, also called the tetraspanin family [7]. Tetraspanin family proteins are characterised by four transmembrane domains, with one short and one large extracellular loop. TSPAN7 is a glycoprotein located at the cell surface and is expressed in the brain, lung and pancreas [5]. In the pancreas, TSPAN7 is specifically expressed in the islets [8]. Previous studies have found that TSPAN7A are present in 19–43% of white individuals with type 1 diabetes [5, 6, 9, 10]. Unfortunately, its diagnostic value for type 1 diabetes is limited. However, the prevalence and clinical value of TSPAN7A in individuals with LADA have not been reported; in particular, information regarding their association with beta cell

function is lacking. Therefore, the major aim of our study was to evaluate the prevalence of TSPAN7A and their potential clinical value in individuals with LADA. Furthermore, we investigated the frequency of TSPAN7A in Chinese individuals with type 1 diabetes because all previous studies have been restricted to white people.

## Methods

**Study participants** Individuals with LADA ( $n = 173$ ), type 2 diabetes ( $n = 204$ ) and type 1 diabetes ( $n = 158$ ) and healthy control individuals ( $n = 170$ ) were enrolled from the Second Xiangya Hospital of Central South University (Changsha, Hunan, China) from May 2014 to August 2017 for the cross-sectional study. Another 157 individuals with type 1 diabetes (duration >1 year) were recruited to examine the change in the time course of TSPAN7A, GADA, ZnT8A and IA-2A prevalence. Another 53 individuals with LADA were enrolled from the Second Xiangya Hospital of Central South University from October 2010 to December 2013 for a follow-up study in which clinical characteristics were determined annually for 3 years. Sera from another 199 healthy participants were collected from the Second Xiangya Hospital of Central South University to establish the threshold of positivity for TSPAN7A. The criteria of the WHO (version 1999) were applied to the diagnosis of diabetes [11]: fasting plasma glucose (FPG)

$\geq 7$  mmol/l or 2 h plasma glucose during 75 g OGTT  $\geq 11.1$  mmol/l with at least one obvious diabetic symptom (thirst, polyuria or unexplained weight loss). For asymptomatic individuals, a confirmatory test was conducted on another day. For children, the oral glucose load was based on body weight (1.75 g/kg). Individuals with LADA were recruited based on the criteria used in previous studies [2, 12]: (1) positive for at least one autoantibody (GADA, IA-2A or ZnT8A); (2) age  $\geq 30$  years at onset of diabetes and (3) at least 6 months of therapy without insulin. Type 1 diabetes was diagnosed according to the following criteria: acute-onset ketosis or ketoacidosis; reliance on insulin therapy; impaired islet function or islet autoantibody (GADA, IA-2A or ZnT8A) positivity. The individuals with type 1 diabetes presented with diabetes within 1 year. All individuals with type 2 diabetes were negative for GADA. All healthy participants underwent a standard 75 g OGTT to confirm that their blood glucose was normal. The exclusion criteria for healthy participants were: (1) other autoimmune diseases; (2) infectious disease; (3) pregnancy; (4) history of immunosuppressive drugs or steroids  $> 7$  days and (5) malignant disease. This study was approved by the ethics committee of the Second Xiangya Hospital of Central South University and all participants or their parents gave written informed consent.

Physical characteristics (sex, age, body height and weight) were recorded by professional researchers. Fasting blood was used for measurement of FPG, HbA<sub>1c</sub> and fasting C-peptide (FCP). Postprandial blood samples were used to test 2 h postprandial plasma glucose (PPG) and 2 h postprandial C-peptide (PCP).

**C-peptide and HbA<sub>1c</sub> assays** FCP and PCP were measured by a chemiluminescence method using the Adiva Centaur Systema kit (Siemens, Munich, Germany). HbA<sub>1c</sub> was detected by automated liquid chromatography (VARIANT II Hemoglobin Testing System; Bio-Rad Laboratories, Hercules, CA, USA).

**Islet autoantibody assays** Islet autoantibodies, including GADA, IA-2A and ZnT8A, were detected by radioligand assays in duplicate [13]. Based on the 99th percentile observed in 405 healthy participants, the cut-off values of positivity for GADA and IA-2A were 18 U/ml and 3.3 U/ml of WHO units, respectively. The threshold of antibody index for ZnT8A was 0.011 [14]. For antibody-positive individuals, blood was drawn again within 7 days to exclude false-positive results. In the 2016 islet autoantibody standardization programme (IASP 2016), the sensitivity and specificity in our laboratory were, respectively, 82% and 97.8% for GADA, 76% and 100% for IA-2A and 72% and 100% for ZnT8A.

**Cloning and expression of TSPAN7** Luciferase-tagged full-length TSPAN7 was cloned into the pREN-2 vector, which

was kindly provided by P. D. Burbelo (National Institute of Dental and Craniofacial Research, National Institutes of Health, MD, USA) [15]. The untagged TSPAN7 expression vector was purchased from Origene (Rockville, MD, USA). Plasmids with full-length TSPAN7 or untagged TSPAN7 were transfected into 293T cells cultured in DMEM supplemented with 10% FBS and 100 U/ml penicillin–streptomycin (Gibco, Carlsbad, CA, USA). After 48 h, cells were lysed in Glo Lysis Buffer (Promega, Madison, WI, USA) for 15 min at 4°C followed by centrifugation (12,000 g at 4°C for 15 min). The supernatant fraction was collected for further testing.

#### Luciferase immunoprecipitation system assay for TSPAN7A

TSPAN7A were assayed in duplicate by a luciferase immunoprecipitation assay (LIPS) as described previously [6, 16] with minor modifications. Briefly, 5  $\mu$ l serum was incubated at 4°C overnight with 25  $\mu$ l assay buffer (0.05% Triton X100 and 0.1% Tween 20 in TBS, pH 7.2) containing  $5 \times 10^6$  counts/s of luciferase-tagged TSPAN7 measured in a MicroBeta LumiJET (PerkinElmer, Waltham, MA, USA). The mixture was then transferred in to a 96-well microfiltration plate (Merck Millipore, Darmstadt, Germany). Then, 15  $\mu$ l Protein A-agarose (Invitrogen, Carlsbad, CA, USA) and 5  $\mu$ l assay buffer containing 0.1% IgG-free BSA (Yeasten, Shanghai, China) were added to each well, and the plates were shaken (300 rev/min) at 4°C for 60 min. Plates were washed ten times using 200  $\mu$ l assay buffer and Renilla luciferase substrate (Promega) was added. For potential positive serum, a competition assay was performed to confirm the binding specificity of the serum antibodies to TSPAN7. Briefly, sera were simultaneously incubated with or without luciferase-free TSPAN7.

The final results were expressed as TSPAN7A index (sample CPS – negative standard CPS) / (positive standard CPS – negative standard CPS), where CPS is counts/s. Serum that was negative for TSPAN7A was obtained from one healthy individual and serum that was positive for TSPAN7A was obtained from one individual newly diagnosed with type 1 diabetes. Based on the 99th percentile of 199 healthy participants, the cut-off value of TSPAN7A was 0.024. Intra-assay and inter-assay CV was in the range 6.3–12.4% and 14.9–35.7%, respectively.

**Statistical analysis** Statistical analysis was performed with SPSS software version 19 (IBM, New York, NY, USA). The data are presented as the mean  $\pm$  SD or medians (25th–75th percentile). A normality test was performed before the data analysis. For non-normal data, logarithmic transformation was conducted. ANOVA was used to compare normal variables among groups. Non-parametric test was performed by Mann–Whitney assay. A  $\chi^2$  test was used to compare categorical variables. A McNemar test was used to determine whether TSPAN7A could increase the fraction of multiple-antibody-

positive individuals. Binary logistic regression was performed to investigate possible risk factors for worsening islet function. A generalised linear mixed model was performed to compare the repeated measures data. There was no imputation on missing values. A  $p$  value  $<0.05$  was considered statistically significant.

## Results

**Addition of testing for TSPAN7A helps to identify multiple-antibody positivity in individuals with LADA** All previous studies on TSPAN7A have been conducted in white people. However, whether TSPAN7A are valid islet autoantibodies for East Asian populations remains unknown. Therefore, we first evaluated the frequency of TSPAN7A in individuals with LADA, type 1 diabetes and type 2 diabetes and in healthy control individuals. Potential positivity of sera for TSPAN7A was further confirmed in a competitive binding assay (electronic supplementary material [ESM] Fig. 1). Our results showed that the prevalence of TSPAN7A in individuals with LADA, type 1 diabetes and type 2 diabetes and healthy control individuals was 21.4% (37/173), 26% (41/158), 0.5% (1/204) and 1.2% (2/170), respectively (Table 1). The prevalence of TSPAN7A in type 1 diabetes (26%) is comparable with the data reported by Walther et al (27%;  $p > 0.05$ ) using

the same assay [6]. In individuals with LADA, the prevalence of GADA, IA-2A, ZnT8A and TSPAN7A was 95.4%, 17.9%, 16.8% and 21.4%, respectively (Table 1 and Fig. 1a). In individuals with type 1 diabetes, the frequency of GADA, IA-2A, ZnT8A and TSPAN7A was 69%, 43%, 31% and 26%, respectively (Table 1 and Fig. 1b). As for GADA, IA-2A and ZnT8A, positivity for TSPAN7A significantly decreased during disease progression (Fig. 1c). Comparing the prevalence of TSPAN7A in the presence or absence of other autoantibodies showed that there was a significant association of TSPAN7A with IA-2A and ZnT8A in individuals with either LADA or type 1 diabetes (all  $p < 0.01$ ); there was no association between TSPAN7A and GADA (ESM Fig. 2). All the data strongly suggest that TSPAN7A are valid islet autoantibodies for East Asian populations and might be valuable in the diagnosis of autoimmune diabetes.

We next evaluated whether TSPAN7A could improve the diagnosis of autoimmune diabetes in Chinese individuals with type 1 diabetes. Among 29 individuals with type 1 diabetes who were negative for GADA, IA2A and ZnT8A, four (13.8%) were positive for TSPAN7A. The addition of measurement of TSPAN7A slightly increased the identification of beta cell autoimmunity from 81.6% to 84.2% ( $p > 0.05$ ) (Fig. 1b). Adding measurement of TSPAN7A also slightly increased the number of individuals with type 1 diabetes

found to have multiple-antibody positivity, from 43.7% (69/158) to 46.2% (73/158), an increase of 5.8% ( $p > 0.05$ ) (Fig. 1b,d). These results were consistent with previous reports showing that TSPAN7A provided minor utility in the diagnosis of type 1 diabetes [6]. In contrast, additional measurement of TSPAN7A significantly increased the percentage of individuals with LADA found to have multiple-antibody positivity, from 22% (38/173) to 32.4% (56/173) (an increase of 47.3%,  $p < 0.001$ ) (Fig. 1a,d).

**Positivity for TSPAN7A is associated with poor beta cell function** Previous studies have suggested that the presence of multiple islet autoantibodies is associated with rapid loss of beta cell function [17]. Therefore, we next investigated whether TSPAN7A were associated with low C-peptide levels in individuals with LADA in the cross-sectional study. Compared with individuals who had high C-peptide levels, those with poorer beta cell function had a lower BMI ( $p < 0.001$ ), a

higher GADA titre ( $p < 0.01$ ) and a higher frequency of IA-2A ( $p < 0.05$ ) and positivity for TSPAN7A ( $p < 0.01$ ) (Table 2). For further analysis, sex, age at onset, duration, BMI, GADA titre, IA-2A, ZnT8A and TSPAN7A were evaluated in the logistic regression. Analysis of logistic regression demonstrated that duration of disease (OR 1.83,  $p = 0.019$ ), GADA titre (OR 2.67,  $p = 0.009$ ) and positivity for TSPAN7A (OR 2.87,  $p = 0.034$ ) were risk factors for beta cell function, while BMI was a protective factor (OR 0.34,  $p = 0.001$ ) (Table 3). We further compared C-peptide levels between single-antibody individuals who were positive and negative for TSPAN7A. Both FCP and PCP levels were decreased in individuals with LADA who were positive for TSPAN7A ( $p < 0.05$ ; Fig. 2).

**Positivity for TSPAN7A predicts progressive decline in beta cell function in individuals with LADA** To further confirm that TSPAN7A were risk factors for beta cell function, we followed up 41 TSPAN7A-negative and 12 TSPAN7A-positive individuals with LADA at baseline, 1, 2 and 3 years. The clinical characteristics, including sex, age, duration, BMI, HbA<sub>1c</sub>, GADA titre, FPG, PPG, FCP or PCP were comparable at baseline (ESM Table 1). However, after a 3-year follow-up in individuals with LADA, both FCP and PCP decreased significantly in TSPAN7A-positive, compared with TSPAN7A-negative individuals with LADA (Fig. 3). The median annual decrease in rates of FCP and PCP in individuals with LADA who were positive for TSPAN7A was much higher than in individuals who were negative for TSPAN7A (34.6% vs 7.9%,  $p = 0.043$ ; 33.2% vs 11%,  $p = 0.041$ , respectively).

**Fig. 2** FCP (a) and PCP (b) in single-antibody-positive individuals with LADA who were positive or negative for TSPAN7A. Data are expressed as median (25th–75th percentile). \* $p < 0.05$ , with vs without TSPAN7A

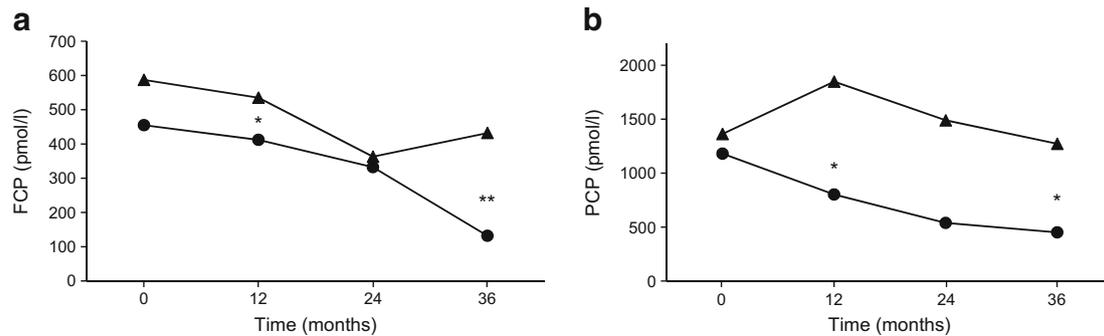

## Discussion

TSPAN7A are newly discovered islet autoantibodies in autoimmune diabetes. In this study, we confirmed that TSPAN7A are valid islet autoantibodies for East Asian populations. Using cross-sectional and longitudinal cohort studies, for the first time we demonstrate that TSPAN7A can be a valuable predictor for the progressive loss of beta cell function in individuals with LADA.

TSPAN7, a four-transmembrane glycoprotein, is difficult to properly express with in vitro transcription/translation systems, making it is unsuitable for the radioligand binding assay. In contrast, the LIPS assay offers several advantages for detecting TSPAN7A. First, it is cheaper and more convenient. More importantly, because TSPAN7 is expressed by 293T cells, a mammalian cell line, it may undergo post-translational modifications, such as glycosylation [18]. Therefore, the LIPS assay was used to test TSPAN7A in our study. Correlation assays showed that TSPAN7A were positively correlated with IA-2A and ZnT8A. One possible explanation is that TSPAN7, IA-2 and ZnT8 are beta cell secretory granule membrane proteins. When beta cells are damaged, those proteins could easily be released and cause seroreaction [19–21].

LADA, an important type of autoimmune diabetes, is defined as a subgroup of individuals who are independent of insulin for the first 6 months after diagnosis but have

**Fig. 3** FCP (a) and PCP (b) in TSPAN7A-positive or -negative individuals with LADA during the 3-year follow-up. Circles, TSPAN7A-positive ( $n=12$ ); triangles, TSPAN7A-negative ( $n=41$ ). Missing data in LADA without TSPAN7A group: 2 in FCP and 4 in PCP at 12 months;

3 in FCP and 4 in PCP at 24 months; 1 in PCP at 36 months. Missing data in LADA with TSPAN7A group: 1 in FCP and 1 in PCP at 24 months. Data are expressed as median. \* $p<0.05$  and \*\* $p<0.01$  vs TSPAN7A-negative group

detectable islet autoantibodies [22]. We found that the prevalence of TSPAN7A in individuals with LADA was 21.4% (similar to IA-2A and ZnT8A), whereas in individuals with type 2 diabetes the prevalence was 0.5%. Considering the very low frequency of TSPAN7A in individuals with type 2 diabetes, TSPAN7A do not appear to increase the diagnostic rate of LADA.

GADA are the most widely used of the islet autoantibodies for the diagnosis of LADA because positivity for GADA is not affected by the age at diagnosis and GADA are more sensitive than IA-2A or ZnT8A [22]. However, previous studies have suggested that the majority of GADA, as well as IAA, measured by the radioligand binding assay in single-antibody-positive individuals, are low-affinity [23, 24], which does not completely reflect the degree of islet autoimmunity [25]. Several laboratories have also reported that GAD antibody affinity is higher in multiple-antibody-positive individuals than in single-antibody-positive individuals [25, 26], suggesting that the number of islet autoantibody types present could be an indicator of islet autoimmunity. Due to the complicated procedure involved in testing antibody affinity, it is more convenient and feasible to test for more islet autoantibodies than for antibody affinity in clinical practice on a large scale. Interestingly, our study found that the combination of TSPAN7 autoantibody measurement can improve the diagnosis of multiple-antibody-positive individuals with LADA. Therefore, it is meaningful to test for TSPAN7A in individuals with LADA to improve the identification of those with multiple islet autoantibodies.

Multiple islet autoantibodies have been reported to be associated with the rapid loss of beta cell function [27]. The detection of TSPAN7A in individuals with LADA increased the number of multiple-antibody-positive individuals detected, raising the question of whether TSPAN7A are associated with the poor beta cell function in individuals with LADA. We addressed this question using cross-sectional and follow-up studies. Because individuals with LADA who had FCP <250 pmol/l are unable to achieve glycaemic control without

insulin [28], we divided participants with LADA into two groups, FCP <250 pmol/l and FCP  $\geq$ 250 pmol/l, in a cross-sectional study. Logistic regression analysis indicated that TSPAN7A were risk factors for lower C-peptide levels. This was confirmed by comparing FCP and PCP levels in single-antibody-positive individuals with LADA who were positive and negative for TSPAN7A. Interestingly, ZnT8A were not associated with beta cell function in another cross-sectional study [29]. The subsequent cohort study with a 3 year follow-up proved the predictive value of TSPAN7A for beta cell function. Taken together, positivity for TSPAN7A can predict a rapid loss of beta cell function in individuals with LADA.

We also explored the diagnostic value of TSPAN7A for type 1 diabetes in a Chinese population. Although TSPAN7A exist in 26% of Chinese individuals with type 1 diabetes, they largely overlap with other islet autoantibodies and only provide a minor value in type 1 diabetes diagnosis. This is consistent with data reported by Walther et al [6]. Consistent with our previous studies [30, 31], the frequencies of GADA, IA-2A and ZnT8A were much lower in Chinese individuals with type 1 diabetes when compared with white individuals with type 1 diabetes. This may be due to differences in genetic background between races. HLA plays an essential role in type 1 diabetes susceptibility and is associated with islet autoantibodies. *HLA-DR3* is associated with GADA, while *HLA-DR4* is strongly associated with IA-2A [32, 33]. However, the distribution of *HLA-DR3* and *HLA-DR4* is lower in Chinese than in white individuals with type 1 diabetes [4], which may in part explain the low frequencies of islet autoantibodies in Chinese individuals with type 1 diabetes.

In conclusion, TSPAN7A are valuable in discriminating individuals with poor beta cell function after disease progression in LADA. There are several potential limitations of our study. The number of individuals with LADA in the prospective study was relatively small and the time of follow-up was relatively short. It will be helpful to perform a longer course of

study and a larger-scale randomised control trial to confirm our findings.

**Acknowledgements** The authors thank E. Bonifacio (DFG Research Center for Regenerative Therapies Dresden, Technische Universität Dresden, Dresden, Germany) for his support in the establishment of LIPS in our laboratory. Thanks also go to the investigators for following up the individuals.

**Data availability** The datasets generated during and/or analysed during the current study are available from the corresponding authors on reasonable request.
