1. INTRODUCTION

Recently, considerable interest has been shown in questions concerning the complexity of the membership problem for various types of L systems. Van Leeuwen showed in [11] that there are ETOL systems G such that L(G) is complete for no (nondeterministic polynomial time). Opatrný and Culik showed in [7] that EOL membership (for fixed grammars) may be decided deterministically in time n^4 , and Sudborough gave a (log n)² space algorithm for the same problem in [10], based on a construction by van Leeuwen [12]. Sudborough also gave a deterministic log n space algorithm for EDOL membership in [10], and showed in [9] that some linear languages (and hence some EOL and deterministic ETOL languages) are complete for nondeterministic log space. In a companion paper [4], we have shown that each deterministic ETOL languages can be recognized nondeterministically in log n space, and therefore deterministically in polynomial time.

In this paper we study the complexity of the emptiness and finiteness questions for each of these classes (ETOL, EOL, and their deterministic counterparts), as well as the general membership problem.

Let \overline{G} be a linearly encoded form of an ETOL system over a fixed alphabet independent of G. (E.g. represent symbols v_1, v_2, \ldots, v_m in the form \sqrt{i} where \overline{i} is the binary representation of i, $1 \le i \le m$.) The problems we discuss may all be represented in terms of membership in the following sets. C denotes any of the system classes just mentioned.

- 1. NONEMPTY = $\{\overline{G} \mid G \text{ is in C and } L(G) \neq \emptyset\}$
- 2. INFINITE = $\{\overline{G} \mid G \text{ is in C and L(G) is infinite}\}$
- 3. MEMBER^C = $\{ \langle \overline{G}, \overline{x} \rangle \mid G \text{ is in C and x is in L(G)} \}$
- 4. L(G) for a fixed grammar G in C

^{*)} At Computer Science Department, University of Kansas, Lawrence, Kansas, USA after summer 1977. Research partially supported by University of Kansas General Research Grant 3802-2038.

The work referenced above establishes upper and lower complexity bounds on problems of type 4 (except for a lower bound on deterministic EOL membership). We shall outline a series of constructions which suffice to establish both upper and lower bounds on the remaining problems (in most cases rather tight). As we shall see, the complexity of the general membership problem (in which the input is the system as well as the terminal string) can be much higher than that of determining whether x is in L(G) for some fixed G. In the most extreme case, if C is the class of deterministic ETOL grammars, membership for fixed systems may be determined in log n space, while the general problem requires essentially linear space (both by nondeterministic algorithms).

2. TERMINOLOGY AND RESULTS

The results may be presented in the form of a table as follows. For the sake of comparison we have included the context-free and context-sensitive classes as well. In the system class names, D indicates "deterministic", and P indicates "propagating" (i.e. the absence of productions with the empty string on the right side).

	PROBLEM				
GRAMMAR CLASS	MEMBÉR (FIXED G)	MEMBER (GENERAL)	NONEMPTY	INFINITE	BOUNDS
CONTEXT - SENSITIVE	NSPACE(n)	NSPACE (n log n)	UNDECIDABLE	UNDECIDABLE	UPPER
		NSPACE(n)			LOWER
ETOL, EPTOL	ኪዮ	NSPACE (n log n)	NSPACE(n)	NSPACE(n)	UPPER
		NSPACE (n ^{1-€})	NSPACE (n ^{1-€})	NSPACE (n ^{1-€})	LOWER
EDTOL, EPDTOL	ng	NSPACE (n log n)	NSPACE(n)	NSPACE(n)	UPPER
		NSPACE (n ^{1-€})	NSPACE (n ^{1-€})	NSPACE (n ¹⁻ €)	LOWER
EOL, EPOL	DSPACE(log ² n) DTIME(n ⁴)	ħ₽	DSPACE(n)	NSPACE(n)	UPPER
	ns		n e	ክዮ	LOWER
EDOL, EPDOL	£	P DSFACE(log ² n)	ከቦ	ne	UPPER
	Σ				LOWER
CONTEXT FREE	DSPACE(log ² n) DTIME(n ³)	b	P	P	UPPER
	ns				LOWER

TERMINOLOGY

 DSPACE(S(n)) = {L | L is accepted by some <u>deterministic</u> offline Turing machine which operates within <u>space</u> S(n) on all inputs of length n}

NSPACE(S(n)) is defined analogously for nondeterministic machines, and DTIME(S(n)), NTIME(S(n)) are defined similarly for the time measure.

2.
$$\mathcal{L} = DSPACE(\log n)$$
, $n\mathcal{L} = NSPACE(\log n)$
 $\mathcal{P} = \bigcup_{k=1}^{\infty} DTIME(n^k)$, $n\mathcal{P} = \bigcup_{k=1}^{\infty} NTIME(n^k)$

- 3. A table entry of the form $\begin{bmatrix} U \\ L \end{bmatrix}$ for problem P indicates that
 - a) Pis in class U.
 - b) If L is h \$, P, h P or NSPACE(n), then some complete problem (and so any problem) in class L is reducible to P.
 - c) If L is NSPACE(S(n, ϵ)), then for any $\epsilon > 0$, P is <u>not</u> in NSPACE(S(n, ϵ)).
 - d) If L is £, then any algorithm which solves P in DSPACE(S(n)) must satisfy $\sup_{n\to\infty}\frac{S(n)}{\log n}>0.$
- 4. A table entry LU for problem P indicates that P is complete for class LU.

3. OVERVIEW OF PROOF METHODS

Theorem NONEMPTY EDOL is he hard.

Proof Method

By Stockmeyer & Meyer [8] the following problem is nP-hard:

Given a regular expression R of the form

$$0^{p_1}(0^{q_1})*+...+0^{p_r}(0^{q_r})*$$

to determine whether $L(R) \neq 0*$.

Construct an ED0L system $G = (\lor, P, Z_1^0, \ldots, Z_r^0, \Sigma)$ where $\lor = \{Z_i^j \mid 1 \le i \le r, 0 \le j \le p_i + q_i - 1\}, \Sigma = \lor - \{Z_1^{p_1}, Z_2^{p_2}, \ldots, Z_r^{p_r}\}$, and P consists of the productions $(i = 1, \ldots, r)$:

$$Z_i^j \rightarrow Z_i^{j+1}$$
 for $j=0,\ldots,p_i+q_i-2$, and $Z_i^{p_i+q_i-1} \rightarrow Z_i^{p_i}$.

Then $L(G) \neq \emptyset$ iff $L(R) \neq 0$ *; consequently NONEMPTY EDOL is h P hard.

Theorem NONEMPTY EDOL is in he.

Proof Method

Let $G = (\lor, P, w, \Sigma)$ be an EDOL grammar. Construct a nondeterministic finite automaton $M = (\lor, \{0\}, \delta, S_0, \Sigma)$ where $S_0 = \{a \in \lor \mid a \text{ occurs in } w\}$, and $\delta(a) = \{a_1, a_2, \ldots, a_m\}$ just in case $a \to a_1 \ldots a_m$ is a production in P. It is easily seen that $L(G) \neq \emptyset$ if and only if $L(M) \neq 0$. By Stockmeyer and Meyer, this test can be carried out nondeterministically in polynomial time.

Corollary NONEMFTY EDOL is he complete.

Theorem MEMBER EPOL is in hp.

Proof Method

Given $\langle \overline{G}, \overline{x} \rangle$, we can determine whether $x \in L(G)$ as follows:

```
\alpha := \text{Axiom of } G;
\begin{array}{l} & \text{for } I := 1 \text{ Step 1 } \text{until } | \times | \text{ do} \\ & \text{begin choose } \beta \text{ so that } \alpha \Rightarrow^* \beta \text{ and } |\alpha| = |\beta|; \\ & \text{if } \beta = \times \text{ then accept;} \\ & \text{choose } \gamma \text{ so } \beta \Rightarrow \gamma \text{ and } |\beta| < |\gamma|; \\ & \alpha := \gamma \end{array}
```

This procedure will provide a polynomial time membership algorithm if the step "choose β ..." can be done in polynomial time; however there can be nonrepeating derivations of length greater than any polynomial in $|\overline{G}|$. Let $\alpha = a_1 \cdots a_m$ and $\beta = b_1 \cdots b_m$. Then $\alpha \stackrel{p}{\Rightarrow} \beta$ iff $a_1 \stackrel{p}{\Rightarrow} b_1, \ldots,$ and $a_m \stackrel{p}{\Rightarrow} b_m$; and $\alpha \Rightarrow^* \beta$ iff $\alpha \stackrel{p}{\Rightarrow} \beta$ for some $p \leq k^m$ where k is the size of the alphabet of G. The test $a_1 \stackrel{p}{\Rightarrow} b_1$ can be done by forming a connection matrix M (M(a,b) = 1 iff $a \rightarrow b$ is a production), and calculating M, M², M⁴, ..., M² by repeated squaring. M^p may be obtained as a product of some of these matrices, chosen nondeterministically; and $\alpha \stackrel{p}{\Rightarrow} \beta$ may be easily determined from M^p.

Theorem NONEMPTY EOL & DSPACE(n).

<u>Proof</u> Let $G = (V, P, w, \Sigma)$ be given. Define $A_0 = \Sigma$, $A_{i+1} = \{a \mid a \rightarrow \alpha \text{ is a production in } P \text{ such that } \alpha \in A_i^*\}$. Then $L(G) \neq \emptyset$ iff $w \in A_i^*$ for some i. The DSPACE(n) algorithm is simply to calculate A_0, A_1, \ldots , storing only the most recent one (as a bit vector), and comparing the letters in w against A_i .

Theorem INFINITEETOL & NSPACE(n).

Proof Method

L(G) is infinite if and only if there exists a derivation of a word $x \in L(G)$ such that $S \Rightarrow^* \vee_1 a \vee_2 \Rightarrow^* \vee_1 \alpha \vee_2 \Rightarrow^* \times$, where $a \Rightarrow^* \alpha$, $Alph(\vee_1 a \vee_2) = Alph(\vee_1 \alpha \vee_2)$, and α contains the letter a and another occurrence of a letter, say b, yielding a nonempty subword of x.

The algorithm simulates such a derivation by nondeterministically choosing v_1av_2 , a, and b and checking whether the statements above are satisfied. The only information needed for that, is information about the alphabet of the current sentential form and two letters derived from a and b.

Theorem MEMBER EDTOL \notin NSPACE($n^{1-\epsilon}$) for any $\epsilon > 0$.

<u>Proof</u> Let $Z = (K, \Sigma, \Gamma, \#, \delta, q_0, \{q_f\})$ be an arbitrary 1 tape Turing machine which operates in space n (# is an end marker). For any $x = a_1, \ldots, a_n$, construct the EDTOL system $G_x = (V_n, \Im_n, w_x, \{0\})$ where

$$V_n = \{g, 0\} \cup \{A^i \mid A \in \Gamma \text{ and } 0 \le i \le n+1\} \cup K$$

$$w_x = p \#^0 a_1^1 a_2^2 \dots a_n^n \#^{n+1}$$

for each (p,a) \in (K - $\{q_f\}$) \times Γ there will be a table $T_{p,a}$ in \mathfrak{I}_n defined as follows:

If $\delta(p, a) = (q, b, R)$ then

$$T_{p,a} = \{p \rightarrow q, a^{0} \rightarrow b^{n+1}\} \cup \{c^{i} \rightarrow c^{i-1} \mid c \in \Gamma, 0 < i \le n+1\} \cup G_{p,a}$$
where $G_{p,a}$ contains $d \rightarrow g$ for every $d \in V_{n}$ other than p,a^{0} or c^{i} for $c \in \Gamma$, $0 < i \le n+1$.

If $\delta(p,a) = (q,b,C)$ then

$$T_{p,a} = \{p \rightarrow q, a^{0} \rightarrow b^{0}\} \cup \{c^{i} \rightarrow c^{i} \mid c \in \Gamma, 0 < i \le n+1\} \cup G_{p,a}$$

If $\delta(p,a) = (q,b,L)$ then

$$T_{p,a} = \{p \to q, a^{0} \to b^{1}\} \cup \{c^{i} \to c^{i+1} \mid c \in \Gamma, 0 < i \le n\}$$

$$\cup \{c^{n+1} \to c^{0} \mid c \in \Gamma\} \cup G_{p,a}.$$

In addition, I_n contains the table

$$\mathsf{T_f} = \{\mathsf{q_f} \to \mathsf{0}\} \ \cup \ \{\mathsf{c^i} \to \mathsf{0} \mid \ \mathsf{c} \in \Gamma, \ \mathsf{0} \le \mathsf{i} \le \mathsf{n+1}\} \ \cup \ \{\mathsf{a} \to \mathsf{g} \mid \ \mathsf{a} \in \mathsf{K} \cup \{\mathsf{g}, \mathsf{0}\} \ - \{\mathsf{q_f}\}\} \ .$$

It is easily verified that Z yields an I.D. $\alpha = b_0 \cdots b_{i-1} p b_i \cdots b_{n+1}$ iff G derives the string $p b_0^{n-i+2} \cdots b_{i-1}^{n+1} b_i^0 \cdots b_{n+1}^{n-i+1}$. Consequently $L(G) = \{0^{n+3}\}$ if Z accepts x, and $L(G) = \emptyset$ if Z does not accept x. Further, $|\overline{G}| = 0$ (n log n). In the usual way this implies MEMBER $EDTOL \notin NSPACE(n^{1-\epsilon})$, for any $\epsilon > 0$.

Corollary MEMBER EDTOL is complete for polynomial space.

Theorem There is a deterministic E0L language L such that if L is in DSPACE(S(n)), then

$$\sup_{n\to\infty}\frac{S(n)}{\log n}>0$$

<u>Proof</u> $L = \{ab^n cd^n \mid n \ge 0\}$ is clearly a deterministic EOL language. By Alt and Mehlhorn [1], L in DSPACE(S(n)) implies that S must satisfy the condition above.
