Abstract. We will demonstrate the impact of the integration of our
most recently developed learning technology for inferring Register Au-
tomata into the LearnLib, our framework for active automata learning.
This will not only illustrate the unique power of Register Automata,
which allows one to faithfully model data independent systems, but also
the ease of enhancing the LearnLib with new functionality.

1 Introduction

Active automata learning (aka regular extrapolation) has been proposed to semi-
automatically infer formal behavioral models of underspecified systems. The re-
sulting formal behavioral models can be used, e.g., for documentation or regres-
sion testing and thus can be an enabler for continued system evolution. Au-
tomated mediation between networked systems by automatically synthesizing
connectors from behavioral models is a current research interest. This approach
is currently in development in the CONNECT project [6].

To cater the various use-cases of automata-learning, LearnLib has been cre-
ated to offer a versatile library of learning algorithms and related tools. Result of
an extensive reengineering effort, the *Next Generation LearnLib* [8] implements a
flexible component-based approach that supports quick iteration and refinement
of learning setups (in the following the Next Generation LearnLib will simply be
referred to as "LearnLib").

The reengineered LearnLib has seen continued evolution, for which a complete
account will not be provided in this paper. We will rather focus on two main
innovations:

- The modeling paradigm in LearnLib Studio underwent significant changes.
  For example, in the old modeling paradigm a dedicated setup phase would
  precede the actual learning process. This has been replaced by on-the-fly
  configuration during the learning phase itself, with only minimal static con-
  figuration needed beforehand.

– LearnLib has been outfitted with support for the Register Automata automaton model [4], which is a simple extension of finite automata with data from infinite domains. It can model data-independent systems [7], i.e., systems that do not compute or manipulate data but manage their adequate distribution, such as protocols and mediators, in an intuitive way.

The demonstration will not only cover these two points in isolation, but will also highlight the ease of integration of new functionality into the overall learning framework.

In the remainder of the paper, we will recall the basics of active automata learning in Section 2, followed by an introduction to Register Automata in Section 3. A learning solution for Register Automata will be presented in Section 4, demonstrating the innovations outlined above. In Section 5 a conclusion is provided, with references showcasing the broad application scope of the presented tool environment.

2 Active Automata Learning

Angluin's seminal algorithm L^* [2] defines two query types to gather information about the System Under Learning (SUL):

– Membership Queries (MQs) are traces of symbols from a predefined alphabet of inputs of the SUL. The learning algorithm will construct such input traces, execute these on the SUL and capture system output. From the gathered information a hypothesis model is generated.
– Equivalence Queries (EQs) compare the produced hypotheses with the target system. If the model is not accurate, a counterexample will be provided revealing a difference between the current hypothesis and the SUL. Evaluating counterexamples the learning algorithm will produce refined hypothesis models using additional MQs. Once no counterexample can be produced the learning procedure has produced an accurate model and can be stopped.

With those two query types, L^* is guaranteed to produce a minimal and correct model. In current practice, however, EQs can only be implemented approximately for a large class of systems, e.g., with additional invocations of the target system.

The original L^* algorithm has originally been presented for DFAs, but has since been adapted to Mealy Machines, which are a better fit for learning actual reactive systems as they can encode system output in a natural way. A major and recent increase in expressiveness is achieved with Register Automata [5], which are described in the following section.

3 Register Automata

Register Automata are an extension of finite automata with data from infinite domains and are, e.g., well-suited for describing communication protocols. Register Automata are defined as follows:
Fig. 1. Partial RA model for a fragment of XMPP

Definition 1. *Let a symbolic input be a pair $(a, \bar{p})$, of a parameterized input a of arity k and a sequence of symbolic parameters $\bar{p} = \langle p_1, \ldots, p_k \rangle$ Let further $X = \langle x_1, \ldots, x_m \rangle$ be a finite set of registers. A guard is a conjunction of equalities and negated equalities, e.g., $p_i \neq x_j$, over formal parameters and registers. An assignment is a partial mapping $\rho : X \to X \cup P$ for a set P of formal parameters.*

Definition 2. A *Register Automaton* (RA) is a tuple $\mathcal{A} = (A, L, l_0, X, \Gamma, \lambda)$, where

- A is a finite set of *actions*.
- L is a finite set of *locations*.
- $l_0 \in L$ is the *initial location*.
- X is a finite set of *registers*.
- Γ is a finite set of *transitions*, each of which is of form $\langle l, (a, \bar{p}), g, \rho, l' \rangle$, where l is the *source location*, l' is the *target location*, $(a, \bar{p})$ is a parameterized action, g is a guard, and ρ is an assignment.
- $\lambda : L \mapsto \{+, -\}$ maps each location to either $+$ (accept) or $-$ (reject).   □

Let us define the semantics of an RA $\mathcal{A} = (A, L, l_0, X, \Gamma, \lambda)$. A *X-valuation*, denoted by ν, is a (partial) mapping from X to D. A *state* of $\mathcal{A}$ is a pair $\langle l, \nu \rangle$ where $l \in L$ and ν is a *X-valuation*. The *initial state* is $\langle l_0, \nu_0 \rangle$, i.e., the pair of initial location and empty valuation.

A *step* of $\mathcal{A}$, denoted by $\langle l, \nu \rangle \xrightarrow{(a, \bar{d})} \langle l', \nu' \rangle$, transfers $\mathcal{A}$ from $\langle l, \nu \rangle$ to $\langle l', \nu' \rangle$ on input $(a, \bar{d})$ if there is a transition $\langle l, (a, \bar{p}), g, \rho, l' \rangle \in \Gamma$ such that (1) g is modeled by $\bar{d}$ and ν, i.e., if it becomes true when replacing all p_i by d_i and all x_i by $\nu(x_i)$, and such that (2) ν' is the updated *X-valuation*, where $\nu'(x_i) = \nu(x_j)$ wherever $\rho(x_i) = x_j$, and $\nu'(x_i) = d_j$ wherever $\rho(x_i) = p_j$.

An example instance of a Register Automaton is provided in Figure 1, which models a subset of the XMPP instant messaging protocol focused on aspects of user authentication. In location l_0 no user account exists. With the parameterized action *register* a new account can be created, with the parameters p_1 and p_2 denoting a username and password. When executing the *register* action, the parameter values are copied into the registers x_1 and x_2 respectively. This action is unconditionally invocable in l_0, meaning that its guard is *true*. In contrast, the *login* in action of l_1 has a guard that specifies that the parameters p_1 and p_2 provided with the login action have to match the register contents of x_1 and x_2, i.e., the credentials provided during login have to match the ones stored in the registers. The other system actions represent logging out, changing the account password, and deleting the user account.
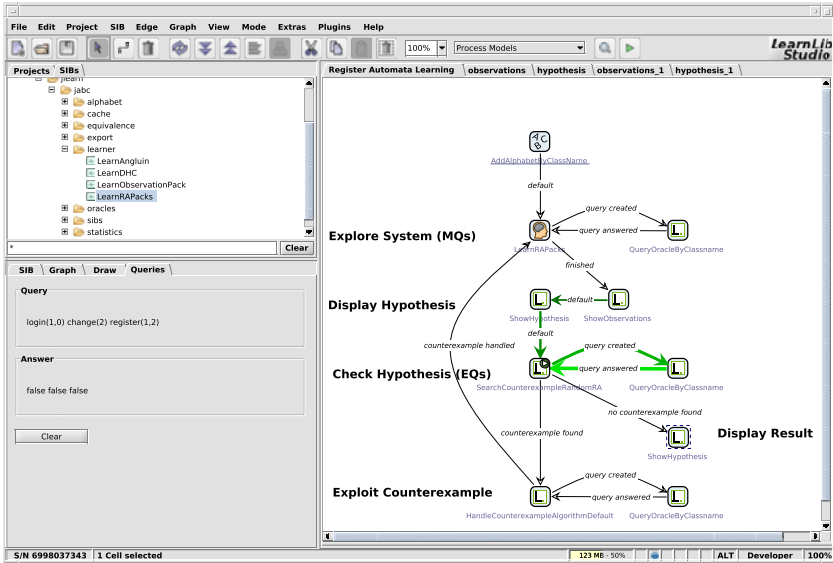

Fig. 2. A modeled learning setup created in LearnLib Studio. The model is currently executed, with bold edges denoting the path of execution. The current query and its answer are made visible in the panel on the lower left side.

4 The Tool Demo

We will present the LearnLib framework and highlight recently integrated innovations. LearnLib Studio allows the model-based composition and execution of learning setups, where LearnLib components are made available as reusable building blocks. In Figure 2 a learning setup tooled for learning register automata is shown, configured to learn the system shown in Figure 1. The result of executing this learning setup is presented in Figure 3.

The reworked modeling approach: In the learning setup presented in Figure 2 the distinct pattern specific to active automata learning can be witnessed: a learning algorithm is invoked, resulting in MQs an "oracle" has to answer. In this context, oracles are components that execute queries on a target system and gather the invocation results, meaning they produce an answer for a given query. Once the learning algorithm has formed a hypothesis it can be displayed and the data structure gathering the observations can be visualized, e.g., for debugging purposes. In the displayed setup, EQs are approximated by a random walk conformance test, which generates additional queries that are answered by the system oracle. If no counterexample can be found, the learning procedure will terminate, displaying the final result. Otherwise the counterexample will be consumed and analyzed, which can result in the production of additional queries. Once these have been answered and the counterexample is exploited so that a refined hypothesis can be produced, the learning process will restart the learning algorithm.
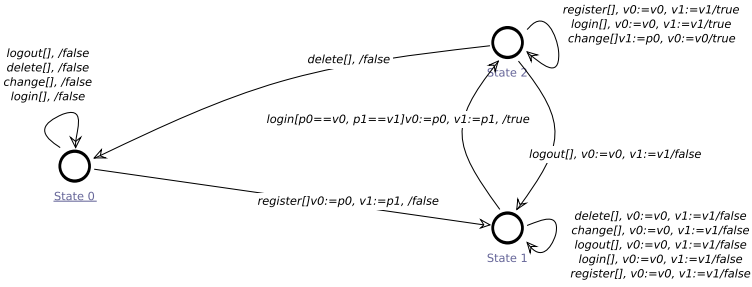

Fig. 3. The resulting model from executing the learning setup. Guards are in square brackets, the next register contents are explicitly denoted on every transition as is the acceptance status of the following state. Register values are denoted as v_i.

The general workflow is reusable in nature. The only application-specific parts that have to be provided are the definition of the alphabet and the system oracle, which has to interface the SUL. These application-specific parts can be loaded in a standardized way with parameterized building blocks.

Compared to the previous modeling style supported by LearnLib Studio, the new modeling style is much improved in terms of usability and flexibility: in the old modeling paradigm, a dedicated setup phase would create a fixed configuration, connecting, e.g., the learning algorithm to the SUL oracle. This setup would then be instantiated and started, with limited ways to influence the behavior of the setup afterwards. In the new modeling paradigm, only an alphabet has to be specified beforehand, after which the learning algorithm can directly begin operation. Learning queries are delegated on-the-fly according to the setup execution flow. This greatly increases flexibility, as, for instance, setups can decide at runtime what oracle instances are used to answer queries.

Integration of Register Automata learning: Thanks to the flexible component-based approach of LearnLib, components for learning this new model type could be integrated into the general framework without changes to the LearnLib architecture.

In the learning setup presented above, the only components that are specific for the RA machine model are the building blocks encapsulating the learning algorithm and the equivalence approximation. The overall infrastructure provided by the LearnLib is reused to a high degree when using RAs despite adapting a much richer automata model. The overall flavor of how learning setups can be created is completely unchanged compared to how setups are specified for other machine models, abstracting from the details of the underlying data structures and algorithms and thus shielding the user from additional complexity.

Due to being integrated into the component framework, learning setups for Register Automata can use all facilities LearnLib offers for debugging, visualization and statistics. Thus our extension provides a powerful and unique framework for learning data independent systems [7].

5   Conclusion

The LearnLib framework and accompanying tools provide a rich environment for experimentation with the new Register Automata formalism. Embedded into a flexible component model, much functionality is shared between learning setups for different machine models, which enables a high degree of reuse. Users already versed in the operation of the LearnLib Studio will not have to learn a new style of modeling when adapting Register Automata, while users new to LearnLib Studio are only exposed to a limited set of generic concepts that are easy to understand.

The LearnLib is mature and used by several independent research groups. It has, e.g., been used to infer the behavior of a electronic passports [1], in security research [3], and it is a central enabler within the CONNECT framework.

LearnLib is available for download at `http://www.learnlib.de` and free for all academic purposes.
