Abstracts from the 2017 Society of General Internal Medicine Annual Meeting

SCIENTIFIC ABSTRACTS

"A PCMH MIND AND A PCMH HEART": PATIENT, FACULTY, AND LEARNER PERSPECTIVES ON THE DEVELOPMENT OF AN INTERPROFESSIONAL TEAM-BASED TRAINING PRACTICE

Daniel J. Coletti[4]; Pratiksha Yalakkishettar[5]; Johanna Martinez[4]; Lauren Block[4]; Nancy A. LaVine[3]; Joseph Conigliaro[2]; Alice Fornari[1]. [1]Hofstra NSLIJ SOM, Hempstead, NY; [2]North Shore LIJ Health System, New Hyde Park, NY; [3]Northwell Health, New Hyde Park, NY; [4]Northwell Health, Great Neck, NY; [5]Hofstra University, Hempstead, NY. (Control ID #2704946)

BACKGROUND: The benefits of interprofessional education (IPE) and clinical training have been documented for learners, yet less is known about the perceptions of the faculty members who facilitate the educational experiences, or the perspectives of patients who receive this interprofessional (IP) care. Aligning the priorities of these three stakeholders would inform a truly patient-centered medical home and also develop an IP workforce skilled and comfortable working in a PCMH delivery model. The objective of this report was to use focus groups to compare stakeholder attitudes about IP education and training.

METHODS: We conducted five groups with 42 participants (31 F, 11 M): A "learner" group, a faculty group and three patient groups. The learner and faculty group represented the disciplines of medicine (students and residents), psychology, pharmacy, and physician's assistants. One of the patient groups was conducted in Spanish. This project was a formative research activity of IMPACcT (Improving Patient Access, Care, and cost through Training), a HRSA-funded program to expand the primary care workforce through IP education, training, and mentorship. Three raters analyzed group transcripts until common themes across the three groups emerged.

RESULTS: Themes present in all stakeholder groups were labeled 1) team engagement, 2) the role of technology in care delivery, 3) insurance/cost of care, 4) involving patients in the learning process, 5) time constraints, 6) scope of practice, and 7) autonomy, interdependence, and decision-making. Both similarities and distinct perspectives emerged across stakeholders when discussing these issues and most attitudes were positive. Learners, faculty, and patients each emphasized the importance of defining roles within a team and communicating roles to patients. Learners were excited about IP work and anticipated high quality interactions with other professions. Patients noted that participating in a teaching clinic was "more than about me" and described benefits receiving care from supervised trainees. Faculty perspectives, however, were more ambivalent. They noted that IP "is not a new thing" and questioned their ability to integrate PCMH mandates with an authentic mission to provide patient-centered care: "there's a difference between…checking off all the boxes for PCMH and…really incorporating the spirit of it…like having a PCMH mind versus a PCMH heart."

CONCLUSIONS: This is the first reported data comparing perceptions about IP education and care across these three stakeholder groups. Commonalities observed across the perspectives of patients, faculty, and learners suggests the need to attend to stakeholder priorities (e.g. regarding scope of practice and role definition) and bridging gaps between teaching PCMH principles and actually providing patient-centered, high quality care. Focus group material has been incorporated into project protocols for interprofessional huddling, communicating with patients, and in the content of our didactic curriculum.

"CONVERSATIONAL ADVICE": A MIXED-METHODS ANALYSIS OF MEDICAL RESIDENTS' EXPERIENCES CO-MANAGING PRIMARY CARE PATIENTS WITH BEHAVIORAL HEALTH PROVIDERS

Patrick Hemming[1]; Rachel Levine[3]; Joseph J. Gallo[2]. [1]Duke University School of Medicine, Durham, NC; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD. (Control ID #2704644)

BACKGROUND: Integrated Behavioral Health Clinicians (IBHC's) are increasingly common in residency primary care clinics. When IBHCs and residents co-manage patients, residents may learn new approaches to counseling and medical management. This survey sought to better understand the impact that patient co-management with IBHCs has on residents' learning about behavioral health management.

METHODS: Residents were surveyed from 2 Internal Medicine (IM) and 3 Family Medicine (FM) residency training programs with behavioral health integration in residents' continuity clinics. To assess the degree of face-to-face interaction during their most recent co-managed case, residents were asked whether or not the co-management included (1) a shared visit with the IBHC and/or (2) meeting face-to-face to discuss the patient's care. Respondents were asked about other features of the visit, including: (1) whether or not they received feedback from the IBHC on their management, and (2) to rate the episode's impact on the patient's care. Associations between the degree of face-to-face interaction and these two outcomes were assessed using multiple logistic regression and linear regression. Residents were asked open-ended questions regarding what they had learned from co-managing with an IBHC. Qualitative responses were coded thematically by two researchers using grounded theory. Associations were examined between face-to-face interactions and the frequency of each major learning theme category.

RESULTS: 113 residents of 117 respondents had experience co-managing a patient and described their most recent experience co-managing a patient with an IBHC (overall response rate 72%, 117/163). Residents were significantly more likely to receive feedback on their patient management if they had a shared visit (Adjusted OR 3.0,

95% CI 1.2–7.6). Residents gave high ratings (mean rating 8.0/10) to the patient impact of their co-management with no association to whether or not they had a shared visit. Fourteen learning sub-themes were reported from the following major themes: BH skills awareness, interpersonal communication skills awareness, and newly-adopted attitudes toward BH. Residents who reported receiving feedback were more likely than those who did not receive feedback to report themes of interpersonal communication skills awareness (yes 26.6% vs. no 9.4%)

CONCLUSIONS: In residency clinic settings with BHI, residents have the opportunity for regular face-to-face co-management with IBHCs. Face-to-face co-management can facilitate increased feedback on skills and management and positively influence residents' attitudes and perceived skills.

Selected Quotes from Each Major Theme Organized by Degree of Co-management and Receipt of Feedback (Yes or No)

	Theme 1 BH Skills Awareness	Theme 2 Interpersonal Communication Skills Awareness	
No shared appointment or face-to-face meeting	"I learned about the severity of my patient's Post-traumatic Stress Disorder, which he had only mentioned to me briefly, and I got more information about his coping resources." N	No residents in this group reported this major theme	"With BHI, patients have additional support and tend to be more compliant." N
Met face-to-face, no shared appointment	"I learned about ethical issues, physician obligations, and reporting requirements to law-enforcement." Y "I learned about community resources available for IV drug addicts." N	"I learned to have a stronger communication with my patient's family." N "I learned different ways of addressing medication problems with the patient and how to approach her about her chronic pain." Y	"I developed more understanding of the impact of social stressors on health" N "The alternate perspective on disease often provides the key to treatment adherence" N
Shared appointment, no outside face-to-face meeting	"I learned about quick interventions for my patient in a single visit." Y	"I learned different ways to presents medical information in ways that patients understand." Y	"It is helpful to have a neutral party and to coordinate the message that the patient receives." Y
Shared appointment and face-to-face meeting	"I learned how to address some of the most common issues–opioid dependence and depression." Y "I learned various weight loss support groups and strategies for patients" Y	"I learned to ask what other concerns patient has- if there is a part that is missing from what the patient is telling me- that can help for therapeutic relationship." Y "The BHC gave conversational advice in steering the interview." Y	"I can delegate this aspect of care to the IBHC to free up time for me to deal with this patient's complex medical conditions" N "I learned that behavioral health issues are complex and require special management considerations." Y

"DOES FORMAL TRAINING IN MEDICAL EDUCATION AND PROFESSIONAL DEVELOPMENT LEAD TO BETTER CAREER OUTCOMES FOR CLINICIAN EDUCATORS? A SURVEY STUDY OF A DEGREE GRANTING PROGRAM IN MEDICAL EDUCATION." Amar Kohli; Maggie K. Benson; Alexandra E. Mieczkowski; Carla Spagnoletti; Rosanne Granieri. University of Pittsburgh, Pittsburgh, PA. (Control ID #2706562)

BACKGROUND: Medical school and residency training programs rely on skilled clinician educators to provide high quality educational experiences. While faculty development programs are common, as of 2012, formal degree-granting programs in medical education existed at only ten institutions in the United Stated. To date, there have been limited outcomes reported for participants of degree-granting programs. Beginning in 2002, the University of Pittsburgh's Institute of Clinical Research Education created both masters and certificate level degree-granting programs in medical education, which now have more than 10 years of graduates. Courses include those focused on teaching skills, medical education research skills, and faculty development. We sought to evaluate the program by surveying its participants with regards to their attitudes, self-reported skills, and career outcomes.

METHODS: All graduates of the program between 2004 and 2014 received an email invitation to complete an anonymous electronic survey regarding their satisfaction with the program as well as their perception of whether the master's program adequately prepared them in domains pertinent to medical educators. Participants were also asked to upload their current CV from which data about educational leadership positions, curriculum development and national dissemination of education-related work was abstracted.

RESULTS: Out of 60 graduates, 47 completed the survey (78%) and out of those 45 uploaded their CV for analysis (75%). More than 90% of respondents agreed that due to completion of the program they were competent in applying principles of learning theory, clinical teaching, small group teaching, ability to give lectures, providing feedback to learners, curriculum development and evaluation, as well as conducting and evaluating educational research. 94% of respondents believed that they were a more effective educator than peers who did not complete a degree. CV abstraction revealed that 98% of respondents hold academic positions. Respondents represent more than 15 different medical specialties, though the majority (40%) are general internists. Of graduates surveyed, 76% held educational leadership positions. 93% published in peer reviewed journals, 67% published on an educationally related topic, 87% participated in curriculum development, and 67% engaged in mentorship. 13 respondents won teaching awards at their respective institutions.

CONCLUSIONS: Because degree-granting programs in medical education require great resource investment, the outcomes of such programs are relevant for institutional support and sustainability. Graduates of the degree granting programs at the University of Pittsburgh reported, because of their training, competence in several key domains crucial to success as a clinician educator. Abstraction of CV's noted almost all hold academic positions in their representative specialties as well as document their prolific nature in several domains essential to academic success as a clinician-educator.

"GETTING LOST" IN HOSPITAL IS A SOURCE OF STRESS AMONG PHYSICIANS AND NON-PHYSICIAN HEALTHCARE PROVIDERS
Grigorios G. Anagnostopoulos[3]; Michel Deriaz[3]; Jean-Michel T. Gaspoz[1]; Dimitri Konstantas[3]; Idris Guessous[1, 2]. [1]Geneva University Hospitals, Geneva 14, Switzerland; [2]University of Lausanne, Lasuanne, Switzerland; [3]University of Geneva, Geneva, Switzerland. (Control ID #2704923)

BACKGROUND: Navigating around large hospitals has been shown to be a stressful and time-consuming experience for all users of the hospital, including staff members. In addition, navigation difficulties in a hospital highlight suboptimal organisation. When staff encounters navigation difficulties this can lead to cost and efficiency issues and potentially put patient safety at risk. Despite the provision of an array of in-hospital navigational aids, 'getting lost' continues to be an everyday problem in these large complex environments. Within the framework of developing a navigation mobile app for the largest university hospital of Switzerland (Geneva University Hospitals), we aimed to identify the navigational needs of, problems encountered by, and consequences to primary care staff.
METHODS: A questionnaire was developed by a primary care physician and an indoor navigation specialist (both from Geneva University) based on factors identified through a review of the literature. The questionnaire was constructed to reflect all professional activities encountered in the primary care division and was sent in 2016 to both physicians and non-physician healthcare providers. The questionnaire includes the identification of current problems in way finding inside the hospital (stationary and ambulatory) and their impacts on the staff's work.
RESULTS: Out of 169 eligible collaborators, 111 (65.7%) answered the questionnaire, 61.3% were completed by physicians, 56.7% of collaborators had >5 years of work at Geneva University Hospitals, 70.5 were female, mean age was 39.5 years (SD 10.3). The majority (52.3%) of the participants answered that they had faced difficulties in finding their destination in the hospital (36.9% occasionally; 14.4% often, 0.9% all the time). Only 9.9% answered "never" and 37.8% "rarely". On average, participants estimated that they spent 11.7 min per week on searching for their destination or answering questions of others trying to reach their destinations. About 70% of the participants reported that the difficulty of finding one's way in the hospital could be a source of stress for staff members. The participants expressed a very positive view over the prospect of the creation of an application for mobile phones that would guide staff to their destination in the hospital.
CONCLUSIONS: These results show that even for staff members of a large hospital, finding their destination is difficult, consume time, and might be a source of stress. Improving way finding could contribute to pursuing organizational change, improve efficiency, and decrease stress.

"IT WAS A LOT OF DIFFERENT THINGS BUT BASICALLY WE WERE BEING EVICTED." PRECURSORS OF HOMELESSNESS AMONG ADULTS AGED 50 AND OLDER: FINDINGS FROM THE HOPE HOME STUDY
Irene Yen; Pamela Olsen; Angela Allen; John Weeks; Kelly R. Knight; Margot Kushel. University of California, San Francisco, San Francisco, CA. (Control ID #2705865)

BACKGROUND: The median age of single homeless adults is approximately 50; little is known about older adults' pathways to homelessness. Among older homeless people, 44% first experienced homelessness after age 50. We conducted in-depth interviews with older homeless adults about life course experiences and precipitants of homelessness, and examined whether these differed by age at first homeless.
METHODS: We recruited 24 participants from the HOPE HOME cohort, a population-based study of homeless adults 50 and older; we sampled purposively so that 1/2 experienced homelessness before age 50. Our interview focused on childhood circumstances, family and social relationships, criminal and victimization history, social services, criminal justice, education and employment, substance use, and precipitants of most recent homelessness. We developed a codebook using open coding. Two researchers coded transcripts independently, and then met to discuss and reach consensus. The research team identified key themes using thematic analysis.
RESULTS: Participants were 52–64 years old, 71% were African American. We identified five key themes: 1) adverse childhood experiences (ACE) had negative consequences throughout the life course; 2) substance use disorders derailed efforts at educational attainment, partnership, employment, and housing; 3) inadequate social ties with partners and family members limited housing options; 4) legal entanglements threatened employment, housing, and entitlement access; 5) institutional and structural racism impeded participants' access to services and criminalized behaviors. Those with early onset homelessness reported a higher severity of ACE and earlier onset of mental health and substance use disorders which interfered with educational and occupational attainment and familial attachments. They were unable to identify discrete precipitants of homelessness. Those with late onset homelessness reported lower severity of ACE and behavioral health conditions. They reported discrete homelessness precipitants, including: catastrophic illness, marital dissolution, job loss, and eviction for non-financial reasons. Men with late onset homelessness reported feelings of shame and loss of masculinity, hampering their ability to seek assistance. African-American participants reported multiple experiences of racism which heightened their vulnerability to homelessness.
CONCLUSIONS: Older homeless adults with early and late onset homelessness shared risk factors for homelessness that differed in severity and timing. Preventing homelessness among those with early onset homelessness requires early interventions for those with ACE and early onset behavioral health conditions. Efforts to prevent late-onset homelessness should focus on interpersonal (e.g. marital dissolution) and structural (e.g. eviction) high risk periods. Homelessness prevention efforts should incorporate structural responses to racism.

"LET ME FINISH THIS NOTE AND THEN WE CAN TALK ABOUT THAT": TRANSITIONS BETWEEN MULTITASKING AND SILENT ELECTRONIC HEALTH RECORD USE IN SAFETY NET VISITS
Neda Ratanawongsa[1, 2]; George Matta[1, 2]; Courtney R. Lyles[2]; Kaylin Yu[3]; Jennifer Barton[5, 6]; Christopher Koenig[4]; Ed Yelin[1, 1]; Dean Schillinger[1, 2]. [1]UCSF, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA; [3]Cornell University, Ithaca, NY; [4]San Francisco State University, San Francisco, CA; [5]Oregon Health & Science University, Portland, OR; [6]VA Portland Health Care System, Portland, OR. (Control ID #2698401)

BACKGROUND: Electronic health record (EHR) use affects communication, but the impact may depend on EHR use styles. We explored how clinicians transition between multitasking and silent EHR use during safety net visits and the benefits & risks of these dynamic EHR styles.
METHODS: We conducted an observational study ≥2 months after certified EHR implementation in 5 academic public hospital clinics. We video-recorded encounters between English- and Spanish-speaking patients with chronic conditions and their primary and/or specialty care clinicians. Using Atlas.ti, we recorded durations of: *multitasking EHR use* (concurrent with patient talk or clinician talk); *silent EHR use* (clinician AND patient silent for ≥5 s); non-

EHR tasks; and focused clinician-patient talk. We calculated median proportions of the total visit spent in these segments. Two investigators independently analyzed 3 videos and generated codes (editing organizing style), negotiating discrepancies to create a coding template. One investigator independently applied the template to the remaining videos. By consensus, we combined codes into themes and selected representative quotes.

RESULTS: We recorded 35 visits between 25 patients & 25 clinicians. Patients averaged 57 years in age; 44% were women; 48% were Hispanic/Latino; 28% reported < high school graduation; and 20% had limited health literacy (LHL). Among clinicians, 72% were women; 48% were primary care providers; 88% physicians; and they averaged 16 years since earning degrees. The median visit length was 25.5 min; 17% visits were in Spanish. The proportion of visit time with clinician EHR use was: 0% in 3 visits, ≤ 25% in 9 visits, >25–50% in 17 visits, and >50% of visit time in 6 visits. Multitasking EHR use occurred in 91% of visits, and silent EHR use in 60% of visits. A median of 28% of the visit was spent in multitasking EHR use (range 0–73%); 3% in silent EHR use (range 0–19%); 3.4% in non-EHR tasks (range 0–59%); and 31% in focused clinician-patient talk (range 2–81%). Table 1 shows the three core themes: 1) varying clarity in signaling the transition to silent EHR use; 2) breaking the silence; and 3) unaddressed patient concerns.

CONCLUSIONS: Most safety net encounters involved both multitasking EHR use and transitions in & out of silent EHR use. Clinicians may be unaware these transitions are occurring. Some patients use the silence to recall or reinsert their concerns; this silence could be particularly beneficial to LHL patients or introverts who need space to process and voice their thoughts. However, both EHR use styles pose risks to missing patient concerns. Future research should explore how different EHR-use styles affect clinician cognitive workload - including outcomes related to safety and clinical decision-making - as well as patient engagement and satisfaction.

Themes Related to EHR Use Styles

Varying clarity in signaling the transition to silent EHR use	Some clinicians overtly voiced a need to pause to use the EHR, Most clinicians gave non-verbal signals (e.g., turning body or gaze) without verbal warnings. Some clinicians drifted into silence without signaling awareness they were halting conversation with patients.	• "I'm going to look into the computer for a second, okay?" • "Give me a minute, I want to review in the computer what we've done before." • "Let me just…oops…hold on one second." • After period of multitasking history- taking: "So…umm…we…" & drifts into 17 sec silence while typing. • "There aren't specific treatments…but they're going to…uh…uh…uh…"
Breaking the silence	Clinicians & patients may break silent EHR use, leading to multitasking. Clinicians may emerge from EHR tasks to re-engage patients. Patients often interjected "chit-chat," but also voiced biomedical or psychosocial concerns.	• After 43 sec, clinician explains: "I'm going to send this to your pharmacy now, ok? This is the new dose of the furosemide." • After 25 sec, pt asks "So are you ready for Christmas?" • After 32 sec, pt asks: "So they didn't talk to you either about my pap machine?" • After 12 sec, pt lifts his foot "My [primary] doctor was worried about this…". Clinician replies "Oh yeah…when did this happen?" and examines it.
Unaddressed patient concerns	Both multitasking and silent EHR use offer risks of unaddressed patient concerns.	Multitasking EHR Use: • Pt describes friend who had a stroke: "He called me to tell me what happened." Clinician: "So let's just review, you're taking simvastatin which is a cholesterol medicine…" • "Yes and sometimes I have tremendous pain." Clinician: "Mm-hm.. and you're still taking…?" Silent EHR Use: Pt explains problems with getting medications on time from pharmacy. Clinician: "That's weird" & resumes silent EHR use.

"WHY DON'T YOU LOOK THAT UP?" VERSUS "COLLABORATIVE SELF-DIRECTED LEARNING:" THE IMPACT OF RESIDENCY TRAINING CONTEXT ON SELF-DIRECTED LEARNING

Adam P. Sawatsky; John T. Ratelle; Sara Bonnes; Jason Egginton; Thomas J. Beckman. Mayo Clinic, Rochester, MN. (Control ID #2698863)

BACKGROUND: Self-directed learning (SDL) is an important component of the Accreditation Council for Graduate Medical Education practice-based learning and improvement competency. Previous research has elucidated the significance of personal characteristics and learning process within SDL. However, there is a need to understand the impact of learning context on SDL within residency training. Therefore, we explored resident physicians' perceptions of the learning context to characterize the roles of faculty and training programs in supporting resident SDL.

METHODS: We drew upon existing principles of SDL and used constructivist grounded theory to explore the effects of context on SDL during residency training. We conducted 7 focus groups (FG) with 46 internal medicine residents. FG guides were developed from literature and expert review. A trained facilitator moderated the FGs, which were transcribed verbatim. Transcripts were explored using open coding and analytic memos to guide subsequent FGs. Constant comparison and axial codes revealed themes related to SDL context. Themes were organized within a theoretical model of SDL to understand the impact of residency training context. The findings were confirmed with member checks.

RESULTS: Residents identified the roles of Individual faculty members and residency programs in supporting SDL throughout the learning process, including triggering SDL, identifying learning objectives, formulating learning objectives, utilizing resources, applying knowledge, and assessing learning. Three archetypes of faculty support for SDL emerged: 1) role modelling personal SDL; 2) challenging learners by asking, "Why don't you look that up?"; and 3) engaging learners in "collaborative SDL." These archetypes incorporate slightly different approaches to supporting SDL, and were seen as complementary means for engaging learners. Residents discussed the importance of residency programs creating and supporting a culture of SDL by providing time and resources for learning, structuring teaching opportunities that deliver a framework for future learning, incorporating opportunities for self-assessment, offering social learning opportunities, and teaching SDL skills.

CONCLUSIONS: SDL is viewed by residents as an internal orientation to learning that integrates process and personal characteristics, like motivation.

This study highlights the effect of contextual factors, including the role of individual faculty members and the residency program, on the process of SDL during residency training. Residents elaborated archetypes of faculty involvement in SDL, and provided perspectives on achieving these strategies. The current findings can be used to assist residency programs with faculty development and creating a culture of SDL.

CROSS-DISCIPLINARY ROLE AGREEMENT IS STILL LACKING IN THE VA PCMH Karleen Giannitrapani[6]; Linda Kim[3]; Alexis K. Huynh[5]; Susan E. Stockdale[2]; Alison Hamilton[4]; Lisa V. Rubenstein[1]. [1]GLA VA, North Hills, CA; [2]Greater Los Angeles VA Healthcare System, Sepulveda, CA; [3]VA-Greater Los Angeles, Los Angeles, CA; [4]Veterans Administration, Los Angeles, CA; [5]Veterans Affairs, Sepulveda, CA; [6]Veterans Health Administration, Menlo Park, CA. (Control ID #2707577)

BACKGROUND: With increasing demand for primary care services and a deficient supply of qualified providers to meet this need, new interdisciplinary team based models of primary care delivery, including the Patient Centered Medical Home (PCMH), have emerged. Under PCMH, the roles of supporting teams members expand in include top-of-license tasks allowing some tasks that historically fell to only physicians to be shared or redistributed. We explore the role expansion of clinical associates (CAs) (licensed practical nurses, health technologists and medical assistants). Specifically, in this study we query team members of a newly implemented patient centered medical home (PCMH) to identify facilitators and barriers of role self-efficacy, a belief of possessing the capacity to execute their new team based roles effectively.

METHODS: We employ longitudinal qualitative analysis involving two waves of 105 semi-structured interviews with interdisciplinary providers based in Veterans Health Administration (VA) PCMH teams. Primary data were collected in 2011–2012 (wave 1) and 2014 (wave 2). We assess team member experiences approximately 1 year after the implementation to identify facilitators and barriers to role self-efficacy; we compare these with facilitators and barriers identified 4 years post implementation.

RESULTS: In wave one, three themes that functioned as facilitators/barriers to the self-efficacy necessary for successful role expansion of CAs were identified: 1) role training 2) time and resources for roles and 3) cross-disciplinary role agreement. By wave two, most training complaints were resolved. Time and resources to complete expanded tasks as well as cross-disciplinary role agreement persisted as challenges. Specifically, insufficient coordination between medicine and nursing or administrative leadership about staff roles was unresolved.

CONCLUSIONS: The goal of freeing up physician time by sharing tasks effectively across a team, will likely not be realized without team member role self-efficacy, specifically time and resources to completed expanded role tasks and cross-disciplinary agreement about roles. When implementing interdisciplinary teams in primary care, existing disciplinary paradigms and leadership pathways are impacted and in turn impact team member role-self efficacy and ultimately team functioning. Investing resources in engaging managers and in interdisciplinary leadership approaches may be an important strategy for supporting PCMH team member role self-efficacy.

CROSS-SECTIONAL STUDY OF PHYSICIAN BURNOUT AND ORGANIZATIONAL STRESSORS IN A LARGE ACADEMIC HEALTH SYSTEM Kristine Olson[3]; Seppo Rinne[4]; Mark Linzer[2]; Christine Sinsky[1]; Sandip Mukherjee[3]; Michael Bennick[3]; Ronald Vender[3]; Harlan M. Krumholz[3]; Theodore Long[3]. [1]American Medical Association, Chicago, IL; [2]Hennepin County Medical Center, Minneapolis, MN; [3]Yale University School of Medicine, New Haven, CT; [4]Center for Healthcare Organization and Implementation Research, Bedford, MA. (Control ID #2703601)

BACKGROUND: Physician burnout is common nationwide and tied to adverse outcomes for physicians, patients, and healthcare systems. The aim of this study is determine the prevalence of burnout among academic faculty, hospital employed, and community private practice physicians, and to identify remediable workplace stressors associated with physician burnout.

METHODS: This was a cross-sectional survey via email of the estimated 4118 clinicians affiliated with a large non-profit academic tertiary medical center. The sample represented three cohorts: academic faculty, hospital employed, and community private practice physicians. Burnout was measured by the Maslach Burnout Inventory, calculated as defined by a score ≥ 27 on emotional exhaustion or a score of ≥ 10 on depersonalization, or both. The perceived presence of seven workplace stressors was measured by the Mini-Z survey, and odds ratios for burnout were determined by separate multivariable logistic regression models, adjusting each for age, gender, full-time equivalent (FTE), and group (academic, employed, private practice).

RESULTS: Of the estimated 4118 clinicians invited by email, 1252 received the survey having clicked the link, and 557 responded (45% completion rate). The prevalence of burnout was 58.6%. Physicians who perceived poor control over workload (53.9%) were more likely to experience burnout (80.4% vs 33.1%, OR 7.6, 95% CI 4.7–12.2, $p < 0.001$). Physicians who perceived team effectiveness as unsatisfactory (16.8%) were more likely to experience burnout (84.3% vs. 53.4%, OR 7.2, 95% CI 3.1–17.1, $p < 0.001$). Physicians who perceived work atmosphere as hectic-chaotic (51.7%) were more likely to experience burnout (74.8% vs. 41.4%, OR 4.3, 95% CI 2.7–6.7, $p < 0.001$). Physicians who felt their values were not in alignment with department leadership (42%) were more likely to experience burnout (72.7% vs 48.0%, OR 3.2, 95% CI 2.0–5.1, $p < 0.001$). Physicians who felt their time for documentation was unsatisfactory (64.6%) experienced more burnout (68.4% vs. 40.7%, OR 4.2, 95% CI 2.6–6.9, $p < 0.001$), as did the 53.4% of physicians who felt the amount of time on the EMR at home was unsatisfactory (65.7% vs. 50.6%, OR 2.1, 95% CI 1.4–3.3, $p = 0.036$). Academic faculty experienced more burnout than those in private practice (62.2% vs 43.7%, $p = 0.006$). Burnout was most prevalent among trainees, early career physicians, and women.

CONCLUSIONS: In this cross sectional study, the prevalence of physician burnout was 58.6%, and highly associated with lack of control over workload, team effectiveness, a more chaotic work atmosphere, unsatisfactory time for documentation, a lack of value-alignment with departmental leadership, and the presence of EMR stress. Private practitioners experienced less burnout than academic faculty or hospital employed physicians. Academic faculty were most affected.

Organizational leadership commissioned this work to guide interventions and begin serial monitoring.

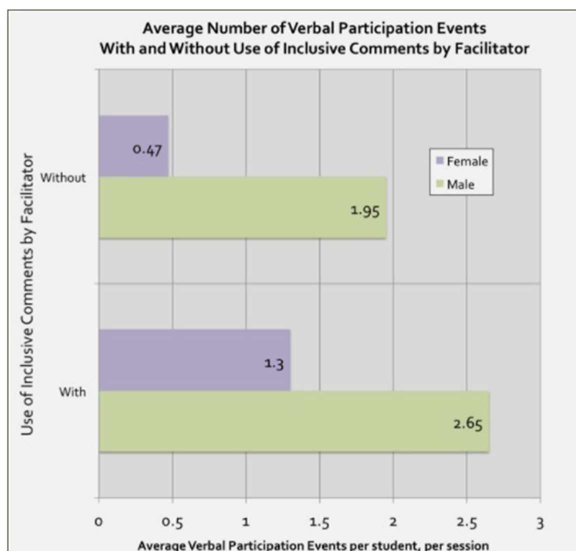
GENDER DISPARITIES IN SMALL GROUP VERBAL PARTICIPATION AMONG 1ST YEAR MEDICAL STUDENTS Mary Clare Bohnett; Sylvia Peterson-Perry; Molly R. Rabinowitz; Mariah Peterson; Shadi Dowlatshahi. OHSU, Portland, OR. (Control ID #2698509)

BACKGROUND: It has been shown that gender disparities exist for female clinicians today and that female trainees are disadvantaged by the so-called "hidden curriculum". However, research is lacking on specific targets at which to aim interventions. Class participation has been correlated with academic success, but it is unknown whether participation disparities exist during preclinical medical education, or whether increasing participation may be a locus for combating gender disparities. This descriptive pilot study explores gender disparities at the level of preclinical medical education, using verbal participation as a proxy metric. It aims to (1) quantify any gender disparities in verbal participation; (2) examine whether factors such as facilitator gender or inclusive facilitation impact verbal participation; and (3) encourage medical education initiatives that address gender gaps before the hidden curriculum widens them later in training.

METHODS: Observational data was collected over a 4-week period during a first year medical school course. Ten small work group sessions were observed and unique verbal participation events were counted by gender. Facilitator gender, gender composition of group, and inclusionary comments by facilitator were also recorded.

RESULTS: Descriptive statistics analysis revealed a disparity in average verbal participation between males and females of 2.5:1, when normalized by group gender composition. At least one instance of inclusive facilitation per session increased female participation, while a lack of inclusive facilitation doubled the disparity.

CONCLUSIONS: Verbal participation disparities exist, but are somewhat mitigated by inclusive facilitation. More research is needed on implications and interventions to promote gender equity.



Average verbal participation events, with and without inclusive comments by facilitator (per student per session), normalized for group gender composition

GEOGRAPHIC VARIATION IN PRESCRIPTION OPIOID USE DURING THE POSTPARTUM PERIOD Nora V. Becker[2]; Brandon Maughan[1, 2]. [1]Emergency Physicians Integrated Care, Salt Lake City, UT; [2]University of Pennsylvania, Philadelphia, PA. (Control ID #2709687)

BACKGROUND: Morbidity from prescription opioid use varies substantially by geography. There is a lack of published literature on opioid use in the immediate postpartum period.

METHODS: We extracted claims data from the Optum Clinformatics Data Mart, a database of approximately 14 million commercially-insured individuals. The sample included women with claims for vaginal or Cesarean delivery during 2001–2013. Extracted data included age, race, inpatient diagnosis and procedural codes, and type of filled prescriptions. Primary outcome was proportion of women who filled an opioid prescription within four days of discharge. Outcomes were stratified by mode of delivery (uncomplicated vaginal, complicated vaginal, uncomplicated Cesarean, complicated Cesarean) and compared across US census divisions using two-tailed tests of proportions.

RESULTS: Among women with uncomplicated vaginal delivery ($n = 905{,}584$), 28.3% filled opioid prescriptions. Opioid use differed by 459% between the lowest-use division (Middle Atlantic, 10.7%) and highest-use division (East South Central, 49.2%) ($p < 0.0001$). Complicated vaginal deliveries ($n = 80{,}510$) had higher opioid use (42.1%) and similarly large variation among divisions (19.2% vs. 61.9%, $p < 0.001$). Opioid use after uncomplicated Cesarean ($n = 357{,}813$) and complicated Cesarean ($n = 85{,}388$) was similar (76.2% vs. 77.0%). The Middle Atlantic division had lower opioid use rates for Caesarean deliveries (61.0 and 60.1%, respectively) compared to other divisions (rates of 76.2–79.6 and 76.8–80.2%, respectively).

CONCLUSIONS: There is significant geographic variation in prescription opioid use following vaginal delivery. This variation in prescription opioid use may identify opportunities to improve prescription safety and reduce opioid-related harms among women in the postpartum period.

IMPLEMENTATION OF THE RURAL VA MULTICENTER MEDICATION RECONCILIATION QUALITY IMPROVEMENT STUDY (R-VA-MARQUIS) Caroline Presley[2, 4]; Kathleene Wooldridge[2]; Susan Byerly[2]; Amy R. Aylor[3]; Christianne Roumie[2, 4]; Robert S. Dittus[4, 2]; Amanda S. Mixon[1]. [1]VA Tennessee Valley Healthcare System and Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Veterans Engineering Resource Center (VERC), Indianapolis, IN; [4]VA Tennessee Valley Healthcare System, Nashville, TN. (Control ID #2704394)

BACKGROUND: Unintentional medication discrepancies at care transitions can contribute to adverse drug events. High quality medication reconciliation can decrease unintentional medication discrepancies but is difficult to implement.

METHODS: R-VA-MARQUIS was a feasibility study to improve inpatient medication reconciliation practices using a mentored-implementation design conducted from 2014–2016 in three VA hospitals caring for rural Veterans. An evidence-based toolkit of best practices in medication reconciliation was adapted to the VA setting. Distance mentors evaluated baseline medication reconciliation practices and guided local improvement teams as they implemented toolkit interventions through monthly site phone calls and yearly site visits. At each

site, the number of unintentional medication discrepancies per Veteran was collected in a sample of control and intervention patients to monitor response to the interventions. These data were obtained by comparing a Best Possible Medication History (BPMH) taken by trained pharmacists with the medication lists in provider notes and orders upon admission and discharge. Data analysis was performed using traditional QI methods; unintentional medication discrepancies per Veteran were plotted on run charts and XmR charts for each site. Student's t-test was used to compare control and intervention patients.

RESULTS: Sites 2 and 3 successfully implemented several toolkit components. Site 2 utilized pharmacy students to take BPMH on admission, implemented risk stratification, and trained providers on how to take BPMH. Site 3 implemented standardized discharge process and documentation, trained providers on how to take BPMH, and, most importantly, hired an inpatient clinical pharmacist. Facilitators of implementation at Sites 2 and 3 included committed multidisciplinary improvement teams and support from senior leadership. Site 1 was unable to implement any toolkit interventions and faced barriers of high turnover of staff and lack of multidisciplinary engagement on the improvement team. Data was collected on a total of 797 patients across the sites. Patients were 68.7 years old on average; 94.5% were male. Patients were on a mean of 10.1 medications at admission; 45.6% had been admitted at least one time in the previous year. At Site 2, unintentional medication discrepancies per Veteran were not improved in intervention patients compared to control (4.45 vs. 3.5, $p = 0.012$). At Site 3, unintentional medication discrepancies per Veteran were reduced in intervention patients compared to control and this reduction was sustained over the course of the study (1.79 vs 4.77, $p < 0.001$).

CONCLUSIONS: The mixed results by site highlight the complexity of implementing evidence-based practices for medication reconciliation. This study adds to understanding of how to implement best practices to improve medication reconciliation in smaller hospitals caring for rural Veterans.

UTILIZATION OF PRIMARY CARE AND PREVENTIVE HEALTH SERVICES AMONGST INDIVIDUALS IN SAME-SEX AND OPPOSITE-SEX PARTNERSHIPS; A CROSS-SECTIONAL OBSERVATIONAL ANALYSIS OF MEDICAL EXPENDITURES PANEL SURVEY (MEPS), 2003–2001 Ani Abrahamyan[1]; Igor I. Bussel[1]; John R. Blosnich[2, 1]; Janel Hanmer[1]. [1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]VA Pittsburgh Healthcare System, Pittsburgh, PA. (Control ID #2706132)

BACKGROUND: The health of sexual minorities is national priority in the US. Prior publications reported health disparities amongst sexual minorities, including health risk behaviors, health service access/utilization, and differences in the prevalence of medical conditions. However, little evidence exists about differences in utilization of primary care and preventative health services. The objective is to describe the differences in utilization of primary care and preventive health services amongst individuals in same-sex (SS) and opposite-sex (OS) partnerships and to elucidate perceptions of the quality of care received.

METHODS: An observational cross-sectional analysis of the Medical Expenditures Panel Survey (2003–2011) was conducted on matched cohorts of 494 individuals in SS and OS partnerships. Measures included identification of a PCP, basic preventive care utilization, and perceptions of quality. Descriptive analysis was performed to determine frequencies for categorical variables and means for continuous variables.

RESULTS: SS partnered men had a higher rate of compliance with colon cancer screenings (i.e., FOBT or colonoscopy) than OS partnered men (50.3% vs 30.2%, $P = 0.001$). The rate of flu shots within the last 2 years was greater amongst SS partnered men compared to their OS partnered cohorts (35.5% vs 53.1%, $P = 0.001$). There were no differences among men or among women in the perception of quality of care, which was assessed by responses to the perceived timeliness and necessity of care, perceptions about providers listening, explaining, and showing respect, as well as the ease of seeing a specialist.

CONCLUSIONS: In sexual minorities who identify themselves as SS partnered, there appears to be minimal difference in utilization patterns of primary care and preventive health services with the exception of greater utilization of colon cancer screening and flu shot compliance by SS partnered men. These differences may be driven, in part, by HIV status and an overlap in screening modalities used to diagnose problems associated with receptive anal intercourse. The lack of differences in perception of quality of care is in conflict with earlier studies that showed greater dissatisfaction with care amongst SS partnered people. This could be explained by a changing political climate with increasing equality and improved quality of life for sexual minorities or it may simply be due to the use of a different sample of same-sex partnered people. These findings are based on a subset population that is in a partnership and identifies themselves as such, thus it may not necessarily be representative of sexual minorities as a whole.

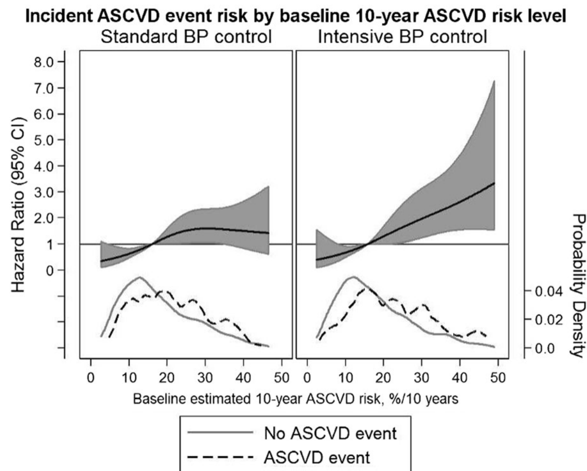
10 year ASCVD RISK AND INCIDENT ASCVD IN THE SYSTOLIC BLOOD PRESSURE INTERVENTION TRIAL (SPRINT) Timothy B. Plante; Stephen P. Juraschek. Johns Hopkins University, Baltimore, MD. (Control ID #2706812)

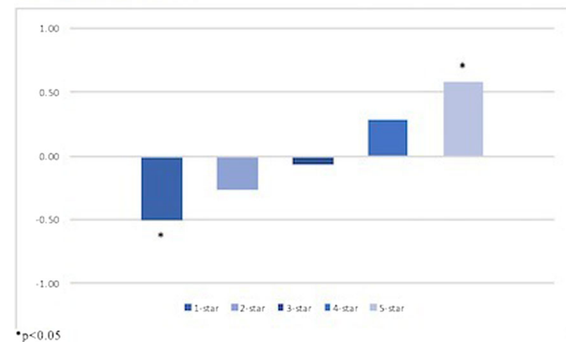
BACKGROUND: Atherosclerotic cardiovascular disease (ASCVD) is the top cause of disability and death in the US. Guidelines recommend integrating 10y ASCVD risk into primary prevention counseling. Observational studies have shown fewer ASCVD events with lower SBP levels but it's unclear if intensive SBP control below 140 mm Hg will further reduce risk. SPRINT randomized adults to standard or intensive BP control. A composite ASCVD outcome has not been reported. Whether intensive BP control reduced risk of incident ASCVD for SPRINT participants is unknown.

METHODS: SPRINT randomized 9,361 adults without diabetes or stroke to standard (135–139 mm Hg) or intensive (<120 mm Hg) SBP control. After excluding baseline ASCVD or ages outside of the risk estimator validated range, we calculated 10y ASCVD risk. HR compared intensive vs. standard BP control and ASCVD events, ASCVD or death, and death alone. Visualization of HR by level of 10y ASCVD risk for ASCVD events used a restricted cubic spline model with 95% CI relative to the median 10y ASCVD risk using Harrell's method. Kernel density plots depicted distribution of 10y ASCVD risk.

RESULTS: After excluding ASCVD at baseline or age >79y, 6,911 participants remained. Mean age was 65y, 37% were female, 35% were Black, median 10y ASCVD risk was 16%. There was a trend towards fewer ASCVD events in the intensive BP control arm ($n = 105$ v. 136; HR 0.78; 95% CI 0.61–1.01). ASCVD events or death was reduced (0.80; 0.65–0.99) but not death alone (0.82; 0.61–1.10). The spline model showed increasing hazard of ASCVD events with increasing baseline 10y ASCVD risk. Intensive but not standard BP control showed increased hazard of ASCVD events at a 10y ASCVD risk level >30%.

CONCLUSIONS: Among adults at increased risk for ASCVD, intensive BP control is associated with a non-significant trend towards reduction in incident ASCVD. Modeling of treatment effects across levels of baseline risk demonstrates a positive association between intensive BP control and incident ASCVD events among those with the highest baseline risk, though few were in this risk range. Further investigation to delineate levels of risk that may benefit from this intervention are warranted.





5-STAR NURSING HOME (NH) REPORT CARD ASSOCIATED WITH PREVENTABLE HOSPITALIZATIONS FROM POST-ACUTE CARE

Kira L. Ryskina[1]; Tamara Konetzka[3]; Rachel M. Werner[2]. [1]University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania and Philadelphia VA, Philadelphia, PA; [3]University of Chicago, Chicago, IL. (Control ID #2697507)

BACKGROUND: In an effort to better inform consumers, Medicare began publicly reporting NH quality using a simple-to-understand 5-star rating. This resulted in increased attention to NH ratings from consumers and NHs themselves. While NH star ratings increased substantially since they were first published in December 2008, whether this represents improvement in quality or, instead, "teaching to the test" is unknown. Our objective was to test whether improvements in star ratings were associated with improvements in patient outcomes.

METHODS: We used Medicare hospital claims and NH clinical assessment data for 2,143,217 fee-for-service Medicare beneficiaries receiving post-acute care in 15,318 NHs Jan 2007 - Jun 2010. We used these data to recreate NHs' star ratings over the study period and to observe hospitalizations and risk-adjustment variables. To account for the differences in patient exposure to NH care, our primary outcome was number of potentially preventable hospitalizations per 100 patients per month (pppm), weighted by the number of days in the NH. We compared the correlation between star ratings and hospitalizations before vs after Dec 2008 by estimating hospitalizations as a function of NH star ratings, an indicator for whether the hospitalization occurred before or after ratings were released, and the interaction between the two. All analyses included risk adjustment from the NH clinical data and NH fixed effects to account for heterogeneity across NHs. Standard errors were adjusted for clustering within NHs.

RESULTS: The association between the number of preventable hospitalizations and a NH's star rating weakened after the ratings became public: the number of hospitalizations was 0.58 pppm higher in 5-star (best-rated) NHs (95% CI 0.06 to 1.11, $p = 0.029$) and 0.51 pppm lower in 1-star (worst-rated) NHs (95% CI −0.86 to −0.16, $p = 0.004$) after star ratings release vs. before (Figure). When stratifying stays by baseline characteristics, these differences were concentrated in NHs with low baseline quality and staffing levels.

CONCLUSIONS: Recent improvements in NH star ratings were not accompanied by improvements in preventable hospitalizations for post-acute care patients. This suggests improvements in star ratings were driven by potentially superficial changes that impact ratings, but not the underlying quality of care.

A COMMUNICATION INTERVENTION AIMED AT MEDICINE DOCTORS AND NURSES IMPROVES PATIENT SATISFACTION SCORES

Jill Allenbaugh[2]; Jennifer Corbelli[2]; Laurie Rack[2]; Carla Spagnoletti[1]. [1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #2703658)

BACKGROUND: Patient satisfaction continues to play an ever-expanding role in healthcare, from reimbursement to hospital rating. However, effective strategies to improve Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) remain scarce. At the University of Pittsburgh Medical Center, a multidisciplinary patient experience committee aims to improve patient experiences through targeted interventions. The committee identified communication-specific HCAHPS scores, specifically for items "Doctors (nurses) explained things in a way you could understand," as an area for intervention. We hypothesized a lack of adequate training in beside communication and identification of poor health literacy as reasons for suboptimal communication scores. The aims of our study were to (1) develop a multidisciplinary curriculum to teach physicians and nurses to best deliver complex medical information and (2) evaluate the effectiveness of the curriculum by examining HCAPHS scores for doctor and nurse communication.

METHODS: A clear health communication curriculum was developed for 112 internal medicine (IM) residents and 120 nurses from the general medicine wards. The curriculum was disseminated through 60–90 min workshops that were facilitated by IM clinician educators and a nurse educator. The content included didactic teaching on health literacy, small group discussion and simulated videos of optimal communication skills during bedside rounds and the discharge process. Data was collected from 422 HCAHPS surveys from patients discharged from these wards over a 6-month period. We compared that percentage of "top-box" scores (corresponding to a rating of 9 or 10 on a 10-point scale) on communication items between 3 months pre and 3 months post curriculum.

RESULTS: A total of 76 residents (participation rate 68%) and 80 nurses (participation rate 67%) who work in 5 wards across 3 hospitals attended. Percentage of "top-box" scores improved for all doctor and nurse communication-specific HCAHPS items after the intervention (See Table).

CONCLUSIONS: Our data shows that a multidisciplinary clear communication curriculum with a focus on health literacy can significantly improve doctor and nurse communication specific HCAHPS scores at a large academic

hospital. As communication skills are essential to providing quality patient care, our curriculum has value for any medical specialty or healthcare system seeking ways to improve the patient experience.

	Pre (% top box)	Post (% top box)	*P* value
Doctors explained things in a way you could understand	63	70	.15
Doctors listened carefully to you	66	77	.02
Doctor treated you with courtesy and respect	80	84	.25
Overall communication with doctor	70	77	.10
Nurses explained things in a way you could understand	59	73	.003
Nurses listened carefully to you	60	72	.018
Nurses treated you with courtesy and respect	74	80	.199
Overall communication with nurses	65	75	.025

A COMPARISON IN PATIENT REPORTED OUTCOMES RELATED TO TELEPHONE FOLLOW-UP VISITS AND CONVENTIONAL OFFICE VISITS IN ACADEMIC SPECIALTY PRACTICES

Theodore Peng; Nathaniel Gleason; Ralph Gonzales. University of California, San Francisco, San Francisco, CA. (Control ID #2702100)

BACKGROUND: Scheduled telephone follow-up visits are one strategy for improving access to specialty care practices, primarily because telephone follow-up visits can be completed in less time (4–6 telephone visits per hour vs. 2–3 office visits per hour, for instance) with lower overhead costs. However, there is limited data on the relative advantage to patients from such a program. To inform ongoing improvement of the program, and to share the experience with payers, who do not currently reimburse scheduled telephone visits, we conducted a survey to evaluate patient-reported outcomes associated with telephone and office follow-up visits.

METHODS: Scheduled telephone follow-up visits were introduced in January 2015 as a substitute for some scheduled follow-up office visits in specialty care practices at UCSF. Physicians determine the appropriate patients based upon clinical condition and patient acceptability. Patients are not charged for the service and the UCSF physician receives a modest internal RVU credit. English-language surveys were delivered to all patients (>18 y.o.) who completed a follow-up visit (either telephone or office) at UCSF in Endocrinology, Hepatology, or Multiple Sclerosis clinics between March and May 2016 (n = 2741). Patients with email addresses on file were sent the survey electronically (Qualtrics LLC), and those without were contacted by phone.

RESULTS: 96% of patients had email addresses, of which 16% (n = 426) responded. An additional 8 patients without email addresses completed telephone surveys. The final study sample included 13 and 17% of patients with telephone visits and office visits, respectively. Respondents and non-respondents were similar with regard to clinic, sex, and mean age. Main results are show in Table below. Among telephone visit respondents, 87% reported that it replaced the need for an office visit. When telephone visit respondents were asked about their out-of-pocket costs and total time spent for previous office visits, they had similar responses as office visit respondents. 87% of telephone visit respondents and 85% of office visit respondents agreed that insurance companies should pay for telephone visits that substitute for an office visit, and more than half were willing to pay a co-payment of approximately $20 (median).

CONCLUSIONS: This study fills an important gap in understanding the patient's perception of telephone follow-up care, and represents a critical first step in mobilizing health plans to pay for telephone visits.

	Phone Visit N = 110	Office Visit N = 324	*P*-value
Age, mean	55 years	56 years	0.525
Female sex	69%	60%	0.10
Very satisfied or satisfied with telephone visit	98%	N/A	
Out-of-pocket costs, median (IQR)	$0 (0,0)	$50 (20,100)	<0.001
Total Time Spent, median (IQR)	10 min (5, 50)*	240 min (150, 420)	
Urgent/emergency care visit	5%	4%	0.92

*imputed based on 10 min scheduled telephone visit time, and request of patients to be available for phone visit 30 min before and after scheduled visit time.

A COMPARISON OF MEDICATION-BASED VERSUS MEDICAL CLAIMS-BASED RISK ADJUSTMENT TO PREDICT 1-YEAR MORTALITY AMONG VETERANS DUALLY-ENROLLED IN VA AND MEDICARE PART D

Thomas R. Radomski[3, 4]; Xinhua Zhao[4]; Joseph T. Hanlon[3, 4]; Joshua M. Thorpe[2, 4]; Carolyn T. Thorpe[2, 4]; Florentina Sileanu[4]; John P. Cashy[4]; Jennifer A. Hale[4]; Maria K. Mor[4]; Leslie R. Hausmann[4, 3]; Julie M. Donohue[6]; K J. Suda[1]; Kevin T. Stroupe[1]; Chester Good[4]; Michael J. Fine[4, 3]; Walid F. Gellad[5, 3]. [1]Hines VA Hospital, Hines, IL; [2]University of Pittsburgh, Pittsburgh, PA; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA; [4]VA Pittsburgh Healthcare System, Pittsburgh, PA; [5]VA Pittsburgh/University of Pittsburgh, Pittsburgh, PA; [6]University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA. (Control ID #2700094)

BACKGROUND: There is systematic undercoding of medical comorbidities within administrative claims in the Veterans Health Administration (VA) as compared to Medicare. This undercoding may lead to bias when applying claims-based risk adjustment indices in studies of Veterans who dually use both VA and Medicare services, or when comparing medical outcomes between VA and Medicare. Medication-based risk adjustment models may be an unbiased method of risk adjustment in these circumstances or when medical claims are not uniformly available. Our objective was to adapt a medication-based risk index for use with combined VA and Medicare data and compare its prognostic accuracy to commonly used claims-based risk adjustment methods in predicting 1-year mortality.

METHODS: Our cohort was all individuals enrolled in both VA and Medicare Part D who filled at least one opioid prescription from either system in 2012. We adapted an existing VA-based medication risk index (Rx Risk-V) to also incorporate Medicare pharmacy and durable medical equipment claims. VA and Medicare medications/supplies were classified into 1 of 45 disease categories, applying previously derived category weights. Using the C-statistic (C), we compared the prognostic accuracy of the adapted Rx Risk-V + demographics (age, gender, race, Medicaid eligibility, and disability status) in predicting 1-year mortality to models that included demographics with and without alternative risk adjustment methods (prescription count, Charlson index, or Elixhauser index). We also compared the adapted Rx Risk-V model to models that included demographics, adapted Rx Risk-V, and Elixhauser or Charlson. We conducted a sensitivity analysis by restricting our cohort to dual

enrollees who had a clinical encounter and/or received a medication within both VA and Medicare (i.e. dual users), as we expected the adapted Rx Risk-V model may perform better among this cohort.

RESULTS: The 271,343 Veterans in the overall cohort had a mean age of 70.5 years; 96.1% were male, 81.7% were non-Hispanic white, and 63.4% were dual users. Overall, 9.4% died within 1 year. The prognostic accuracy of the adapted Rx Risk-V (C = 0.76) was significantly greater than models using demographics alone (C = 0.72) or a prescription count (C = 0.74), but significantly lower than models using Charlson (C = 0.79) or Elixhauser (C = 0.79) ($P < 0.001$ for all comparisons). The model combining demographics, adapted Rx Risk-V, and Charlson provided significantly greater prognostic accuracy than all other models (C = 0.80, $P < 0.001$). We found similar patterns of relative model performance in analyses limited to dual users.

CONCLUSIONS: The adapted Rx Risk-V index, when used in combination with common claims-based indices, enhances prognostic accuracy in regard to 1-year mortality. Using this model in place of claims-based indices marginally lowers prognostic accuracy, but remains a viable method of risk adjustment when medical claims are not available or the use of claims-based indices may lead to bias.

A COMPARISON OF QUALITY END-OF-LIFE CARE IN PATIENTS WITH HEMATOLOGIC AND SOLID MALIGNANCIES: IDENTIFYING DEFICIENCIES IN PATIENT CARE Ramy Sedhom[1]; Daniel Sedhom[1]; David Barile[2]. [1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [2]University Medical Center of Princeton at Plainsboro, Plainsboro, NJ. (Control ID #2670839)

BACKGROUND: Limited data is available on the differences in end-of life care for patients with hematologic and solid malignancies. We retrospectively analyzed and compared the quality of end-of-life care between patients with hematologic malignancies and those with solid tumors.

METHODS: All adult patients who died of advanced cancer between 1/1/2015 and 5/1/2017 at our institution were included. We collected baseline demographics and indicators reflective of quality end-of-life care including: hospitalizations, emergency room visits, admissions to the intensive care unit, and chemotherapy use during the final 30 days of life. Data analysis included descriptive statistics, Chi-square tests, and multivariate logistic regression.

RESULTS: 57/316 (18%) of patients who died had hematologic malignancies. In the final 30 days of life, patients with hematologic cancers had more visits the emergency room (56%vs. 41%, $P = 0.03$), admissions to the hospital (84% vs. 45%, $P < 0.001$), >2 admissions (26% vs. 11%, $P < 0.001$), extended lengths of stay (48% vs. 6%, $P < 0.001$), transfers to the intensive care unit (42% vs. 8%, $P < 0.001$) and death (35% vs. 4%, $P < 0.001$). They also had more frequent chemotherapy use (48% vs. 12%, $P < 0.001$) compared to patients with solid tumors. In addition, patients with hematologic malignancies were less frequently referred to palliative care (5% vs. 21%, $P = 0.02$) or hospice (4% vs. 20%, $P = 0.02$). Chart review, and multivariate analysis, revealed more aggressive care among patients with hematologic malignancies.

CONCLUSIONS: Patients with hematologic malignancies receive different treatment at end-of-life and are less likely to receive palliative services when compared to patients with solid malignancies. Future research is needed to identify differences in overall patient care in order to provide higher quality care.

A CRITICAL APPRAISAL OF GUIDELINES FOR ELECTRONIC COMMUNICATION: DO CURRENT RECOMMENDATIONS NEED MODERNIZATION Joy L. Lee[2, 1]; Nir Menachemi[3]; Michael Weiner[1, 2]. [1]Indiana University, Indianapolis, IN; [2]Regenstrief Institute, Indianapolis, IN; [3]Richard M. Fairbanks School of Public Health at IUPUI, Indianapolis, IN. (Control ID #2704852)

BACKGROUND: Patients are increasingly interested in electronic access to providers (e.g., via emailing, secure messaging, or texting), and federal policies are encouraging secure messaging. Nevertheless, little is known about how providers should use electronic tools to communicate with patients. We sought to identify published evidence that underpins guidelines for electronic communication, and to evaluate evidence-based recommendations for electronic-communication between patients and members of the healthcare team. We identified a dearth of published work in both areas and instead critically appraise existing published guidelines and suggest an agenda for future work in this area.

METHODS: We performed a narrative review of provider-targeted guidelines on electronic communication, searching Ovid MEDLINE, EMBASE, and PubMed databases using relevant search terms (e.g. 'patient' and 'email,' 'webmail,' or 'messaging' and 'guideline,' or 'standard'). We limited the search to articles published in English. We also manually searched the citations of relevant articles. We identified the themes and suggested practices of each guideline, and evaluated whether promoted practices reflect current practice.

RESULTS: We identified 11 guidelines on electronic communication between providers and their patients. Although many articles referenced emerging evaluations of electronic communications, no recommended practices were underpinned by evidence of the effectiveness of the practices. Within the guidelines, privacy and data security were major themes. Most guidelines recommend a discussion with patients regarding expectations for communication. They focused little on suggested practices regarding the content of electronic communications, communication delivery, and how best to achieve communication functions such as providing information and emotional support. Many guidelines are out of step with current practice regarding both how email is used and how patients and clinicians interact. For example, they include suggestions that providers should direct patients to use the auto-reply e-mail feature to acknowledge reading messages and to also direct patients to use specific subject headings in electronic communications.

CONCLUSIONS: Although current guidelines for electronic communication may be rooted in a solid conceptual basis, they have three major flaws: a) the guidelines are not founded on evidence, b) they offer little guidance on how best to use electronic tools to communicate effectively, and c) many guidelines are out of line with current practice. Just as clinicians and clinical trainees are being taught face-to-face communication with patients based on an evidence-rich foundation, the same rigorous work needs to be applied to electronic communication. Researchers need to evaluate and identify effective practices systematically, create a framework to evaluate quality of communication, and test the relationship between electronic communication delivery and quality of care.

A CROSS SECTIONAL PROSPECTIVE COMPARISON OF COLLABORATIVE CARE AND CO-LOCATION TREATMENT FOR DEPRESSED, LOW INCOME, DIVERSE PATIENTS IN PRIMARY CARE Michelle Blackmore; Henry Chung; Sarah Ricketts; Urvashi Patel. Montefiore Medical Center, Bronx, NY. (Control ID #2689889)

BACKGROUND: Although substantial research demonstrates the effectiveness of integrated care models, there are very few studies that compare clinical outcomes in depression for a co-location model versus a collaborative care model (Krahn, Bartels, Coakley, et al., 2006; Unützer, Katon, Callahan, et al. 2002) As health care reform efforts support integrated model sustainability and scalability, understanding whether there are differential outcomes achieved can help practices allocate resources appropriately. An academic medical center with large ambulatory primary care practices ($N = 19$), serving primarily Medicare and Medicaid recipients with significant racial and ethnic diversity, began offering integrated care primarily through co-location (usually a licensed clinical social worker and a part time psychiatrist) in the Fall of 2014. In February 2015, 7 sites were chosen to begin implementation of the integrated collaborative care model (CCM) as part of a Health Care Innovations Award from the Center for Medicare and Medicaid Innovations. The CCM program aimed to improve care quality through the addition of a care manager to the behavioral health team, allowing enhanced "between visit" care and case reviews in a multidisciplinary team, facilitated by a measurement-informed care patient registry.

METHODS: A cross sectional natural experimental design compared depression symptom severity outcomes for patients attending Montefiore primary care sites employing co-located care ($N = 12$) and sites utilizing CCM ($N = 7$). Depression symptom severity was measured with the Patient Health Questionnaire 9 (PHQ-9). Patients were enrolled in the study if they scored 10 or above on the PHQ-9, indicating moderate to severe depression. Eligible patients receiving both intervention types had access to short-term, psychotherapy, concrete social services, and medication management. At 10 to 16 weeks (mea$n = 12$ weeks) following enrollment, patients were re-administered the PHQ-9 by a trained and blinded independent assessor over the phone.

RESULTS: A total of 240 participants were enrolled ($N = 122$ at co-location sites; $N = 118$ at CCM sites). Significant within group reductions in depressive symptoms were observed in the co-location sites (difference, 2.23, $p < 0.0003$) and the CCM practices (difference, 5.04, $p < .0001$). Between group differences indicated patients in CCM sites demonstrated significantly greater reduction in depressive symptoms compared to patients at the co-location sites (difference, −2.81; $p = .0005$).

CONCLUSIONS: The CCM intervention appears to result in a significantly greater reduction in depressive symptoms compared to the co-location model across a range of Montefiore primary care clinics serving low income, diverse patients. Replication will be necessary in larger samples to further support these findings.

A CROSS SECTIONAL STUDY REVEALS AN ASSOCIATION BETWEEN ELECTRONIC CIGARETTE USE AND MYOCARDIAL INFARCTION

Taher M. Tayeb; Talal Alzahrani; Nardos Temesgen; Ivan Pena. The George Washington University, Arlington, VA. (Control ID #2689119)

BACKGROUND: Electronic cigarettes (E-cigarettes) have grown in popularity as an alternative to traditional cigarettes especially among consumers who want to reduce the risk of morbidity and mortality associated with smoking. Nonetheless, a recent study showed that both E-cigarettes and traditional cigarettes cause an increase in oxidative stress and endothelial dysfunction, however this effect is less pronounced with E-cigarettes. Currently, there is a limited study that shows the impact of E-cigarette in the cardiovascular system. Therefore, data from the 2014 National Health Interview Survey (NHIS) was used to evaluate the effect of E-cigarettes on the cardiovascular system, specifically the effect on myocardial infarction(MI).

METHODS: Analysis of the 2014 National Health Interview Survey (NHIS) database was performed to examine the effect of E-cigarettes on MI. Initially, subjects were assigned to one of two groups: those with a history of MI and those without a history of MI. The t-test and chi-square test were subsequently applied to compare the different demographics and health characteristics between these two groups. A logistic regression model was then used to measure the association between E-cigarettes and history of MI. Data was adjusted for multiple risk factors for MI including age, gender, race, body mass index, income, the status of smoking cigarettes, and history of hypertension, diabetes, and hypercholesterolemia.

RESULTS: A total of 35,156 subjects were included in the final logistic model. [Summarize a number of baseline variables with respect to health and demographic characteristics] Analysis showed that increasing age (OR, 1.04; p <0.001), history of hypertension (OR, 2.72; $p < 0.001$), high cholesterol (OR, 2.19; $p < 0.001$), and diabetes (OR, 1.68; $p < 0.001$) are associated with an increased odds of myocardial infarction. With respect to smoking, increased frequency of smoking was associated with increasingly higher odds of MI when compared to patients who had never smoked: every day smokers (OR, 2.75 $p < 0.001$), some day smokers (OR, 2.39; $p < 0.001$), and former smokers (OR 1.80; $p < 0.001$.) In contrast, females (OR, 0.49; $p < 0.001$), Hispanics (OR, 0.62; $p < 0.001$), and people with higher incomes (OR, 0.93 [95% CI, 0.90–0.96]; $p < 0.001$) have lower odds of heart attack. With respect to Electronic cigarette use and MI, analysis revealed an odds ratio of 1.42 with $p = 0.017$.

CONCLUSIONS: Our findings indicate that Electronic cigarette use, when adjusted for other risk factors, is associated with a 42% increased odds of myocardial infarction. This increase in odds is consistent regardless of traditional cigarette smoking history. More studies are needed to further assess this risk.

A CROSS-SECTIONAL STUDY OF SELF-REPORTED COLORECTAL CANCER SCREENING STATUS IN US ADULTS WITH AND WITHOUT DISABILITIES

Bliss Temple[2]; Lisa I. Iezzoni[1]. [1]Harvard Medical School, Boston, MA; [2]University of California San Francisco, San Francisco, CA. (Control ID #2703635)

BACKGROUND: Colorectal cancer screening is a life-saving aspect of primary care recommended for most adults 50 to 75 years old. People with disabilities face difficulties accessing health care services and disparities in rates of cervical and breast cancer screenings. This study used a large, nationally representative database to examine rates of self-reported colorectal cancer screening to determine whether there are disparities for people with disabilities compared to those without disabilities.

METHODS: This was a secondary analysis of cross-sectional data from adults 50–75 years old in the 2013 National Health Interview Survey, which uses a multistage area probability design to sample the civilian non-institutionalized US population. The outcome was self-reported current colorectal cancer screening status. The main predictor was self-reported limitation in functional abilities (i.e. disability) in at least one of 12 domains. Severe disability and type of disability (physical, sensory, cognitive/intellectual, chronic disease, mental health) were secondary predictors. Covariates included age, sex, race, Hispanic

ethnicity, and seeing a primary care provider (PCP) in the previous year. Logistic regression analyses were used to model the odds of current screening status. The model was evaluated for interactions, collinearity, goodness of fit, and misspecification.

RESULTS: Of the 13,332 subjects in the analysis, 51.3% reported any disability and 28.2% severe disability. Subjects with any disability reported a 59.3% current colorectal cancer screening rate; those with severe disabilities, 58.8%. Both groups had higher screening rates than those without disabilities (52.1%). Those with disabilities did not have significantly different adjusted odds (OR 1.05; 95% CI 0.98,1.13) of current screening compared with those without disabilities. Statistically significant covariates were age, Asian race, Hispanic ethnicity, and seeing a PCP within the past year. The odds ratio for those with versus without severe disability was not statistically significant (OR 0.95; 95% CI 0.87,1.03). Odds ratios for health condition subgroups compared to those without that condition were statistically significant only for the groups with physical health conditions (OR 1.15; 95% CI 1.06,1.24) and chronic diseases (OR 0.89, 95% CI 0.80,0.99).

CONCLUSIONS: Overall rates of colorectal cancer screening for people with and without disabilities were not significantly different, despite barriers to accessing care and disparities in other cancer screening rates. This may reflect an increased focus on health by people with disabilities compared to the nondisabled and/or fewer barriers to colorectal cancer screening than for other cancers. Policy initiatives aimed at decreasing health disparities for people with disabilities may be more productively focused on areas other than colorectal cancer screening.

A DIFFERENCE-IN-DIFFERENCE ANALYSIS OF TRENDS IN UTILIZATION FOLLOWING A PRIMARY CARE REDESIGN INTERVENTION Kevin Nguyen[1]; Alyna T. Chien[2, 4]; David J. Meyers[1, 3]; Sara Singer[1, 2]; Meredith Rosenthal[1]. [1]Harvard T.H. Chan School of Public Health, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Brown University School of Public Health, Providence, RI; [4]Boston Children's Hospital, Boston, MA. (Control ID #2699123)

BACKGROUND: Many academic medical centers (AMCs) are seeking novel approaches to deliver higher quality care and lower costs for patients cared for in primary care practices. Beginning in mid-2012, 20 practices across 6 AMCs affiliated with Harvard Medical School launched a learning collaborative to establish team-based care at both hospital- and community-based practices. We describe trends and changes in utilization 3 years before and 1 year following this intervention.

METHODS: The learning collaborative followed a sequenced change strategy, and relied on in-person learning sessions, monthly calls, and leadership training. We conducted difference-in-difference analyses using generalized linear models to compare changes in utilization between intervention practices and controls before and after the intervention using the Massachusetts All-Payer Claims Database (APCD) for 2009 to 2013. The APCD aggregates medical claims each year for private payers and Medicaid in the Massachusetts. The 20 intervention practices were identified by linking National Provider Identifier number to the Massachusetts Health Quality Partnership Physician database, which trackers physician hierarchy within practices and systems. We used propensity weights to identify controls that were of comparable size and affiliated with AMCs. Patients were attributed to intervention or control practices annually. Utilization measures included outpatient visits, emergency room (ER) visits, inpatient hospitalizations, ambulatory care sensitive inpatient (ACSIP) hospitalizations, and ambulatory care sensitive ER (ACSER) visits. We adjusted the utilization outcomes based on the number of months a patient was enrolled. We estimated percent change in intervention practices' utilization relative to changes in controls' utilization.

RESULTS: One year following the beginning of the intervention, we found a statistically significant reduction in outpatient use in intervention sites compared to controls by 0.72 visits per patient per year, or approximately 7.3% ($p < 0.01$). From baseline, ER use decreased in intervention sites compared to controls by 0.06 visits per patient per year (8.3%, $p < 0.01$) and inpatient hospitalizations in intervention practices decreased by 0.1 admissions per patient per year (19.2%, $p < 0.01$). ACSIP admissions decreased by 0.02 per patient per year in intervention sites compared to controls (28.6%, $p < 0.01$) and ACS ER decreased by 0.01 visits per patient per year (9.1%, $p < 0.01$).

CONCLUSIONS: We observed significantly larger reductions in utilization in intervention practices when compared to control practices. Our findings suggest that involvement in the learning collaborative was associated with significant reductions in healthcare utilization.

A DIGITAL LANGUAGE DIVIDE? THE RELATIONSHIP BETWEEN INTERNET MEDICATION REFILLS AND MEDICATION ADHERENCE AMONG LIMITED ENGLISH PROFICIENT PATIENTS Alejandra Casillas[2]; Leo Morales[3]; Jonathan Grotts[2]; Chi-Hong Tseng[1]; Gerardo Moreno[1]. [1]UCLA, Los Angeles, CA; [2]University of California Los Angeles, Los Angeles, CA; [3]University of Washington, Seattle, WA. (Control ID #2703287)

BACKGROUND: Use of an Internet portal to refill medicines positively affects medication adherence among English-speakers. However, no studies examine if Internet refills also affect medication adherence for patients with Limited English Proficiency (LEP). Our objectives were to 1) examine the relationship between use of an Internet medication refill system and medication adherence among linguistically diverse patients with chronic conditions and 2) compare this relationship between LEP and English Proficient (EP) patients.

METHODS: We analyzed 2013–2014 data from 509 surveyed adults with hyperlipidemia, hypertension, and/or diabetes mellitus in the Group Health Cooperative. Data were merged from a multilingual phone survey, plan enrollment, claims data, and electronic medical records. The primary outcome, medication adherence rate (%), was calculated for patients with at least two pharmacy fills over a 12-month period by the "Continuous Measure of Medication Gaps" (CMG) method. For Internet refill system use, patients were asked, "Have you used the health systems Internet site to refill any medications in the last 12 months?". LEP status was captured by patient self-identification with a non-English primary language, and/or a claims record of interpreter use. We used multivariate linear regression models to examine the adjusted effects of use of the Internet refill system on medication adherence, and compared this association between LEP and EP patients. We adjusted for age, gender, education, insurance, chronic conditions, and number of medications.

RESULTS: 384 patients (75%) had a calculable CMG (to produce adherence rate): 134 EP and 250 LEP, included in the models. Patients who had calculable CMG's were older, prescribed more medications, and more likely to have Medicare or Medicaid coverage, versus patients without a CMG. In unadjusted analyses, LEP patients had lower use of the Internet refill system ($p < .001$) and lower adherence versus the EP group ($p < .001$). In multivariate analyses, LEP

status (b = −0.022, $p = .047$) was negatively associated with adherence. Use of the internet refill system (b = 0.030, $p = .002$), and Medicare or Medicaid insurance (b = 0.030, $p = .007$), were positively and independently associated with adherence. In stratified models, use of remote Internet refills was positively associated with adherence, even when examining EP (b = 0.029, $p = .003$) and LEP patients (b = 0.027, $p = .049$) separately.

CONCLUSIONS: We found that the use of remote medication refills through an Internet portal was independently and significantly associated with higher medication adherence in both EP *and* LEP patients. These findings suggest that LEP patients could be under-utilizing a beneficial Internet tool. Should our health-care system fail to ensure that LEP patients can digitally manage their health care (such as refilling medications) through an Internet portal, we face the risk of widening the existing health care gaps via this digital divide.

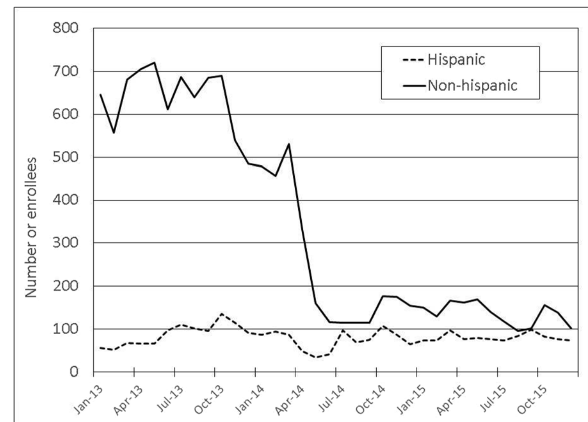
A LOOK AT WHO STILL NEEDS BREAST AND CERVICAL CANCER SCREENING SERVICES FROM SAFETY NET PROGRAMS FOLLOWING IMPLEMENTATION OF THE AFFORDABLE CARE ACT Latonya Riddle-Jones; Julie George; Robert Burack. Wayne State University School of Medicine, Detroit, MI. (Control ID #2708275)

BACKGROUND: The rate of uninsured adults in the United States has declined by nearly 40% since the Affordable Care Act in 2013, nevertheless, more than 20 million adults in the US remain uninsured. Safety net programs are necessary to help address the needs of those who remain uninsured, but to what degree? We have examined the enrollment of people in a safety net breast and cervical cancer screening program (BCCCP), serving uninsured and low-income women in an area of Metro Detroit, Wayne County, MI, to better understand the magnitude and determinants of this need.

METHODS: We examined patterns of enrollment by age, ethnicity, and income, in our community-based breast and cervical cancer control program for the period from 2013 through 2015. We used logistic regression to estimate adjusted odds ratios for enrollment according to race/ethnicity.

RESULTS: Please see the attached graph depicting the number of breast and cervical cancer screenings of non-Hispanic and Hispanic women enrolled in our safety net program from January 2013 through October 2014. - The graph shows a decline in the number of non-Hispanic women enrolled in our program from October 2013 through July 2014. - The graph also demonstrates that Hispanic enrollment in the program remained steady during this time, which correlates with the implementation of the ACA in Michigan (April 2014). - Our adjusted Odds Ratio for being Hispanic in 2015 compared to 2013 was 4.44.

CONCLUSIONS: The ACA has reduced, but not eliminated the need for specific safety net programs in the United States. While enrollment in the BCCCP declined by 70% pre-post ACA, we have served over 15,000 women from 2013 through 2015 who, in the absence of this safety net program, would likely have remained unscreened. In particular, we note that the BCCCP has taken on increased importance for Hispanic women in our community, who remain disproportionately uninsured, here and elsewhere.



A NARRATIVE REVIEW OF PHYSICIAN PERSPECTIVES REGARDING THE SOCIAL AND ENVIRONMENTAL DETERMINANTS OF OBESITY Feenalie Patel[2]; Ashley K. Haddad[1]; Debra A. Werner[1]; Monica E. Peek[1]. [1]University of Chicago, Chicago, IL; [2]University of Tennessee Health Sciences Center, Cordova, TN. (Control ID #2703874)

BACKGROUND: Obesity is a multifactorial disease with influences from biology, behavior, social norms, physical environment, and the larger health system. However, current guidelines for managing obesity discuss only biologic and behavioral therapeutic options, without suggesting ways to address the social and/or environmental determinants of obesity. In this review, we evaluate the ways that physicians conceptualize and address the social and environmental determinants of obesity to better understand current practice.

METHODS: We searched PubMed, Ovid, and PsycINFO databases and conducted hand searches of relevant bibliographies over the past 30 years. Search terms included variations on the following: obesity, attitude, perception, belief, knowledge, physician, adult, recommendation, treatment, cause, and etiology. Our final review included all articles that elicited physician perspectives on the causes or management strategies of obesity. We categorized causes and management strategies into the following domains, defined by the ecologic model of health: individual (i.e. biological, psychological, behavioral), social, environmental, and macro-level.

RESULTS: We found 1144 total articles, 24 of which met inclusion criteria. Eleven articles (46%) assessed physician perspectives on obesity *causes* and 18 (75%) assessed physician perspectives on obesity *management*. Of the 11 articles that discussed obesity cause, all (100%) evaluated physician perspectives on at least one non-individual domain, but no paper evaluated physician perspectives across all domains. Of the 18 articles that discussed obesity management, 12 (66%) evaluated physician perspectives on at least one non-individual domain, and again, none evaluated physician perspectives across all domains. When asked to rank the causes of obesity across multiple domains, physicians ranked individual causes as more important than social or environmental causes in all except one study. Physicians also used individual management strategies more frequently (and believed individual management strategies were more successful) than social or environmental management strategies in all studies.

CONCLUSIONS: No articles in our review allowed physicians to evaluate the causes or management strategies of obesity across all domains that might

influence weight. However, within this limitation of available literature, our review suggests that clinicians rank individual characteristics as more important in the development and management of obesity than social or environmental factors. While clinicians may simply under-value the impact of social and environmental obesity determinants, this finding may also represent a lack of perceived ability or responsibility to address non-individual health determinants in clinical practice. As we move into the era of population health management, more research is needed to understand the most appropriate ways for physicians to address the social and environmental determinants of chronic diseases such as obesity.

A NEEDS ASSESSMENT FOR EMPANELMENT IN A RESIDENT CONTINUITY CLINIC Jennifer Bracey; Alanna Stone; Sara Turbow. Emory University School of Medicine, Atlanta, GA. (Control ID #2704973)

BACKGROUND: Empanelment is the act of assigning patients to a primary care provider (PCP). Improving empanelment could create greater satisfaction in clinic by increasing continuity and enabling closer relationships with patients, both of which could decrease resident clinic burnout and create interest in GIM careers. In this analysis, we sought to define the baseline accuracy of current PCP assignments for our resident continuity clinics, and we investigated if residents were engaging in empanelment by assigning themselves as PCP for patients without accurate PCP assignments.
METHODS: This analysis was performed in three IM resident continuity clinics at a large urban hospital. We examined charts for all patients scheduled in clinic on two dates in December 2016. We recorded if the patient had a PCP assigned prior to the visit and, if they did, whether the listed PCP was the resident the patient was scheduled to see that day, a different current resident, a graduated resident, or another type of provider (ex. advanced practice provider, subspecialist, or community provider). We reviewed the same charts after clinic to determine if patients without a PCP or with an incorrect PCP had been reassigned to the resident they saw that day. Patients who did not show to clinic or who were added to the schedule after our initial pre-clinic chart review were excluded from the analysis. SAS Studio was used for data analysis.
RESULTS: We reviewed 496 charts. Of those, 45.6% ($n = 226$) had the resident they were scheduled to see that day listed as their PCP. 13.1% ($n = 65$) had another current IM resident listed, 13.9% ($n = 69$) had a graduated resident listed, 10.5% ($n = 52$) had another type of provider listed, and 16.9% ($n = 84$) were unassigned. Of the 205 patients eligible to be assigned a new PCP at their visit, 44.4% ($n = 91$) came to the appointment. Five patients were assigned to PCPs other than the resident they saw that day. Of the remaining 86 patients, 45.4% ($n = 39$) had their PCP assignment changed to the resident they saw that day.
CONCLUSIONS: We found that residents assign themselves to be the PCP at a low rate. There was no statistically significant difference in the percent of patients reassigned to a current resident between patients in each of the "inaccurate" PCP categories ($p = 0.7314$). This also does not appear to differ by PGY level. This analysis was limited by high no-show rates: 42.3 overall and 67.9% for patients without an assigned PCP. Overall, this project shows a need for increased focus on empanelment in our resident continuity clinic. Our next steps will focus on resident-level interventions to: 1) educate them on empanelment and why this process is important and 2) strategize ways for them to improve empanelment. By improving empanelment, we may see greater resident satisfaction with clinic, less clinic burnout and an increased interest in GIM careers.

A NEW FRAMEWORK FOR STAKEHOLDER ENGAGEMENT IN EARLY STAGE TRANSLATIONAL SCIENCE Amy LeClair[1]; Thomas Concannon[3]; Virginia Kotzias[3]; Allison M. Cole[2, 2]; Simona Kwon[4]; Alexandra Lightfoot[5]. [1]Tufts Medical Center, Boston, MA; [2]University of Washington, Seattle, WA; [3]RAND Corporation, Boston, MA; [4]NYU School of Medicine, New York, NY; [5]University of North Carolina at Chapel Hill, Chapel Hill, NC. (Control ID #2705519)

BACKGROUND: Stakeholder and community engagement (SCE) is a national priority for the National Center for Advancing Translational Science (NCATS). There is an established framework for stakeholder engagement for the latter stages (T2-4) of translational science, but no such framework currently exists for early stage (T1) clinical researchers. Four Clinical Translational Science Award (CTSA) hubs launched a collaboration to develop a new framework for engaging communities and stakeholders in T1 research.
METHODS: We led structured individual and group discussions with T1 investigators to learn about: (1) the health decisions they seek to inform with research evidence, (2) the actors who make those decisions, and (3) the individuals and organizations that are affected by those decisions. Focus groups lasted, on average, one hour. Interviews lasted approximately 30 min. Both were recorded. Audio recordings were transcribed and de-identified, and transcripts were coded using Dedoose™. We used a deductive-inductive procedure to develop the framework for stakeholder engagement in T1 research. A deductive codebook was development from the focus group & interview guides; emergent themes were added and the codebook was revised after preliminary inductive analysis. Two coders analyzed all transcripts using a constant comparison approach. Analysis included input from research participants to assure the framework could be used by T1 researchers.
RESULTS: Eighteen individuals connected to four CTSA hubs participated in the discussions. Participants came from the fields ranging from basic chemistry and drug development to infectious disease and pediatrics and represented both methodological and topical experts. Preliminary analysis produced several findings. First, basic scientists can identify stakeholders, contrary to concerns that stakeholder engagement is not applicable at this stage. Second, stakeholders in early stage translational research (T1), as identified by the research participants, do not fit into the same framework as those further down the translational spectrum (T2-T4). A unique framework may therefore assist early stage researchers in the process of stakeholder engagement. Finally, participants indicated they would like more guidance on who, how, and when to engage them in their research.
CONCLUSIONS: By showing T1 researchers how to identify and involve their stakeholders in (1) defining research questions, (2) carrying out research activities, and (3) disseminating research evidence, this work has the potential to improve the use of basic science evidence in latter stages of translation from bench to bedside.

A NEW MODEL FOR EXPANDING AAMC MEDICAL EDUCATION RESEARCH CERTIFICATION Joshua T. Hanson; Jeffrey Jackson. University of Texas Health Science Center, San Antonio, San Antonio, TX. (Control ID #2702129)

BACKGROUND: It is difficult to provide large-scale faculty development in medical education scholarship. This type of development frequently requires formal training and, in response, the Association of American Medical

Colleges (AAMC) has created the Medical Education Research Certificate (MERC) program. MERC courses are offered at national meetings; however, this can be costly and time consuming to the individual faculty member. In an effort to provide this to faculty at the University of Texas School of Medicine (UTSOM), we engaged with AAMC to host the MERC program locally. Our goal was to create a sustainable faculty development program in medical education scholarship by increasing opportunity while reducing resource utilization.

METHODS: MERC faculty traveled to the UTSOM campus where all the sessions were held. All workshop topics were offered in morning and afternoon sessions to accommodate clinical and administrative duties of the attendees. Attendees were recruited through the Division of General & Hospital Medicine, Office of Undergraduate Medical Education, and the Office of Graduate Medical Education. To measure impact of the program, ten-item pre and post surveys were administered and were constructed to measure increases in skills and knowledge of educational research. Individual paired comparisons were made between pre- and post- survey results by paired samples t-test and grouped according to certification completion. Survey data were compiled and analyzed using Microsoft Excel and Stata.

RESULTS: The total number of registrants was 53 and the average number of workshops attended was 5. Twenty-nine registrants completed certification, for which the criterion is completion of six sessions. The total cost of the week of sessions was $16,179, which calculates to $305 per registrant or $558 per certificate. Complete pre- and post-survey data were available for 38 registrants (71.7%). All items had mean increases self-reported knowledge and skills. Among those that completed certification, comparisons demonstrated statistically significant improved knowledge and skills in 10/10 domains. Among those that did not complete certification, 4/10 domains had statistically significant improvements.

CONCLUSIONS: Engaging with the AAMC to host the MERC program locally resulted in significant cost savings considering attendance and certification typically requires national meeting registration, travel costs, and is a multi-year endeavor. Certification was associated with increased knowledge and skills in all of the domains. Even partial attendance resulted in knowledge increases. This early success has led to the planning of a second annual MERC intensive program with recruitment of attendees from more departments. Future plans include measurement of sustained self-reported knowledge and measurement of increased scholarship after attendance and certification.

A NOVEL APPROACH TO BLINDING IN A RANDOMIZED CLINICAL TRIAL (RCT) OF A COMPLEX BEHAVIORAL INTERVENTION: THE PREVENTING AMPUTATION BY TAILORED RISK-BASED INTERVENTION TO OPTIMIZE THERAPY (PATRIOT) STUDY Xiao Xiao[1]; Kimberly L. Stone[1]; Sarah Sullivan[1]; Yvonne Ye[1]; Madeline Russell[1]; Tova Bergsten[1]; Trina Wijangco[1]; Samantha M. Hill[1]; Sundar Natarajan[2]. [1]Department of Veteran's Affairs New York Harbor Health System, New York, NY; [2]VA New York Harbor Healthcare System, New York City, NY. (Control ID #2705763)

BACKGROUND: In order to generate valid results in RCTs, it is important to collect unbiased data. Behavioral intervention trials are more difficult to blind than pharmacologic trials. In our ongoing behavioral trial, PATRIOT, which aims to prevent foot complications in diabetes through improved self-care, we are intervening both face-to-face as well as remotely. Consequently blinding is more difficult. Here we illustrate the different blinding processes used.

METHODS: In the PATRIOT trial, following randomization during the baseline visit, the intervention group receives computer-based education and demonstration on how to use a special foot thermometer. Following that, intervention participants receive a comprehensive intervention that includes regular telephone counseling and tailored mailings. The control group receives health prevention strategies not related to foot care. For this complex intervention, we needed to develop new strategies to maintain blinding at the participant, research assistant (RA), counselor, outcome adjudicator and data analyst levels. We created a "Blinding Tracker" to identify unblinded and blinded staff so that participants pass from unblinded to blinded staff so that only blinded staff collect data. The integrity of the study is maintained by careful monitoring of blinding with any break in blinding being contained.

RESULTS: To date, we have enrolled 221 participants. While participants know the arm to which they are randomized, we needed to make sure that the staff collecting data are blinded. Participants are educated throughout the whole study process by the telephone counselors about the importance of blinding using non-scientific descriptions. Though the counselors know their participant's treatment assignment, they do not know their foot photography results and other outcomes. The RA's, who conduct study visits and collect data, are blinded to treatment assignment. To improve efficiency and preserve blinding, we have different RAs for different phases of a participant's progress. Initially, RAs are initially blinded, but by the end of their involvement with a particular subject, when data collection is done, they become unblinded so they can show the educational videos and demonstrate foot thermometer use. However, RA's can also become unblinded prematurely. To date, out of 96 six-month visits, there have been 26 such instances. RAs are subsequently transitioned off a particular subject to be replaced by a blinded RA. We will also control for RA blinding in the analysis. The adjudicators who read the foot photographs to determine outcomes and the statisticians are blinded to treatment assignment.

CONCLUSIONS: Novel techniques have been used to achieve and maintain blinding, but it is resource intensive. While conducting complex trials, vigilance and responsiveness are needed. Finally, blinding information should be incorporated in the analysis in order to get the most valid results.

A PALLIATIVE CARE (PC) ELECTIVE ROTATION FOR SENIOR INTERNAL MEDICINE RESIDENTS IMPROVES COMFORT LEVEL WITH PRIMARY PALLIATIVE CARE SKILLS Maie El-Sourady; Mohana Karlekar; Sumathi Misra. Vanderbilt University, Mount Juliet, TN. (Control ID #2702217)

BACKGROUND: Palliative Care (PC) specialists assist patients with serious illness, their families, and their clinicians with medical decision making, symptom management, advance care planning, and end of life care. As the population ages, the need for PC services will increase, and will exceed the supply of PC clinicians. Primary care physicians will need to feel comfortable in navigating many primary PC skills.

METHODS: We describe a 2 week PC rotation for third year internal medicine (IM) residents at a large academic medical center. Between 2012 and 2016, 32 IM residents completed a PC elective rotation. The curricular components included didactic sessions and bedside teaching on a busy inpatient PC consult service and inpatient unit. All 32 residents completed a pre and post survey during the elective rotation in which they ranked their comfort level with primary PC topics using the RedCap survey tool (1 = Need further basic

instruction, 2 = Competent to perform with close supervision, 3 = Competent to perform with minimal supervision, 4 = Competent to perform independently). They also ranked their overall comfort level in working with seriously ill and dying patients (1 = very uncomfortable to 10 = very comfortable).Surveyed topics included conducting a family conference, breaking bad news, discussing DNR orders, home hospice, shift in treatment to comfort care, treatment withdrawal and advance directives, performing a basic pain assessment, using oral and parenteral opioids, adjuvant analgesics, assessing and managing difficult symptoms, and assessing decision-making capacity.

RESULTS: Prior to beginning the rotation, the IM resident average comfort level was 2.5 (range 2 to 3.5) for the above topics, indicating that their comfort was between "competent to perform with close supervision" and "competent to perform independently." After completion of the rotation, the average comfort level was 3.3 (range 2.4 to 3.5), indicating they felt that they were competent to perform these tasks with minimal supervision. IM residents also indicated an increase in their comfort level in working with seriously ill and dying patients, from 6.7 prior to 8.6 after the rotation.

CONCLUSIONS: We have shown that the self-reported comfort level of IM residents improves after a 2 week elective rotation with primary PC topics. At the end of the rotation, participants felt that they are able to perform these tasks with minimal supervision, which is reassuring as they complete residency. The limitations of this study are that it is an elective rotation, so we are unable to speak to the comfort level of IM residents who did not complete this rotation. This study raises questions as to the comfort level for PC topics of IM residents that have not participated in a PC rotation, and whether this improvement in resident comfort level translates to improved patient outcomes.

A PERSONAL TOUCH TO DECREASE NO-SHOWS Jay L. Mathur[2]; Noor Khan[1]; Mehrshid Kiazand[2]. [1]UPMC Mercy, Moon Township, PA; [2]UPMC Mercy, Pittsburgh, PA. (Control ID #2699304)

BACKGROUND: Outpatient non-attendance, or no-shows, produces major consequences for both patients and providers. A recent review of 42 studies found that telephone reminders, mostly automated, were the most effective system to reduce no-shows (9.4% reduction). Our Internal Medicine Clinic continues to have high no-show rates (27.1% annually) despite automated reminders. We sought to understand the impact personal phone reminders may have on no-show rates vs automated reminders. We were particularly interested in evaluating whether PGY1 no show rates were impacted at the beginning of their training.

METHODS: Our teaching outpatient center is divided into two separate sections, Firms A and Z, each with its own resident panel, patient sets, and dedicated staff. All patients receive automated phone reminders 48 hours prior to their office visit. Only Firm A patients also received a personal phone reminder by a staff member during the first 4 months of the academic year. We analyzed the effect of this additional personal phone reminder versus automated reminders in improving no-show rates.

RESULTS: 4,121 scheduled clinic visits from 6/29/15 - 10/31/15 were analyzed. 1,067 (25.9%) no-shows occurred over this period. The mean average scheduled visits per resident was 72.4 for A firm and 75.0 for Z firm ($p = .7188$). The cancellation rate per resident was similar in both firms (A = 22.0%, Z = 20.8% $p = .3951$). The average rate of no-shows per resident was significantly less for firm A (A =23.3%, Z = 28.7%, $p < .0007$). PGY1's did have a lower no-show rate in firm A although the numbers were not statistically significant (A = 23.5%, Z = 29.2%, $p = .0639$)

CONCLUSIONS: Personalized reminders may have resulted in significantly less no-shows in our study. We postulate that despite the cheaper and convenient alternative of automated telephone reminders, personalized reminders can reduce no-shows and lead to more efficient care and better outpatient training. Personalized reminders can also increase initial R1 clinic visits and subsequent continuity experience. Lack of statistical significance for R1 data from our review maybe from small sample size (firm A $n = 10$, Z $n = 10$).

A POSITIVE DEVIANCE APPROACH FOR LARGE-SCALE DISSEMINATION OF AN EVIDENCE-BASED HYPERTENSION PROGRAM. Shari Bolen[2]; Thomas Love[3, 2]; Randall D. Cebul[1]. [1]Case Western Reserve University, Chagrin Falls, OH; [2]MetroHealth/Case Western Reserve University, Cleveland, OH; [3]Case Western Reserve University, Cleveland, OH. (Control ID #2706516)

BACKGROUND: Improvements in blood pressure (BP) control across diverse populations is challenging. Although evidence-based interventions for BP improvement have been successfully disseminated within large integrated health systems serving insured patients, less is known regarding successful large-scale dissemination approaches of evidence-based interventions for hypertension management across multiple health systems serving diverse patients. Our objective was to compare BP control over time within diverse practices that participate in a large regional health improvement collaborative (called Better Health Partnership, BHP) which used a positive deviance approach to identify and disseminate a best practice for hypertension management across multiple health systems.

METHODS: We compared cross-sectional results for the 116,042 patients seen in July 2015 - June 2016 to the 97,847 seen in July 2011 - June 2012 at all 33 practices who reported to BHP throughout that period. Using clinics' electronic health records (EHR), patients are included in BHP's biannual reports if they have a diagnosis of hypertension, are 18+ years of age, not pregnant, and have at least two primary care visits in the past 2 years and one in the last year at a participating clinic. BHP used the reported clinic-level EHR data to identify a best practice for hypertension management between 2009–2011 based on a protocol in one health system that showed dramatic improvement and high achievement of BP control. BHP disseminated this best practice using twice yearly public reports and region-wide learning collaboratives; practice coaching for sites with lower levels of good BP control; and EHR-catalyzed patient-centered care.

RESULTS: In 2015–16, patients in the 33 practices were middle-aged (mean 62 years) and diverse (52% Female, 62% White, 32% Black and 3% Hispanic). Across seven Northeast Ohio counties, 28% lived in low-income neighborhoods (median income below $33,000). Patients in these practices showed similar characteristics across reporting periods except for insurance, which went from 5% Medicaid and 9% Uninsured in 2011–12 to 13.2% Medicaid and 3.2% Uninsured in 2015–16. Across all patients in the 33 practices, rates of good BP control (<140/90 mmHg) rose from 67 to 72% (a difference of 5.2 percentage points) from 2011–12 to 2015–16, with increases of at least 4.8 percentage points in all insurance, race/ethnicity, sex, income and educational subgroups. Most improved were patients of Hispanic ethnicity (from 62 to 71%) and the uninsured (from 59 to 66%).

CONCLUSIONS: A positive deviance approach substantially accelerated the dissemination and implementation of a best practice protocol for hypertension management across multiple health care systems with diverse patients in a regional health improvement collaborative. A specific focus on low income and minority populations may have led to the greater improvements seen in uninsured and Hispanic subgroups.

A PRECISION MEDICINE APPROACH FOR PATIENT-REPORTED MENTAL HEALTH SCORES

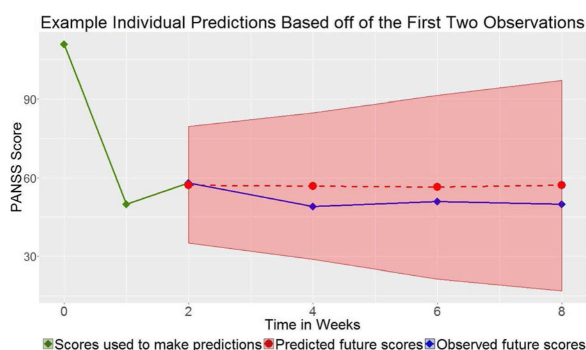
Anthony T. Fojo[2]; Katherine L. Musliner[1, 3]; Peter P. Zandi[1]; Scott L. Zeger[1]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Johns Hopkins School of Medicine, Baltimore, MD; [3]University of Aarhus, Aarhus, Denmark. (Control ID #2706653)

BACKGROUND: In recent years, precision medicine approaches have been developed for a variety of diseases. Early successes have rested on genomic data and laboratory markers. Precision medicine techniques are underutilized in the field of mental health, partly because clinical management depends on patient symptoms and not genetic targets or biomarkers. The increasing use of the electronic medical record (EMR) and patient reported outcome (PRO) data offers an opportunity to develop algorithms to predict patient outcomes on an individual level. Our objective was to develop a precision medicine framework for mental health symptom scores, which we applied to data from a clinical trial of risperidone for schizophrenia.

METHODS: We constructed a novel, multilevel prediction model that learns from serial symptom scores and predicts future symptom trajectories. We fit our model to the trial data - comprising scores on the Positive and Negative Syndrome Scale (PANSS) at weeks 0, 1, 2, 4, 6, and 8 - using Markov-Chain Monte-Carlo. We used 10-fold cross-validation to evaluate predictive accuracy, and analyzed how many observations were necessary to accurately predict outcomes at study completion.

RESULTS: Predictions were most accurate for the subsequent clinic visit, with diminishing accuracy farther into the future. Predictions of outcomes at study completion performed better after at two observations; additional observations yielded only marginal improvements. We present a sample of predictions for an individual based off of the first two clinic visits in the figure. Predictions of symptom scores at study completion based on the first two clinic visits deviated from the observed scores by a mean of 17.6 (interquartile range 6.8 to 23.0) on a scale from 30 to 210, and uncertainty intervals contained the true observation 98% of the time.

CONCLUSIONS: We demonstrate how a rigorous statistical model can leverage repeated measurements to predict disease trajectory on an individual level. Our methodology could be extended to other diseases, such as depression, anxiety, or substance abuse, where PROs are measured serially to guide treatment. Our methods could also be extended to time frames beyond eight weeks, or used to predict outcomes such as suicidal behavior or hospitalization. The systematic use of repeated PROs offers the promise of precision medicine in the field of mental health.



A QUALITATIVE ANALYSIS OF SYMPTOMATOLOGY IN OLDER HOMELESS ADULTS: RESULTS FROM THE HOPE HOME STUDY

Adam Bazari[1]; Maria Y. Patanwala[2]; Colette Auerswald[1]; Margot Kushel[3, 4]. [1]UC Berkeley-UCSF Joint Medical Program, Berkeley, CA; [2]University of California, San Francisco, San Francisco, CA; [3]UCSF/ZSFG, San Francisco, CA; [4]UCSF, San Francisco, CA. (Control ID #2706528)

BACKGROUND: The homeless population is aging. Older homeless adults experience the premature development of age-related conditions, but less is known about their symptom burden or experience. Somatic symptoms (physical symptoms) increase with age. Social (loneliness) and existential (guilt, regret, hopelessness) symptoms are distinct from but can overlap with mental health symptoms such as anxiety and sadness. We used qualitative methods to characterize the experience of somatic, social, existential and social symptoms in older homeless adults.

METHODS: We conducted semi-structured interviews with participants from the HOPE HOME cohort, a longitudinal study of homeless adults age 50 and older. Inclusion criteria included: current homelessness and high somatic symptom burden, or at least one somatic symptom with high psychological, social, or existential symptom burden. Interviews covered participants' views on symptom etiology, impact on daily activities, personal strengths and management strategies. We employed Grounded Theory to analyze our data, including open coding, selective coding, and writing theoretical memos.

RESULTS: We interviewed 25 participants (60% men, 80% African American, ages 52–71). We found three emergent themes: 1) *Existential and social symptoms cause as much distress as somatic symptoms*. "My back pain actually is pretty real because I'm sleeping on cement but the thing that really gets me is the future. Sometimes there is a hopeless feeling that comes on." "Right now [my feelings are] combined because the more mental, the more physical I go through…the only thing that is really destroying me now is I want to see my mother." 2) *There is a clear relationship between the experience of homelessness and symptoms*. Participants describe how the experience of homelessness causes existential suffering that can manifest as somatic symptoms. "When I start thinking that I'm not gonna get off of this situation, my body starts to hurt, my stomach gets nauseated. It's burning like it's on fire." 3) *Participants manage symptoms with strategies from within and outside of biomedicine*, *including formal healthcare*, *religion*, *use of alternative medicines*, *and reliance on social supports*. "[When I'm feeling angry], I just start praising God until He comes and allow his spirit to wrap his arm around me; put me in a nice sleep. When I wake up, I feel a lot better."

CONCLUSIONS: The traumatic experience of homelessness causes and exacerbates physical and psychological distress. Among older homeless adults, existential symptoms are intertwined with and as distressing as somatic symptoms. To provide optimal care for this population, health care providers should screen for and address a broad range of symptoms, including somatic, psychological, existential and social.

A QUALITATIVE STUDY OF HOSPITALISTS' PERCEPTIONS OF PATIENT SATISFACTION METRICS ON PAIN MANAGEMENT

Susan L. Calcaterra[1, 2]; Anne Drabkin[1, 2]; Ingrid A. Binswanger[2, 4]; Joseph W. Frank[2, 3]; Jennifer Reich[5]; Stephen Koester[5]. [1]Denver Health, Denver, CO; [2]University of Colorado, Aurora, CO; [3]Denver Veterans Affairs Eastern Colorado, Denver, CO; [4]Kaiser Permanente Colorado, Denver, CO; [5]University of Colorado, Denver, CO. (Control ID #2707048)

BACKGROUND: Patient satisfaction metrics for pain management impacts federal incentive payments to hospitals. Hospitalists are key players in the delivery of high quality healthcare and are often financially compensated by their institutions for high satisfaction scores. Hospital-based initiatives to promote pain management may unintentionally contribute to excessive opioid prescribing. We aimed to understand hospitalists' perceptions of the impact of satisfaction metrics on pain management in their clinical practice.

METHODS: We conducted 25 open-ended, in-depth interviews with hospitalist physicians practicing in one of five hospitals (two university, one safety-net, one Veterans Affairs, and one private) located in Colorado or South Carolina. Four team members, two hospitalist physicians and two qualitative researchers, systematically analyzed transcribed interviews to identify emergent themes using a team-based, mixed inductive and deductive approach.

RESULTS: Hospitalists felt institutional pressure to earn high satisfaction scores for pain management, which they believed led to increased opioid prescribing. One hospitalist stated: "I'm well aware that I'm being watched for my patient satisfaction scores. So at least consciously it does not affect my position on opioids, which is not to say unconsciously it doesn't affect my decision." Hospitalists expressed concern that tying physician compensation to satisfaction scores commoditized pain to the patients' detriment. One physician recalled: "In my community practice, we were incentivized to keep people happy. It was expected that we keep up those scores. There is always pressure and you certainly don't want your patients to not be satisfied, but I think when you are given individual incentives based on that, it does sometimes change your procedures." Hospitalists believed that satisfaction scores would likely improve with more time spent at the patient's bedside discussing pain management alternatives and options, but felt they lacked the time to do so. One hospitalist explained: "I think the patient's satisfaction is mostly related to their relationship with the doctor rather than the pain. If you actually take the time to talk to the patient and they understand and they agree with you, then of course, the satisfaction scores are not going to be low." Finally, hospitalist perceived that hospital administrators interpreted high satisfaction scores as representative of quality healthcare delivery. One physician stated: "I think patient satisfaction is one of the things in medicine where it is so far removed from what is actually happening clinically at the bedside. I don't trust administrators who worry on a daily basis about patient satisfaction."

CONCLUSIONS: Patients should be educated about reasonable expectations for pain management in the hospital. Institutionally supported methods to improve physician-patient communication and engagement may promote both patient-centered, safe pain management and patient satisfaction.

A RANDOMIZED COMPARATIVE EFFECTIVENESS TRIAL OF A TRANSITIONAL CARE CLINIC: 180-DAY EFFECTS David T. Liss[1]; Christine Schaeffer-Pettigrew[1]; Emily Finch[1]; Andrew J. Cooper[1]; Avani Sheth[2]; Ashanti D. Tejuosho[1]; Caroline Teter[1]; Ronald T. Ackermann[1]. [1]Northwestern University, Chicago, IL; [2]Cook County Health and Hospital System, Chicago, IL. (Control ID #2706621)

BACKGROUND: Care transition interventions following hospital discharge can reduce subsequent rehospitalization. Early experimental evidence is mixed, particularly for vulnerable populations. This randomized trial examined a transitional care clinic for high-risk patients with no trusted medical home.

METHODS: We conducted a pragmatic comparative effectiveness trial of the Northwestern Follow-up Clinic (NFC), a transitional care clinic where a multidisciplinary care team provided coaching and assistance navigating the post-discharge transition through clinic visits and phone outreach, medication management support, social service and behavioral health coordination and transitioning to a permanent medical home. Between September 2015 and February 2016, patients were randomized to either NFC referral or referral to a federally qualified health center (FQHC); we used a 3:1 allocation ratio to meet the NFC site's capacity constraints. Following an emergency department (ED) visit, observation stay or inpatient admission, adults were eligible for inclusion if they had no medical home; were referred to the NFC by a hospital provider, or; expressed that they did not wish to return to their medical home or their medical home was insufficient to manage their needs. We examined differences in hospital care utilization during the 30 days after initial discharge (primary outcomes) and over 90-day and 180-day follow-up. Negative binomial regressions estimated differences in rates of: A) ED visits; B) observation stays; C) inpatient admissions, and; D) total hospital visits (i.e., A-C combined). Regressions adjusted for age, sex, insurance, race/ethnicity, driving distance, prior NFC use and type of initial hospital visit.

RESULTS: A total of 654 eligible patients were randomized and included in analyses (490 NFC arm, 164 FQHC arm). The sample was balanced on all sociodemographic characteristics; most patients were uninsured (34.6%) or insured through Medicaid (49.7%). At 30 days, intent-to-treat analysis demonstrated non-significant differences in adjusted rates of ED visits (incidence rate ratio [IRR] 0.82, $p = 0.46$), observation stays (IRR 0.61, $p = 0.19$) and inpatient admissions (IRR 0.67, $p = 0.16$), but there were fewer total hospital visits in the NFC arm (IRR 0.65, $p = 0.04$). After 90 days, NFC patients had fewer adjusted inpatient admissions (IRR 0.60, $p = 0.03$) and total hospital visits (IRR 0.60, $p = 0.01$). Over 180 days, NFC patients had fewer adjusted ED visits (IRR 0.62, $p = 0.04$), observation stays (IRR 0.52, $p = 0.02$), inpatient admissions (IRR 0.51, $p = 0.003$) and total hospital visits (IRR 0.49, $p < 0.001$).

CONCLUSIONS: Over 180-day follow-up, rates of all utilization outcomes under study were significantly lower in the NFC arm. These results demonstrate the potential of transitional care clinics to improve transitions and reduce hospital care use in high-need populations.

A RANDOMIZED TRIAL OF DIFFERENT LEVELS OF INPATIENT MEDICAL ATTENDING SUPERVISION OF TRAINEES Kathleen M. Finn[2]; Christiana Iyasere[2]; Yuchiao Chang[1]; Joshua Metlay[3]. [1]Harvard Medical School, Boston, MA; [2]MGH, Boston, MA; [3]Massachusetts General Hospital, Boston, MA. (Control ID #2703602)

BACKGROUND: While the relationship between resident work hours and patient safety has been extensively studied, there is limited data on the impact of different levels of inpatient attending supervision of internal medicine residents on patient safety or resident education.

METHODS: We conducted a 9-month clustered randomized trial on an academic inpatient medicine teaching service where 22 experienced faculty were asked to provide two different types of resident supervision: "routine oversight" (joining morning rounds to review new admissions only) and "responsive oversight" (joining morning rounds to review both new admissions and established patients). Each faculty served as their own control and the order of routine vs. responsive oversight was randomized for different 2-week blocks on service. The primary outcome was the rate of potential medical errors using an established algorithm based on medical record review. Secondary outcomes

included number of orders written, consultations and radiology studies. Resident education was evaluated with a time motion study to assess resident participation on rounds and surveys to assess both resident and attending perceived educational value of the two models.

RESULTS: A total of 1503 patients (5,691 patient-days) were included in the analysis. While the medical-error rate decreased by 9% from the routine oversight to the responsive oversight rounding models, this was not statistically significant (109.0 vs. 93.7 per 1000 patient days, $P = 0.26$). There was no difference in mean orders written in the morning (7 am–12 pm) or afternoon (12 pm–5 pm) in either routine vs. responsive models (63.8 vs. 81.3 total orders per day - morning, $P = 0.12$), in consultation notes (11.3 vs. 13.2 total consults notes per day, $P = 0.31$) or radiology studies (5.7 vs. 6.2 studies done per day, $P = 0.89$). A time motion analysis of 161 work rounds, found no difference in mean length of total time spent discussing established patients in the two models (202 +/− 46 min-routine vs. 202 +/− 57 min responsive, $P = 0.99$). The time a supervising resident spoke on work rounds did not change (58 +/− 20 min vs. 57 +/− 20 min, $P = 0.58$) but the time interns spoke did decrease when the attending joined rounds (64 +/− 19 min vs. 55 +/23 min, $P = 0.008$). In surveys both residents and interns reported that when an attending joined rounds they were less efficient, had decreased autonomy and had more fear of being judged. Attendings believed that the team knew their plan of care better though residents did not perceive this.

CONCLUSIONS: In an academic inpatient medical service, increased attending supervision did not significantly reduce medical errors or affect number of orders written, consultations or radiology studies. Residents perceived less autonomy and efficiency, though a time motion analysis found no difference in length of rounds or level of supervising resident participation.

A RANDOMIZED TRIAL OF INPATIENT LABORATORY TEST PRICE TRANSPARENCY IN THE ELECTRONIC HEALTH RECORD: THE PRICE TRIAL Mina Sedrak[3]; Jennifer S. Myers[4, 1]; Dylan Small[1]; Irving Nachamkin[4]; Justin B. Ziemba[5]; Dana Murray[4]; Gregory Kurtzman[1, 4]; Jingsan Zhu[1]; Wenli Wang[1]; Deborah Mincarelli[4]; Daniel Danoski[4]; Brian Wells[4]; Jeffrey S. Berns[4]; Patrick Brennan[4]; Bill Hanson[4]; C J. Dine[1, 4]; Mitesh Patel[1, 2]. [1]University of Pennsylvania, Philadelphia, PA; [2]Crescenz VA Medical Center, Philadelphia, PA; [3]City of Hope Comprehensive Cancer Center, Duarte, CA; [4]University of Pennsylvania Health System, Philadelphia, PA; [5]Johns Hopkins School of Medicine, Baltimore, MD. (Control ID #2700021)

BACKGROUND: While many health systems are considering increasing price transparency at the time of order entry, the evidence of its longer-term impact on clinician ordering behavior is unclear. Few randomized trials exist and among those conducted, they are single site, of limited duration (<6 months) and outcomes are not adjusted for patient characteristics or comorbidities.

METHODS: The Pragmatic, Randomized Introduction of Cost Data in the Electronic health record (PRICE) trial was a randomized, controlled trial conducted at three hospitals to evaluate the effect of displaying Medicare allowable fees for inpatient laboratory tests on clinician ordering behavior comparing changes during a one-year pre- and one-year post-intervention period. Test groups were randomly assigned to display fee data (intervention, $n = 30$) or not (control, $n = 30$) in the electronic health record. The main outcome measure was change in number of tests ordered per patient-day. Secondary outcome measures were change in number of tests performed per patient-day and associated fees per patient-day for tests ordered and performed. Multivariate adjusted models were fit to outcome measures adjusting for time trends and patient demographics, insurance, disposition, and comorbidity severity.

RESULTS: The sample included 98529 patients comprising 142921 admissions. Pre-intervention trends of order rates among the intervention and control groups were similar. In adjusted analyses of the intervention group compared to the control group over time, there were no significant changes in overall test ordering behavior (0.05 tests ordered per patient-day; 95% CI, −0.002, 0.09; $P = 0.06$) or associated fees (0.24 US dollars per patient-day; 95% CI, −0.42, 0.91; $P = 0.47$). Subset analyses found small but significant differences in tests ordered per patient-day based on patient intensive care unit (ICU) stay [(Patients with ICU stay: −0.16, 95% CI: −0.31, −0.01, $P = 0.04$)(Patient without ICU stay: 0.13, 95% CI, 0.08, 0.17; P <0.001)] and the magnitude of associated fees [(top quartile of tests based on fee value: −0.01, 95% CI, −0.02, −0.01; $P = 0.04$)(bottom quartile: 0.03, 95% CI, 0.002, 0.06; $P = 0.04$)]. Adjusted analyses of tests that were performed found a small but significant overall increase in the intervention group relative to the control group over time (0.08 tests performed per patient day, 95% CI, 0.03, 0.12; $P < 0.001$).

CONCLUSIONS: Displaying Medicare allowable fees for inpatient laboratory tests in the electronic health record did not lead to any meaningful or consistent changes in overall clinician ordering behavior. To our knowledge, this is one of the largest and longest evaluations of a randomized introduction of price transparency in a health care setting.

A RANDOMIZED TRIAL OF USING LOSS AVERSION AND ENHANCING GROUP-BASED INCENTIVES IN A PHYSICIAN PAY-FOR-PERFORMANCE PROGRAM Amol S. Navathe[1]; Andrea B. Troxel[2]; Amanda Hodlofski[1]; Kristen Caldarella[1]; Amelia Bond[1]; Qian Huang[1]; Shireen E. Matloubieh[1]; Lee Sacks[3]; Pankaj Patel[3]; Kevin G. Volpp[1]; Ezekiel J. Emanuel[1]. [1]University of Pennsylvania, Philadelphia, PA; [2]New York University, New York, NY; [3]Advocate Physician Partners, Chicago, IL. (Control ID #2706589)

BACKGROUND: Pay-for-performance (P4P) is the most pervasive value-based payment scheme despite little evidence of positive effects on patient outcomes. Yet, Medicare's upcoming Merit-based Incentive Payment System (MIPS) will expand traditional P4P even further. In this study, we examine whether two principles from behavioral economics, loss aversion and social pressure, can improve the effectiveness of physician financial incentives.

METHODS: We conducted a cluster randomized 3-arm clinical trial among 43 primary care and specialist practices at Advocate Physician Partners (APP), Chicago, IL. The active phase of the trial was January 1, 2016 to December 31, 2016, with follow-up through March 31, 2017. The control arm (Arm 1) was compromised of 21 physicians enrolled in the existing physician incentive payment design with quarterly performance feedback and a one-time bonus check (to be distributed April 1, 2017). Arm 2 tested the use of loss aversion among 26 physicians, in which incentive accounts were pre-funded with the total incentive dollars available over the 2016 program year. Arm 3 evaluated the performance of 24 physicians in an enhanced social pressure design that increased the group portion of the bonus to 50 percent. We performed an intention-to-treat analysis of treatment assignment on quality measure performance, including wellness (e.g. body mass index (BMI) screening), chronic care (e.g., appropriate beta blocker prescription), and mental health (e.g. depression screening) measures. Pairwise comparisons were evaluated with the Tukey range test. NOTE: Because the trial is still in follow-up period we present blinded results below - at the SGIM conference we will present final unblinded results.

RESULTS: There were 16,375 attributed patients with conditions related to APP P4P quality measures in the 2016 program year. Significant differences in performance were observed between the trial arms for 7 measures across 3 categories, though this tended to be true only in the greater than 65 age population. For example, for the 'beta blockers for chronic heart failure' measure in the chronic care category, we observed scores of 73% in Arm Y, 67% in Arm X, and 68% in Arm Z, differences of 5 and 6% ($P = 0.033$), however there was no significance for patients less than 65 years ($P = 0.75$). Similarly, for blood pressure measurement among cardiovascular disease patients over 65, we observed a score of 90% in Arm Y, 59% in Arm X, and 49% in Arm Z, differences of 31 and 41 percentage points ($P = 0.028$), while there was no significance for patients less than 65 years ($P = 0.66$). We observed similar trends for other measures such as 'depression screening and follow-up' and 'BMI assessment.'
CONCLUSIONS: The trial results suggest that the intervention in Arm Y may be a useful technique to make physician P4P incentives more effective. The performance improvements for patients over 65 may in part be explained by applicability of the quality measures.

A SAFE SPACE FOR SOLIDARITY, CONVERSATION, AND FINDING MEANING IN MEDICINE: REFLECTIVE WRITING WORKSHOPS LED BY NEAR-PEERS DURING THIRD-YEAR CLERKSHIPS Lorenzo R. Sewanan[2]; Kayleigh Herrick-Reynolds[2]; Priscilla Wang[1]; Andi Shahu[1]; Daniel Zheng[2]; John Encandela[2]; Anna Reisman[1]. [1]Yale School of Medicine, New Haven, CT; [2]Yale University, New Haven, CT. (Control ID #2704999)

BACKGROUND: Third-year medical students (MS3s) routinely experience mentally and emotionally challenging situations. They often lack the opportunity to debrief about these experiences due to time constraints, clinical hierarchy, and peer isolation during clerkships. Medical schools are increasingly incorporating reflective writing into curricula. A growing body of literature demonstrates the positive impact of reflective writing for medical students, including increased empathy and improved learning. These sessions are usually conducted by faculty facilitators, whose presence may prevent truly open discussion. We proposed that reflective writing workshops led by near-peers built into the third-year curriculum would provide a more effective model for honest reflection.
METHODS: Students and facilitators were medical students at Yale School of Medicine. The study occurred over a one-year period as MS3s rotated through four core clerkships. Facilitators were trained upperclassmen volunteers. MS3s were split into groups of 10–15 and required to attend a workshop at the end of each rotation. Rules of engagement were reviewed (confidentiality, title IX, commitment to active, judgment-free participation and listening). Workshops followed a structured but flexible series of questions progressing from warm-up questions to more challenging prompts. Evaluations were voluntary and anonymous, including (1) a paper survey of open-ended questions at the end of the session and (2) a longer, online end-of-year survey. We used a randomized iterative consensus process within a phenomenological framework to analyze the qualitative data. Major themes arising from this formal categorization process were used, along with representative quotes.
RESULTS: 266 session questionnaires were collected across 28 sessions, and 82/102 possible participants filled out the end-of-year survey. Most respondents (62%) indicated that they would attend the workshops even if not required. Our qualitative analysis revealed that the workshop provided a safe space for reflection and sharing. Many students were surprised to learn how willing peers were to share experiences. Students valued having protected time and found the prompt-based format beneficial. Common themes included challenges of patient care, medical hierarchy, interprofessional tension, and burnout. Students found that the format of writing and sharing provided solidarity within the class. Many stated that the workshops helped them process experiences not discussed before and encouraged them to focus more on emotions in clinical care. Most indicated that they would rather share negative experiences in a group led by near-peers than by faculty. Many described a desire to write and engage in active reflection in the future as a result of workshop participation.
CONCLUSIONS: The near-peer reflective writing workshops provided protected space to process difficult clerkship experiences, increased solidarity and support within the class, and encouraged MS3s to actively reflect.

A SIMULATED NIGHT ON CALL (NOC): ASSESSING THE ENTRUSTMENT OF NEAR GRADUATING MEDICAL STUDENTS FROM MULTIPLE PERSPECTIVES. Adina Kalet[1, 1]; Tavinder Ark[2]; Kinga L. Eliasz[1, 1]; Mike Nick[1, 1]; Grace Ng[1, 1]; Demian Szyld[3, 1]; Sondra Zabar[1, 1]; Martin V. Pusic[1, 1]; Thomas S. Riles[1, 1]. [1]New York University School of Medicine, New York, NY; [2]University of British Columbia, School of Population Health, Vancouver, BC, Canada; [3]Harvard Medical School, Boston, MA. (Control ID #2705395)

BACKGROUND: The AAMC has identified 13 Entrustable Professional Activities (EPAs) that all entering residents should be expected to perform on day 1 of residency without direct supervision regardless of specialty choice. We developed an immersive, Night on call (NOC) simulation to understand the measure of entrustment of all 13 Core EPAs from the perspective of patients, nurses, attendings, and peers.
METHODS: NOC is a 4-hour simulation, during which a medical student rotates through a series of authentic clinical coverage scenarios including: 4 standardized patient (SP) cases with varying degrees of complexity, each of which require first answering a call from a standardized nurse, (SN), then evaluating a SP with the SN in the room, making immediate management decisions and writing a coverage note; a phone call to an attending (Attn, an experienced clinician) to orally present (OP), and discuss the case, formulation of a clinical question and finding a best answer using digital library resources (EBM), a test of ability to recognize a pre-entrustable peer, and a handoff of 4 cases to a peer (HOff, portrayed by an senior medical student). Competency assessments were based on validated tools where available. Each rater provided an entrustment judgment. This included 9 raters providing a total of 16 entrustment judgments: 4 SPs and 3 SNs (1 rating competency and 1 rating communication each), 1 Attn based on OP, 1 peer rating based on the HOff (1 item each). Raters were trained in both case portrayal and rating reliability. This study is IRB approved. After exploring the relationships among competency measures and entrustment judgements, to test the hypothesis that NOC measures trustworthiness of our near graduates, we conducted a one-factor (entrustment) confirmatory factor analysis (CFA) with the 16-entrustment items allowing the ratings from the same raters and between raters on the same case to correlate. The CFA was conducted with a means and variance adjusted weighted-least squares estimation (WLSMV) to take the ordinal distributions of the entrustment items into account.
RESULTS: 73 medical students (39 women; Age 26.5 (+2.6) years) completed NOC. The one-factor CFA model fit the data ($\chi^2 = 155.27$, df = 112, $p < .001$, CFI = 0.97, TLI = 0.97, RMSEA = 0.07, $p > 0.05$). All but 2 of the 16 factor loadings were greater than 0.3, (Attn factor loading = 0.23 and the SP ratings from the first clinical case of NOC sequence (0.21)).

CONCLUSIONS: A single-factor model with 16 measures fit the entrustment framework within an ecologically valid simulated workplace suggesting that an individual student's clinical trustworthiness is measurable across discrete work activities. This work provides an assessment framework for the educational handoff from medical school to residency to ensure quality of care and patient safety.

A SYSTEMATIC REVIEW OF THE EXPERIENCES OF HEALTH CARE STAFF ON USING ELECTRONIC SYSTEMS FOR THE FOLLOW-UP OF PATIENT TEST RESULTS. Abdulaziz A. Mohammed[1]; Alaa Bagalagel[2]; Ahmad Noor[2]; Andrew K. Husband[1]; Simon P. Forrest[1]; Sarah P. Slight[1]. [1]Durham University, Teesside, United Kingdom; [2]King Abdulaziz University, Jeddah, Saudi Arabia. (Control ID #2706937)

BACKGROUND: Health Information Technology has the potential to improve the transfer of patient test results; [1] however, abnormal test results are still missed even with the use of electronic systems. The aim of this review was to explore health care staff experiences of using electronic systems for the follow-up of patient test results.

METHODS: The review followed the PRISMA guidelines and was registered on PROSPERO (CRD42016042944). Four databases were searched from Jan 2005-July 2016: Embase, Medline, CINAHL and PsycINFO. Primary articles were included if they focused on (1) any type of Electronic Health Records (EHRs) used for the follow-up of test results, (2) healthcare staff opinions and views of system(s), (3) any type of test result(s), (4) all disease states in both adult and paediatric populations, and (5) any health care setting. Commentaries, editorials, letters and any studies not available in English language were excluded. Three reviewers independently screened the titles, abstracts, and full texts of articles for inclusion, and also assessed the quality of those included using the Critical Appraisal Skills Programme (CASP) tool.

RESULTS: Our search returned 1,178 publications, 79 of which were duplicates. One thousand and eighty three were eliminated at the title (600), abstract (478) and full text stages (5). Fifteen articles and one abstract met our inclusion criteria. Six main themes were identified: (1) systems' design, (2) workload, (3) systems' infrastructure, (4) communication, (5) training, and (6) feedback. Users highlighted a number of benefits of using electronic systems (e.g. ability to access test results quickly). However, some reported having a lack of knowledge about system features and receiving insufficient training. [2] A proper training could highlight existing features specific to alert managements, which might be helpful in the follow-up of patient test results. On the other hand, lack of knowledge and training could increase follow-up time using electronic systems and contribute to a heavy workload. [2]

CONCLUSIONS: Users need to receive sufficient training on the use of electronic systems. More research is needed to explore how electronic systems could be further improved. This review only focused on healthcare staff experiences and did not cover patients' experiences. References: Singh H, Arora H, Vij M, Rao R, Khan M, Petersen L. A SYSTEMATIC REVIEW ON THE IMPACT OF SURGICAL INCIDENTS ON MEDICAL AND NON-MEDICAL OPERATING STAFF. Naresh Serou[1, 2]; Lauren M. Sahota[1]; Andrew K. Husband[1]; Simon P. Forrest[1]; Krishna Moorthy[2, 4]; Sarah P. Slight[1, 3]. [1]Durham University, Teesside, United Kingdom; [2]Imperial College Healthcare NHS trust, London, United Kingdom; [3]Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; [4]Imperial College London, London, United Kingdom. (Control ID #2700381)

BACKGROUND: The occurrence of surgical incidents can have a devastating effect, not only on the patient and their families, but also on the health professionals involved.

METHODS: The aim of this review was to explore the effect of surgical incidents on operating staff and what different coping strategies they used. This review followed the PRISMA-P reporting guidelines and was registered with the PROSPERO database (number: 42016042175). Studies were eligible for inclusion if they were primary research or reviews that focused on the effect of surgical errors on operating theatre staff in any health care setting. We were interested in articles that included data about the professional and personal impact of a surgical incident on staff, and the different coping mechanisms used by staff. We conducted the search in June 2016: MEDLINE in Process (Ovid) Jan 1950-Present, EMBASE (Ovid) Jan 1974-Present, CINALH 1982-Present, and PsycINFO 1967-Present. A customised data extraction form was used to capture pertinent information from included studies and the Critical Appraisal Skills Programme (CASP) tool to appraise their quality.

RESULTS: A total of 3,918 articles were identified, with 667 duplicate articles removed, and 3,251 excluded at the title (540), abstract (2,386) and full text (304) stages. Twenty-one articles (19 full text articles, 2 review articles) were included in the final review, eight of which focused on the impact of a surgical incidents on surgeons and anaesthetists. Only two articles involved theatre nurses and operating theatre team. Five key themes emerged: 1) the emotional impact on health professionals, 2) organisation culture and support, 3) individual coping strategies, 4) learning from surgical complications, 5) recommended changes to practice. Most articles reported that health professionals used different coping strategies in the aftermath of a surgical incident. Some surgeons discussed the event with their peers (more likely amongst senior surgeons), while others chose to reflect on the incident privately. Irrespective of different coping mechanisms used, informal open discussion with peers was viewed as helpful to regain self-confidence and positive thinking. Studies recommended establishing a mechanism by which deaths, serious incidents and never events were reviewed at an organisational level.

CONCLUSIONS: Health professionals can suffer emotional distress and use different coping strategies in the aftermath of a surgical incident. This review excluded studies that focused solely on the effect of malpractice claims on health professionals; these studies may have provided further insights on the emotional effects of incidents. Future research is needed to explore whether the impact of surgical complications differs amongst the wider operating theatre team.

ABNORMAL LFTS: FINDING THE NEEDLE IN THE…STACK OF NEEDLES? Andrew Schreiner[2]; William P. Moran[2]; Jingwen Zhang[1]; Justin Marsden[2]; Patrick D. Mauldin[2]. [1]MUSC, Charleston, SC; [2]Medical University of South Carolina, Charleston, SC. (Control ID #2707614)

BACKGROUND: Primary care physicians commonly encounter liver function tests in patients. The prevalence of abnormal liver function tests (LFTs) ranges from 9 to 21.7% in the general population, and the cause often remains unknown. Abnormal LFTs may indicate a wide range of pathologic processes, including cirrhosis, a leading cause of liver transplantation and death in patients with liver disease. The goal of this research is to better understand the burden of abnormal liver function tests in the primary care setting.

METHODS: We performed a retrospective analysis of patients with abnormal liver function testing in the primary care setting. We searched the electronic health record of an academic, internal medicine, patient-centered medical home (PCMH) at the Medical University of South Carolina (MUSC) over an 8 year period with patients seen by the clinic at least once, and with at least 1 abnormal liver function test element. Abnormal liver function tests were stratified by the degree to which they were abnormal and the pattern of abnormality.

RESULTS: Since 2008, the clinic provided care to 30,891 unique patients, of whom 26,907 underwent liver function testing, and 11,945 possessed at least one abnormal result. Total bilirubin values 3 times the ULN occurred in 722 patients, AST 3 times the ULN occurred in 2,177 patients, ALT 3 times the ULN in 1,399 patients, and alkaline phosphatase 3 times the ULN occurred in 362 patients. The proportion of these patients retested with similar results is shown in Table 1 (attached). Cholestatic patterns occurred in 2.9% of the test results, mixed patterns in 17.6% of the results, and hepatocellular injury patterns in 79.6% of the results.

CONCLUSIONS: Patients with abnormal liver function tests present to primary care physicians with remarkable frequency. Though most tests results fall into patterns of mild abnormality (<2 times the ULN) with a hepatocellular injury pattern, a wide array of abnormalities and patterns do appear.

Table 1: Proportion of Patients with Abnormal Liver Function Tests with Similar Results on Repeat

	Total bilirubin	AST	ALT	Alk phos
Abnormal (<2X ULN)	56.50%	63.20%	58.90%	67.40%
3X ULN	76.30%	59.90%	61.60%	69.60%
p-value	< 0.001	0.004	0.062	0.398

ACCESS TO A SCALE AND SELF-WEIGHING HABITS AMONG PUBLIC HOUSING RESIDENTS Carolyn Bramante[1]; Jeanne M. Clark[2]; Kimberly Gudzune[2]. [1]Johns Hopkins, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD. (Control ID #2702362)

BACKGROUND: Regular self-weighing is an effective weight management tool. This activity is contingent on an easily accessible scale; however, few studies examine how many people actually have regular access to a scale. Financial constraints might preclude the purchase of a scale, particularly among low-income populations that are disproportionately affected by obesity. Our objective was to determine the proportion of low-income public housing residents who have access to a scale and their self-weighing habits, as well as determine individual characteristics associated with scale access.

METHODS: We conducted a cross-sectional survey of randomly selected households in public housing developments in Baltimore, MD. We asked participants if they had “regular access to a scale where they can weigh themselves,” and to describe their self-weighing habits (“I weigh myself daily” with responses dichotomized as ‘never or hardly ever/no scale access’ versus ‘some/about half/much of the time/always’). We then used t-tests or Chi^2 tests, as appropriate, to examine the association of scale access with the following characteristics: age, gender, marital status, education, employment, food insecurity, smoking status, physical activity, diet, BMI, and health status.

RESULTS: Overall, 266 head of households participated (48% response rate). Mean age was 45 years, 86% were women, 95% were black, and 54% were obese. Only 32% reported having access to a scale; however, 78% of people who had access reported engaging in at least some self-weighing. Table 1 compares characteristics between those with and without access to a scale. Residents who had access to a scale were significantly older ($p = 0.03$) and significantly less likely to be disabled/unemployed ($p = 0.01$) or food insecure ($p < 0.01$). We found no other statistically significant associations with any other factors.

CONCLUSIONS: While only one-third of public housing residents have access to a scale, those who do have access self-weigh with some regularity. Economic status appears to be a factor influencing scale access in this population, as we found a significant inverse association with markers of low economic status. Therefore, addressing economic barriers to scale ownership may be a reasonable target for future weight management interventions in low-income populations.

Table 1. Characteristics associated with scale access

	No Scale Access (N=181)	Access to a Scale (N=85)	p-value
Demographics			
Mean age (years)	43	47	0.03
% Female	88	81	0.11
% Single	80	74	0.32
% Less than high school education	38	26	0.13
% Disabled/unemployed	77	61	0.01
% Food insecure	74	53	<0.01
Health behaviors			
% Never smoker	27	31	0.56
% Physically active	18	24	0.31
% High fruit/vegetable intake	25	26	0.94
% High added sugar intake	28	20	0.18
Health status			
Mean BMI (kg/m^2)	32	32	0.84
% Heart failure	4	5	0.92
% Hypertension	57	55	0.74
% Diabetes	21	18	0.64
% Depressive symptoms	33	27	0.36

ACCESS TO MEDICAL CARE FOR AMERICANS WITH EXCHANGE-BASED INSURANCE: EARLY EVIDENCE FROM THE NATIONAL HEALTH INTERVIEW SURVEY Ilana B. Richman[3]; Douglas K. Owens[1]; Jay Bhattacharya[4]; Steven Asch[2]. [1]VA Palo Alto/Stanford University, Stanford, CA; [2]VA/Stanford, Menlo Park, CA; [3]Yale University School of Medicine, New Haven, CT; [4]Stanford University School of Medicine, Stanford, CA. (Control ID #2706424)

BACKGROUND: In 2016, an approximate 12.7 million Americans purchased health insurance through exchanges established by the Affordable Care Act. Plans sold on the exchanges, though, have been criticized for offering excessively narrow networks, which may limit access to care. The goal of this study was to evaluate access to care for those with exchange-based coverage compared to those with employer-sponsored insurance.

METHODS: We used data from the National Health Interview Survey, an annual, nationally representative survey, during 2014 and 2015. We included adults ages 18–64 who had either an employer-sponsored plan or an individual plan purchased on an exchange. In evaluating access to care, we used logistic regression to adjust for age, sex, race/ethnicity, poverty status, employment status, health status, history of uninsurance, and survey year. Results are expressed as predicted probabilities.

RESULTS: Our analysis included 15,795 adults, of whom 2,023 had purchased insurance on an exchange. Exchange participants were older (43.6 vs 41.3 years, $p < 0.001$) and were less likely to be white (74% vs 84%, $p < 0.001$) than those with employer sponsored coverage. Those with exchange-based plans were less likely to be working (67% vs 85%, $p < 0.001$), were more likely to have a household income below 400% of the federal poverty level (74% vs 40%, $p < 0.001$), and were more likely to be in poor or fair health (10% vs 5.6%, $p < 0.001$). Those who purchased insurance on the exchanges were less likely to identify a usual source of care (79% vs 84%, $p < 0.001$) and were more likely to have had trouble finding a primary care physician (6.6% vs 3.2%, $p < 0.001$) than those with employer-sponsored coverage. Those with exchange-based coverage were also more likely to have waited for appointments (7.2% vs 5.1%, $p = 0.007$) and were more likely to have had trouble affording specialty care (6.8% vs 3.9%, $p < 0.001$). In spite of these differences, those with exchange-based coverage were not less likely to receive treatment for chronic conditions including hypertension (82% vs 83%, $p = 0.70$) and hypercholesterolemia (72% vs 76%, $p = 0.32$). Lastly, despite barriers to care, those with exchange-based coverage were more likely to report that their coverage was an improvement from the year prior (31% vs 11% $p < 0.001$), though more also reported that their coverage was worse (18% vs 11%, $p < 0.001$).
CONCLUSIONS: Although exchange-insured patients faced some barriers to care compared to those with employer-sponsored insurance, differences were small and compared favorably to previously published rates among the uninsured. Those with exchange-based coverage also received care for chronic conditions at rates similar to those with employer-sponsored insurance. Many with exchange-based insurance viewed their coverage as an improvement, likely reflecting a prior history of uninsurance or underinsurance. Tracking access to care will be even more crucial as the federal policy environment changes.

ACCESSIBILITY OF OUTPATIENT BEHAVIORAL HEALTHCARE IN ONE METROPOLITAN AREA Hannah Spellman[2]; Daniel J. Coletti[1]; Leslie Rosenberg[1]; Lauren Block[1, 2]. [1]Northwell Health, Lake Success, NY; [2]Hofstra Northwell School of Medicine, Hempstead, NY. (Control ID #2706395)

BACKGROUND: The USPSTF recommends screening for depression in primary care, provided that adequate systems are in place to ensure timely and "appropriate" follow-up. It is unclear whether adequate access exists for patients with non-emergent behavioral health needs. The objective of this project was to assess availability of outpatient behavioral healthcare within two densely populated counties in the New York metropolitan area.
METHODS: The cross-sectional survey included all community-based, hospital-affiliated, and university-affiliated outpatient behavioral health centers located in Nassau and Queens Counties in NY. Facilities were compiled from the Northwell General Internal Medicine Directory of Behavioral Health Services and service directories from the local county Department of Health. Calls were made by a single caller with a predetermined script weekdays from June through July 2016, between 10 am and 4 pm. Data collected were summarized and analyzed with descriptive statistics.
RESULTS: The inclusion criteria were met by 40 facilities. Contact was made with 93% of facilities within three calls, but only 50% of facilities on the first call. Over half of the facilities (55%) had intake appointments available within the week; however, only 20% had *treatment* appointments within the week, and only 3% offered an appointment with a prescribing provider within a week. Within one month, 53% of facilities had psychotherapy treatment appointments and 32% also had medication evaluation appointments. Two-thirds (65%) of facilities had waits of more than a month to see a prescribing provider. The availability of additional treatment services varied widely, with 68% offering a provider who spoke a language other than English. 86% of facilities accepted an assortment of public and private insurance plans, and 76% of facilities had an income-based sliding payment scale for uninsured patients.
CONCLUSIONS: The availability of intake appointments masks longer wait-times for medication management. Shorter wait times to intake may help patients with urgent needs find adequate treatment, and longer wait times to medication management may be suitable for patients with mild behavioral health problems. However, behavioral healthcare may be inadequate for patients with moderate diagnoses who will not be treated urgently, but who should not wait the length of time to an appointment. More research is needed to assess the true adequacy of behavioral healthcare for adults in our region and nationwide. Integrating additional behavioral healthcare services into primary care settings might improve access.

ACCULTURATION IS ASSOCIATED WITH DIETARY PATTERNS IN SOUTH ASIANS IN AMERICA Meghana D. Gadgil[2]; Namratha R. Kandula[1]; Alka M. Kanaya[2]. [1]Northwestern University, Chicago, IL; [2]University of California, San Francisco, San Francisco, CA. (Control ID #2699896)

BACKGROUND: Cultural beliefs and practices may affect dietary patterns in South Asians. We aimed to determine whether the strength of cultural beliefs and practices affects adherence to a particular dietary pattern in South Asians in the United States.
METHODS: We conducted a cross-sectional analysis including South Asians aged 40–84 years without known cardiovascular disease who were enrolled in a community-based cohort called Mediators of Atherosclerosis in South Asians Living in America (MASALA). A validated food frequency questionnaire, a multi-dimensional measure of traditional cultural beliefs and assessment of cultural practices were collected at baseline. We used principal component analysis with varimax rotation to determine dietary patterns, and multivariable logistic regression models for associations with cultural beliefs and practices.
RESULTS: Of the 892 participants included in our analysis, 47% were women. We identified 3 major dietary patterns, which we termed "Animal Protein," "Fried snacks, Sweets, High-fat dairy" and "Fruits, Vegetables, Nuts, Legumes." A weaker traditional cultural beliefs score was associated with higher odds of adherence to the Animal Protein dietary pattern [OR(95%CI) 1.66 (1.40, 1.97)] and lower odds of adherence to the Fried snacks, Sweets, High-fat dairy pattern [0.76 (0.64, 0.90)]. Participants who do not fast [3.34 (1.27, 8.83)], eat South Asian food in restaurants [5.56 (1.09, 28.29)], shop at South Asian grocery stores {11.91(2.26, 62.71)], eat outside of the home [0.26 (0.16, 0.42)] or who have fewer South Asian friends [5.50 {1.13, 26.63)] had higher odds of consuming the "Animal Protein" dietary pattern (all $p < 0.05$). Those who do not fast [0.25 (0.10, 0.63)] or shop at South Asian grocery stores [0.15 (0.04 .53)] were less likely to consume the "Fried Snack, Sweets and High-fat dairy" dietary pattern (all $p < 0.05$). There was no significant association of strength of cultural beliefs or practices with the Fruits, Vegetables, Nuts and Legumes pattern.
CONCLUSIONS: South Asians in the United States with stronger traditional cultural beliefs and practices were more likely to consume the Fried Snacks, Sweets and High-fat dairy dietary pattern, and less likely to consume the Animal Protein pattern. Prevention programs should consider how to modify these dietary patterns as part of comprehensive risk reduction in South Asians.

ACUTE AMBULATORY ASSESSMENT TO AVOID ADMISSION (5ALPHA): A QUALITY IMPROVEMENT STUDY Tara O'Brien[2, 1]; Robert Wu[2, 3]; Ian Stanaitis[1]; Geetha Mukerji[2, 1]; Minnie Rai[1]; Sam Sabbah[2, 3]. [1]Women's College Hospital, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]University Health Network, Toronto, ON, Canada. (Control ID #2700001)

BACKGROUND: In Canada, changing patient demographics caused by aging and increased patient multimorbidity has contributed to an increased number of emergency department (ED) visits and hospitalizations. The University Health Network (UHN) in Toronto, Ontario has experienced a 6% yearly increase in ED visits and general internal medicine (GIM) hospitalizations. The goal of this quality improvement (QI) initiative is to prevent GIM referrals and inpatient admissions at UHN by providing rapid follow up to patients in a short stay medical unit staffed by a GIM physician, the Acute Ambulatory Care Unit (AACU) at Women's College Hospital (WCH).

METHODS: This was a pre-post design study, using the Model for Improvement QI framework. For UHN ED patients who required an urgent GIM consultation but were stable for discharge, we provided a follow up in the AACU within 24–48 hours of discharge. Consent was obtained from patients and data was collected prospectively. Process measures were collected including patient demographics, need for inpatient admission, and impact of AACU as perceived by the ED physician. The primary outcome was the monthly rates of GIM consults at the Toronto General Hospital (TGH) and hospitalizations at UHN. Qualitative data was collected using a patient experience survey. The investigators met monthly to review referrals and patient outcomes and PDSA cycles were used to improve the model of care delivery over time.

RESULTS: A total of 788 patients were seen in the AACU over a one-year period. The mean age of patients was 56, 52% females and 46% had 3 or more chronic medical conditions. The three most common reasons for referral were anemia (7%), hypertension (6%) and abdominal pain (6%). The rate of TGH GIM consults remained stable at a mean of 570 consults per month despite a 3.5% increase in ED visits. Similarly the number of inpatient admissions at UHN remained unchanged with a mean of 975 per month. While in the AACU, 36% of patients had medical imaging, 27% had subspecialty consultation and 24% had non-invasive cardiac testing. Additional follow up in the AACU was required in 58% of patients and 2.5% required transfer back to UHN for admission. The goal of the referral as perceived by the ED physician was to avoid admission, avoid GIM consult and provide rapid follow up in 27 37 and 63% of cases respectively. Results from the patient experience survey demonstrated that 77% of patients were extremely satisfied with their care in the AACU and 92% would recommend this experience to other patients.

CONCLUSIONS: This QI initiative successfully provided safe rapid follow up to GIM patients discharged from the ED in the AACU, resulting in perceived avoidance of GIM consult or admission and high patient satisfaction. Our cross-institutional model of care likely contributed to the flattening of inpatient admissions at UHN which had been steadily increasing. This model of care is a potential scalable solution to address the problem of hospital overcrowding.

ACUTE MYOCARDIAL INFARCTION READMISSION RISK PREDICTION MODELS: A SYSTEMATIC REVIEW OF MODEL PERFORMANCE Lauren N. Smith; Anil N. Makam; Douglas Darden; Ethan Halm; Oanh K. Nguyen. UT Southwestern Medical Center, Dallas, TX. (Control ID #2700088)

BACKGROUND: Hospitals are subject to federal financial penalties for excessive 30-day hospital readmissions for acute myocardial infarction (AMI). Prospectively identifying AMI patients at high risk for readmission could help prevent 30-day readmissions by enabling targeted interventions. However, the effectiveness of AMI readmission risk prediction models is unknown.

METHODS: We systematically searched Ovid MEDLINE, Embase, the Cochrane Library, and CINAHL databases from inception through March 2016 for studies of risk prediction models for 30-day hospital readmission among adults with AMI. Two independent reviewers abstracted data and assessed the risk of bias.

RESULTS: We identified 4532 unique titles; after full-text review, we identified 8 studies describing 9 unique risk prediction models across both academic and community hospitals. Seven studies assessed models predicting all-cause 30-day readmissions; of these, we included only the 5 studies that assessed model performance in a validation cohort in our final analysis (Table). Three studies only included patients ≥65 years old. Observed readmission rates ranged from 13.0–19.7%. Four models used administrative data, 1 used electronic health record data, and 1 used 'hospital data' not otherwise specified. Models included between 7–37 predictors; comorbidities, demographic characteristics, and utilization metrics were the most frequently included predictors. Most models ($n = 4$), including the Centers for Medicare and Medicaid Services (CMS) AMI administrative model had modest discrimination (C-statistic range 0.62-0.66). A modified version of the CMS AMI model enriched with idiosyncratic combinations of SES variables had the best discrimination (C-statistic 0.76 for both); but this was assessed among Medicare fee-for-service beneficiaries in a single state, potentially limiting generalizability. Predicted readmission rates ranged from 8% among the lowest risk individuals to 35.7% among the highest risk individuals, though these data were unavailable for 3 of 5 studies.

CONCLUSIONS: We found a limited number of validated AMI readmission risk prediction models with modest predictive ability. Future modeling strategies should assess the potential impact of including more clinically detailed data on improving model performance.

Table – Summary of Acute Myocardial Infarction-Specific Risk Prediction Models for 30-Day Readmissions

Study	Model	Setting	Validation cohort (N)	Domains of Predictors [a]	No. of predictors	Discrimination (c-statistic) [b]	Calibration [c]
Hebert et al, 2014	EHR Model	1 AMC in Ohio, USA	594	D, C, L, U, M	7	0.66	Not reported
Hilbert et al, 2014	Administrative Model	California State Inpatient Database	1,171	D, C, U, P	31	0.65	9.6-35.7% [d]
Krumholz et al, 2011	CMS Administrative Model	National Medicare data	(1) 100,285 (2) 220,803 (3) 130,944	D, C	31	(1) 0.63 (2) 0.62 (3) 0.59	(1) 8-32% (2) 8-32% (3) 13-31%

ADAPTING A HEALTH SYSTEM INTERVENTION FROM KAISER PERMANENTE TO IMPROVE HYPERTENSION MANAGEMENT AND CONTROL IN A LARGE NETWORK OF SAFETY NET CLINICS Valy Fontil[1, 2]; Reena Gupta[1]; Kirsten Bibbins-Domingo[1, 2]. [1]University of California San Francisco, San Francisco, CA; [2]Zuckerberg San Francisco General Hospital, San Francisco, CA. (Control ID #2703857)

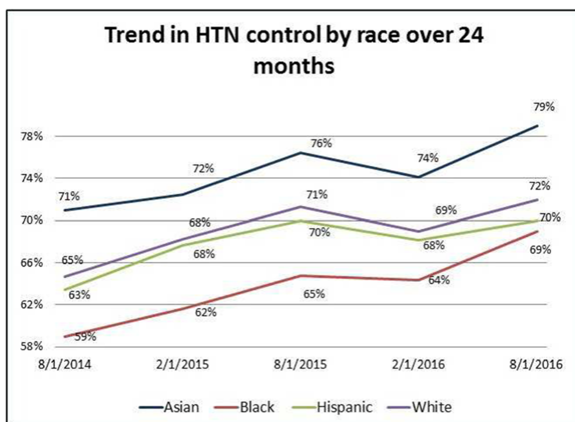
BACKGROUND: Nearly half of Americans have uncontrolled blood pressure (BP). Health system interventions that include evidence-based hypertension (HTN) treatment algorithms have successfully improved BP control in high-functioning integrated health systems such as Kaiser Permanente (KP),

but it is unclear whether these interventions can work in safety-net clinics that disproportionately care for populations at highest risk for HTN. National efforts to improve population control and to reduce disparities in HTN will require adaptation of proven interventions to safety-net settings.

METHODS: We used the precede-proceed framework to adapt KP's treatment algorithm within a multi-component health system intervention for HTM management, implement it in a network of 12 safety-net clinics in the San Francisco Health Network, and evaluate its impact on BP control. We evaluated the program's effectiveness in improving the BP control rate (proportion of patients whose BP is at the target goal) and use of recommended medications such as fixed-dose combination drugs (FDC) at 24 months post-intervention. We used linear regression analyses to assess for post-intervention trends in BP control and use of FDCs. We assessed BP control rates by race and examined trends in ACE-inhibitor monotherapy in African Americans, which is associated with lower efficacy and delays in achieving BP control.

RESULTS: At 24 months post-intervention, there was a significant trend in increasing rates of BP control (65 to 72%, $P < 0.01$). Improved BP control occurred in blacks (59 to 67%, $P < 0.01$) Whites (65 to 73%, $P < 0.01$), and Latinos (63 to 73%, $P < 0.01$). Improved BP control among Asians did not reach statistical significance (71 to 75%). Use of fixed-dose combination drugs increased from 8 to 15% ($P < 0.01$). ACE-inhibitor monotherapy among blacks trended downward but remained high (33 to 14% $P < 0.01$).

CONCLUSIONS: Adaptation of a HTN treatment intensification algorithm from Kaiser Permanente led to improved BP control at a large network of safety-net clinics. Our findings can inform best practices for health system interventions to improve BP control at safety-net clinics which must play a pivotal role in achieving improved BP control and reducing HTN disparities.



ADDICTION TREATMENT ORGANIZATIONS' ADOPTION OF ELECTRONIC HEALTH RECORDS: A NATIONAL SURVEY AT THE ONSET OF HEALTH REFORM Peter D. Friedmann[1, 2]; Donna Wilson[1, 2]; Christina Andrews[4]; Harold Pollack[3]; Thomas D'Aunno[5]; Keith Humphreys[6]. [1]UMass Medical School - Baystate, Springfield, MA; [2]Baystate Health, Springfield, MA; [3]University of Chicago, Chicago, IL; [4]University of South Carolina, Columbia, SC; [5]New York University, New York, NY; [6]Stanford University, Palo Alto, CA. (Control ID #2705630)

BACKGROUND: Electronic Health Record (EHRs) are essential technology for health care organizations to participate in health reform innovations. Addiction treatment organizations were excluded from federal initiatives to promote adoption of EHRs; their use of EHRs is uncertain.

METHODS: This analysis uses data from a 2014 survey of a national random sample of addiction treatment organizations. Directors and supervisors responded to detailed questionnaires about program structure and processes, including adoption of EHRs.

RESULTS: Of 692 responding programs, directors of 390 (weighted 55%) reported having an EHR and another 160 (weighted 24%) planned to adopt one within 2 years. Only 157 (weighted 22%) participated in Health Information Exchanges. In multinomial logistic models, correlates of having an EHR were state funding for EHR adoption (OR 3.5, 95% CI 1.2–10.6); private not-for-profit (OR 3.6, 95% CI 1.4–9.2) or public (OR 4.6, CI 1.1–19.5) compared to for-profit ownership; having accreditations (e.g. JCAHO, CARF) (OR 2.96, CI 1.4–6.5); being a new program (OR 8.3, CI 1.4–50.9); having an average caseload greater than 40 clients (versus 10; OR 10.2, CI 2.4–43.5); and reporting more perceived barriers to an EHR (OR 0.81, CI 0.72–0.92). Planning for EHR adoption within 2 years was correlated with increasing perceived competition (OR 2.5, 95% CI 1.1–5.6). State implementation of the Affordable Care Act did not influence EHR adoption.

CONCLUSIONS: Only 55% of addiction treatment programs had an EHR at the advent of health reform. Another 24% planned to adopt with 2 years. State funding, non-profit or public ownership, larger caseload, and fewer perceived barriers appeared to be related to EHR adoption. Fewer than one-quarter participate in Health Information Exchanges. These technological limitations may constrain addiction treatment organizations ability to participate in innovations and modernization resulting from health reform.

ADDRESSING COMPLEX PATIENTS' PSYCHOSOCIAL PRIORITIES DURING TIME-LIMITED PRIMARY CARE VISITS

Eilann C. Santo[1]; Michelle T. Vo[2]; Richard W. Grant[2]. [1]Kaiser Permanente Northern California, San Francisco, CA; [2]Kaiser Permanente Northern California, Oakland, CA. (Control ID #2706484)

BACKGROUND: Providing patient-centered primary care during time-limited visits is challenging. Complex patients in primary care often present with both medical and psychosocial concerns. Given the important impact of psychosocial issues on medical management, addressing patients' psychosocial concerns is essential to providing effective, patient-centered clinical care. As part of an ongoing multi-site, randomized trial examining patient priorities, we had the unique opportunity to examine how patient self-identified psychosocial vs medical visit priorities were addressed by their primary care physicians.

METHODS: Patients identified their top 1 or 2 visit priorities in the waiting room prior to a primary care visit as part of the Aligning Patient and Provider Priorities clinical trial (ClinicalTrials.Gov NCT02707146). We categorized patient visit priorities as either psychosocial (e.g. depression, anxiety, substance use, stress, or personal safety) or medically related. We performed a structured chart review of visit progress notes, after-visit summaries, and follow up secure email messages to determine whether the provider addressed the patient's visit priority. Evidence that the priority was addressed was based on documentation in progress note, change to problem list, prescription of diagnostic or therapeutic interventions, referral to specialist, or communication about the problem through after visit summary or secure messages. We used Fisher's exact tests to compare provider action for psychosocial vs. medically related patient priorities.

RESULTS: Patients in our cohort ($n = 103$) had a mean age of 62 (SD 12) years; 69.9% were female, 43.0% were African American, and 53.4% had a history of a mental health disorder. Nearly one quarter of patients (18.6%)

reported a psychosocial concern as one of their top two priorities for their primary care visit. Overall, patients listed 137 unique priorities (1.3/patient). Psychosocial priorities were less likely to be addressed during the visit compared to medically related priorities (62.5% vs 91.2% $p = 0.001$). Similarly, psychosocial priorities were less likely to receive clinical action or follow up (50.0% vs 86.7%, $p < 0.0002$) or post-visit information from a primary care doctor than medically related health priorities (12.5% vs 33.6%, $p = 0.05$).
CONCLUSIONS: Our findings suggest that patient psychosocial priorities are less likely to be addressed by primary care physicians than medically related priorities. To provide truly patient-centered primary care for patients with complex disease, physicians should be sure to acknowledge patients' psychosocial concerns and provide the same guidance and follow up as medically related problems.

ADDRESSING THE SOCIAL NEEDS OF HYPERTENSIVE PATIENTS: THE ROLE OF PATIENT-PHYSICIAN COMMUNICATION AS A PREDICTOR OF MEDICATION ADHERENCE Antoinette Schoenthaler[1]; George Knafl[2]; Kevin Fiscella[3]; Gbenga Ogedegbe[1]. [1]NYU School of Medicine, New York, NY; [2]UNC Chapel Hill, Chapel Hill, NC; [3]University of Rochester School of Medicine & Dentistry and Wilmot Cancer Center, Rochester, NY. (Control ID #2701644)

BACKGROUND: Poor medication adherence is a significant public health problem in patients with hypertension. The patient-physician relationship offers an ideal opportunity to address patient non-adherence as physicians' communication skills contribute to as much as 50% of the quality of care patients' receive. Despite this evidence, there is no empirical data on how the informational and relational aspects of patient-physician communication affect patient's actual medication-taking behaviors. The aim of this study was to evaluate the impact of patient-physician communication on medication adherence among a sample of primary care physicians and their Black and White hypertensive patients.
METHODS: Cohort study of 92 hypertensive patients (mean age: 60 years) and 27 primary care physicians (mean age: 36 years) in two safety-net primary care practices in New York City. Patient-physician encounters were audiotaped at baseline; medication adherence data were gathered continuously over the 3-month study with an electronic monitoring device. Audiotape analyses of patient-physician communication were coded using the Medical Interaction Process System. Six categories of communication were computed: 1) patient centeredness; 2) patient assertiveness; 3) psychosocial focus; 4) information exchange; 5) physician disclosure-promoting; and 6) physician verbal dominance. Frequencies of content codes were also calculated for the proportion of the discussion specific to: hypertension; antihypertensive medications; patient-physician social conversation; and discussions about patient's social circumstances (i.e., patient's living situation, relationship with spouse/partner). Adaptive statistical modeling methods based on likelihood cross validation were used to analyze the adherence data.
RESULTS: The majority of patients were Black, 58% women, and most were seeing the same physician for at least 1 year. Approximately half of physicians were White (56%), 67% women, and have been in practice for 6 years. Fifty-eight percent of patients exhibited poor adherence to prescribed antihypertensive medications. Two categories of patient-physician communication predicted poor medication adherence in the multivariate adaptive logistic regression model: fewer discussions about patients' social circumstances (OR: 6.03, 95CI:2.15-17) and about their antihypertensive medications (OR: 5.64, 95CI:1.49-21.3).
CONCLUSIONS: The odds of poor medication adherence are nearly six times greater when patient-physician interactions do not address patients' social circumstances or their medication regimen. These findings support the importance of adherence counseling and attending to the social determinants of health in routine care of low-income patients in ambulatory practices.

ADOLESCENTS AND ADULTS WITH DOWN SYNDROME RARELY RECEIVE AGE-, GENDER-, AND SYNDROME-SPECIFIC PREVENTIVE HEALTHCARE Kristin M. Jensen[1, 2]; Elizabeth J. Campagna[2]; Elizabeth Juarez-Colunga[2, 2]; Desmond K. Runyan[2]; Allan V. Prochazka[1]. [1]University of Colorado School of Medicine, Aurora, CO; [2]University of Colorado, Aurora, CO. (Control ID #2705315)

BACKGROUND: Down syndrome (DS) has known preventive healthcare recommendations that require lifelong supervision. Given the increasing life expectancy of persons with DS into their 50s, they now face age- and gender-specific health conditions in addition to their DS-specific comorbidities. However, their medical care is increasingly provided by PCPs less familiar with the special health risks of DS. In this retrospective study, we evaluate adherence to DS- and age/gender-specific preventive recommendations among adolescents and adults with DS.
METHODS: Using Medicaid claims data (2006–2010) in CA, CO, MI, and PA, we defined our cohort as DS patients ≥12yo who were enrolled in Medicaid for ≥45/60mo without concurrent Medicare. Providers were considered PCPs if they billed ≥10 well exams in a year. Patients without a PCP were excluded ($n = 450$) for a total of 3501 patients. PCPs with ≥80% of their well-examinations billed as well-child or well-adult examinations were categorized as child- or adult-focused, respectively. The remaining PCPs were classified as mixed-focus. Age-appropriate PCPs are defined as having a focus consistent with a patient's age: 12–17yo = child-focused, ≥26 = adult-focused; 18–25yo are in transition and can be appropriately seen by any PCP. Levels of adherence to DS- and age/gender-specific preventive screening activities were classified as good (≥80%), moderate (50– <80%), and poor (<50%). Differences in adherence were evaluated using Pearson's chi-squared tests.
RESULTS: Our cohort was 52% male, with 21% adolescent (12-17yo), 32% transition age (18-25yo), and 47% adult (≥26 yo). 52% of the cohort (40% of adults) received primary care from child-focused PCPs, with the remaining split equally between adult- and mixed-focus PCPs. Less than half of our cohort had ≥1 well examination during the study (44% of those with an age-appropriate PCP vs. 37% of those without an age-appropriate PCP, $p < 0.001$). Influenza vaccination rates were similarly low (age-appropriate PCP 33%; age-inappropriate PCP 38%, $p = 0.003$). Most preventive healthcare recommendations had poor adherence (<50%) regardless of whether they were DS- or age/gender-specific: well examinations; vaccinations; breast, cervical, and colon cancer screenings; sleep apnea; and hearing. Lipids, vision, prostate cancer, and thyroid screenings met moderate adherence (50– < 80%). Echocardiograms to screen for acquired valve disease were highly utilized in patients with preexisting congenital heart disease (89%) but less so in those without congenital heart disease (22%, $p < 0.001$)
CONCLUSIONS: Adherence to age/gender- and DS-specific preventive healthcare recommendations was low during this 5 yr study in adolescents and adults with DS, regardless of patient age or PCP focus. Given the medical complexity of this otherwise vulnerable population, this represents a significant opportunity to improve primary care for persons with DS to decrease morbidity and improve overall health.

ADVANCED CARE PLANNING AT AN ACADEMIC PRIMARY CARE CLINIC Carlene P. Partow; Omar Mesina; Leslie Sheu; Brent Kobashi. University of California, San Francisco, San Francisco, CA. (Control ID #2692158)

BACKGROUND: Advanced care planning (ACP) is becoming increasingly important in a primary care setting due to the growing aging population. Despite this, recent studies show that conversations around ACP between patients and their providers are low, as low as 30% even among terminally ill cancer patients.[1] Providers and clinic leaders are turning to completion of Advanced Directive (AD) and, in some cases, Physician Orders for Life-Sustaining Treatment (POLST) forms as objectives measures of physician ACP conversations. Little is known about ACP practices in academic primary care settings where patients with complex medical issues often receive care.
METHODS: We sought to understand current local practice of AD and POLST form completion at our urban academic primary care clinic at the University of California, San Francisco, and explored physician barriers to having these conversations. We extracted patient data from our clinic's electronic health record to determine AD and POLST completion rates. Concurrently, we administered an anonymous 13-question electronic survey to physicians, residents, medical students and nurse practitioners. The survey was designed to: 1) assess provider comfort conducting ACP conversations, 2) identify the greatest barriers to ACP, and 3) gain feedback on interventions to increase rates of AD and POLST completion. In addition, we collected qualitative data through provider focus groups.
RESULTS: As of October 7, 2016, 2,578 out of 23,216 (11%) of patients have ADs completed and only 618 (3%) have POLSTs completed. Among patients 60 years of age and older, 19% had an AD and 6% had a POLST. Fifty-nine of the 77 (77%) providers completed the survey. Thirty-four of the 59 providers (58%) did not believe AD/POLST completion rates were satisfactory and 41% were unsure. Fifty-seven (97%) providers identified time as the greatest barrier to ACP. Additional barriers included logistical uncertainty with AD form completion (29%) and concern with patient discomfort (24%). Provider focus groups confirmed that time was the most important barrier and provider discomfort was a greater factor for residents.
CONCLUSIONS: Completion of AD and POLST forms are crucial for successful ACP, but completion rates in our academic primary care setting remains low. Our provider surveys and focus groups suggest there are opportunities for improving completion rates and establishing best practices for introducing ACP to patients. As next steps, we plan to provide both patients over the age of 60 and their providers with AD and POLST forms during appointment check-in to encourage patients and providers to discuss ACP during their visit. Additionally, flyers will be placed in exam rooms to remind both patients and physicians to complete AD and POLSTs. We hope this intervention will serve as a model for improving the rate of ACP in an outpatient setting. [1] Temel, J.S., Greer, J.A., Admane, S. et al. J GEN INTERN MED (2010) 25: 150. doi:10.1007/s11606-009-1161-z

ADVERSE CHILDHOOD EXPERIENCES IN ADDICTION MEDICINE PATIENTS RECEIVING BUPRENORPHINE THERAPY

Kristin Rodriguez; Scott Davis; Zach Ferguson; Krishna Suthar; Martina Jelley. University of Oklahoma School of Community Medicine, Tulsa, OK. (Control ID #2706820)

BACKGROUND: It is well established that adults with a significant history of adverse childhood experiences (ACEs) are more likely than their non ACE-affected counterparts to experience poor health outcomes. In a prior study conducted at the University of Oklahoma School of Community Medicine (OUSCM) in 2012, a team of ACE researchers gathered data on 354 patients in Internal Medicine, Family Medicine, and Community Health that indicated the prevalence of ACEs was higher (0–1 ACE, 35.5%; 2–3 ACEs, 27.3%; 4 or more ACEs, 37.2%) than the cohort examined in the original CDC ACE study (0–1 ACE, 62.1%; 2–3 ACEs, 25.4%; 4 or more ACEs, 12.5%). Data from that original ACE study also indicate that individuals with exposure to 4 or more ACEs have a 7- to 10-fold increased risk for drug abuse and addiction compared to their non ACE-affected peers. Data from the OUSCM study indicated a mean ACE score associated with any substance abuse in our patient population of 3.62. Having experienced traumatic events has been acknowledged as a significant risk factor for substance abuse. To our knowledge, there is no available literature examining the prevalence of ACEs in patients treated for substance use disorder with buprenorphine.
METHODS: We conducted a survey of current adult patients in the OU addiction medicine practice to determine the prevalence of ACEs in patients treated for substance use disorder with buprenorphine. Patients were approached to complete the self-administered survey during a regular clinic visit with their addiction medicine physician. The survey included demographics, ten ACE screening questions, and information about the patient's substance use history.
RESULTS: Forty-eight patients completed the survey. Analysis indicated that 20.8% of these patients had experienced 0–1 ACE, 20.8% 2–3 ACEs, and 58.3% had 4 or more ACEs. The prevalence of 4 or more ACEs in this sample of patients is much higher than than our primary care population (37.2%) or CDC (12.5%) samples. The mean ACE score was 4.52. Patients in this sample reported high levels of several of the ACE categories: emotional abuse (52.1%), emotional neglect (47.9%), parental divorce (71.1%), household alcohol or drug abuse (78.7%), household mental illness (47.9%), and family member incarceration (29.2%).
CONCLUSIONS: We found that the prevalence of ACEs in a sample of patients treated for substance use disorder with buprenorphine is considerably higher than in the general population and in our primary care patients. Screening for ACEs in this population and investigating treatment approaches that include ACE awareness deserves further study, as this may improve success rates of medication assisted addiction treatment.

AGE, GENDER AND RACIAL DIFFERENCES IN THE ASSOCIATION BETWEEN TIME-VARYING DEPRESSIVE SYMPTOMS AND MORTALITY

Kelsey Bryant[2]; Deanna Jannat-Khah[5]; Yulia Khodneva[6]; Jessica R. Singer[4]; Monika M. Safford[3]; Nathalie Moise[1]. [1]Columbia University Medical Center, New York, NY; [2]Columbia University Medical Center, New York Prebyterian, New York, NY; [3]Weill Cornell Medical College, New York, NY; [4]New York Presbyterian Hospital - Columbia University Medical Center, New York, NY; [5]Weill Cornell Medical School, New York, NY; [6]University of Alabama, Birmingham, AL. (Control ID #2706480)

BACKGROUND: Depressive symptoms relapse and remit, and the timing of the relationship between depressive symptoms and mortality remains poorly elucidated. We recently demonstrated that time-varying depressive symptoms may be associated with all-cause and noncardiovascular (CVD) disease mortality, suggesting a proximal association. Here, we aim to identify whether age, gender, and race modify the association between time-varying depressive symptoms and mortality.
METHODS: Reasons for Geographic and Racial Differences in Stroke (REGARDS) is a prospective cohort study of black and white individuals (≥45 years) without a history of CVD or active cancer recruited between 2003 and 2007. The associations between time-varying depressive symptoms (CES-D ≥4 vs. <4) and all-cause and nonCVD mortality were measured using Cox

proportional hazard regression analyses adjusting for demographic (age, gender, region, income, health insurance, education), medical (blood pressure, cholesterol, antihypertensives, statins, aspirin, antidepressants, cardiovascular disease, body mass index, diabetes, renal disease, pulmonary disease and cognitive impairment), behavioral (smoking, alcohol use, physical inactivity, medication adherence), and physiologic (C-reactive protein, functional status, and stress) risk factors. *P*-values for interaction terms were reported. All results were stratified by self-reported health status to isolate the effect of depressive symptoms on mortality.

RESULTS: Of the 29491 participants included in the analysis, 3253 (11%) had elevated depressive symptoms at baseline. The mean age was 65 (9.4) years; 55.1% were female; 41.1% black, 46.4% reported excellent/very good health. Depressive symptoms were measured at baseline and on average 5 and 7 years later. In those with excellent/very good self-reported health, time varying depressive symptoms were significantly related to: all cause mortality, particularly in those 45–65 years (vs. ≥65 years) (aHR = 1.56 [1.01-2.42] vs. aHR = 1.48 [1.21–1.81], $p = 0.018$) and nonCVD mortality, particularly in males (vs. females) (aHR = 1.72 [1.28–2.31] vs. aHR = 1.44 [1.04–2.00], $p = 0.006$) and blacks (vs. whites) (aHR = 1.80 [1.28–2.54] vs. aHR = 1.47 [1.10–1.96], $p = 0.025$).

CONCLUSIONS: In this large cohort of non-institutionalized adults with excellent/very good self-reported health status, we demonstrate that depressive symptoms appear to be associated with an increased proximal risk of mortality, particularly in those 45–65 years old, blacks, and males. In light of recent increases in mortality rates amongst middle-aged males, our study lends further support to calls for improved diagnosis and treatment in these high-risk groups who often fail to come into contact with healthcare providers.

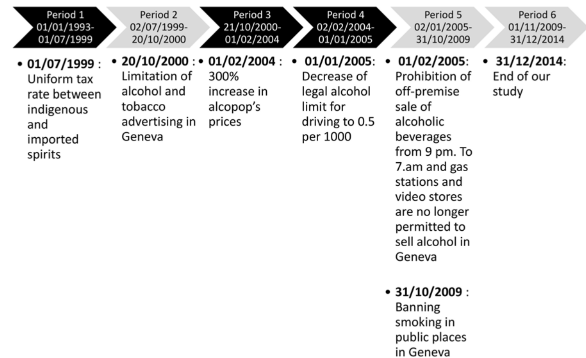
ALCOHOL POLICY CHANGES AND 22-YEAR TRENDS IN INDIVIDUAL ALCOHOL CONSUMPTION IN A SWISS ADULT POPULATION: A 1993–2014 CROSS-SECTIONAL POPULATION-BASED STUDY Shireen Dumont[1]; Pedro Marquez-Vidal[4]; Thierry Favrod-Coune[1]; Jean-Marc Theler[1]; Jean-Michel T. Gaspoz[2]; Barbara Broers[1]; Idris Guessous[1, 3]. [1]Geneva University Hospitals, Geneva 14, Switzerland; [2]University Hospitals, Geneva 14, Switzerland; [3]University of Lausanne, Lausanne, Switzerland; [4]University Hospital of Lausanne, Lausanne, Switzerland. (Control ID #2704839)

BACKGROUND: Evidence on the impact of legislative changes on individual alcohol consumption is limited. We assessed trends in individual alcohol consumption of a Swiss adult population following the public policy changes that took place between 1993 and 2014, while considering individual characteristics and secular trends.

METHODS: We used data from the "Bus Santé" study, an annual health survey conducted in random samples of the adult population in the State of Geneva, Switzerland. Individual alcohol intake was assessed using a validated food frequency questionnaire. Individual characteristics including education were self-reported. Seven policy changes (six about alcohol and one about tobacco) that occurred between 1993 and 2014 defined 6 different periods. We predicted alcohol intake using quantile regression with multivariate analysis for each period adjusting for participants' characteristics and tested significance periods. Sensitivity analysis was performed including drinkers only, the 10th percentile of highest drinkers and smoker's status.

RESULTS: Data from 18,963 participants collected between 1993 and 2014 (aged 18–75 years) were included. Between 1993 and 2014, participants' individual alcohol intake decreased from 7.1 to 5.4 g/day (24% reduction, $p < 0.001$). Men decreased their alcohol intake by 34% compared to 22% for women ($p < 0.001$). The decrease in alcohol intake remained significant when considering drinkers only (28% decrease, $p < 0.001$) and the 10th percentile highest drinkers (24% decrease, $p < 0.001$). Consumption of all alcoholic beverages decreased between 1993 and 2014 except for the moderate consumption of beer, which increased. After adjustment for participants' characteristics and secular trends, no independent association between alcohol legislative changes and individual alcohol intake was found.

CONCLUSIONS: Between 1993 and 2014, alcohol consumption decreased in the Swiss adult population independently of policy changes.



Study period divided in 6 periods according to policy changes between 1993–2014

ALGORITHMS FOR MANAGING CONCERNING BEHAVIORS IN PATIENTS PRESCRIBED OPIOIDS FOR CHRONIC PAIN: A DELPHI STUDY Jessica S. Merlin[4]; Sarah Young[8]; Joanna L. Starrels[1]; Soraya Azari[5]; E. J. Edelman[7]; Jamie Pomeranz[9]; Payel J. Roy[2]; William Becker[6]; Jane M. Liebschutz[3]. [1]Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY; [2]Boston University Medical Center, Boston, MA; [3]General Internal Medicine, Boston Medical Center, Boston University School of Medicine., Boston, MA; [4]University of Alabama at Birmingham, Birmingham, AL; [5]University of California, San Francisco, San Francisco, CA; [6]VA Connecticut Healthcare System, West Haven, CT; [7]Yale University School of Medicine, New Haven, CT; [8]SUNY Binghamton, Binghamton, NY; [9]University of Florida, Gainesville, FL. (Control ID #2700506)

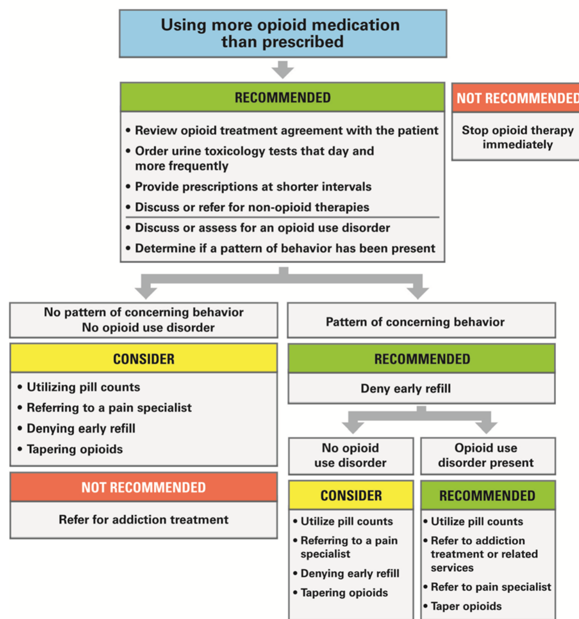
BACKGROUND: Opioid prescribing and addiction have increased dramatically in the last decade. Current guidelines recommend careful monitoring of patients prescribed long-term opioid therapy (LTOT) for chronic pain, and will likely lead to increased identification of concerning behaviors. Minimal research informs strategies to manage these behaviors, which pose an important management challenge and potential source of burnout for primary care providers. Our objective was to establish consensus treatment approaches for common and challenging concerning behaviors that arise among patients on LTOT.

METHODS: We used a Delphi approach, which allows for generation of consensus by a panel of experts. Participants were experts in chronic pain and opioid prescribing recruited from professional societies and other expert groups. The Delphi process consisted of four online rounds: brainstorming to identify common and challenging behaviors, identification of management strategies for each behavior, and two rounds to establish consensus and explore disagreement/uncertainty.

RESULTS: The most frequently-cited common and challenging behaviors were missing appointments, taking opioids for symptoms other than pain, using more opioid medication than prescribed, asking for an increase in opioid dose, aggressive behavior, and alcohol and other substance use. Results are

synthesized in 7 management algorithms (see Figure for example). Across algorithms, participants agreed that patient education and information gathering were important approaches. Participants also agreed that stopping opioids is not an important intiial approach to these behaviors.

CONCLUSIONS: These algorithms provide much-needed guidance on how to manage several important concerning behaviors among patients on LTOT. Future research is needed to investigate the impact of the algorithms on patient outcomes. The long-term goal of this program of research is to provide primary care providers with a decision-support algorithm to manage concerning behaviors in patients on LTOT.



AMBULATORY CARE-SENSITIVE EMERGENCY VISITS AMONG PATIENTS WITH MEDICAL HOME ACCESS Dina H. Griauzde; Laurence F. McMahon; Linda M. Balogh; Floyd J. Brinley; John Crump; Mark Ealovega; Audrey Fan; Yeong Kwok; Kristen Krieger; Thomas O'Connor; Elisa Ostafin; Heidi Reichert; Jennifer Meddings. University of Michigan, Ann Arbor, MI. (Control ID #2698154)

BACKGROUND: Ambulatory care-sensitive conditions (ACSCs) are a group of acute and chronic conditions for which early and effective management in the primary care setting may prevent an Emergency Department (ED) encounter. Among insurers, ambulatory care-sensitive ED encounters are used as a quality metric to guide payment. Accordingly, the Patient Centered Medical Home (PCHM) model aims to reduce ambulatory care-sensitive ED encounters through strategies such as extended clinic hours, yet it is unknown whether patients attempt to access their medical home prior to ED presentation. Further, certain symptoms may not be appropriate for management in the primary care setting (e.g. chest pain), even if they are ultimately attributed to an ambulatory-sensitive condition (e.g. gastroesophageal reflux). This study aims to (1) characterize patterns of ED utilization for ACSCs among patients with established primary care within a General Medicine medical home and (2) to describe the appropriateness of the care location (e.g. ED vs. primary care clinic).

METHODS: We conducted a retrospective chart review using our institution's Electronic Health Record of ambulatory care-sensitive ED encounters that occurred between January 1, 2014 and December 31, 2014 among patients of a General Medicine medical home. Ten General Medicine physicians reviewed a random sample ($n = 263$) of these encounters and abstracted from the medical record the day and time of ED presentation and the source of ED referral (e.g. patient self-referral vs. physician referral). Physicians also assessed the appropriateness of the care location (e.g. Emergency Department vs. primary care). Inter-rater reliability was assessed using the kappa statistic.

RESULTS: Compared to all other days of the week, the fewest number of ED visits occurred on weekend days, and nearly half of patients (47 percent) with ACSCs presented to the ED after business hours (8 am to 3:59 pm). Most patients (83 percent) were self-referred to the ED. Among the 119 cases considered appropriate for management by General Medicine, almost all (95 percent) of these patients were self-referred to the ED. The ED was considered the most appropriate care location for over half (54 percent) of the reviewed encounters.

CONCLUSIONS: Patients diagnosed with ambulatory care-sensitive conditions often present to the ED without contacting their medical home. Frequently, the ED is indeed the most appropriate location to manage the patient's presenting condition.

AMBULATORY VISIT INTENSITY FOR PATIENTS WITH TYPE 2 DIABETES: A REPORT FROM THE HIGH VALUE HEALTHCARE COLLABORATIVE Brooke Herndon. Dartmouth-HItchcock, Lebanon, NH. (Control ID #2708887)

BACKGROUND: In the setting of high and rising prevalence of type 2 diabetes among US adults, guideliens for clinical interventions and quality targets abound. Yet, how to organize medical care to efficienty achieve these best practices is not clear. Visit frequency yielding the greatest value for both individual patients and society remains especially uncertain. We sought to determin whether poor glucose control is associated with more frequent ambulatory visits among adult patients with type 2 diabetes who are medically homed at High Value Healthcare Collaborative (HVHC) member organizations.

METHODS: We conducted a retrospective cohort study of patients 18 years and older with type 2 diabetes who received at least 12 months of ambulatory care at organizations that were members of the High Value Healthcare Collaborative between February 2013 and February 2015. HVHC is a voluntary association of 14 non-profit US health care organizations with a common goal of improving quality while reducing costs. Our primary exposure is the patient HbA1c value at the start of a qualifying 12 month observation period. Our main outcome measure is the mean number of ambulatory visits with primary care or endocriniology clinicians per person in the 12 months following index HbA1c, and our secondary outcome measure is the proportion of those visits provided by an endocrinology specialist. We adjusted for age, sex, race, ethnicity, and poverty status.

RESULTS: We examined visit frequency for 103,220 patients from nine system-specific cohorts ranging in size from 693 to 30,973 patients. Race, ethnicity, sex, poverty status, and index HbA1c value varied substantially across sites. In unadjusted analyses, the overall mean ambulatory visit rate was 4.6 visits per year and ranged from 2.0 to 5.4 visits per year across member organizations. The proportion of annual visits with an endocrinology specialist was 3.7% overall and ranged from 0.3 to 11.4%. The association between index HbA1c value and annual visit rate was very modest ranging from 4.5 for patients with an index HbA1c less than 7.0 to 4.8 for those with an index HbA1c value of 9 or greater.

CONCLUSIONS: Mean ambulatory visit frequency varied across HVHC organizatons but only correlated meaningfully with index HbA1c value at 2 sites. In contrast, the proportion of visits delivered by endocrinology specialists was low across sites but did increase with higher index HbA1c values across all sites studies

AN ANALYSIS OF STUDENTS' REFLECTIVE WRITING PROVIDES A WINDOW INTO PROFESSIONAL IDENTITY FORMATION, RESILIENCE, AND BURNOUT PROTECTION IN THE DENVER HEALTH LONGITUDINAL INTEGRATED CLERKSHIP (DH-LIC)

Michelle Cleeves[2]; Mim Ari[3]; jennifer gong[4]; Jennifer Adams[1]. [1]Denver Health, Denver, CO; [2]Denver Health and Hospital Authority, Denver, CO; [3]Cook County, Chicago, IL; [4]University of Colorado School of Medicine, Aurora, CO. (Control ID #2706503)

BACKGROUND: Burnout, prevalent among practicing physicians, is also found in U.S. medical students. Undergraduate medical educators are therefore ideally placed to address burnout during the clinical years when professional identity begins to take shape. Students in longitudinal integrated clerkships (LICs) complete core clerkships longitudinally working with core faculty preceptors. LIC students finish 3rd year with more positive attitudes about their clerkships, stronger patient-centeredness, and more confidence in their patient care abilities compared to traditional 3rd year students. In the DH-LIC, students learn exclusively in Denver's only safety-net hospital system, providing care for the underserved for the duration of their 3rd year. The DH-LIC curriculum incorporates reflective exercises designed to help students process their experiences in this setting. Through qualitative analysis, these reflections provide insight into students' professional identity formation, resiliency, and strategies protecting against burnout.

METHODS: DH-LIC students completed reflective writing exercises followed by facilitated small group discussions throughout 3rd year. Topic included: social determinants of health, boundary setting with patients, and closure with patients. The authors analyzed 2 years of essays ($n = 45$ essays, 15 students). Through an iterative process we identified themes, then independently coded to find agreement among coders on consistent themes within and across essays. We then totaled the percentage of students reflecting on each theme.

RESULTS: Reflections were firmly rooted in understanding the system of disadvantage constraining patient care (100% of students recognized the impact of patient disadvantage & 87.7% healthcare system failure on patients' health) and a commitment to treat patients as people (60% demonstrated sympathy & empathy for patients and 73% humility when learning from patients). Reflections also revealed behaviors & attitudes that demonstrated efficacy & self-monitoring. Common themes included: advocating for & engaging with patients (86.67%), understanding provider vulnerability & learning to set professional boundaries (73%), valuing continuity with patients (60%), & feeling valued by patients & preceptors (60%). More than 60% of students identified these behaviors & attitudes as key to their role and identity as physicians. Students identified the LIC structure (100%) and positive & negative role models (73%) as contributing to these experiences.

CONCLUSIONS: Through the course of the LIC year, students demonstrate a developing sense of professional identity consonant with that needed to provide compassionate care to the underserved. Analysis of the reflective essays acted as a window into the themes gleaned from the students' experience. Student reflections demonstrated self-efficacy, identification of and commitment to key values, and resilience in the face of challenges.

AN E-LEARNING MODULE ON CHRONIC LOW BACK PAIN IN OLDER ADULTS: EFFECT ON MEDICAL RESIDENT ATTITUDES, CONFIDENCE, KNOWLEDGE, AND PRACTICE PATTERNS

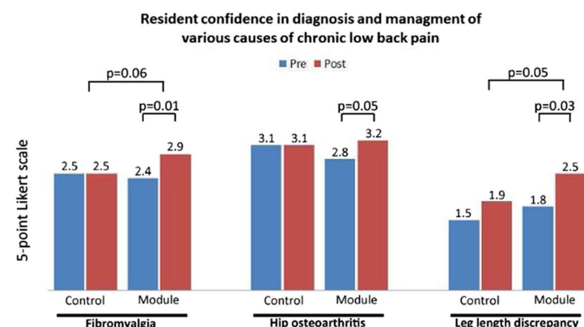
Zachary G. Jacobs[2]; Michael Elnicki[1]; Subashan Perera[2]; Debra K. Weiner[2]. [1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #2672639)

BACKGROUND: Chronic low back pain (CLBP) negatively impacts the lives of millions of Americans each year, posing an enormous financial burden; this is in large part due to an inadequacy of chronic pain education. The goal of this study is to investigate the feasibility of using an online module to teach medical residents about CLBP in older adults, and to determine its impact on their attitudes, confidence, knowledge, and ability to evaluate and manage CLBP in the clinic.

METHODS: All categorical internal medicine residents at the University of Pittsburgh Medical Center from 2015–2016 were assigned to intervention ($N = 73$) or control groups ($N = 70$) based on clinic schedule. The intervention group was instructed to complete an online, self-guided module previously developed by a panel of experts. The control group was exposed instead to the Yale "Office-Based Medicine Curriculum" on CLBP. Knowledge, attitudes and confidence were assessed pre- and post-intervention. Knowledge was assessed with 1) the *KnowPain-12 survey* (a validated, 12-item questionnaire), and 2) ten multiple choice CLBP-specific questions written by pain specialists. A reviewer masked to group assignment conducted a retrospective review of resident clinic encounters, rating physical exams and diagnoses as either beginner or advanced based on terms used in documentation.

RESULTS: Survey results from pre- ($N = 44$) and post-intervention ($N = 42$) showed no improvement on the 10-item multiple choice test or the KnowPain-12 survey in either group (60% average on both metrics). There were tendencies for greater improvements in the intervention group compared to controls in confidence in managing fibromyalgia (2.4 to 2.9 vs 2.5 to 2.5; $p = 0.06$) and leg length discrepancy (1.8 to 2.5 vs 1.5 to 1.9; $p = 0.05$). Those exposed to the module were also more likely to use more advanced diagnosis codes (15% vs 5%) and physical exam documentation (62% vs 45%) compared to controls.

CONCLUSIONS: This study demonstrates the use of an online module is a feasible method for teaching medical residents about CLBP. One of the most startling findings is the paucity of knowledge amongst participants. These data highlight the importance of developing effective methods for educating clinicians about chronic pain. While the module did not lead to greater overall improvements on knowledge tests, it did lead to improved resident confidence, and greater sophistication in evaluating patients with CLBP.



AN ELECTRONIC HEALTH RECORD-ENABLED (EHR) UNIVERSAL MEDICATION SCHEDULE TO PROMOTE ADHERENCE: A PRAGMATIC TRIAL Guisselle del Salto[1]; Deesha Patel[1]; Laura M. Curtis[1]; Ruth Parker[3]; Fred Rachman[4]; Sarah S. Rittner[4]; Elizabeth Adetoro[4]; Andrew Hamilton[4]; Michael S. Taitel[2]; Jenny Jiang[2]; Amisha Wallia[1]; Michael S. Wolf[1]. [1]Northwestern University, Chicago, IL; [2]Walgreens Co, Deerfield, IL; [3]Emory University, Atlanta, GA; [4]Alliance of Chicago Community Health Services, Chicago, IL. (Control ID #2705084)

BACKGROUND: Many patients misunderstand prescription medication (Rx) instructions, and this has been repeatedly linked to medication errors, adverse drug events and poor adherence. Patients with limited literacy and English proficiency, and those with more complicated drug regimens, are especially at risk of unintentional misuse. We collaborated with federally qualified health centers and a national pharmacy chain to impart a health literacy 'best practice' - the Universal Medication Schedule (UMS) - via EHR and mobile technologies to better convey dosing instructions and help organize multi-drug regimens among type 2 diabetic patients.
METHODS: We randomized 59 providers from 11 practices to usual care or one of two intervention arms: 1. UMS Arm: Leveraging the GE Centricity EHR platform, patients received 1) UMS Rx instructions that guided patients to take all of their medication at 4 standard time intervals (morning, noon, evening, bedtime); 2) a single-page, plain language medication information sheet in English and Spanish that was designed following health literacy best practices was generated with an After Visit Summary (AVS) once ordered; and 3) A complete list of patients' current medications mapped to UMS intervals was automatically generated with the AVS to help patients consolidate their entire regimen to the 4 standard daily intervals. 2. UMS + SMS: Patients also were exposed to the UMS tools at the point of care, but also received SMS text reminders about when to take medicines based on UMS intervals. 452 English and Spanish-speaking type 2 diabetic patients who were prescribed 3+ medications for chronic conditions and could receive text messages were assessed by phone at baseline, 3 months, and 6 months. Patient outcome measures include medication knowledge, demonstrated proper use, medication adherence (measured by self-report and pill count) and clinical outcome measures.
RESULTS: In multivariable analyses, no significant differences in any of the outcomes were found by study arm. By six months, however, patients receiving the UMS + SMS intervention were significantly more knowledgeable of their medications' indication (Adjusted Odds Ratio (AOR) 1.43, 95% Confidence Interval (CI) 1.06-1.93, $p = 0.02$) and adherent to their regimen according to self-report of missed doses (AOR 2.33, 95% CI 1.02-5.31, $p = 0.045$). No differences in rates of proper use, adherence via pill count, or clinical outcomes count were noted. In addition, no interactions between study arm and literacy level or language were found to be statistically significant.
CONCLUSIONS: Our trial tested embedding the UMS and tools within an EHR platform at primary care practices. While we did find an effect on self-reported adherence and even knowledge, this health literacy intervention did not improve adherence via the more objective metric of pill count, nor clinical outcomes. Furthermore, these benefits only occurred with the UMS + SMS intervention, and not UMS arm alone.

AN EMOTIONAL WELL-BEING CAMPAIGN: MESSAGING FOR THE PUBLIC Jessica Kaltman[1]; Sophie Feller[1]; Lello Tesema[1]; Enrico G. Castillo[1, 2]; Kenneth B. Wells[1]. [1]UCLA, Los Angeles, CA; [2]Los Angeles County, Los Angeles, CA. (Control ID #2706351)

BACKGROUND: As part of the Affordable Care Act, the National Prevention Council comprising multiple federal agencies and led by the Office of the Surgeon General (OSG) was created. In 2011, the council released the National Prevention Strategy which identified seven prevention priority areas to target in order to improve the health of the nation. Mental and emotional well-being (EWB) is one of the seven priority areas setting the foundation to develop a national EWB campaign. An important aspect of a successful campaign is to understand the terminology currently used to discuss this issue amongst the American public. We conducted a rapid review of the popular media to understand how the concept of EWB is portrayed to the public.
METHODS: A rapid review of popular media sources was conducted between June 8, 2016 to July 5, 2016 to assess the terminology used by the media to discuss the subject of EWB. Google alerts, which prospectively pulls articles from media outlets on topics specified by search terms, were created for 18 terms related to EWB. These terms were chosen from the academic tradition (e.g., thriving, flourishing, coping, positive psychology, grit and resilience), interviews with key community and academic stakeholders and commonly used terminology (e.g., well-being, wellness, emotional fitness, and emotional well-being). Additionally, the websites for *New York Times*, *Washington Post*, *The Atlantic*, and *New Yorker* magazine were searched separately, as Google Alerts excludes these outlets. A team of three people reviewed over 150 media articles that used the terminology chosen. Articles were evaluated for use of the terminology.
RESULTS: Our findings demonstrate that happiness, resilience and stress pervade the public media. Thriving, and occasionally grit, are terms applied to topics not related to well-being and are more often used to describe crops, athletes, sports teams and economies. Importantly, EWB did not appear to be a widely-referenced term in the popular media. Happiness was used in ways that most closely related to EWB research and interventions.
CONCLUSIONS: A review of the popular media lends insight into how the media process and the public receive information related to EWB. These preliminary findings may carry implications on the challenges in developing unified public messaging on EWB. The preference of the media to use terms other than EWB should be taken into consideration when messaging about an EWB initiative.

AN EMR-BASED RANDOM GLUCOSE PREDICTIVE MODEL TO DETECT DIABETES AND DYSGLYCEMIA OUTPERFORMS NATIONAL SCREENING GUIDELINES Michael E. Bowen; Hua Lin; Ildiko Lingvay; Ethan Halm. UT Southwestern Medical Center, Dallas, TX. (Control ID #2705886)

BACKGROUND: Random blood glucose (RBG)-based case findings strategies perform better than national screening guidelines to detect undiagnosed diabetes in community-based studies. However, the performance of electronic medical record (EMR)-based RBG predictive models using real-world clinical data is unknown.
METHODS: We conducted a retrospective cohort study using EMR data from a large, integrated, safety-net health system and developed a model to predict diabetes (A1C $\geq$ 6.5 or fasting blood glucose (FBG) $\geq$ 126 mg/dL) and dysglycemia (A1C $\geq$ 5.7 or FBG $\geq$ 100 mg/dL). Non-pregnant primary care patients, age 18–64, with an index visit and a resulted diabetes screening test (A1C or FBG) between June 1, 2011 and December 31, 2014 and $\geq$1 outpatient RBG value 12 months prior to the screening test were eligible. We excluded patients with diagnosed diabetes or prediabetes on or 18 months before the index visit using ICD9 codes and lab results. Patient demographics, comorbidities, and diabetes risk factors were extracted from the EMR. We built RBG-

only and a RBG+risk factor (RF) models to predict diabetes and dysglycemia using logistic regression with backwards selection to retain age, race, BMI, and hypertension in the final RBG+RF model. The most recent RBG prior to the date of the screening test was the primary predictor. In a subgroup analysis of patients with >1 RBG value ($N = 8{,}060$), we also modeled mean RBG as a predictor. We report model c-statistics as a measure of discrimination.

RESULTS: A total of 22,058 patients met inclusion criteria. Mean age was 49 years and mean BMI was 31. Overall, 60% were female, 84% were non-Caucasian, 59% had hypertension, and 54% had a family history of diabetes. All patients satisfied American Diabetes Association Screening criteria and 62% met the 2015 USPSTF Diabetes screening criteria. C-statistics in the RBG-only models were 0.88 (undiagnosed diabetes) and 0.73 (undiagnosed dysglycemia). In the RBG+RF model, c-statistics to detect undiagnosed diabetes (0.91) and dysglycemia (0.78) were significantly higher than the RBG-only models ($p < 0.01$). Both the RBG-only and RBG+RF models performed significantly better than the 2015 USPSTF Screening to detect undiagnosed diabetes (0.57) and dysglycemia (0.61) ($p < 0.001$). In the subgroup with >1 RBG, c-statistics for the RBG +RF models using mean RBG performed slightly better than those using the most recent glucose to detect undiagnosed diabetes (0.91 vs. 0.89) and dysglycemia (0.79 vs 0.77) ($P < 0.01$).

CONCLUSIONS: Predictive models using only a single, most recent RBG to detect diabetes and dysglycemia are superior to national screening guidelines, and adding diabetes risk factors commonly available in the EMR further improves performance. Further validation using prospectively collected screening tests is needed to address potential biases in retrospective EMR data.

AN EVIDENCE MAP OF THE WOMEN VETERANS' HEALTH RESEARCH LITERATURE (2008–2015) Elisheva Danan[1]; Kristine E. Ensrud[2]; Erin E. Krebs[1]; Eva Koeller[1]; Tina L. Velasquez[1]; Roderick MacDonald[1]; Nancy Greer[1]; Timothy Wilt[1]. [1]Minneapolis VA Health Care System, Minneapolis, MN; [2]Univeristy of Minnesota/VA Health Care System, Minneapolis, MN. (Control ID #2705633)

BACKGROUND: Women comprise the most rapidly growing population of Veterans seeking care at the Department of Veterans Affairs. Clinical, research and policy initiatives to serve female Veterans exist, yet the corresponding literature has not been systematically reviewed since 2008. In 2015, VA Women's Health Services and the VA Women's Health Research Network jointly requested an updated literature review to assess the scope of research related to female Veterans, determine if research was aligning with priority areas and guide planning.

METHODS: As part of the VA Evidence-based Synthesis Program we conducted a systematic review and created an evidence map of research related to female Veterans' health published from January 2008 to December 2015. We searched the MEDLINE, CINAHL and VA HSR&D databases to find literature related to female Veterans' health. From included studies, we extracted study characteristics including healthcare topic, design, participant number, proportion women, research setting, funding source, and more. We organized and presented results via visual representation and text summary within and across healthcare topics. We identified patterns, strengths and gaps.

RESULTS: We identified 2,276 abstracts that were independently assessed for relevance. Eligible articles ($k = 437$) were sorted into 39 healthcare topics and described according to 14 additional study characteristics. Nearly half the articles were related to mental health (207/437 studies, 47%), particularly post-traumatic stress disorder, military sexual trauma, and substance abuse (these 3 topics comprised 61% of the mental health articles). Few studies addressed common chronic diseases often seen by general internists such as diabetes and hypertension (3 studies) or depression and anxiety (4 studies). Nearly all (396/437, 91%) articles described observational studies. Less than 2% (8/437) presented primary findings of randomized trials. We found growth in the number of articles published per year. In the first half, 2008–2011, 134 studies were published, whereas more than double that (303 articles) were published from 2012–2015. The number of studies within smaller VA priority topic areas increased over time, including post-deployment health, reproductive health, access and utilization, and healthcare organization and delivery. We excluded many identified studies that included female Veterans from our evidence map because they did not stratify results by gender, thereby limiting their applicability to female Veterans.

CONCLUSIONS: Female Veterans' health and healthcare literature grew substantially from 2008–2015. Observational studies in mental health make up the majority of recent research, though additional research agenda priority areas demonstrate progress. Methodological and health condition gaps remain. This evidence map can inform clinical, research, and policy initiatives.

AN EXPENSIVE WHITE COAT Salam Hawa[1]; Raynata Ramkhelawan[1]; Ravneet Randhawa[1]; Niket Sonpal[2]. [1]American University of Antigua, Newark, NJ; [2]Touro College of Osteopathic Medicine, New York, NY.
(Control ID #2706288)

BACKGROUND: A dream is a mere goal sometimes cut short by reality; this is one realization made by many medical students striving towards their career. As the years pass and the financial burden grows, the reason of dreaming of a medical degree, whether an innate passion, parental demand, or simply a change in career path, is no longer the only significant factor in making career decisions. The purpose of this survey is to collect data to investigate the level of impact of how accumulated debt imposes on the choice of specialty by medical students and residents. Studies have shown a trending decline in primary care with a simultaneous inclination towards specialty medicine.

METHODS: The survey consisted of 26 questions administered via Google forms and made accessible for 20 days. The questions were designed to acquire the demographics of each student pertaining to the accumulated loans, level of financial understanding, and furthermore how accumulated debt affects their medical specialty choice.

RESULTS: At the end of the 20 day period, there were 118 responses collected. Of total respondents, 56.8% were in the 1st or 2nd year of medical school, 40.7% were in there 3rd or 4th year, and 2.5% were in their 1st to 3rd year of residency. Of 118 respondents, only 117 responded regarding total accumulated debt; and among those responses, 14 will be excluded due to their lack of a specified answer. Among the remaining respondents, 30.09% have an accumulated debt of less than $60,000, 34.95% have between $60,001 to $140,000, 22.33% have between $140,001 to $220,000, and 12.6% have above $220,001. When asked if loan amounts were sufficient to cover their obligations, there were 116 responses. Of those responses, 28 were excluded due to lack of a specified answer. Of the remaining responses, 60.22% stated their loans were sufficient and 39.77% stated they were not able to meet their financial obligations with their loans. When asked if the amount of accumulated debt provoked a change in the choice of specialty, 117 responses were collected. Among those, 17 responses will be excluded due to their lack of specified answer. Among the remaining responses, 52% stated their choice did not change and 48% stated it did.

CONCLUSIONS: Upon review, most students fall within the debt range of $60,001 to $140,000 and the majority of students stated loans sufficiently covered their needs and furthermore indicated debt was not a factor in choice of field. However, there is a substantial 39.77% of students who counteract this notion and a greater 48% who indicated their interest in pursuing a high paying specialty serves as a means to pay their accumulated debt. Further comparisons in the changing rates of medical school costs versus compensation rates for physicians will be essential in defining the root of the problem.

AN IN-DEPTH CASE STUDY OF ADAPTING PATIENT EXPERIENCE DATA COLLECTION FOR LOWER LITERACY PATIENT POPULATIONS USING TABLETS IN CLINIC Courtney Lyles[1]; Lina Tieu[1]; Alicia Hobbs[2]; Erin E. Curtis[2]; Urmimala Sarkar[1]. [1]University of California, San Francisco, San Francisco, CA; [2]San Francisco Department of Public Health, San Francisco, CA. (Control ID #2705455)

BACKGROUND: Healthcare policy supports the inclusion of patient experience in healthcare quality measurement and reporting. However, response rates to the gold-standard, paper-based Consumer Assessment of Healthcare Providers and Systems (CAHPS) surveys are low and differ significantly by racial/ethnic and language subgroups. There is little discussion about whether CAHPS captures the true domains of patient healthcare experience, how to improve reporting for underserved patient populations, or whether data collection via mobile technology might result in higher response rates from more representative populations.

METHODS: Our study sought to 1) design and evaluate tablet-based CAHPS administration, and 2) conduct formative qualitative work to create shorter, lower literacy patient experience items (informed by CAHPS) and explore broader concepts of patient experience among vulnerable patients. We partnered with a start-up company Shift Health to create a tablet interface that was visually attractive and simple to use and created multi-lingual, low-literacy questionnaires. Next, we used 25 think-aloud interviews with patients to validate a new literacy-appropriate tablet questionnaire compared to the standard paper version, eliciting their perspectives about using a tablet-based survey to report their care experiences.

RESULTS: Of the 25 participants, 52% were male, 80% were non-White, and 68% had limited health literacy; the mean age was 53. Almost a quarter (24%) and over a third (36%) had never used a smartphone or tablet, respectively. Patients answered the majority of questions similarly on the paper vs. tablet versions, but strongly preferred the tablet, even among those without significant previous experience using mobile technology: “This [the tablet] is quite easy to do, because everything is easy to read. You just literally have to point your finger at your answer.” Patients emphasized the importance of reporting feedback to their clinics, particularly concerning wait times, quality of provider communication, and ability to access care, and valued the option to complete the survey at the point of care: “It’s better in the clinic because you’re in the same environment.” The final literacy-appropriate questionnaire made concrete improvements to the CAHPS items, including 1) reducing the total number of items from 31 to 17 while preserving core domains, 2) reducing the reading level required to understand survey questions from 7th to 5th grade (Flesch-Kincaid test), and 3) adding open-ended questions to capture patient-directed perspectives of care.

CONCLUSIONS: As we move forward with federal policy supporting patient experience data collection, this study provides clear next steps to ensure under-represented and vulnerable patient perspectives are engaged and represented in this process. If designed with patient input, tablet-based surveys may be a feasible and effective method for collecting patient experience data at the point of care.

AN INTERDISCIPLINARY STRATEGY FOR IMPROVING HAND HYGIENE ON AN INPATIENT MEDICINE UNIT Katherine A. Hochman[2]; Nicole Adler[1]; Lisa Gumbrecht[3]; Brian Bosworth[1]. [1]NYULMC, New York, NY; [2]New York University School of Medicine, New York, NY; [3]NYU Langone Medical Center, New York, NY. (Control ID #2701187)

BACKGROUND: The CDC reports that 5% of hospitalized patients develop hospital acquired infections, which are responsible for 100,000 deaths annually. Poor hand hygiene compliance on the Medicine service placed patients at higher risk for infection and was the impetus for our Clean Hands Save Lives Initiative.

METHODS: The Clean Hands Save Lives initiative was a triple-prong systems-based strategy that required the leadership of the medical director and nurse manager and the engagement of the entire floor. First, unit leadership dedicated a portion of the the morning unit-based safety huddle to identify daily handwashing champions. Each day a new group of champions was identified, including 2 nurses, one one floor patient unit technician, and two physicians. Champions were responsible for reinforcing correct hand hygiene procedures in real time, promoting a culture of “if you see something, say something.”Each week, 35 different health care providers were hand-hygiene champions, hardwiring best practice. Second, proper hand hygiene procedures were reinforced at the safety huddle several times a week and Purell dispensers were installed outside every patient room.Third, an email was sent to each team member regarding the hand hygiene initiative at the start of each rotation. Real-time feedback on hand hygiene technique was provided by unit leadership.

RESULTS: At the start of the initiative in quarter 1 of 2015, hand hygiene compliance for the 17 East Medical Unit was at 64%. By quarter 1 of 2016, hand hygiene compliance was at 93 and has remained above 90% for the past 4 quarters (Figure 1).

CONCLUSIONS: Successful implementation of our Clean Hands Save Lives Initiative on a hospitalist led medicine unit was due in large part to making this a daily focus of all members of the team, leading to unit culture change. The interdisciplinary approach to the problem, daily reinforcement of the initiative, regular education of unit staff and ease of practicing proper hand hygiene all were contributing factors to its success and sustainability. The initiative is now practiced in all units on the Medicine service.

AN INTERVENTION TO REDUCE BLACK-WHITE CANCER TREATMENT DISPARITIES: THE CASE OF EARLY STAGE NON-SMALL CELL LUNG CANCER Samuel Cykert[1]; Lloyd Edwards[2]; Paul Walker[3]; Rohan Arya[4]; Peggye Dilworth-Anderson[2]. [1]University of North Carolina, Chapel Hill, NC; [2]UNC Gillings School of Global Public Health, Chapel Hill, NC; [3]ECU Brody School of Medicine, Greenville, NC; [4]University of South Carolina School of Medicine, Columbia, SC. (Control ID #2702897)

BACKGROUND: African-Americans (AA) with lung cancer experience a higher annual death rate compared to Whites (W) with AA men particularly affected (79 vs 66 deaths per 100,000 population). Despite this risk, Bach and others have shown that treatment rates for AA patients with early stage disease lag behind rates for W. In this report, we describe results from a multisite interventional trial designed to optimize lung surgery and overall treatment rates for all patients and reduce treatment disparities.

METHODS: Baseline rates for curative surgery and radiation were established using 3-year chart review for all patients with biopsy proven lung cancer at 3 institutions. We then prospectively recruited AA and W patients with newly diagnosed stage I or II non-small cell lung cancer. Patients were identified at initial visit either through biopsy proven disease or a Bayesian probability algorithm. Informed consent was obtained. Intervention components for enrolled patients included: (1) entry into a real time electronic registry that provided warnings for missed appointments or unfulfilled, pre-designated milestones in care, (2) quarterly feedback of treatment rates by race and co-morbid illness to cancer care personnel, and (3) provision of a specially trained navigator to enhance communication with affected patients and between patients and the care team. Descriptive statistics, bivariate analyses, and logistic regressions were performed with a primary outcome of surgical treatment for lung cancer cure and a secondary outcome of surgery or stereotactic radiation for cure.

RESULTS: Baseline surgical rates from the retrospective analysis of 714 early stage, non-small cell patients were 69% for W and 66% for AA patients. Using logistic regression controlling for comorbidities, COPD, age, and other demographic data, we determined the odds ratio for surgery for AA compared to W lung cancer patients as 0.64 (95% CI 0.43, 0.96). When surgery was combined with stereotactic radiation for cure, the treatment rates improved to 80% for W and 76% B. The same regression analysis applied to combined treatment rates yielded an OR of 0.61 (95% CI 0.40, 0.96) for AA vs W. 244 patients were recruited prospectively including 89 AA (36%) for the intervention. The mean age for this group was 65.7 years; 54% were women. Findings in the intervention group show an overall surgical rate of 74% (74.8% W, 71.4%AA, $p = 0.6$). Combined treatment rates increased to 91.9% for W and 94.1% AA patients ($p = 0.5$). Logistic regression was performed comparing the intervention group to the baseline group. Results showed that overall treatment improved for both W and AA, the surgical and overall treatment disparity resolved, while age, COPD, and clinical stage remained significant predictors of treatment.

CONCLUSIONS: Results from an interventional study designed to optimize lung cancer treatment and narrow Black-White treatment disparities appear promising and could be applicable in reducing other cancer disparities.

ANALYSES OF VENTILATION PERFUSION (VQ) SCAN RESULTS AS COMPARED WITH CLINICAL PROBABILITY OF PULMONARY EMBOLISM IN A PREDOMINANTLY BLACK POPULATION Fasil Tiruneh; Ahmad A. Awan; nicole hunt; nahom tegegn; Daniel Larbi. Howard University, Washington DC, DC. (Control ID #2700608)

BACKGROUND: Current guidelines suggest the use of the more specific Wells score could safely reduce the number of unnecessary scans. There is a lack of research to support whether these guidelines apply to the Black population.

METHODS: A retrospective descriptive study to determine the diagnostic utility of VQ scan was conducted among patients who were seen during January 2012 to January 2016. The study population included patients who underwent VQ scan for evaluation of pulmonary embolism. A total of 180 charts were reviewed and 49 were excluded due to poor quality data. A review of the initial history and physical progress notes, as well as discharge summaries was performed. Clinical presentation and Wells probability of pulmonary embolism were compared with the results of the scan.

RESULTS: We collected data on 131 patients who underwent VQ scan for evaluation of pulmonary embolism. The median age of the study population was 63.02 ± 16.12 years. Majority of the study population 121 (92.4%) was black. Sixty four (48.9%) VQ scans were done for a low clinical probability for pulmonary embolism as defined by the well's clinical score. The most common clinical presentations were shortness of breath (SOB) 74 (58%), Leg pain 39 (29.8%), chest pain 36 (27.4%), and syncope 4 (3.1%). Sixty two (96.9%) patients with low clinical probability had low probability VQ scan($p = 0.030$). Among patients who did CT angio and VQ scan, low probability scan was noted in patients with no pulmonary embolism in CT in 25(96.2%) ($p = 0.006$).

CONCLUSIONS: Using the accepted guidelines in which a high pretest probability leads to further imaging and a low probability leads to a D-dimer blood test, use of the more specific Wells score could safely reduce the number of unnecessary scans. [13]The combination of a negative D-dimer with a low or moderate clinical probability can safely exclude pulmonary embolism in many patients.[14]This was reflected in our study, which showed that in patients with normal D-dimer, the result of VQ scan was low probability in 100%. However, no statistically significant correlation was observed between elevated d-dimer and results of VQ scan. In view of this finding, we suggest even in patients with elevated d-dimer other possible diagnosis should be explored. The study showed strong correlation between low clinical probability and low probability VQ scans and its utility to safely rule out PE in a predominantly black population. Studies conducted in other populations have detected similar findings.

Correlation between the clinical pretest probability with *VQ scan probability. Sixty two (96.9%) patients with low clinical probability had low probability VQ scan.($p = 0.030$)

	Low Probability VQ scan n(%)	Intermediate Probability VQ scan n(%)	High Probability VQ scan n(%)	Total n(%)
Low clinical probability	62(96.9%)	2(3.1%)	0(0.0%)	64 (100.0%)a
Moderate clinical probability	46(93.9%)	0(0.0%)	3(6.1%)	49 (100.0%)
High clinical probability	10(76.9%)	1(7.7%)	2(15.4%)	13 (100.0%)

*VQ - Ventilation perfusion scans. *p*- Value: a 0.030

ANXIETY AND DEPRESSION IN UNIVERSITY STUDENTS EXPERIENCING INTIMATE PARTNER VIOLENCE: PRELIMINARY FINDINGS OF A CROSS-SECTIONAL STUDY Danny Lee[1]; Arif Pendi[2]; Alfonzo Valdez[2]; Jose L. Aguilar[3]; Kate Basia Wolitzky-Taylor[4]; Joshua Lee[4]; Kasim Pendi[3]; David Safani[2]. [1]Virginia Commonwealth University School of Medicine, Yorba Linda, CA; [2]University of California Irvine, Orange, CA; [3]University of California Riverside, Riverside, CA; [4]University of California Los Angeles, Los Angeles, CA. (Control ID #2685507)

BACKGROUND: Intimate partner violence (IPV) is an under-reported but commonly occurring phenomenon affecting people of all ages. Among university students, IPV and its consequences are not thoroughly studied. Given that anxiety and depression may follow IPV, it is imperative to research IPV and its potential effects in university students, a group already characterized by high rates of anxiety and depression. Furthermore, recent reports have suggested that the mental health sequelae of IPV may cause greater long-term harm than physical injuries. This may indicate a need for internists to screen for anxiety or

depression in this sub population. Thus, this study had the following objectives: (1) report the prevalence of IPV in university students and (2) investigate the association between IPV and both anxiety and depression.
METHODS: A cross-sectional study design was employed; an anonymous survey was sent to all professors at a large public university in the United States with a request to forward the link to undergraduate and/or graduate students. The instrument consisted of a socio-demographic questionnaire, HITS Domestic Violence Screening Tool, Generalized Anxiety Scale 7 (GAS-7), and Patient Health Questionnaire-9 (PHQ-9). Full-time students over the age of 18 were included; part-time students or those below the age of 18 were excluded. Participants that screened positive for IPV according to HITS were compared via *t*-test to those that screened negative in terms of their continuous scores on the GAS-7 (for anxiety) and PHQ-9 (for depression). All standardized scales (HITS, GAS-7, and PHQ-9) have displayed adequate validity and reliability according to the literature. Analyses were conducted with IBM® SPSS® Version 22.
RESULTS: Completed responses ($n = 396$; 24% female; 86% undergraduates) were scored on the HITS Domestic Violence Screening Tool. Approximately 5% of student respondents (18 of 396 participants) screened positive for IPV. This group exhibited greater anxiety (10.83 ± 5.711 versus 6.23 ± 5.355; $p = 0.003$) and greater depression (12.06 ± 6.384 versus 7.34 ± 6.266; $p = 0.007$) compared to respondents that screened negative for intimate partner violence.
CONCLUSIONS: A small but significant minority of respondents reported IPV. This group was associated with significantly greater anxiety and depression, suggesting that experience of intimate partner abuse is correlated with increased generalized anxiety and depression severity. As a result, this sub-group of students may benefit from augmented screening efforts for anxiety and depression by general internists. Given that university students have already been associated with a large burden of anxiety and depression, those that have experienced intimate partner violence may subsequently experience greater disorder severity.

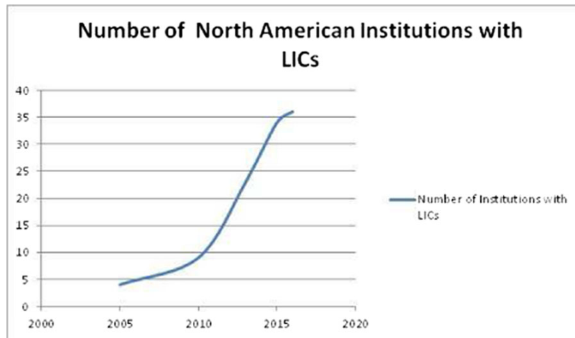
ARE ALL PATIENTS IN FEDERALLY QUALIFIED HEALTH CENTERS EQUALLY READY TO USE HEALTH INFORMATION TECHNOLOGY? Nazia Naz S. Khan; Karen Kelly-Blake; Gurpreet Chahal; Saman Kandola; Zhehui Luo; Ade B. Olomu. Michigan State University, East Lansing, MI. (Control ID #2705525)

BACKGROUND: Health information technology (HIT) has emerged as an innovative way to engage, empower patients and improve access to health care. However, patients navigating health care in low resource communities may not benefit from this potential even when information and communication technologies are readily available. Our objectives were: 1) to assess Federally Qualified Health Center (FQHC) patient readiness and interest in adopting telecommunication, i.e. cell phone, text message and email to communicate with healthcare providers, and 2) to determine whether there are differences in the readiness and usage of technology between FQHC clinics.
METHODS: This analysis is part of the larger Office-Guidelines Applied to Practice (Office-GAP) study designed to improve secondary prevention of heart disease for DM and CVD patients in FQHCs in Michigan. Office-GAP is a quasi-experimental design with 2 FQHC clinics. 499 patients were enrolled in Office-GAP program. 304 patients completed the Technology Usage Readiness Survey, which evaluated their readiness, interest, and barriers to health information technology for communication with providers. There were 153 patients in Clinic 1 and 151 in Clinic 2. Data were analyzed using descriptive statistics and logistic regression models. We adjusted for education, race, insurance, smoking and depression between the two clinics.
RESULTS: Mean age was similar (52 years +/− 11) between Clinic 1 and 2. In Clinic 1, 37% had no high school degree compared to 52% in Clinic 2. Whites comprised 37% of patients in Clinic 1 and 24% in Clinic 2. There was no difference in the percentage of Black patients between the two clinics. We compared Clinic 1 and Clinic 2 patient responses in adjusted analyses: have a cell phone (OR = 1.3, 95% CI = 0.7–2.7); ability to text controlling for having a cellphone (OR = 0.9, 95% CI = 0.4–1.8); like doctors to text controlling for having a cellphone (OR = 1.8, 95% CI = 1.0–3.2); access to internet/email (OR = 1.6, 95% CI = 0.9–2.9); like doctors to email (OR = 1.5, 95% CI = 0.8–2.9). Out of 151 patients in Clinic 2, 55 patients were immigrants: 38% had cell phone; 16% had the ability to text; 13% like doctors to text, 22% have access to internet/email, and 9% like doctors to email them about their conditions.
CONCLUSIONS: We found a statistically significant difference in patient readiness to engage/communicate with their providers using text messages between the two FQHCs. Immigrant patients are less ready to use mobile health (m-Health). With the push for m-Health, assessment of individual clinic patient populations is necessary before telecommunication interventions are implemented. With differences in patient population who have cellphone, ability to text and email it is evident that many patients in FQHCs are not ready to adopt m-Health.

ARE LONGITUDINAL INTEGRATED CLERKSHIPS (LICS) AT A TIPPING POINT? A NORTH AMERICAN SURVEY OF INTERNAL MEDICINE CLERKSHIP DIRECTORS Lindsay A. Mazotti[4, 6]; Jennifer Adams[1]; Bruce Peyser[2]; Katherine C. Chretien[5]; Briar Duffy[7]; David Hirsh[3]. [1]Denver Health, Denver, CO; [2]Duke, Durham, NC; [3]Harvard Medical School, Cambridge, MA; [4]Kaiser Permanente Oakland, Oakland, CA; [5]Washington DC VAMC, Washington, DC; [6]University of California San Francisco, San Francisco, CA; [7]Univeristy of Minnesota, Minneapolis, MN. (Control ID #2688452)

BACKGROUND: LICs are an example of educational innovation, fueled by a desire to improve educational continuity and address the "hidden curriculum." The number of North American (NA) institutions adopting LICs is increasing, but the extent of the change remains unknown. Clerkship Directors (CDs) in Internal Medicine (IM) can provide information on LIC program growth, as every school has an IM clerkship. CDs serve as leaders within institutions and are likely aware of or directly involved in LICs. This study aims to quantify the number of current and planned LICs at NA schools and to characterize the intended purpose of starting LICs.
METHODS: In 2015, the Clerkship Directors in Internal Medicine (CDIM) survey included a section on LICs. This section queried the number of current and planned LICs, their duration and capacity, and the purpose of starting a new LIC.
RESULTS: The response rate was 76% (94/123) of CDIM schools, representing 67% (94/146) of NA medical schools. Thirty six percent ($n = 34/94$) of responding schools have ≥1 LIC. Thirty schools have year-long LICs. The majority (22/34) of LICs are <5 years old. Nineteen institutions are planning a new LIC or increasing the number of students participating in LICs, nine of which are schools without existing LICs. CDs believe LICs are being implemented to foster continuity of care, support students' patient-centeredness, advance interprofessional education, and address workforce shortages. Four schools are converting their entire class to an LIC experience.
CONCLUSIONS: The number and scope of LICs are increasing across NA, especially in the last 5 years. The increase in LICs may be due to early adopters

having demonstrated the benefit of LICs, the compatibility with sought-after goals of medical education, the value of tests of change, and the ability to observe the change first before adopting. Applying the theory of diffusion innovation[1] suggests that a critical momentum may now exist such that the LIC innovation may now be self-propagating. [1] Rogers EM. Diffusion of Innovations.1995.



ARE PATIENTS TRANSFERRED TO HOSPITALS THAT CAN APPROPRIATELY TREAT THEM? Stephanie Mueller[1]; Jie Zheng[3]; Endel J. Orav[1]; Jeffrey L. Schnipper[2]. [1]Brigham and Women, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]TH Chan Harvard School of Public Health, Boston, MA. (Control ID #2703663)

BACKGROUND: Patients are often transferred between hospitals to provide access to specialty care, although receiving hopsitals are not always chosen based solely on patient need. We evaluated the frequency with which patients are transferred to hospitals with availability of required specialty services.

METHODS: We performed a retrospective analysis using 2013 CMS Master Beneficiary and Inpatient claims files merged with 2013 American Hospital Association data. Eligible beneficiaries included those continuously enrolled in Medicare A/B with an acute care hospitalization claim, excluding Medicare managed care and ESRD beneficiaries. We defined transferred patients as those with corresponding "transfer in/out" claims, or either claim with corresponding hospital admission/discharge within 24 hours. We identified top primary diagnoses at time of transfer using ICD-9 codes, selected those requiring specialty services via expert opinion, and used McNemar's test to compare the availability of each specialty service between receiving and transferring hospitals, stratified by diagnosis.

RESULTS: Of the 101,507 transferred patients, 46,030 (45.3%) had a primary diagnosis requiring a specialty service. For each diagnosis, availability of each corresponding specialty service was more often present at the receiving compared to the transferring hospital (Table), although depending on diagnosis, in 35–85% of transfers, services were just as available at the transferring hospital, and in 7–28% of transfers, the receiving hospitals did not have availability of any corresponding specialty service.

CONCLUSIONS: In this national evaluation of transferred patients, we found patients requiring specialty services are transferred to hospitals more likely to have appropriate services compared to transferring hospitals, implying appropriate transfer. However, exceptions to this rule were frequent, suggesting other possible reasons for transfer in these instances, warranting further investigation into hospital transfer practices.

Table. Availability of Specialty Services at Receiving versus Transferring Hospitals

Primary Diagnosis with Corresponding Specialty Services, n(%)	Transferring Hospital	Receiving Hospital	p-value
AMI (n=13,018)			
Presence of adult cardiology service	8,989(69.1)	11,650(89.5)	<0.0001
Presence of adult interventional cardiac catheterization	5,447(41.8)	11,708(89.9)	<0.0001
Presence of cardiac surgery services	1,895(14.6)	11,443(87.9)	<0.0001
Presence of cardiac ICU	4,049(31.1)	10,824(83.2)	<0.0001
Presence of any pertinent specialty service	9,607(73.8)	11,781(90.5)	<0.0001
CHF (n=7,643)			
Presence of adult cardiology services	4,976(65.1)	6,970(91.2)	<0.0001
Presence of cardiac ICU	2,568(33.6)	6,474(84.7)	<0.0001
Presence of any pertinent specialty service	5,228(68.4)	7,047(92.2)	<0.0001
Sepsis (n=6,982)			
Presence of other intensive care	803(11.5)	3,072(44.0)	<0.0001
Presence of Medical ICU	5,648(80.9)	6,430(92.1)	<0.0001
Presence of any pertinent specialty service	5,795(83.0)	6,465(92.6)	<0.0001
Arrhythmia (n=6,887)			
Presence of adult cardiology services	4,566(66.3)	6,129(89.0)	<0.0001
Presence of cardiac ICU	2,266(32.9)	5,696(82.7)	<0.0001
Presence of adult cardiac electrophysiology	2,045(29.7)	5,943(86.3)	<0.0001
Presence of any pertinent specialty service	4,862(70.6)	6,233(90.5)	<0.0001
Stroke (n=3,640)			
Presence of neurological services	2,512(69.0)	3,225(88.6)	<0.0001
Presence of magnetic resonance imaging (MRI)	2,930(80.5)	3,178(87.3)	<0.0001
Presence of any pertinent specialty service	3,079(84.6)	3,272(89.9)	<0.0001
GI Bleed (n=3,089)			
Presence of endoscopic ultrasound services	1,134(36.7)	2,524(81.7)	<0.0001
Presence of optical colonoscopy services	2,079(67.3)	2,638(85.4)	<0.0001
Presence of virtual colonoscopy	596(19.3)	1,853(60.0)	<0.0001
Presence of any pertinent specialty service	2,261(73.2)	2,833(91.7)	<0.0001
Renal Failure (n=2,185)			
Presence of hemodialysis services	763(34.9)	1,578(72.2)	<0.0001
Hip Fracture/Dislocation (n=1,690)			
Presence of orthopedic services	1,374(81.3)	1,502(88.9)	<0.0001
Chest Pain (n=896)			
Presence of adult cardiology services	578(64.5)	784(87.5)	<0.0001

ASKING IS NEVER BAD. I WOULD VENTURE ON THAT! : PATIENT PERCEPTIONS OF PAIN SCREENING IN VA PRIMARY CARE Karleen Giannitrapani[4]; Marie C. Haverfield[3]; Roger T. Day[3]; Jesse Holliday[3]; Steven Dobscha[1]; Robert D. Kerns[2]; Karl Lorenz[3]. [1]Portland VAMC, Portland, OR; [2]VA Connecticut, West Haven, CT; [3]VA Palo Alto Healthcare System, Menlo Park, CA; [4]Veterans Health Administration, Menlo Park, CA. (Control ID #2705833)

BACKGROUND: It is now more than 15 years since the 'Pain as the 5th Vital Sign' routine pain screening initiative was implemented in Department of Veterans Affairs (VA) primary care settings. However, the patient perspective on and experience of routine pain screening has not been characterized. The objective of this study is to understand patients' perspectives on and preferences about pain screening in primary care.

METHODS: We conducted semi-structured qualitative phone interviews with 35 Veterans from five outpatient clinics associated with three large VA medical centers. These were recorded and professionally transcribed; all personally identifying patient information was redacted. Using content analysis methods, we coded transcripts for perceptions of and experiences with routine pain screening in VA primary care. We compared codes across transcripts to identify key themes.

RESULTS: We identified five key themes: 1) Patients affirm it is important to screen for pain because some patients, particularly older ones, may not feel comfortable bringing it up: "if your focus is on managing pain then the question should always come from the provider… to ask a veteran 65-plus to bring up pain… (they) may not be accustomed to talking about their pain because in prior generations that was a sign of weakness." 2) Patients believe it is important to ask about function in relation to pain. One patient suggested: " ask has your pain ever inhibited you from completing a task this last week?" if you leave it…open like that… if you say, "a task," you allow the veteran to determine what level that task is." 3) Patients want to be screened for pain over being screened for something more broad like quality of life: "I'd rather have the nurse ask me about pain because the nurse can't do anything more for my quality of life". 4) Patients recommend asking about pain over a look back period and not just pain now: "when you ask me right then and there I might not be feeling any pain. But the thing that drove me to the clinic might've been a 5 or a 6." 5) In order for it to be an 'appropriate' use of clinic visit time patients want to know providers are going to use the information collected in pain screening: "I'm a process guy…the question is what do you do with that information about my pain."

CONCLUSIONS: Patients endorse the perceived value of pain screening, especially when they perceive pain to be actionable, and because some patients may not report it. Patients highlighted the perceived value of function and

chronicity in assessing pain. These perspectives can inform improving the identification and management of pain in primary care.

ASSESSING MOTIVATION AND BARRIERS TO WEIGHT LOSS

Christina Fahey; Abigail Lawson; Garrett Oberst; Dylan Woolum; David Rudy; Stephanie A. Rose. University of Kentucky, Lexington, KY. (Control ID #2705367)

BACKGROUND: Obesity and its comorbidities continue to increase in prevalence across the United States. While patients and physicians are increasingly recognizing the importance of weight loss, patients continue to express barriers to losing weight. Understanding these barriers, both medical and personal, can improve care by tailoring weight loss programs to each individual. The aim of this study was to assess barriers to weight loss in patients enrolled in a primary-care based weight loss program, through studying motivations for weight loss and self-efficacy in avoiding situations that trigger poor dietary choices.

METHODS: Patients with a BMI ≥30 kg/m^2 or a BMI ≥25 with obesity related comorbidities were invited to enroll in the Physician Weight Management Clinic in a university-based Internal Medicine Clinic. Patients were asked to complete a survey that included validated questions from the Treatment Self-Regulation Questionnaire (TSRQ), which measures motivation (autonomous [AM], versus controlled [CM]) for weight loss, and validated questions from the Weight Efficacy Lifestyle Questionnaire (WEL-Q), which measures self-efficacy in the ability to resist making poor dietary choices in certain situations. All weight loss clinic patients were asked to complete the survey, but only patients who gave consent to be part of the study were analyzed.

RESULTS: Of 114 consented patients, 27 completed the survey. Mean patient AM for weight loss was 6.2, while mean CM was 3.0 (ranges = 1 [low motivation] to 7 [high motivation]). Patients felt most confident in resisting poor dietary choices in situations involving Positive Activities (mean confidence = 6.4), followed by situations involving Physical Discomfort (6.3), situations involving Social Pressures (6.0), situations involving Availability (5.3), and situations involving Negative Emotions (4.6) (range 0 [low confidence] to 9 [high confidence]).

CONCLUSIONS: Of the surveyed patients, we found that internal confidence for losing weight was greater than external motivators. We also found that situations in which patients had the least confidence in resisting poor dietary choices were those associated with negative emotions. Patients had the most confidence in resisting poor choices in situations associated with positive activities. Limitations include generalizability, as we surveyed patients already in a weight loss program. Future goals include comparing individual barriers to weight loss outcomes, administration of a follow-up survey every 3 months to re-assess self-efficacy and motivations, and comparing motivation and confidence between patients enrolled in and not enrolled in a weight loss program. Assessing individual barriers to weight loss is critical in order to tailor weight loss programs appropriately. This research shows the areas patients struggle with the most and thus provides physicians with the best areas in which to focus treatment.

ASSESSING OUTCOMES FOR MEDICAL STUDENTS INVOLVED IN THE EMORY PIPELINE PROGRAM

Caroline B. Maness[4]; Kevin Luk[4, 2]; Chidiogo Anyigbo[4, 2]; Jennifer O. Spicer[1]; Jordan Rose[3]; Yolanda Hood[4]; Robert Lee[4]. [1]Emory University School of Medicine, Decatur, GA; [2]Rollins School of Public Health, Atlanta, GA; [3]Emory Center for Science Education, Atlanta, GA; [4]Emory University School of Medicine, Atlanta, GA. (Control ID #2698482)

BACKGROUND: The Emory University Pipeline Program is a multi-tiered mentorship and educational program comprised of students from five Atlanta Public Schools, Emory College, Rollins School of Public Health, and Emory University School of Medicine that provides a three year health science enrichment curriculum for underprivileged high school students. High School students in the program receive longitudinal mentorship from Emory undergraduates in the areas of college preparation and career interest development. They also receive in-depth exposure to the health science fields through enrichment curricula taught by graduate students. While Pipeline has conducted annual evaluations of high school and undergraduate members' satisfaction with the program, career skills development, and health science knowledge, Pipeline has not been evaluated in terms of its effect on graduate members' careers. Specifically, our study sought to assess the impact of Pipeline on medical student alumni's teaching ability, communications skills, career preparation, and mentorship involvement.

METHODS: We created a 28 question online survey that was sent via email to the 40 alumni who participated in Pipeline while medical students at Emory University School of Medicine as of 2014. The survey assessed what effect participation in Pipeline had in the following domains: teaching ability and comfort, communication skills, career preparation and fulfillment, and mentorship. A portion of survey responses were scored on a 1 (Strongly Disagree) to 5 (Strongly Agree) Likert scale and the second survey portion inquired about continued participation in extracurricular teaching and mentoring. Likert scale responses of 4 or 5 were used to indicate a beneficial impact of Pipeline, and scores of 3 or below were interpreted to indicate that Pipeline had no impact or a negative impact.

RESULTS: Out of 40 alumni who received the survey, 24 began the form and 21 completed all sections. Pipeline alumni reported benefit in their teaching ability in small group settings (100%, $n = 23$) and lecture settings (91.3%, $n = 23$), and 78.3% ($n = 23$) of respondents reported engaging in teaching activities outside of those required on service. 82.6% ($n = 23$) of alumni reported participating in Pipeline improved their ability to communicate with patients, and 91.3% ($n = 23$) indicated that Pipeline strengthened their ability to communicate with undergraduates and medical students. Many of the respondents (79.2%, $n = 24$) agreed that participating in Pipeline helped clarify the types of settings in which they would like to practice. Furthermore, 95.5% ($n = 22$) of Pipeline alumni endorsed continued participation in mentorship relationships beyond Pipeline.

CONCLUSIONS: The Emory Pipeline Program enhanced medical students' teaching and communication abilities. Pipeline alumni also continued to participate in high rates with teaching and mentorship activities. Participation in Pipeline programs should be encouraged to facilitate the development of clinician educators.

ASSESSING THE EFFECTIVENESS OF A TRAINING INTERVENTION ON COMMUNITY HEALTH CENTER STAFF'S ABILITY TO IMPLEMENT DIABETES GROUP VISITS

Ivana I. Barouhas[2]; Sarah P. Hermans[4]; Erin M. Staab[2]; Amanda Benitez[5]; Amanda Campbell[1]; Cynthia T. Schaefer[3]; Michael T. Quinn[2]; Arshiya A. Baig[2]. [1]Midwest Clinicians' Network, East Lansing, MI; [2]University of Chicago, Chicago, IL; [3]University of Evansville, Evansville, IN; [4]American University, Washington, DC; [5]Enlace Chicago, Chicago, IL. (Control ID #2703682)

BACKGROUND: Group visits, which supplement one-on-one medical care with patient education and social support, have been shown to improve outcomes among adults with diabetes. We designed and evaluated the

effectiveness of a training intervention to prepare community health center (CHC) staff to implement and sustain diabetes group visits. We also identified facilitators and barriers to the adoption of this care model, our aim being to help guide best practices in its widespread implementation.

METHODS: This 18-month pilot study included monthly webinars and two in-person learning sessions designed to guide the execution of six monthly group visits by twenty-six CHC staff at seven sites within the MidWest Clinicians' Network. We conducted surveys assessing staff preparedness to implement group visits before Learning Session 1 (LS1), after LS1, and after Learning Session 2 (LS2). Most questions were scored on a scale from 1 = strongly disagree to 5 = strongly agree. Questions asking the degree to which factors were barriers to group visits were scored from 1 = major barrier to 4 = not a barrier. We used paired t-tests to assess for change between pre- and post-LS1 values and between post-LS1 and post-LS2 values. $P < 0.05$ was considered significant. We performed a qualitative analysis of audio-recorded team check-ins and telephone interviews to identify challenges and successes of the group visit programs.

RESULTS: The surveys showed increased staff awareness of: group visit barriers from 3.74 ± 0.76 (mean ± SD) pre-LS1 to 4.30 ± 0.47 post-LS1 ($P = 0.004$), and to 4.83 ± 0.38 post-LS2 ($P = 0.0005$); benefits of the group visit model from 3.96 ± 0.71 pre-LS1 to 4.48 ± 0.51 post-LS1 ($P = 0.0001$); and key factors for group visit success from 3.00 ± 0.92 pre-LS1 to 4.26 ± 0.45 post-LS1 ($P = 0.0000$). From post-LS1 to post-LS2, the degree to which transportation, concerns regarding individual medical attention, and concerns regarding patient privacy impeded group visits improved from: 2.04 ± 0.76 to 2.50 ± 0.79 ($P = 0.0144$), from 3.00 ± 0.68 to 3.67 ± 0.49 ($P = 0.0036$), and from 3.00 ± 0.83 to 3.56 ± 0.51 ($P = 0.0014$), respectively. General preparedness to conduct group visits increased from 3.78 ± 0.85 pre-LS1 to 4.17 ± 0.39 post-LS1 ($P = 0.01$). Group visit facilitators included: thorough preparation and knowledge about the care model; a motivated team; experienced diabetes educators; supportive CHC leadership; and adequate space for the visits. Common barriers included patient barriers (recruitment, transportation, motivation), and staff barriers (time limitations).

CONCLUSIONS: While CHC staff noted several barriers to the implementation of diabetes group visits, our training intervention increased staff confidence, preparedness, and awareness of key group visit elements. Facilitators to sustaining group visits included preparation-, team-, and facility-related factors. Future research is needed to assess our training program in a larger sample of CHC sites and assess the impact of diabetes group visits on patient outcomes.

ASSESSING UTILIZATION OF PRIMARY CARE PRACTICES BY PATIENTS WITH SELF-REPORTED EXCESSIVE ALCOHOL USE

Dennis Keselman[1]; Jeanne Morley[2, 1]; Laura Harrison[3]; Linda DeMasi[3]; Vladislav Fomin[1]; Megan O'Grady[4]; Nancy Kwon[3, 1]; Jonathan Morgenstern[2, 1]; Joseph Conigliaro[2, 1]; Sandeep Kapoor[3, 1]. [1]Hofstra Northwell School of Medicine, Hempstead, NY; [2]Northwell Health, Great Neck, NY; [3]Northwell Health, New Hyde Park, NY; [4]The National Center on Addiction and Substance Abuse, New York, NY. (Control ID #2705317)

BACKGROUND: There is widespread consensus that screening patients for alcohol misuse and providing brief interventions in primary care settings could lead to improvements in clinical outcomes through early identification, reduction in alcohol misuse, and reduction of alcohol related comorbidities. This would explain the healthcare cost savings seen with SBIRT interventions. However, there are no large-scale data on the primary care utilization patterns of patients who potentially misuse alcohol. The Screening, Brief Intervention, and Referral to Treatment (SBIRT) program implemented at a Level-III Patient-Centered Medical Home incorporates universal screening of patients for potential alcohol misuse, and data from the alcohol screens, together with demographic data, can be used to better understand the patterns of primary care utilization in specific populations.

METHODS: Patients were screened by frontline staff for potential alcohol misuse during all appointments. Patients who screened positive for potential alcohol misuse ($n = 998$), along with a cohort of patients of similar demographics who screened negative ($n = 968$) between 7/1/15 and 6/30/16 were included in a chart review. The chart review obtained data from AllScript Electronic Health Record about each patient's SBIRT alcohol "pre-screen" score using the AUDIT-C standardized tool, demographic information, insurance type, appointment type, number of visits to the PCMH, and the total scheduled appointment time for all their visits to the PCMH. The data was inputted into a HIPPA-certified database system (REDcap) and then analyzed using SPSS and SAS Studio.

RESULTS: Patients that pre-screened positive for potential alcohol misuse used primary care less (mea$n = 87.79$ min and 2.50 visits) than the control group of patients who pre-screened negative (mea$n = 110.33$ min and 3.44 visits) over the 1-year period ($p < 0.0001$). Hispanic/Latino, African-America/Black, middle aged (35–64 years), uninsured, and Medicaid patients have the largest disparities in primary care utilization between the pre-screen positive and negative groups ($p < 0.01$).

CONCLUSIONS: This study shows that patients who drink at higher-risk levels utilize primary care services less, as opposed to more. Hispanic/Latino, African-American/Black, middle-aged, uninsured, and Medicaid patients have the largest disparities in primary utilization between the pre-screen positive and negative groups. This underutilization highlights the importance of identifying patients in need of services at every potential touch point to maximize opportunity for intervention, as well as enhancing outreach and patient engagement. Understanding these primary care utilization patterns will better illustrate future directions for improving care for different patient populations, including those at risk for alcohol misuse.

ASSESSMENT OF A CURRICULUM ON INTIMATE PARTNER VIOLENCE (IPV) FOR INTERNAL MEDICINE RESIDENTS

Emily R. Insetta[1, 2]; Colleen Christmas[2, 1]. [1]Johns Hopkins Bayview Medical Center, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD. (Control ID #2701490)

BACKGROUND: Intimate partner violence (IPV) is a widespread problem in the US, affecting 1 in 4 women and 1 in 7 men. IPV is associated with detrimental physical, mental, and behavioral health consequences. However, there are no standardized IPV requirements in medical education. Studies show that physicians in training and practice have limited IPV knowledge and desire more education. Existing curricula for medical students and practicing physicians have improved IPV knowledge and screening. There are little data for IPV education in residency, particularly for internal medicine residents who are primary care providers during training and beyond. This study aimed to evaluate a curriculum designed to improve residents' knowledge, attitudes, and practices in caring for patients who are IPV victims.

METHODS: 15 first-year internal medicine residents at Johns Hopkins-Bayview participated in two, 1-hour classes during July and August of 2016. The first class included a speaker with IPV experience, a case discussion, and a didactic presentation. The second part reviewed evidence for IPV interventions and focused on patient-doctor communication using role plays. Data were

collected via voluntary, pre- and post-curriculum surveys with questions adapted from the validated tool, PREMIS (Physician Readiness to Manage Intimate Partner Violence Survey). Changes in IPV knowledge, attitudes, and practices were compared using 2-tailed t-tests. Additional responses evaluating the curriculum in the post-test were described.

RESULTS: 15 first year residents participated in the baseline survey and 12 participated after the educational intervention. IPV knowledge was high at baseline and did not improve except for one question about health consequences of IPV ($p = 0.032$). Assessment of attitudes showed an existing recognition of IPV and its health impact, which did not change. The curriculum produced significant changes in self-efficacy including improved confidence in detecting IPV ($p = 0.022$), documenting IPV ($p = 0.000035$), and referring to resources ($p < 0.00001$). Participants reported increased comfort with managing their emotions regarding IPV ($p = 0.0080$) and discussing IPV with female (<0.00001) and male ($p = 0.021$) patients. Self-reported frequency of IPV screening for females remained the same ($p = 0.45$) but improved for male patients ($p = 0.033$). All participants agreed or strongly agreed that after the curriculum they would be more skillful in discussing IPV, more likely to screen for IPV, and better equipped to refer to IPV resources.

CONCLUSIONS: A curriculum for residents improved their confidence and comfort in addressing IPV. After training, all participants felt they were more prepared to screen for IPV, discuss IPV, and refer to resources. Incorporating IPV curricula into residency may promote greater detection of IPV and better care for victims.

ASSESSMENT OF ADHERENCE TO DEPRESSION MANAGEMENT GUIDELINES USING UNANNOUNCED STANDARDIZED PATIENTS: ARE RESIDENT PHYSICIANS EFFECTIVELY MANAGING DEPRESSION IN PRIMARY CARE? Sondra Zabar[1]; Kathleen Hanley[1, 3]; Amanda Watsula-Morley[1]; Lisa Altshuler[1]; Heather Dumorne[1]; Andrew B. Wallach[2, 3]; Barbara Porter[2, 3]; Adina Kalet[1]; Colleen Gillespie[1]. [1]NYU School of Medicine, New York, NY; [2]Bellevue Hospital, New York, NY; [3]Gouverneur Healthcare Services, New York, NY. (Control ID #2705368)

BACKGROUND: All physicians need to be skilled at diagnosing, treating, and managing depression. We designed an unannounced standard patient (USP) case to assess residents' clinical skills in addressing depression and explored how those skills are associated with residents' general clinical skills in order to design targeted curriculum on depression.

METHODS: The USP was a 26 y.o. male presenting as a new patient to a clinic complaining of fatigue and problems sleeping. Goals of the case were to diagnose a common presentation of depression and make a treatment/follow-up plan. The USP was trained to have a positive PHQ 2 & PHQ 9, family history of depression, and be willing to engage in medication and/or therapy if offered. A post-visit checklist was used by the SPs to assess communication, patient education, and assessment skills using behaviorally anchored items rated as not done, partly done, or well done. A systematic chart review was conducted to examine treatment, quality of documentation, and referrals. Case fidelity was checked by audiotape and confirmed by PHQ 9 score in the EHR. Evidence-based treatment was defined as prescribing an SSRI and/or providing a psychiatric referral; if neither of those, scheduling follow-up for within 2 weeks.

RESULTS: 122 residents saw the USP case from 2009–2015. Mean visit length = 45 min, SD 25 (14 to 183 min). The patient was screened for depression with a PHQ 2 in 93% of visits; 82% also had a PHQ 9. Overall, 77 residents (63%) provided appropriate treatment: 8% prescribed an SRRI, 23% provided a referral, 19% did both, 7% prescribed a sleep aid and <2 week follow-up, and 43% provided a combination of these treatments. 45 residents (37%) did not provide appropriate treatment: 27 (60%) prescribed a sleep aid and follow-up >2 weeks and 18 (40%) provided no treatment/referral and follow-up >2 weeks. There were no differences in exploration of medical history or substance use, but 83% of residents who treated appropriately had a PHQ 9 compared to 62% of residents who did not treat appropriately. 71% also included depression on the problem list compared to 13% of residents who did not treat appropriately. Residents who treated appropriately had significantly better clinical skills assessed by the USP including: overall communication (71% vs. 54%, $p = 0.00$), information gathering (72% vs. 55%, $p = 0.01$), relationship development (75% vs. 60%, $p = 0.03$), patient education (55% vs. 21%, $p = 0.00$), and patient activation skills (33% vs. 13%, $p = 0.01$).

CONCLUSIONS: Although almost all residents obtained the relevant information, only about 50% of residents diagnosed depression. PHQ 9 appears to be associated with providing more effective treatment, supporting the importance of health system screening protocols. Residents' communication and depression-specific patient education and activation skills seem to be related to how they identify and manage depression, suggesting that interventions to build these skills may lead to higher quality care.

ASSESSMENT OF SELF-REPORTED MEDICATION ADHERENCE TO INHALED COTICOSTEROIDS AMONG ADULTS WITH ASTHMA AND CHRONIC OBSTRUCTIVE PULMONARY DISEASE. Neelima C. Tangirala[2]; Li Chen[2]; Michael S. Wolf[4]; Rachel O'Conor[4]; Juan P. Wisnivesky[3]; Alex Federman[1]. [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Mount Sinai Health System, New York, NY; [3]Mount Sinai School of Medicine, New York, NY; [4]Northwestern University, Chicago, IL. (Control ID #2707002)

BACKGROUND: Regular use of inhaled corticosteroids (ICS) is the standard of care for patients with persistent asthma and chronic obstructive pulmonary disease (COPD). In research, adherence to ICS is often measured using the 10-item Medication Adherence Report Scale (MARS), a self-reported medication adherence assessment designed to minimize social desirability bias. However, there are limited data on the validity of this measure.

METHODS: Data for this analysis were obtained from the baseline interviews from two cohort studies that examined the association of health literacy with self-management behaviors among adults ages 65 and older with asthma ($n = 452$) and adults ages 40 and older with COPD ($n = 393$). Patients for both studies were recruited from primary care practices in New York City and Chicago. In both studies, research assistants administered the MARS in English or Spanish as part of the baseline assessment. ICS adherence was also objectively measured over a 4-week period, within 3 months of the baseline interview, using electronic monitoring devices that record every actuation of the ICS inhaler, both metered dose and dry powdered devices. Adequate adherence by MARS assessment was defined as a score ≥4.5 based on prior literature, and by electronic monitoring as actuation of ≥80% of doses prescribed. We assessed the criterion validity using correlations between self-reported adherence and electronic adherence. Receiver Operating Characteristic (ROC) curve analysis of the continuous value for MARS scores against the dichotomized outcome of adherence as measured electronically was also performed.

RESULTS: In the study of asthma patients, 78% were prescribed ICS medications and MARS and electronic adherence data were available for 75 and 53% of all patients respectively. In the study of COPD patients, 30% were prescribed ICS medications and MARS and electronic adherence data were available for 87 and 24% of all patients respectively. There were no significant differences between patients missing MARS or electronic data and those with complete data for either study. Among patients with asthma, the continuous values for adherence measured by self-report and electronically were weakly correlated ($r = 0.33$, $p < 0.001$); similarly, the agreement between the discrete measures was weak (kappa 0.30, $p < 0.001$). Findings were similar for COPD patients: $r = 0.29$, $p = 0.003$; kappa 0.27, $p = 0.005$. Area under curve (AUC) values generated from ROC analysis was 0.68 and 0.69, for asthma and COPD patients, respectively.

CONCLUSIONS: Commonly used measure for adherence performed weakly compared to electronic monitoring in separate populations of patients with asthma and COPD. Investigators measuring self-reported medication adherence among patients with these pulmonary diseases should consider using alternative instruments or using objective measures exclusively

ASSESSMENT OF THE SAFETY AND TOLERABILITY OF THE ANTIBIOTIC RIFAXIMIN FOR IRRITABLE BOWEL SYNDROME (IBS): A POOLED ANALYSIS OF THREE PHASE 3 STUDIES

Christopher Chang[4]; Mark Pimentel[1]; Zeev Heimanson[3]; Brian E. Lacy[2]. [1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Dartmouth-Hitchcock Medical Center, Lebanon, NH; [3]Salix Pharmaceuticals, Calabasas, CA; [4]University of New Mexico School of Medicine, Albuquerque, NM. (Control ID #2699361)

BACKGROUND: IBS prevalence in North America is approximately 12%, and studies suggest females are almost twice as likely to have IBS as males. Substantial differences in the gut microbiota (eg, composition and diversity) have been observed in patients with IBS vs healthy individuals. The nonsystemic antibiotic rifaximin 550 mg, taken 3 times daily for 14 days, is indicated for diarrhea-predominant irritable bowel syndrome (IBS-D) in adults. Given that IBS symptoms may be episodic or chronic, patients may require repeated courses of therapy. To gain a better understanding of the rifaximin safety profile, a pooled analysis evaluated safety and tolerability of rifaximin in IBS.

METHODS: This was a post hoc pooled analysis of two phase 3 studies (Trials 1 and 2; rifaximin 550 mg or placebo 3 times daily for 2 weeks) and double-blind retreatment phase of a phase 3 study (Trial 3; 2 courses of rifaximin 550 mg or placebo 3 times daily for 2 weeks, with courses separated by 10 weeks). Safety was assessed through 10 weeks posttreatment in Trials 1 and 2, and through 4 weeks posttreatment after second treatment course in Trial 3. Analysis included patients with ≥1 dose of study medication and ≥1 postbaseline safety assessment.

RESULTS: The analysis included 952 rifaximin-treated and 942 placebo-treated patients. Most AEs were mild to moderate in intensity. The most common AEs (≥2% of patients in rifaximin group) were upper respiratory tract infection, headache, and nausea (Table).. Increased alanine aminotransferase levels were reported in 1.6% (rifaximin) and 1.2% (placebo) of patients. Constipation was reported in 0.7% (rifaximin) and 1.6% (placebo) of patients. Only 1 serious AE in rifaximin group (alcohol withdrawal syndrome) was considered related to study drug. One patient developed a serious AE of *Clostridium difficile* posttreatment. This patient had a history of *C difficile* and received a 10-day course of cefdinir for a urinary tract infection; the AE was not considered to be drug-related but likely due to cefdinir exposure.

CONCLUSIONS: This pooled safety analysis of 952 rifaximin-treated patients supports the safety and tolerability profile of rifaximin in an adult population with IBS.

Table. AE Summary

Parameter, n (%)	Rifaximin ($n = 952$)	Placebo ($n = 942$)
Any AE	480 (50.4)	477 (50.6)
Severe AEs	39 (4.1)	59 (6.3)
Drug-related AEs	81 (8.5)	109 (11.6)
Serious AEs	14 (1.5)	19 (2.0)
AEs leading to study discontinuation	9 (0.9)	9 (1.0)
Upper respiratory tract infection	47 (4.9)	47 (5.0)
Headache	42 (4.4)	51 (5.4)
Nausea	39 (4.1)	31 (3.3)
Diarrhea	34 (3.6)	25 (2.7)
Abdominal pain	32 (3.4)	37 (3.9)
Nasopharyngitis	29 (3.0)	43 (4.6)
Sinusitis	24 (2.5)	23 (2.4)
Urinary tract infection	23 (2.4)	26 (2.8)
Bronchitis	22 (2.3)	22 (2.3)

ASSOCIATION BETWEEN GENDER MINORITY STATUS AND SELF-REPORTED MENTAL AND PHYSICAL HEALTH IN THE U.S.

Carl G. Streed[3]; Ellen P. McCarthy[2]; Jennifer Haas[1]. [1]BWH, Boston, MA; [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; [3]Brigham & Women's Hospital, Boston, MA. (Control ID #2703097)

BACKGROUND: Gender minorities, including transgender and gender non-conforming individuals, experience disparities in mental and physical health. Prior investigations are limited in size and geographic scope due to the lack of national survey data on gender identity.

METHODS: We pooled 2014 and 2015 Behavioral Risk Factor Surveillance System (BRFSS) data and analyzed measures of participant-reported mental health and physical function among gender minority adults (transgender 1,173, representing an estimated 727,983 adults; gender non-conforming 270, representing 184,038 adults) compared to cisgender peers (314,450 representing 162,400,000). We used bivariable and multivariable analyses to identify differences by gender minority status. We performed logistic regression to assess the effects of age, education, race, employment status, and income. We performed analyses using SAS 9.4 and utilized survey procedures to account for the complex sampling design and were weighted to reflect national estimates.

RESULTS: Compared to cisgender adults, gender minority adult respondents are younger (19.2% vs 24.4% under 30 years-old), less likely to be white (69.9% vs 56.7% white, non-Hispanic), less likely to be employed (57.2% vs 50.8% employed) and have lower annual household incomes (15% vs 22.1% less than $20,000; all p <0.001). After adjusting, gender minority participants are at increased odds compared to cisgender peers of self-reported fair or poor health and self-reported serious difficulty concentrating, remembering, or making decisions. In sub-group analyses, transgender respondents are at increased odds compared to cisgender peers of self-reported serious difficulty concentrating, remembering, or making decisions. Gender non-conforming respondents are at increased odds compared to cisgender peers of self-reported fair or poor health, self-reported serious difficulty concentrating,

remembering, or making decisions, and self-reported limitation in any way because of physical, mental, or emotional problems (all $p < 0.001$).

CONCLUSIONS: Significant self-reported mental and physical health disparities exist for transgender and gender non-conforming adults in the United States; these disparities persist even when adjusting for known protective factors, such as employment or income. These disparities in self-reported mental and physical health beg the need for additional research into potentially unmeasured stressors transgender and gender non-conforming people experience. In addressing mental and physical health, clinicians should be sensitive to the need to be aware of the unique needs of gender minorities.

Adjusted Odds Ratio of Gender Minority Status and Self-Reported Mental and Physical Health Outcomes

ASSOCIATION BETWEEN PURPOSE IN LIFE AND GLUCOSE CONTROL AMONG OLDER ADULTS

Dina H. Griauzde[2, 3]; Michele Heisler[3]; HwaJung Choi[2]; Claire Ankuda[2]; Tyler N. Winkelman[4, 3]; Jeff Kullgren[1]. [1]Ann Arbor VA Healthcare System and University of Michigan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Ann Arbor VA/University of Michigan, Ann Arbor, MI; [4]University of Michigan, St. Paul, MN. (Control ID #2707330)

BACKGROUND: Greater purpose in life is associated with lower rates of certain chronic conditions such as cardiovascular disease and stroke. Whether purpose in life can protect against development of prediabetes or type 2 diabetes is unknown. The objectives of our study were to examine associations between purpose in life and subsequent (1) change in hemoglobin A1c (HbA1c) and (2) development of clinically meaningful categories of abnormal glucose metabolism (i.e., prediabetes or type 2 diabetes) among US adults. We hypothesized that greater levels of purpose in life would be associated with smaller increases in HbA1c and lower rates of developing abnormal glucose metabolism compared to lower levels of purpose in life.

METHODS: We conducted a national study of 3,907 adults age 50 and older who did not have type 2 diabetes or prediabetes and were participants in the Health and Retirement Study. Baseline purpose in life was measured using a 7-item, validated adaptation of Ryff and Keyes' Scales of Psychological Well-Being and grouped into tertiles (high, medium, low). We used multivariable linear regression to examine the association between baseline purpose in life and change in HbA1c from baseline to 4-year follow-up. Multivariable logistic regression was used to examine the association between baseline purpose and incident prediabetes or type 2 diabetes over the same period.

RESULTS: After adjusting for sociodemographic factors, body mass index, physical activity, and physical and mental health factors, change in HbA1c was 0.07 percentage points lower among participants with high purpose than those with low purpose (95% CI −0.12 to −0.02; $p = 0.011$). Participants with high purpose had lower odds of developing prediabetes or type 2 diabetes than those with low purpose (adjusted odds ratio 0.78; 95% CI 0.62 to 0.98; $p = 0.037$).

CONCLUSIONS: Among older adults, greater purpose in life is associated with a lower incidence of prediabetes or type 2 diabetes. Strategies to promote greater purpose in life should be tested as part of type 2 diabetes prevention efforts.

ASSOCIATION OF CITIZENSHIP STATUS WITH KIDNEY TRANSPLANTATION IN PATIENTS ON MEDICAID

Jenny I. Shen[1, 2]; Daniel Hercz[2]; Lilly Barba[1, 2]; Holly Wilhalme[2]; Erik L. Lum[2]; Edmund Huang[2]; Leslie K. Salas[1]; Sitaram Vangala[2]; Keith Norris[2]. [1]LaBiomed at Harbor-UCLA Medical Center, Torrance, CA; [2]Medicine, University of California, Los Angeles, Los Angeles, CA. (Control ID #2692159)

BACKGROUND: Although undocumented immigrants can receive emergency dialysis in the US regardless of their ability to pay, most states do not provide them with subsidized care for renal transplantation, a more cost-effective form of renal replacement therapy that provides better outcomes for patients. The objective of the study was to determine whether undocumented immigrants have similar outcomes to U.S. citizens after receiving kidney transplants covered by Medicaid.

METHODS: In this observational cohort study, we identified from the United States Renal Data System and followed for 5 years all adult patients on Medicaid who received their first kidney transplant from 1990–2011 and categorized them by citizenship status. We applied Cox proportional hazards frailty models with transplant center as a random effect to estimate the hazard ratios (HR) and 95% confidence intervals (CI) for all-cause graft loss.

RESULTS: Of 10,495 patients, 8660 (82%) were U.S. citizens, 1489 (14%) were permanent residents, and 346 (3%) were undocumented immigrants. Undocumented immigrants were younger, healthier, on dialysis longer, and more likely to have had a living donor. 71% were transplanted in California, and 61% were transplanted after 2005. We identified 42 graft failures in undocumented immigrants (3.7/100 person-years) and 2,445 in U.S. citizens (7.9/100 person-years). Undocumented immigrants had a lower unadjusted risk of graft loss compared to US citizens (HR 0.48, 95% CI: 0.35–0.65). Results were attenuated but still significant when adjusted for demographics, comorbidities, dialysis, and transplant-related factors (HR 0.67, 95% CI: 0.46–0.94).

CONCLUSIONS: Only 3% of patients with Medicaid transplanted in the US were undocumented immigrants. The transplants occurred mostly in California, have increased in recent years, and our study suggests that they do no worse, and perhaps even better, than US citizens. Policymakers should consider expanding coverage for kidney transplantation in undocumented immigrants is it leads to high quality outcomes while lowering the overall costs of renal replacement therapy in these patients.

ASSOCIATION OF HYPERTENSION AMONG SELF-REPORTED BINGE DRINKERS IN A PATIENT-CENTERED MEDICAL HOME WITH A SCREENING, BRIEF INTERVENTION, AND REFERRAL TO TREATMENT PROGRAM Vladislav Fomin[1]; Jeanne Morley[2, 1]; Laura Harrison[3]; Linda DeMasi[3]; Dennis Keselman[1]; Megan O'Grady[4]; Nancy Kwon[3, 1]; Jonathan Morgenstern[2, 1]; Joseph Conigliaro[2, 1]; Sandeep Kapoor[3, 1]. [1]Hofstra Northwell School of Medicine, Hempstead, NY; [2]Northwell Health, Great Neck, NY; [3]Northwell Health, New Hyde Park, NY; [4]The National Center on Addiction and Substance Abuse, New York, NY. (Control ID #2705251)

BACKGROUND: 70 million adults in the United states have hypertension, of which only half is properly controlled. Binge drinking has been found to be associated with a modest increase in blood pressure and in certain populations, with an increased prevalence of hypertension. There is not an established link between self-reported binge drinking and prevalence of hypertension in a diverse urban population. This study sought to compare self-reported drinking patterns with blood pressure and hypertension status at the time of visit.

METHODS: The Screening, Brief Intervention, and Referral to Treatment (SBIRT) protocol has been implemented within the workflow of a Level-III Patient-Centered Medical Home, in which every patient is given a standardized three question pre-screen (AUDIT-C) to evaluate their drinking patterns. We used data from this pre-screen in connection with a linked AllScripts Electronic Health Record to collect demographic and patient visit data. 998 patients who screened positive for potential alcohol misuse over the past year (7/1/15-6/30/16) were controlled matched based on age, gender, race and ethnicity ($n = 968$). AllScripts Electronic Health Records were linked to the patients' responses to the pre-screen questionnaire and were used to collect patient data at time of visit. Hypertensive status was qualified as either having a systolic blood pressure greater than 140, having a previous diagnosis of hypertension, or being currently treated for hypertension. Data was analyzed using SPSS software. The primary statistical tool used was a logistic regression with covariates.

RESULTS: When adjusted for age, BMI, and tobacco usage, there was no association found between the rate of hypertension and binge drinking compared with those who screened negative for potential alcohol misuse (p >0.05). Similarly, there was no association found between hypertension and those who screened positive for potential alcohol misuse when compared to those who screened negative ($p > 0.05$). When compared to non-binge drinkers, binge drinkers had an average of 3.7 units (mmHg) higher systolic blood pressure with no significant difference in diastolic blood pressure ($p > 0.05$). When compared to those who screened negative for potential of alcohol misuse those who screened positive had an average of 2.5 units (mmHg) higher systolic blood pressure and 1.4 units higher diastolic blood pressure ($p < 0.05$).

CONCLUSIONS: This study illustrates that self-reported binge drinking and alcohol consumption over healthy NIAAA guidelines did not correlate with a diagnoses of hypertension in our population of patients. The modest trend towards increased blood pressure highlights the importance of understanding a patient's alcohol consumption when addressing, counseling and managing elevations in blood pressure. Irrespective of diagnosis of HTN, alcohol misuse is associated with higher BP's which may have long term implications if treated early.

ASSOCIATION OF PLANT-BASED PROTEIN WITH SLEEP QUALITY AND DURATION IN WOMEN Allison Crawford[1]; Brooke Aggarwal[1]; Heidi M. Greenberger[1]; Ming Liao[2]; Marie-Pierre St-Onge[1]. [1]Columbia University, New York, NY; [2]Columbia University Medical Center, NEW YORK, NY. (Control ID #2705746)

BACKGROUND: Experimental evidence has demonstrated that diet composition affects sleep; however, examinations in a non-experimental context are few. The purpose of this study was to assess the relation between sleep duration and quality and plant-based dietary protein intakes.

METHODS: Women, age 20–75 ($n = 106$), were recruited from an urban academic health center. Study population characteristics were as follows: mean age 40+/−18 years, 61% white, 83% employed, 93% college degree, 24% current/former smokers, 61% chronic disease, and 44% BMI <25 kg/m^2. Participants taking sleep medications ($n = 20$) and/or participants with missing data ($n = 7$) were excluded from the analyses; analytic population $n = 82$. Sleep quality and duration were assessed using the Pittsburgh Sleep Quality Index (PSQI) and the Insomnia Severity Index (ISI). Dietary history was obtained using the Block Brief Food Frequency Questionnaire (FFQ). Food items were coded as plant or animal based. Total protein was calculated for each food using the USDA Food Composition Database. The sum of daily protein from plant-based foods was calculated as a percentage of total daily caloric intake. The proportion of energy consumed from protein included only food items coded as plant-based in this analysis. The associations between the proportion of plant-based protein energy intake and sleep variables were assessed using logistic and linear regression models. Logistic regression models included sample medians for plant-protein intake (≥4% vs. <4) and ISI score (<7 vs ≥7); recommended cut points were used for sleep duration (<7 vs. ≥7 h) and sleep quality (PSQI score <5 vs ≥5). Multivariate adjustment included age, race, education, income, and smoking status.

RESULTS: Sample mean sleep duration was 6.70+/−1.35 hours, sleep quality scores 5.50+/−3.74, and mean plant-protein daily consumption 4.07%+/−1.51%. In bivariate linear models, percentage of plant-based protein intake was positively associated with sleep duration ($ß = 0.22$, $p = 0.04$). Higher percentage of plant-based protein intake was also associated with better sleep quality ($ß = -0.571$, $p = 0.02$), and lower insomnia ($ß = -0.87$, $p = 0.046$). In bivariate logistic models, consuming ≥4% of energy from plant protein was associated with lower odds of short sleep duration (OR 0.27, CI 0.10–0.74, $p = 0.01$) and there was a trend for higher sleep quality (OR 0.41, $p = 0.07$). In multivariate adjusted logistic models, the association of plant-based protein intake with sleep duration was statistically significant (p =0.01) and marginally significant for sleep quality ($p > 0.05/\leq 0.11$) and in the expected direction for both.

CONCLUSIONS: Plant-based protein consumption in women was associated with sleep duration and possibly with better sleep quality. Completion of cohort recruitment will increase statistical power to test these associations. Limitations include possible confounding for unmeasured covariates.

ASSOCIATION OF STRUCTURED ASYNCHRONOUS VIRTUAL VISITS FOR HYPERTENSION FOLLOW-UP IN PRIMARY CARE WITH BLOOD PRESSURE CONTROL AND USE OF CLINICAL SERVICES David M. Levine[2]; Ronald F. Dixon[3]; Jeffrey A. Linder[1]. [1]Brigham and Women's Hospital, Boston, MA; [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [3]Massachusetts General Hospital and Harvard Medical School,, Boston, MA. (Control ID #2704278)

BACKGROUND: Optimal management of hypertension requires frequent monitoring and follow-up. Novel, pragmatic interventions are needed to engage patients, maintain blood pressure control, and enhance access to busy primary care practices. "Virtual visits" are structured asynchronous online interactions between patients and their primary care clinicians to extend medical care beyond the initial office visit. Virtual visits have high patient and clinician satisfaction, but clinical outcomes and subsequent utilization of primary and other health care are unknown.
METHODS: We studied patients presenting to primary care practices with a principle diagnosis of hypertension at a large health care network in the Northeast United States. The exposure group was every patient who had engaged in a hypertension virtual visit. After a visit where hypertension was discussed, clinicians could ask their patients to follow-up online. A patient entered blood pressure, adherence, and other items. Once submitted, the clinician responded with treatment decisions. The usual care group was drawn from all patients who presented to a primary care office for hypertension in the same network, but where virtual visits were not yet available. For both groups, the "pre-visit" and "post-visit" time periods were 180 days before and after the index visit. We used logistic regression to create a propensity score of receiving a virtual visit. We propensity-score matched on age, gender, language, partner status, veteran status, smoking, race/ethnicity, health insurance, total chronic conditions, mean pre-visit systolic blood pressure (SBP), total pre-visit antihypertensive medications, and pre-visit primary care visits, specialist visits, emergency visits, and inpatient admissions. We developed multivariable linear and negative binomial regression models to examine the difference-in-differences in mean SBP change, primary care visits, specialist visits, emergency department visits, and inpatient admissions from the pre to the post period between virtual visit and usual care patients.
RESULTS: Of the 1,051 virtual visit patients and 35,050 usual care patients, we propensity-score matched 878 patients from each group. Both groups were 61 years old, 43% female, 85% White, and had about 5 chronic conditions. Virtual visit patients completed a mean of 2.5 (95% CI, 2.3 to 2.7) virtual visit encounters. Compared to usual care, virtual visit patients had an adjusted 0.9 (95% CI, 0.4 to 1.5) fewer primary care office visits and 0.4 (95% CI, 0.03 to 0.7) fewer specialist visits. There was no significant adjusted difference in SBP control (0.6 mmHg [95% CI, −2.0 to 3.1]), emergency department visits (0.0 more visits [95% CI, 0.0 to 0.01]), or inpatient admissions (0.0 more visits [95% CI, 0.0 to 0.1]).
CONCLUSIONS: In a propensity-matched cohort of primary care patients with hypertension, virtual visit participation was associated with equivalent blood pressure control and reduced in-office primary and specialty care utilization.

ASSOCIATION OF TRIGLYCERIDES TO HDL RATIO WITH CARDIOMETABOLIC DISEASE OUTCOMES May Yang; Joseph Rigdon; Sandra A. Tsai. Stanford University School of Medicine, Stanford, CA. (Control ID #2701588)

BACKGROUND: In the US annually, cardiovascular disease (CVD) is the leading cause of death for men and women and roughly 1.4 million people receive a new diagnosis of diabetes. Due to the importance of early intervention, accurately assessing patients' risk for cardiometabolic disease, such as CVD and diabetes, may be clinically beneficial. An elevated plasma triglyceride (TG)/high-density lipoprotein cholesterol (HDL-C) ratio reflects insulin resistance and has been associated with a higher cardiometabolic risk in European and Asian populations. Whether TG/HDL-C predicts CVD is less understood. A database of ethnically diverse patients in an academic center was used to study the association between TG/HDL-C and cardiometabolic disease outcomes.
METHODS: The Stanford Translational Research Integrated Database Environment (STRIDE) identified patients who were over the age of 50 with available data from January 2008 through December 2015. Demographic information and laboratory results were extracted from the database. Data on cardiovascular risk factors and CVD and diabetes diagnoses were collected through chart review. Using a TG/HDL-C ratio measured in 2008, high-risk patients were identified based on previously studied cutoffs (>2.5 for females, >3.5 for males). Logistic regression modeling with adjustments for relevant confounders was used to estimate associations between risk category and diagnosis of CVD or diabetes in follow-up.
RESULTS: One thousand patient charts were reviewed, 29.5% of which were categorized as high-risk by TG/HDL-C ratio. Of the 762 subjects who did not have a diagnosis of diabetes in 2008, 26.1% were categorized as high-risk by TG/HDL-C. There were 14.6% of high-risk TG/HDL-C subjects and 7.1% of low-risk TG/HDL-C subjects diagnosed with diabetes in follow-up. After adjusting for cofounders, high-risk TG/HDL-C ratio was associated with a diabetes diagnosis in follow-up (OR = 1.61, 95% CI: 0.93–2.78) with borderline significance. Asian ancestry significantly increased the risk of diabetes diagnosis in follow-up (OR = 4.82, 95% CI: 2.4–9.7). Of the 772 patients free of CVD diagnoses in 2008, 28.6% were categorized as high-risk by TG/HDL-C. There were 15.4% of high-risk TG/HDL-C subjects and 7.4% of low-risk TG/HDL-C subjects diagnosed with CVD in follow-up. After adjusting for confounders, high-risk TG/HDL-C ratio significantly increased the risk of CVD diagnosis in follow-up (OR = 1.79, 95% CI: 1.03–3.1).
CONCLUSIONS: TG/HDL-C ratio can be used in conjunction with other cardiometabolic risk factors such as body mass index (BMI) to determine risk of diabetes and CVD. The logistic regression findings further suggest that alternative TG/HDL-C criteria may be necessary to identify Asian patients most at risk for diabetes.

ASSOCIATIONS BETWEEN INCARCERATION AND VIRAL LOAD AND HIV TRANSMISSION RISK AMONG HIV-POSITIVE MEN WHO HAVE SEX WITH MEN IN THE US
Laura Hawks[6]; Maria R. Khan[2]; Kathleen A. McGinnis[3]; Joy D. Scheidell[2]; Christian Grov[1]; Amy C. Justice[5]; Emily A. Wang[4]. [1]CUNY School of Public Health, New York, NY; [2]New York University School of Medicine, New York, NY; [3]VA Pittsburgh Healthcare System, Pittsburgh, PA; [4]Yale School of Medicine, New Haven, CT; [5]Yale University, West Haven, CT; [6]Yale University, New Haven, CT. (Control ID #2708548)

BACKGROUND: While new HIV infections have decreased in recent years, new infections are not decreasing among men who have sex with men (MSM), especially MSM of color. Studies have shown that, in general, people at risk for and living with HIV have increased interaction with the criminal justice system than the general population, but little is known about the relationship between criminal justice history and HIV risk among MSM. This study seeks to measure associations between recent and prior history of incarceration and HIV risk behavior and viral load in HIV-positive MSM.
METHODS: The Veterans Aging Cohort Study Survey Substudy (VACS Survey) is an observational cohort of veterans living with HIV that began in 2002 that was designed to evaluate the role of alcohol use with clinical outcomes. We analyzed VACS Survey data from the 2011–2012 follow-up, and include men who reported having at least one male sex partner in the year prior to the survey and who provided data regarding incarceration history ($N = 487$). The

independent variable of interest is self-reported history of incarceration (recent, ever, or never), and the dependent variables are detectable viral load and HIV risk behaviors: injection drug use (IDU), 2+ sexual partner in past 12 months, sex without a condom in the past 12 months, sex without a condom due to alcohol or drug use, and sex with partners who had other sexual partners. Covariates included age, race, education, relationship status, income, and homelessness.

RESULTS: Participants had a mean age of 52 years (sd = 9.5) and included 292 (60%) African-American, 131 (27%) white, and 64 (13%) of other race/ethnicity. The prevalence of incarceration history was 40%. In both unadjusted and adjusted models for age, education, marital status, income, and homelessness, recent and prior incarceration versus no incarceration were strongly associated with having a detectable HIV viral load (recent adjusted odds ratio [AOR] 3.25 95% CI: 1.35–7.83; prior AOR: 3.30 95% CI: 1.84–5.91). Those with a history of incarceration also had significantly higher odds of past 12 month IDU (recent AOR 17.11, 95% CI: 2.78–105.48; prior AOR 6.10, 95% CI 1.15–32.44). Recent and prior incarceration were strongly associated with having two or more sex partners (recent AOR 2.74, 95% CI: 1.25–6.02; prior AOR 1.71, 95% CI 1.11–2.64) and engaging in sex without a condom due to alcohol (recent AOR 14.34, 95% CI: 3.17–64.74; prior AOR 8.30 95% CI: 2.25–30.63) or drug use (recent AOR 5.74 95% CI 1.83–18.03; prior 2.90 95% CI: 1.13–7.42 respectively) and with partners who had other partners (recent AOR 3.31, 95% CI: 1.42–7.72; prior AOR 2.62, 95% CI 1.47–4.68).

CONCLUSIONS: Among HIV positive MSM, incarceration is linked with multiple proximate determinants of HIV transmission including detectable viral load, IDU and high risk sexual activity. This study highlights the importance of targeting this population for intervention following release from incarceration as a means of reducing new HIV infections.

ASSOCIATIONS OF SELF-REPORTED PAIN AND PAIN-RELATED FUNCTION WITH OBJECTIVE PHYSICAL PERFORMANCE IN VETERANS WITH CHRONIC MUSCULOSKELETAL PAIN

Elizabeth S. Goldsmith[1, 2]; Amy Gravely[1]; Agnes C. Jensen[1]; Indulis R. Rutks[1]; Erin E. Krebs[1]. [1]Minneapolis VA Health Care System, Minneapolis, MN; [2]University of Minnesota, Minneapolis, MN. (Control ID #2701126)

BACKGROUND: Chronic musculoskeletal pain affects over 60% of veterans in primary care clinic and is the most common cause of physical disability in the US. Despite this, measuring pain-related physical function remains a challenge. Though self-report measures are the gold standard for pain outcome assessment, their relationship to objective physical performance is unclear. Our objective was to examine associations of self-reported pain-related functional impairment and pain severity with objective physical performance among veterans with chronic musculoskeletal pain.

METHODS: The Strategies for Prescribing Analgesics Comparative Effectiveness (SPACE) trial enrolled 264 veterans (primary care patients of the Minneapolis VA Health Care System) aged 21–80 with chronic (≥6 months) musculoskeletal back or hip/knee arthritis pain for randomization to opioid or non-opioid medication therapy. At baseline, participants completed two self-report measures of pain-related functional impairment—Brief Pain Inventory (BPI) Interference scale and Roland Disability Questionnaire (RDQ)—and a measure of pain severity, the BPI Severity scale. Participants completed study-staff-assessed physical performance measures including 6 meter gait speed, chair stand test, and the Fullerton Advanced Balance Scale (FAB). We compared baseline self-reported and objective measures via general linear regression models adjusted for participant age and sex, considering BPI Interference as the primary measure.

RESULTS: 259 patients had complete pain-related measures at baseline. On average, each one point higher on the 0–10 BPI-Interference scale was associated with 0.2 s slower 6 meter walk ($p < 0.0001$), 0.5 fewer chair stands in 30 s ($p < 0.0001$), and 1.1 points lower on the Fullerton Advanced Balance Scale ($p < 0.0001$). Similarly, higher self-reported pain severity (BPI-Severity) and pain-related impairment on the RDQ were also significantly associated with worse objective physical performance by all measures (gait speed, chair stands, and FAB).

CONCLUSIONS: Measures of self-reported pain-related functional impairment and pain severity were strongly associated with objective physical performance in this population of veterans with chronic musculoskeletal pain. These findings support the validity of patient-reported measures of pain-related function. Future analyses will examine whether self-reported pain measures and physical performance respond similarly to pain treatment over the 12-month SPACE trial. Further research may identify subcategories of patients and pain conditions in which self-reported pain measures relate differently to observed physical performance, and may clarify roles of additional pain dimensions such as pain sensitivity.

AT-THE-BEDSIDE WALKING INTERDISCIPLINARY ROUNDS - STREAMLINED COMMUNICATION BUT NOT YET THE ANSWER FOR PATIENT SATISFACTION

Katherine A. Hochman[3]; Nicole Adler[2]; Ramon Jacobs[1]; Brian Bosworth[1]; Anne Meara[1]; Regina Presa[1]; Thomas Sedgwick[1]; Patricia Lanzelloti[1]; Lisa Gumbrecht[1]. [1]NYU Langone Medical Center, New York, NY; [2]NYULMC, New York, NY; [3]New York University School of Medicine, New York, NY. (Control ID #2701239)

BACKGROUND: Prior To March 2016 interdisciplinary rounds were held in the back of the nurses' stations on two inpatient medial units. Patients satisfaction scores around the discharge process and communication were consistently low. Medical director and nurse manager dyad leadership teams redesigned interdisciplinary rounds to improve communication between the patient and the health care team.

METHODS: With the At-The-Bedside Walking Interdisciplinary Rounds initiative, every patient is visited by the entire interdisciplinary team each afternoon. The interdisciplinary team consists of the Hospitalist, the unit nurse manager, the bedside nurse, the care manager, the social worker and the medicine resident. Each visit takes 3–5 min and is led by the resident, who starts by introducing every member of the team. Importantly, the patient is surrounded by every person on the team (a design to be literally and figuratively patient centric). Rounds are structured around four simple questions designed to effectively communicate the diagnosis, the milestones for discharge and the discharge disposition and date. Updated information is written on the patient's white board, located at the foot of the bed. Patients and caregivers have an opportunity to ask clarifying questions. Moreover, the patient can experience first-hand the collaboration that takes place amongst the team members with a streamlined and unified message. The team will use a video language access network for interpreter services for those patients who feel more comfortable speaking in their native language. For those patients who prefer not to discuss discharge planning in large groups, members of the team will return individually.

RESULTS: When comparing pre (Q1CY2016, $N = 81$) and post (Q2CY2016, $N = 80$) intervention top box HCAHPS patient satisfaction scores, the results were

mixed. Care transitions improved slightly from 46 to 48 and communication with doctors increased from 74 to 75%. Communication with nurses decreased from 78 to 75%. Discharge information, however, improved from 78 to 84%.
CONCLUSIONS: While these early results are disappointing, we believe that patient centered care starts with streamlined communication at the bedside with the interdisciplinary team. We will be tweaking how to better contextualize these rounds for patients in the future.

ATTITUDES TOWARD PEOPLE LIVING WITH HIV AMONG MEN WHO HAVE SEX WITH MEN USING AND NOT USING PREP: IMPLICATIONS FOR PREP DISSEMINATION

Evan Rausch[1]; Patel V. Viraj[2]. [1]Montefiore Medical Center, New York, NY; [2]Montefiore Medical Center/Albert Einstein College of Medicine, New York, NY. (Control ID #2706094)

BACKGROUND: HIV Pre-exposure Prophylaxis (PrEP) with antiretroviral medications is highly effective in preventing HIV acquisition, but social barriers to access have hampered adoption among certain groups at highest risk, including young Black and Latino men who have sex with men (YBLMSM). Little is known about the relationship between PrEP adoption and attitudes toward people living with HIV (PLWHA). We conducted a qualitative study interviewing YBLMSM on their views on PrEP and HIV to identify differences between PrEP adopters and non-adopters and inform PrEP uptake interventions.
METHODS: We conducted individual semi-structured interviews with YBLMSM recruited through Facebook from July 2015 to November 2015. Patients met inclusion criteria if they were between 18 and 29 years of age, had engaged in condomless anal sex with a man in the past year, were HIV negative by self-report, were living or working in the Bronx, New York, and were fluent in English or Spanish. We continued interviews until reaching thematic saturation and used a modified grounded theory approach for analysis. Two investigators independently coded all interviews using an iteratively developed codebook.
RESULTS: Participants ($n = 19$) all identified as gay and had a primary care provider. About half ($n = 10$) used PrEP at the time of interview (adopters). Three themes related to attitudes toward PLWHA emerged that differed between adopters and non-adopters: relationships with people with HIV, HIV status disclosure, and severity of HIV. Most participants knew a PLWH, but adopters were more likely to have a close friend with HIV or multiple friends with HIV. Although both adopters and non-adopters had experienced sexual encounters where an PLWH withheld their status, those who adopted PrEP viewed the experience in a more positive light and framed it in the context of challenges around HIV stigma and disclosure. Non-adopters were more likely to view HIV as a severe diagnosis, while adopters were more likely to view HIV as a chronic illness.
CONCLUSIONS: Although PrEP is used to prevent HIV acquisition, our findings suggest that PrEP adoption in YBLMSM is associated with more accepting views of PLWH. Reduction of HIV stigma is a potential focus of interventions promoting PrEP adoption, offering a way to unify future HIV treatment and HIV prevention strategies around a common goal of reducing HIV disparities.

ATTRITION AMONG WOMEN VETERAN COMMUNITY CARE USERS NEW TO VA

Susan M. Frayne[1]; Ciaran S. Phibbs[1]; Elizabeth M. Yano[2]; Donna L. Washington[2]; Fay Saechao[1]; Eric Berg[1]; Sarah Friedman[1]; Andrea Finlay[1]; Katherine J. Hoggatt[2]; Alison Hamilton[2]. [1]VA Palo Alto, Palo Alto, CA; [2]VA Greater Los Angeles HSR&D Center, Sepulveda, CA. (Control ID #2702970)

BACKGROUND: The Veterans Health Administration (VA) purchases care in the community for many patients, and disproportionately for women. Little is known about the patient experience of community care, especially for new patients who are forming their first impressions of VA. For women newly joining VA, we characterized facility-level variability in use of community care, then examined whether use of community care predicted attrition from VA.
METHODS: Among women Veterans with 1+ VA primary care (PC) clinic visit in fiscal year 2011 who were new to VA (no VA or fee basis use in the prior 8 years), those with at least one outpatient or inpatient non-VA (fee) medical care visit in the year following T0 (date of first outpatient visit) were "community care users." Attrition was defined as no VA care in person-specific years 2–3 following T0.
RESULTS: Among the 18,395 new women VA primary care patients nationally, 5,555 (30.2%) were community care users in their first year of VA care. Across facilities, 1.7 to 69.9% (median 35%) were community care users. The attrition rate of was 7.8% for community care users vs 19.3% for others; this pattern was similar for patients at VA Medical Centers (VAMCs) and Community-Based Outpatient Clinics (CBOCs). In a logistic regression, odds of attrition were lower for community care users than for others (adjusted OR 0.43, 95% CI 0.38-0.48), controlling for age, race/ethnicity, marital status, urban/rural residence, service-connected disability, receipt of care from a designated women's health provider, and receipt of care in a VAMC versus CBOC.
CONCLUSIONS: Nearly one in three new women PC patients received community care at least once within a year of joining VA, although community referral rates varied markedly by facility. Those who received part of their care through VA's community care program had less than half the odds of attriting from VA in the subsequent 2 years compared to women who did not. While further inquiry is needed regarding how assignment to a facility with low versus high reliance on community care impacts the patient experience, these findings offer some reassurance that sending new women patients out to the community for care not available at the local VA does not adversely affect attrition, a patient-centered construct.

AWARENESS OF BULLYING IN INTERNAL MEDICINE RESIDENCIES: RESULTS OF A NATIONAL SURVEY OF INTERNAL MEDICINE PROGRAM DIRECTORS

Manasa Ayyala[1]; Saima Chaudhry[3]; Donna Windish[5]; Denise Dupras[2]; Shalini Reddy[4]; Scott Wright[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Mayo Clinic, Rochester, MN; [3]Memorial Healthcare System, Hollywood, FL; [4]University of Chicago Pritzker School of Medicine, Chicago, IL; [5]Yale University, Cheshire, CT. (Control ID #2705010)

BACKGROUND: Bullying in medical education has been described as a significant and ubiquitous problem in studies of residents and medical students. American and international studies cite upwards of 50% of trainees reporting experiencing bullying, most commonly in its verbal form. Being bullied creates psychological pressure which can lead to mental health consequences including depression, anxiety, and post-traumatic stress disorder. The authors conducted this study to describe perceptions of internal medicine (IM) program directors about the bullying of internal medicine residents.
METHODS: The 2015 Association of Program Directors in Internal Medicine (APDIM) Annual survey was sent to 368 program directors (PDs) with APDIM membership, representing 92.9% of the IM residency programs. To understand internal medicine PDs' perspectives and awareness about bullying in their programs, several questions about bullying were included in the annual

survey. Bivariate analyses were performed on PD characteristics and program characteristics with regard to their answer to the following specific question, "To the best of your knowledge, were one or more of your trainees bullied during the last academic year?"

RESULTS: A total of 227/368 (61.6%) of PDs responded to the survey. Less than one third of respondents (71/227, 31%), reported being aware of bullying in their residency program during the previous year. There were no significant differences between those reporting bullying in their programs and those who did not when gender, tenure as PD, geographic location, or specialty of PD were considered in the analyses (all $p > 0.05$). Those who acknowledged bullying in their program were more likely to agree that bullying was a problem in graduate medical education ($p < 0.0001$), and that it had a significant negative impact on the learning environment ($p < 0.0001$).

CONCLUSIONS: Most IM PDs believe that bullying does not occur in their training programs. Because bullying is thought to negatively affect the learning environment and threaten the well-being of trainees, program directors may wish to more proactively assess its actual prevalence.

AZITHROMYCIN IS ASSOCIATED WITH IMPROVED SURVIVAL IN PATIENTS WITH HEALTHCARE-ASSOCIATED PNEUMONIA

Eric Mortensen[1]; Russell Attridge[2]; Antonio Anuzeto[3]. [1]University of Connecticut Health Center, Farmington, CT; [2]University of the Incarnate Word, San Antonio, TX; [3]South Texas Veterans Health Care System, San Antonio, TX. (Control ID #2705318)

BACKGROUND: Many studies of patients hospitalized with healthcare-associated pneumonia (HCAP) have demonstrated worse survival for those patients who received HCAP concordant therapy as compared to community-acquired pneumonia (CAP) concordant therapy. We hypothesize that this is because azithromycin is a part of CAP concordant therapy, but not HCAP concordant therapy. Therefore the purpose of this study was to examine the association of azithromycin use with 30-day mortality for patients hospitalized with HCAP after adjusting for potential confounders.

METHODS: We conducted a retrospective national study using Department of Veterans Affairs administrative data of patients hospitalized at any Veterans Administration acute care hospital. We included patients >65 years hospitalized with pneumonia in fiscal years 2002–2012 with at least 1 HCAP risk factor. HCAP risk factors include prior hospital admission <90 days, nursing home residency, prior outpatient intravenous antibiotics <90 days, and hemodialysis. Our outcome was 30-day mortality. We used a generalized linear mixed effect model ("multilevel regression") to control for potential confounders, including sociodemographics, comorbid conditions, prior outpatient health care utilization, and severity of illness, as well as for the admitting hospital.

RESULTS: We identified 26,113 patients who meet the inclusion criteria and 7,864 (29.8%) received azithromycin as part of their inpatient antibiotic therapy. After adjusting for potential confounders, we found that 30-day mortality was significantly lower in those who received azithromycin (odds ratio 0.60, 95% confidence interval 0.55-0.64) as part of their inpatient antibiotic therapy.

CONCLUSIONS: In patients hospitalized with pneumonia with HCAP risk factors, we identified a significant association between azithromycin use and 30-day mortality. Our study suggests that for patients with HCAP, azithromycin use may be associated with improved outcomes. Randomized clinical trials are needed to identify what are the best empiric antibiotics regimens for patients hospitalized with healthcare-associated pneumonia.

BARRIERS AND FACILITATORS AFFECTING THE IMPLEMENTATION OF SUBSTANCE USE SCREENING IN PRIMARY CARE CLINICS: A QUALITATIVE STUDY OF PATIENTS, PROVIDERS, AND STAFF

Jennifer McNeely[1, 1]; Pritika Kumar[1]; Traci Rieckmann[3]; Erica Sedlander[1]; Sarah Farkas[1]; Joseph Kannry[2]; Aida C. Vega[2]; Eva Waite[2]; Lauren Peccoralo[2]; Richard N. Rosenthal[2]; Dennis McCarty[3]; John Rotrosen[1]. [1]NYU School of Medicine, New York, NY; [2]ICAHN School of Medicine at Mount Sinai, New York, NY; [3]Oregon Health and Science University, Portland, OR. (Control ID #2707175)

BACKGROUND: Alcohol and drug use is a leading cause of morbidity and mortality that frequently goes unidentified in medical settings. As part of a multi-phase study to implement the NIDA Common Data Elements for collecting substance use screening information in electronic health records (EHRs), we interviewed key clinical stakeholders with a goal of identifying barriers and facilitators affecting the implementation of substance use screening in primary care clinics.

METHODS: Focus groups and individual qualitative interviews were conducted with 67 stakeholders, including primary care patients, medical providers (faculty and resident physicians, nurses), and medical assistants, in two urban academic health systems. Themes were identified, discussed, and revised through an iterative process, and mapped to the Knowledge to Action (KTA) framework (Graham, 2006), which guides the selection and implementation of new clinical practices.

RESULTS: Factors affecting implementation based on KTA elements were identified from participant narratives. Identifying the problem: Participants unanimously agreed that having knowledge of a patient's substance use is important because of its impacts on health and medical care, that substance use is not properly identified in medical settings, and that universal screening is the best approach. Adapting knowledge: The majority of patients and providers stated that the primary care provider should play a key role in substance use screening and interventions. There was discrepancy of opinion regarding the optimal approach to delivering screening. Some felt that patients should self-administer questionnaires, while others thought that patients would be more comfortable having face-to-face discussions with their primary care provider - though not with other members of the care team. Many providers reported that being able to take effective action once unhealthy substance use is identified is crucial. Assessing barriers: Patients expressed concerns about confidentiality, 'denial', and providers' lack of empathy. Barriers identified by providers included individual-level factors such as lack of knowledge and training, and systems-level factors including lack of time, resources, and space, disjointed communication between members of the medical team, and difficulty accessing addiction treatment.

CONCLUSIONS: Based on these findings, we designed and are testing an implementation strategy utilizing universal screening, patient self-administered questionnaires, and EHR-integrated clinical decision support to assist providers in conducting brief motivational counseling and linking patients to behavioral health services, to address unhealthy substance use in primary care clinics.

BARRIERS AND MOTIVATORS TO DIABETES CONTROL IN A NAVIGATOR-PHOTOVOICE INTERVENTION: A QUALITATIVE ANALYSIS

Jenny Jia; Lisa M. Quintiliani; Ve Truong; Cheryl Jean; Karen E. Lasser. Boston Medical Center, Boston, MA. (Control ID #2690649)

BACKGROUND: Diabetes mellitus is a major public health issue that disproportionately affects minorities and individuals with low socioeconomic

status and has major implications on patients' daily lives. We developed and pilot tested a community-based diabetes self-management intervention using photovoice and group education sessions to explore diabetes disease control.

METHODS: Patients with poorly controlled diabetes living in Boston census tracts that we had previously identified as having large numbers of patients with diabetes and who receive primary care at Boston Medical Center, the largest safety-net hospital in New England, were invited to participate in 6 group sessions held at a local library. Sessions included photovoice, a methodology whereby patients use photography and write accompanying narratives to facilitate deeper thinking about controlling their diabetes. We designed three photovoice missions, each with different prompts for participants to take photos in their day-to-day lives related to diabetes. After each mission, a patient navigator facilitated discussions to elucidate patients' experiences. The navigator also invited guest speakers to provide educational presentations (e.g., dentistry) based on requests from participants. Sessions were audio recorded and transcribed. We coded transcripts for themes of barriers and motivators in diabetes control.

RESULTS: The majority of participants ($n = 16$) were 67% female (67%), and African American or Black (89%). Less than half had greater than a high school education. Participation in the group sessions was 68.8% amongst all participants averaged over all sessions. The most common barriers mentioned by participants were 1.) issues with self-control over diabetes self-management ("I have a love affair with food."), 2.) lack of dietary knowledge ("Does it matter if it's white, wheat, or whole wheat [bread]?"), and 3.) frustration and fatigue towards self-management of diabetes ("I've gotten to the point where I'm rebellious. I don't take insulin and I won't take my medication."). Subanalysis of statements related to frustration and fatigue showed that common root issues include the chronic nature of diabetes and no demonstration of improvement in participants' disease control despite individual efforts. Motivators included interpersonal elements, such as the intervention's group sessions ("I enjoy coming down here because you don't feel so alone because a lot of times you don't mention diabetes but it's always in your head."), clinicians, family members, and caregivers.

CONCLUSIONS: The combination of perceived lack of self-control and frustration and fatigue, often related to the chronicity of diabetes and poor outcomes in disease control, is concerning for the development of burnout in the diabetic patient population. Interventions to build resilience in diabetics should be considered. Participants were generally receptive to the group sessions, which may be enhanced by hosting sessions at a community-based location.

BARRIERS AND STRATEGIES FOR TAPERING LONG-TERM OPIOID MEDICATIONS: A QUALITATIVE STUDY OF PRIMARY CARE PROVIDER EXPERIENCES Laura C. Kennedy[2]; Ingrid A. Binswanger[3, 1]; Shane Mueller[1, 3]; Cari Levy[5, 4]; Daniel Matlock[4, 2]; Susan L. Calcaterra[4, 6]; Steve Koester[3]; Joseph W. Frank[4, 5]. [1]Kaiser Permanente Colorado, Denver, CO; [2]University of Colorado, Aurora, CO; [3]University of Colorado Denver, Denver, CO; [4]University of Colorado School of Medicine, Aurora, CO; [5]VA Eastern Colorado Health Care System, Denver, CO; [6]Denver Health Medical Center, Denver, CO. (Control ID #2701272)

BACKGROUND: Since 1999, prescribing of opioid medications quadrupled, as has the rate of drug overdose deaths. Growing observational evidence describes the dose-dependent risks of opioids, but evidence of long-term benefits is lacking. Healthcare providers increasingly seek to taper or discontinue chronic opioid use, but little evidence exists on how to approach this challenging process. We sought to explore primary care providers' (PCPs) experiences discussing and implementing tapers of long-term opioid therapy with patients in their clinical practice.

METHODS: We conducted 6 semi-structured, in-person focus groups with PCPs. A multidisciplinary team developed the focus group interview guide, with areas of focus on discussing risks and benefits of opioid medications with patients, approaches to opioid tapering, and barriers and facilitators to tapering opioids. Focus groups were recorded, transcribed, and coded in ATLAS.ti. We performed qualitative analysis in a mixed inductive-deductive manner and identified themes through an iterative, multidisciplinary, team-based approach.

RESULTS: PCPs ($N = 40$; 70% non-Hispanic white, 85% physicians) at a large academic medical center, an urban safety-net hospital, and a VA medical center participated. Emergent themes were identified in 2 domains: 1) barriers to tapering, and 2) strategies to facilitate tapering. Barriers to tapering opioids include providers' pessimism, limited time and lack of patient-provider trust. One provider noted, "*The patient has to be receptive to the idea. If you don't have that as a baseline, I don't think there's anything you can say where they will be willing to do it*." Describing the impact of time constraints, one provider stated, "*This is never the only conversation I'm having with a patient in that room and patients never come to discuss that, so to sneak that into a visit where they might have three or four other agenda items… can be quite difficult*." Regarding trust, one provider perceived that patients "*fear that if they tell me their pain is better I might decrease their medicine*." Facilitators emerged as both provider- and system-level strategies. Providers sought to connect with patients by demonstrating empathy ("*I understand you're in pain. I get it*"), using simple language ("*This puts you at higher risk of death*") and planning ahead ("*We're going to talk about coming down so it's almost like a quit date*"). A clinic-wide upper limit on opioid dosing supported their efforts to taper opioids. One provider noted, "*The triggering point of the discussion was that new change in policy establishing a new ceiling dose of opiates. So, it's out of my hands*."

CONCLUSIONS: Discussing and implementing opioid tapering presented significant challenges for time-strapped providers. A feasible primary care model to support tapering of long-term opioid therapy may involve communication training for providers, dedicated time to discuss tapering opioids, and clinic-wide policies establishing upper-limits on opioid dosing.

BARRIERS TO IMPLEMENTATION OF A TRANSITIONAL CARE INTERVENTION: A QUALITATIVE ANALYSIS Jeffrey L. Schnipper[1, 3]; Hilary Heyison[1]; Cherlie Magny-Normilus[1]; Elyse R. Park[2]; Nyryan V. Nolido[1]; Ryan Thompson[2, 3]; Gwen Crevensten[2, 3]. [1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA. (Control ID #2706649)

BACKGROUND: Transitions from hospitals to the ambulatory setting are high risk periods for patients. Many interventions have been tried, with varying degrees of success, and often the problem has been with implementation rather than theoretical efficacy of the intervention. The objective of this analysis was to better understand barriers to implementation in the context of a real-world quality improvement study.

METHODS: We developed, implemented, refined, and evaluated a multi-faceted, multi-disciplinary transitions intervention across two hospitals and 18 primary care practices within a Pioneer Accountable Care Organization. We then conducted focus groups of 2–8 clinicians each that were part of or affected by the intervention: inpatient and outpatient physicians, nurses, pharmacists, and care coordinators. We used a semi-structured qualitative interview guide to

standardize data collection. Preliminary themes, including barriers to implementation, were identified a priori using the Systems Engineering Initiative for Patient Safety model of work-system design, then iteratively refined. Each focus group session, approximately 60 min each, was audio-recorded, transcribed, and then uploaded into NVivo 11 (QSR, Melbourne, 2012). Two coders independently coded all transcripts then met to resolve discrepancies.

RESULTS: A total of 8 focus group interviews were conducted, involving 21 participants. Several barriers to implementation of the intervention were identified. Regarding those related to the inherent nature of the intervention, barriers included complexity of certain tasks, such as post-discharge phone calls, relative to the personnel carrying them out, as well as the number of personnel involved. Logistical barriers included different modes of communication between inpatient and outpatient nurses, having enough advanced warning of a pending discharge to perform medication counseling, and lack of staffing to conduct the intervention on weekends. Handoffs between roles and locations was a barrier, with inadequate information systems to keep everyone on the same page and communicate important issues to be followed up. Several providers linked the lack of sufficient staffing for this intervention to the institution's lack of commitment to improving transitions of care. The barriers most often cited by providers were lack of communication and lack of time availability/"bandwidth," followed by lack of institutional commitment, difficult patient population, competing priorities, variable staffing, and logistics.

CONCLUSIONS: This qualitative analysis identified several barriers to the success of transitional care interventions. While some barriers were specific to the intervention being studied, many provide generalizable lessons learned to improve the success of future transitional care interventions.

BEYOND HEALTH INSURANCE: REMAINING DISPARITIES IN U.S. HEALTH CARE IN THE POST-ACA ERA Benjamin D. Sommers[1,2]; Caitlin McMurtry[1]; Robert Blendon[1]; John Benson[1]; Justin Sayde[1]. [1]Harvard School of Public Health, Brookline, MA; [2]Brigham & Women's Hospital, Boston, MA. (Control ID #2704169)

BACKGROUND: The Affordable Care Act (ACA) has reduced the U.S.'s uninsured rate to an historic low, though it faces an uncertain future after the 2016 election. However, coverage is only one of many factors that may contribute to racial and income-based disparities in health care access, affordability, and quality. There has been little post-ACA analysis of remaining disparities in health care and how much of a role health insurance coverage still plays in these gaps.

METHODS: Using a novel national telephone survey of over 8,000 Americans conducted in late 2015, we examined disparities between low-income and high-income adults, and between racial/ethnic minorities and whites. We examined three main outcomes: self-reported quality of care, cost-related delays in care, and emergency department (ED) use due to lack of available appointments. We conducted a series of cross-sectional regression analyses, starting with models that only took into account income or race, and then sequentially adjusted for health insurance, state of residence, demographics, and health status, in order to assess the extent to which disparities were mediated by insurance differences. Then we used multivariate regression to assess respondents' views of whether quality and affordability had improved over the past 2 years and whether the ACA was helping them.

RESULTS: Quality of care ratings were significantly worse among lower-income adults than higher-income adults. Only 10–25% of this gap was explained by health insurance coverage. Cost-related delays in care and ED use due to lack of available appointments were nearly twice as common in the lowest-income group, and less than 40% of these disparities was explained by insurance. There were significant racial/ethnic gaps: reported quality of care was worse among blacks and Latinos than whites, with 16–70% explained by insurance. In contrast to these disparities, lower-income and minority groups were generally *more* likely than whites or higher-income adults to say that the ACA was helping them and that the quality and/or affordability of care had improved in recent years.

CONCLUSIONS: Our post-health reform survey shows ongoing stark income and racial disparities in the health care experiences of Americans. We find evidence that the ACA has helped narrow some of these gaps, suggesting that a potential repeal of the law poses significant risk particularly to low-income groups and racial/ethnic minorities. But even if the ACA survives in some form under the new administration, the law's coverage expansion should not be considered the primary solution to racial and socioeconomic disparities in health care, since health insurance coverage only explains a moderate portion of ongoing disparities in affordability, quality, and access. Additional policy attention will be needed to address these serious problems in the post-ACA era.

BP REPAIRED: EFFECT OF REPEAT MEASUREMENT OF INITIALLY ELEVATED BLOOD PRESSURE ON BLOOD PRESSURE CONTROL Douglas Einstadter[2]; Shari Bolen[3]; Randall D. Cebul[1]. [1]Case Western Reserve University, Chagrin Falls, OH; [2]MetroHealth Medical Center, Cleveland, OH; [3]MetroHealth/Case Western Reserve University, Cleveland, OH. (Control ID #2704668)

BACKGROUND: Hypertension (HTN) affects nearly 70 million people in the US. However, only 53.0% of HTN patients seen in primary care have their BP controlled to <140/90 mm Hg according to national surveys. BP measurement error is recognized as a major cause of poor BP control. Although many aspects of measurement error have been described, the effect of a second BP measurement on overall clinic-measured BP control in real-world practices has not been reported. We evaluated the effect of a second BP measurement on the rate of elevated BP among more than 48,000 patients with diagnosed HTN and followed in primary care at an urban safety-net health system.

METHODS: In mid-2015, we introduced an electronic health record (EHR) prompt to remind staff to repeat a BP measurement for HTN patients whose initial BP was ≥140/90 mm Hg. To evaluate the effect of repeating the BP, we obtained all recorded BP values for HTN patients who were seen in a primary care clinic between January and December, 2016 at MetroHealth, an urban safety-net system in Cleveland, Ohio. We compared the rate of BP control based on the first recorded BP with that of the final recorded BP at each visit. We also determined the change in systolic BP (final-initial) overall and by age, sex, race, insurance and initial systolic BP subgroups.

RESULTS: From January through December, 2016 there were 130,687 primary care office visits for 48,007 patients with HTN. The mean age was 61 years, 59% were female, 43% black, and 30% Medicaid or uninsured. The initial BP was ≥140/90 at 50,684 (39%) visits and an initially high BP was re-measured at 42,464 (84%) visits. The median change (final-initial) in systolic BP was −10 mm Hg (IQR −2 to −18). Among those with a repeat BP, 37% of final BPs were <140/90. Thus, repeating the BP increased the overall HTN control rate by 12% (i.e., 39% × 84% × 37%) from 61 to 73%. Control of BP on repeat measurement was not associated with age, sex, race or insurance type. However, BP change was positively associated with the initial BP value; the higher the initial systolic BP, the greater the change in final systolic BP. While the absolute BP change was greatest for patients with the

highest initial systolic BP, those closest to the control threshold were most likely to have normalization of their BP on repeat measurement.

CONCLUSIONS: Repeat measurement of an initially elevated BP resulted in a meaningful improvement in overall BP control, comparable to that seen with addition of an antihypertensive medication. The absolute BP change was greater for patients with a higher initial systolic BP, but patients with an initial BP value closer to the goal were more likely to normalize on repeat. Implementing routine repeat measurement for an initially elevated BP may contribute to improved decision-making around hypertension management and should be included as a component of programs to improve BP control.

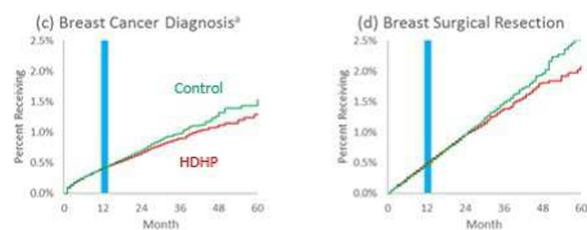
BREAST CANCER DIAGNOSIS AND TREATMENT BEFORE AND AFTER HIGH-DEDUCTIBLE INSURANCE ENROLLMENT James F. Wharam[1]; Fang Zhang[2]; Christine Lu[2]; Anita Wagner[2]; Larissa Nekhlyudov[4]; Craig C. Earle[3]; Stephen B. Soumerai[2]; Dennis Ross-Degnan[2]. [1]Harvard Medical School and Harvard Pilgrim Healthcare, Boston, MA; [2]Harvard Medical School and HPHCI, Boston, MA; [3]Ontario Institute for Cancer Research, Toronto, ON, Canada; [4]Harvard Medical School, Boston, MA. (Control ID #2702914)

BACKGROUND: Primary care physicians play a key role in ensuring appropriate cancer screening, initial workups for breast cancer, and timely transitions through subsequent oncologic care. High-deductible health plans (HDHP) have recently become the predominant commercial health insurance product in the US and the centerpiece of Affordable Care Act replacement proposals. However, HDHP effects on patients undergoing evaluation and treatment for cancer are unknown.

METHODS: We studied Optum health insurance claims and enrollment data derived from a large national health insurer. We used a controlled segmented survival design to examine employer-mandated HDHP transitions, minimizing selection bias. We included approximately 273,000 intervention group women age 25–64 without evidence of breast cancer prior to inclusion. These women were continuously enrolled for 1 year in a low-deductible (≤$500) plan followed by up to 4 years in a HDHP (≥$1000) after an employer-mandated switch. Women were included on a rolling basis and followed between 2004–2012. The comparison group comprised contemporaneous, 1:1 propensity score-matched women whose employers offered only low-deductible plans. Primary outcome measures included times to first diagnostic breast imaging (diagnostic mammogram, breast ultrasound, or breast MRI), breast biopsy, breast cancer diagnosis, and surgical resection (lumpectomy or mastectomy) and were analyzed using segmented survival models adjusted for age group, race/ethnicity, education level, poverty level, US region, index month, and duration of enrollment prior to baseline.

RESULTS: At follow-up, HDHP members experienced delays in receipt of diagnostic imaging (adjusted hazard ratio, aHR: 0.97 [0.94,0.99]), biopsy (aHR: 0.94 [0.89,0.99]), breast cancer diagnosis (aHR: 0.82 [0.74,0.90], Figure), and surgical resection (aHR: 0.90 [0.84,0.98], Figure) compared with controls (*p*-values comparing follow-up aHRs with baseline aHRs: 0.013, 0.026, 0.002, and 0.004, respectively).

CONCLUSIONS: HDHP enrollment was associated with delays in breast cancer diagnostic testing, diagnosis, and surgical resection. Such delays might lead to adverse long-term breast cancer outcomes among HDHP members. Primary care physicians, oncologists, and population health managers should consider closely monitoring women at risk for breast cancer who are enrolled in HDHPs.



Time to first (c) breast cancer diagnosis and (d) breast surgical resection 12 months before and 48 months after a mandated HDHP switch (red line), compared to contemporaneous control group women who remained in low-deductible plans (green line).

BREAST CANCER RISK ASSESSMENT IN A PRIMARY CARE, FEDERALLY QUALIFIED COMMUNITY HEALTH CENTER POPULATION Mita S. Goel. Northwestern University, Chicago, IL. (Control ID #2710534)

BACKGROUND: Since 2005, the U.S. Preventive Services Task Force (USPSTF) has recommended genetic counseling for women at increased risk of breast cancer or ovarian cancer due to BRCA mutations, however, only 18% of primary care physicians use a formal breast cancer risk calculator to identify women at high risk. As a result, we sought to evaluate the feasibility and impact of two methods of assessing the risk of having a genetic mutation increasing breast cancer risk (i.e., in person and via the patient portal) within a primary care setting in a federally qualified community health center (FQHC).

METHODS: We identified women ages 18 and older with established care with Internal Medicine, without a breast cancer diagnosis. To assess possible need for genetic counseling and testing, we administered the Breast Cancer Genetics Referral Tool (B-RST). This test takes approximately 5 min to complete and relies primarily on patient-reported family history. Results are reported as “positive” or “negative.” A positive result connotes increased risk of a genetic mutation and the possible need for detailed genetic counseling. For in-person assessment, we approached all adult women in the waiting area at the FQHC prior to a scheduled appointment and introduced the study. A research assistant administered the B-RST survey in English or Spanish to consenting women. We are currently administering the B-RST through a secure, online patient portal to remaining eligible women who are enrolled in the portal. These women receive an online, secure message with information about breast cancer risk and the B-RST survey. All patients were informed of their results and were given information to assist with interpretation of results. For those patients with positive results, study staff also notified their primary care providers, who were provided detailed information on how to refer patients for genetic counseling, if desired.

RESULTS: For in-person recruitment, we identified 177 eligible women, of whom 168 consented to participate for a 95% recruitment rate. The mean age of participants was 46 years; 144 (95%) were Latina, and 103 (61%) preferred Spanish. Of women surveyed in-person, 38 (23%) reported a family history of breast or ovarian cancer and 4 (7%) had positive scores on the B-RST. For online assessments, we sent messages to 10 women so far, of whom 3 responded, for a response rate of 30%. Mean age was 44 years, and 7 (70% were Latina). One person had a family history of breast or ovarian cancer; none had positive B-RST scores. We are awaiting final data on assessment results from both methods, as well as data regarding referrals for genetic counseling and testing.

CONCLUSIONS: We identified previously unrecognized risk of BRCA gene mutations in a substantial number of women, highlighting the importance of developing systematic methods of risk assessment in this population.

BURNOUT AMONG PRIMARY CARE PROVIDERS AND STAFF IN SMALL TO MEDIUM SIZED PRIMARY CARE PRACTICES: EARLY FINDINGS FROM EVIDENCENOW

Samuel T. Edwards[2, 3]; Miguel Marino[2]; Bijal A. Balasubramanian[1]; Steele H. Valenzuela[2]; Rachel Springer[2]; Leif Solberg[4]; Alex Preston[1]; Deborah Cohen[2]. [1]University of Texas School of Public Health, Dallas, TX; [2]Oregon Health & Science University, Portland, OR; [3]VA Portland Health Care System, Portland, OR; [4]HealthPartners Institute, Minneapolis, MN. (Control ID #2705392)

BACKGROUND: Clinician burnout is associated with poorer health care quality but it is unknown what practice characteristics are associated with clinician and staff burnout in small to medium sized primary care practices.

METHODS: *Study Design and Sample*: We performed a cross-sectional survey of a large nationwide sample of small to medium sized primary care practices participating in the Agency for Healthcare Research and Quality's EvidenceNOW initiative. The seven cooperatives of EvidenceNOW work with 1685 primary care practices in seven regions of the United States to improve the delivery of heart health care. Surveys were fielded at the beginning of EvidenceNOW from 9/22/2015-10/03/2016. *Measures*: A practice survey was administered to practice leadership that collected characteristics such as practice size, ownership, staffing, patient demographics, provider panel size, urban/rural location, and registry use. A practice member survey administered to practice clinicians and staff included questions on job type, years employed, hours worked per week, and burnout. Burnout was assessed using a single item 5-level measure as used in the Physician Worklife Study. A score of 3 or higher indicated burnout. *Analysis*: We conducted a person-level, generalized estimating equation logistic regression to assess the relationship between practice/person characteristics and burnout. Analyses accounted for clustering of clinicians/staff by practice using robust sandwich standard errors.

RESULTS: Of 1685 enrolled practices, 1468 returned surveys (87% response rate). We analyzed a subset of 904 practices in which >1 practice member survey and a practice survey was returned. Among these practices, 5,953 practice members returned surveys, a mean of 6.6 respondents per practice. Burnout was present in 16.9% of respondents overall, but was higher among physicians (22.3%) than other job types (nurse practitioner = 18.9%, clinical staff = 18.3%, non-clinical staff = 16.8%). Correlates of burnout included physician respondent (MD vs. non clinician, OR 1.38, 95% CI 1.07–1.79), non-solo practice (2–5 clinician practice vs. solo practice, OR 1.92, 95% CI 1.36-2.71), more years in practice (4–8 years in practice vs. < 4 years OR 1.63, 95% CI 1.38-1.93) and rural location (urban vs. rural OR 0.65, 95% CI 0.46–0.91). Clinician panel size, patients seen per week per clinician, staff/clinician ratio and practice ownership were not associated with burnout.

CONCLUSIONS: Burnout is prevalent in small to medium sized primary care practices, but at a lower frequency than seen in prior studies and physicians have only slightly higher levels of burnout than other staff members. Members of solo practices have lower odds of burnout, while clinician panel size, patients seen per week and staffing levels are not associated with burnout, suggesting practice autonomy is a more important determinant of burnout than workload. Policy efforts to bolster primary care should focus on promoting practice characteristics associated with less burnout.

BURNOUT AND COPING IN INTERNAL MEDICINE RESIDENTS

Brielle Spataro[1]; Sarah A. Tilstra[4]; Doris Rubio[2]; Melissa McNeil[3]. [1]UPMC Presbyterian Hospital, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA; [3]University of Pittsburgh Medical Center, Pittsburgh, PA; [4]University of Pittsburgh School of Medicine/Medical Center, Pittsburgh, PA. (Control ID #2705365)

BACKGROUND: Physician burnout is a syndrome characterized by emotional exhaustion, depersonalization, and a low sense of personal accomplishment. It is thought to be a consequence of chronic work-related stress. Coping is how one deals with stress and may affect burnout. The objective of our study was to determine the correlations between assessed burnout and coping mechanisms.

METHODS: All internal medicine residents at the University of Pittsburgh are assessed annually in June for burnout using the Maslach Burnout Inventory-General Survey (MBI-GS) beginning prior to the start of the internship year. Residents are considered to have at least one manifestation of professional buronout if they have a high level of either emotional exhaustion or cynicism. In addition, all residents are asked to complete a Brief COPE survey which measures 14 different coping mechanisms. We analyzed all surveys completed from 2010–2015. Spearman correlation was used to determine the relationship between emotional exhaustion and cynicism and coping at each time point. Residents were stratified into post graduate year (PGY).

RESULTS: We analyzed 1,144 surveys from 587 residents. There were 397 pre intern and 309 PGY-1, 227 PGY-2, and 211 PGY-3 assessments respectively. 577 (50%) of the surveys were from women. When evaluating the relationship between burnout and maladaptive coping mechanisms at each PGY level, we found small to moderate correlations between emotional exhaustion with behavioral disengagement (r = 0.18–0.37), self-blame (r = 0.27–0.45), self-distraction (0.18–0.32,), and venting (0.15–0.47). There were small to moderate correlations with cynicism and behavioral disengagement (r = 0.19–0.40), self-blame (r = 0.24–0.35), self-distraction (r = 0.14–0.34) and venting (r = 0.12–0.38). Denial (r = 0.13–0.20) and substance use (r = 0.15–0.22) had small correlations with emotional exhaustion. There were also small correlations with denial (r = 0.10–0.26), humor (r = 0.13–0.21) and substance use (r = 0.10–0.29). with cynicism. When evaluating the relationship between adaptive coping and burnout, we found a small correlation with the use of acceptance with emotional exhaustion (r = 0.10–0.24) and cynicism (r = 0.11–0.15). No other adaptive coping mechanisms consistently correlated at each PGY with emotional exhaustion or cynicism.

CONCLUSIONS: The use of maladaptive coping mechanisms correlated with professional manifestations of burnout. The strongest correlations were seen with behavioral disengagement, self-blame, self-distraction and venting. This suggests that the assessment of coping mechanisms could identify residents at risk for burnout and could serve as an early warning sign for high risk residents.

CAN A WEB-BASED TRACKING & FEEDBACK TOOL IMPROVE BREAST CANCER TREATMENT AT SAFETY-NET HOSPITALS?

Nina A. Bickell[3]; Maria Castaldi[2]; Ajay Shah[5]; Alan Sickles[6]; Theophilus Lewis[7]; Shalini Arora[8]; Kevin Clarke[12]; Peter Pappas[9]; Margaret Kemeny[10]; Anitha Srinivasan[11]; Rebeca Franco[3]; Kezhen Fei[1]; Michael Parides[1]; Ann S. McAlearney[4]. [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Jacobi Medical Center, Manhasset, NY; [3]Mount Sinai School of Medicine, New York, NY; [4]The Ohio State University, Columbus, OH; [5]Bronx-Lebanon, Bronx, NY; [6]NYU Lutheran Medical Center, Brooklyn, NY; [7]Kings County Hospital Center, Brooklyn, NY; [8]Elmhurst Hospital Center, Elmhurst, NY; [9]The Brooklyn Hospital Center, Brooklyn, NY; [10]Queens Hospital Center, Jamaica, NY; [11]Metropolitan Hospital Center, New York, NY; [12]Newark Beth Israel Medical Center, Newark, NJ. (Control ID #2688645)

BACKGROUND: System failures, a cause of underuse in which doctors order care, patients don't refuse but care doesn't ensue, tend to happen more at safety net hospitals (SNH). Tracking & follow-up approaches that close referral loops

in SNHs may reduce underuse. In a randomized trial, we tested a Tracking & Feedback (T&F) tool to reduce underuse of adjuvant breast cancer treatment.
METHODS: We recruited 5 community & 5 municipal SNHs that serve a large proportion of minorities in the NYC metropolitan area. We implemented rapid case ascertainment, a T&F tool and trained point persons at each site to determine if women with newly operated stage 1–3 breast cancer, connected with the oncologist since such connections are associated with getting treated. The tool created a daily "to do" reminder for point persons to ascertain if patients were seen by the oncologist. Point persons then relayed this information to surgeons to follow through as they deemed necessary. Underuse includes: no RT after lumpectomy or mastectomy with >4 positive nodes; no chemo for HR- and no hormonal therapy for HR+ tumors >1 cm; no trastuzumab for Her2+ tumors. We interviewed key informants about tool usefulness. We conducted intention to treat and pre-post analyses to assess tool and implementation effectiveness, respectively.
RESULTS: Pre-intervention, despite randomizing hospitals, intervention (INT) hospitals had fewer whites (4% vs 14%; $p = 0.0005$), poorer follow-up approaches (0.68 vs 0.80; $p = 0.07$), less Medicaid & uninsured patients (36% vs 62%; $p < .0001$) and more underuse (28% vs 15%; $p = 0.002$) compared to control (CNTL) hospitals; comorbidities and stage were similar. The RCT found no difference in underuse rates (9% at INT & 11% at CNTL hospitals; $p = 0.8$). Because randomization did not result in equivalent distributions, we modeled pre- ($N = 403$) and post ($N = 191$) populations controlling for time period and clustering & found that hospitals with better follow-up (OR = 0.82; 95% CI: 0.71–0.96) had less underuse. In settings with poor follow-up & tracking approaches, key informants found the tool useful.
CONCLUSIONS: While the RCT findings were negative, they suggest a T&F tool may help reduce underuse in SNHs with poor follow-up capabilities.

CAN WE LINK STANDARDIZED ASSESSMENT OF RESIDENTS' CLINICAL SKILLS WITH PATIENT OUTCOME DATA? Adina Kalet[2]; Colleen C. Gillespie[2]; Lisa Altshuler[2]; Heather Dumorne[2]; Kathleen Hanley[2]; Andrew B. Wallach[1]; Barbara Porter[2]; Sondra Zabar[2]. [1]Bellevue Hospital, New York, NY; [2]New York University School of Medicine, New York, NY. (Control ID #2702671)

BACKGROUND: At Bellevue Hospital Center (BHC), we have a robust Unannounced Standardized Patient (USP) program, where trained actors portraying real patients in the clinical setting, incognito, assess the residents' skills following their visit. We sought to determine the relationship between USP ratings of residents' skills and clinical outcomes among the residents' continuity patient panels to define educationally sensitive patient outcomes.
METHODS: We assembled a retrospective cohort of PGY 2 internal medicine residents with at least 2 USP visits between 7/1/14-6/30/15 and ambulatory care patient panels at BHC. The two outcome variables were the percentage of hypertensive patients in the residents' panel with blood pressure (BP) <140/90, and the average of the most recent glycosylated hemoglobin (HbA1C) result among the residents' patients with diabetes. The predictor variables included mean USP ratings of residents' clinical skills and mean faculty rating of the residents' clinic notes (scored for quality on a 0 to 3 scale). USPs used a behaviorally anchored checklist (not done, partly done, well done) for the following domains: communication, case specific assessment, patient education, physical examination, professionalism, management plan, patient satisfaction, and patient activation measure. We tested the correlations between USP scores with BP and HbA1C control, and then developed multivariate, linear regression models of USP scores on BP and HbA1C scores, respectively, each controlling for Avg. Chronic health score (ACHS, derived by scoring different clinical conditions by acuity and used to determine if the panel is getting sicker over time) and total number of patients in the panel (TNPP) because these variables were correlated with both the outcome and predictor variables.
RESULTS: 29 PGY 2 residents had a mean of 2.5 (SD 1.0) USP visits during the study period. Residents' patient panels size varied (median 124, range 62–171) and mean patient age was 48 years (SD 1.4). Patient Activation scores were correlated with Average Chronic Health Score ($r = .482$, $p = .008$) and Panel Average last A1c ($r = -.311$, $p = .10$). Patient activation scores explained 16% variance in the mean panel last HgA1c, (adjusted R2 .137, $p = .08$). Case specific Assessment & Patient Education skills across USP cases explained 21.5% of the variance and the Average Chart Note Score explained 14.4% of the variance in % of Hypertension controlled (adjusted R2.378, $p < .009$).
CONCLUSIONS: This exploratory study suggests that learnable resident clinical skills are associated with quality of care indicators for HTN and DM control. In particular, being able to activate patients, assess and educate them and write high quality notes are pathways to quality care. Next steps are to confirm these findings in a larger dataset. Doing so will help align medical education with patient safety and care quality and provide guidance for educational and clinical research aimed at improving the health of populations served.

CARDIOVASCULAR GENETIC RISK TESTING FOR TARGETING STATIN THERAPY IN THE PRIMARY PREVENTION OF CARDIOVASCULAR DISEASE: A COST-EFFECTIVENESS ANALYSIS Jamie A. Jarmul[2, 3]; Mark J. Pletcher[4]; Stephanie Earnshaw[5]; Morris Weinberger[3]; Daniel Jonas[2]; Christy Avery[3]; Kristen Hassmiller Lich[3]; Stephanie Wheeler[3]; Michael Pignone[1]. [1]Dell Medical School, UT-Austin, Austin, TX; [2]UNC-Chapel Hill, Durham, NC; [3]Gillings School of Global Public Health, Chapel Hill, NC; [4]University of California-San Francisco, San Francisco, CA; [5]Research Triangle Institute, Research Triangle Park, NC. (Control ID #2705618)

BACKGROUND: It is unclear whether additional risk stratification using novel risk factors improves clinical decision-making about statin use for primary prevention in patients with intermediate atherosclerotic cardiovascular disease (ASCVD) risk beyond traditional risk factors. Cardiovascular genetic risk testing is one option for risk stratification. The objective of this study was to estimate the cost-effectiveness of testing for a 27-SNP cardiovascular genetic risk score (cGRS) to target statin therapy in the primary prevention of ASCVD.
METHODS: The UNC-RTI Coronary Heart Disease Prevention Model is a state-transition Markov model that can be used to compare incidence of ASCVD, mortality, quality of life, and costs with and without a prevention intervention, for specific clinical scenarios. In the model, a specific clinical scenario is defined by age, sex, and ASCVD risk factors, including systolic blood pressure, total cholesterol, HDL cholesterol, smoking status and anti-hypertensive medication use in non-diabetic, ASCVD-free individuals. We updated this model to evaluate the cost-effectiveness of testing for a 27-SNP cGRS. We tested a set of clinical scenarios that included 45-year-old, 55-year-old, and 65-year-old men and women, each with an intermediate 10-year ASCVD risk of 7.5%. Our primary outcome measure was cost per quality-adjusted life-year (QALY) gained. We performed one-way and two-way deterministic sensitivity analyses for key parameters, including statin disutility, statin medication costs and cGRS testing costs, as well as a global probabilistic sensitivity analysis.
RESULTS: Under base case assumptions for statin disutility (disutility = 0.001) and cost ($4/month), the preferred strategy is to treat all patients at 7.5% risk with

statins without cGRS testing. Results were similar for patients at lower or higher ASCVD risk (2.5–10%).In deterministic sensitivity analyses, we found that for certain clinical scenarios, such as a 65-year-old man with a 10-year predicted ASCVD risk of 7.5%, cGRS testing can be cost-effective under a very limited set of assumptions; for example, when the cost of obtaining a cGRS test is $100, statin cost of $15/month and statin disutility is 0.013, the preferred strategy (using a willingness-to-pay of $50,000/QALY) is to obtain a cGRS test and treat if cGRS is intermediate or high. However, even when a cGRS testing strategy was preferred, the probabilistic sensitivity analysis showed that the probability of cost-effectiveness at a willingness-to-pay threshold of $50,000/QALY was less than 50%.

CONCLUSIONS: Our analyses demonstrate that testing for a 27-SNP cGRS is not a cost-effective approach for targeting statin therapy in the primary prevention of ASCVD.

CARDIOVASCULAR HEALTH EFFECTS OF 100% FRUIT JUICE VERSUS WHOLE FRUIT IN POSTMENOPAUSAL WOMEN: RESULTS FROM THE WOMEN'S HEALTH INITIATIVE

Brandon Auerbach[1, 1]; Alyson Littman[1]; Lesley F. Tinker[2]; Joseph Larson[2]; James Krieger[1, 3]; Bessie Young[1, 1]; Marian Neuhouser[2]. [1]University of Washington, Seattle, WA; [2]Fred Hutchinson Cancer Research Institute, Seattle, WA; [3]Healthy Food America, Seattle, WA. (Control ID #2702245)

BACKGROUND: One hundred percent fruit juice is rich in nutrients like potassium and polyphenols, but it is also high in naturally occurring sugars and thus may be associated with adverse cardiometabolic health effects. We investigated whether 100% fruit juice and whole fruit were independently related to incident hypertension or incident type 2 diabetes.

METHODS: We included postmenopausal women 50–79 years of age enrolled in the Women's Health Initiative. The risk of incident hypertension was analyzed in 80,539 participants and risk of incident diabetes in 114,219 participants. One hundred percent fruit juice and whole fruit intake were assessed by baseline food frequency questionnaire. Standardized questionnaires assessed medical history and other characteristics at baseline and every 6–12 months during follow-up. Cox regression, adjusted for demographic, socioeconomic, behavioral, and dietary variables (including total energy intake) was used to estimate hazard ratios (HR) for the associations between 100% fruit juice and whole fruit consumption and incident hypertension and diabetes during a mean of 7.8 years of follow-up.

RESULTS: In multivariable analyses comparing the highest versus lowest quintiles of consumption, there was no association between 100% fruit juice consumption (highest quintile mean 9.5 ± 3.7 ounces/day versus lowest quintile mean 0.5 ± 0.4 ounces/day) and incident hypertension (HR 1.00, 95% CI 0.97–1.03) or incident diabetes (HR 0.98, 95% CI 0.92–1.04). There was also no association between whole fruit consumption (highest quintile mean 2.5 ± 0.6 servings/day versus lowest quintile mean 0.3 ± 0.1 servings/day) and incident hypertension (HR 1.02, 95% CI 0.98–1.05) or incident diabetes (HR 1.03, 95% CI 0.96–1.10).

CONCLUSIONS: Consumption of 100% fruit juice up to 9.5 ounces/day or whole fruit up to 2.5 servings/day was not associated with risk of incident hypertension or diabetes among postmenopausal US women.

CAREGIVER BURNOUT IN A SCRIBE MODEL AND PHYSICIAN FINANCIAL PRESSURES IN OUTPATIENT PRIMARY CARE PRACTICES

Anita D. Misra-Hebert[1]; Jacqueline Fox[2]; Lei Kou[1]; Sarah Schramm[1]; Michael B. Rothberg[1]. [1]Cleveland Clinic, Cleveland, OH; [2]Cleveland clinic, Cleveland, OH. (Control ID #2705757)

BACKGROUND: Primary care redesign initiatives in outpatient practice include evolving roles for front-line staff, including physicians, medical assistants, nurses and administrative staff. Changing roles and added responsibilities may contribute to caregiver burnout and may also affect physicians' perception of financial pressures. We assessed burnout levels of caregivers practicing in a scribe model vs. usual care and physician perception of financial pressures in outpatient primary care practices in a large, integrated health system.

METHODS: We created a survey including the Maslach Burnout Inventory (MBI) as well as a 1-item question from the RAND-American Medical Association Survey addressing perceived source of financial pressures for physicians. The survey was distributed electronically using REDCap to 813 outpatient primary care employees including physicians, medical assistants, nurses, and administrative staff at diverse practice sites in an integrated health system.

RESULTS: Ten respondents who reported not working in primary care were excluded. Of the remaining 803 participants, 285 surveys were completed (response rate 35%), including 76 physicians, 79 medical assistants(MAs) and 47 nurses; 65% of respondents worked in Internal Medicine and 35% in Family Medicine at 29 practice sites. Twenty-one percent of respondents worked at the health system for < 2 years and 33% for > 10 years. Nine (12%) physicians worked with a scribe and 26 (33%) MAs and 4 (33%) licensed practical nurses (LPNs) performed scribing duties. On the MBI, 38% of physicians scored high for emotional exhaustion, 24% for depersonalization, while 58% scored high on personal accomplishment. Among MAs and LPNs, 27% scored high for emotional exhaustion, 9% for depersonalization, and 45% on personal accomplishment. No significant differences in MBI scores were noted between physicians or MAs and LPNs who worked in a scribe model compared to those who did not. When asked which factors were important in determining compensation, physicians rated the following as "very important:" Factors reflecting your own productivity (45%), Results of satisfaction surveys completed by your patients (23%), Specific measures of quality of care such as rates of preventive care services for your patients (28%), Results of practice profiling i.e. comparing your pattern of using medical resources with that of other physicians (16%), and The overall financial performance of the practice (31%).

CONCLUSIONS: A significant number of physician and non-physician staff in outpatient primary care report burnout even while reporting high personal accomplishment. Interestingly, burnout scores were unrelated to participating in a scribe model vs. usual care. Physicians perceive financial pressures related to their own productivity, quality measures, and patient satisfaction as very important to their compensation. Efforts to reduce stressors on caregivers in outpatient primary care teams are needed.

CEFTRIAXONE VERSUS AMPICILLIN/SULBACTAM ON THE TREATMENT OF ASPIRATION PNEUMONIA -A PROPENSITY SCORE ANALYSIS FROM A DATA OF JAPANESE MULTICENTER REGISTRY

Shinya Hasegawa[1]; Atsushi Shiraishi[2]; Makito Yaegashi[1]. [1]Kameda Medical Center, Kamogawa, Japan; [2]Kameda Medical Center, Chiba, Japan. (Control ID #2696173)

BACKGROUND: Incidence of aspiration pneumonia is increasing in Japan in association with increase of the number of elderly people. In Japan, ampicillin/sulbactam (ABPC/SBT) and ceftriaxone (CTRX) is preferred for the treatment of aspiration pneumonia with the aim of covering the full spectrum of the oral anaerobes and for the treatment of community acquired pneumonia (CAP), respectively. However, comparison of ABPC/SBT with CTRX on the treatment of aspiration pneumonia has not been investigated.

METHODS: This study is an analysis of prospectively registered data from 4 Japanese hospitals for patients with community-onset pneumonia from September 2011 to January 2013 (the Adult Pneumonia Study Group-Japan: APSG-J). Aspiration pneumonia is defined as the one including at least one of the aspiration related factors which was set preliminarily. A total of 637 consecutive patients with aspiration pneumonia treated by CTRX or ABPC/SBT were enrolled. Propensity score was estimated from the 29 pre-treatment variables including age, sex, comorbidities, use of oral steroids, aspiration related factors, vital signs, laboratory data, and findings of a chest x-ray. Propensity score matching successfully got 164 patients into CTRX and ABPC/SBT groups. The primary endpoint defined as in-hospital mortality was compared between the two groups.

RESULTS: In the propensity-matched cohort, the primary endpoint was observed in 22 patients (6.7%) over a median follow-up period of 25.9 days. In-hospital mortality rates were not significantly different with CTRX compared with ABPC/SBT (4.3% [95% CI: 1.7–8.6] versus 9.1% [95% CI: 5.2–14.7], $P = 0.12$).

CONCLUSIONS: This study found that mortality benefit of patients treated with CTRX as a first line treatment for aspiration pneumonia was not superior to that with ABPC/SBT.

CENTRAL ROLE OF RELATIONSHIPS IN PROMOTING CAREERS IN GLOBAL HEALTH Brent C. Williams; Jason Bell; Katherine Hughey; Patricia Mullan. University of Michigan, Ann Arbor, MI. (Control ID #2700138)

BACKGROUND: Medical school curricula in global health most often center around providing coursework and structured, often scholarly, field experiences. Few studies have examined the role of non-curricular aspects of students' experience in facilitating careers in global health. To guide and refine the Global Health and Disparities (GHD) Path of Excellence at the University of Michigan Medical School, now in its sixth year, we examined the relative value of curricular and non-curricular aspects of the GHD Path to medical students.

METHODS: The GHD Path includes: a) four-year mentoring relationship with a GHD Advisor; b) completion of a scholarly field project; c) small group activities in the second year that include group exercises and interactions with GHD faculty and senior students; and d) a team-based Mini Field Project in the second year focusing on leadership skills. In the spring of 2016 we administered a survey to the 41 graduating UM Medical students who participated in GHD throughout medical school. For each component of the GHD Path, students were asked to rate the extent to which {component of GHD} "provided VALUE to you" and "provided a positive IMPACT on your professional development." Response categories were "Strongly Disagree (SD)", "Disagree (D)", "Neutral (N)", "Agree (A)" and "Strongly Agree (SA)".

RESULTS: Twenty-seven (67%) of the 41 students completed surveys. Other than the capstone project, *all components rated as high value or impact by >80 % of students concerned relationship-building* (*Table*).

CONCLUSIONS: Building personal and professional relationships is as important as field experience, and more important than coursework, to developing a career in global health among medical students. Possible mechanisms include role modeling, increased motivation through sense of community, and resources available through social networks. Providing these results are confirmed in future studies, programs designed to promote careers in global health should create, nurture, and measure opportunities for students to develop personal and professional relationships related to their career paths.

Percent of students who Agree/Strongly Agree that "{GHD activity} provided 'VALUE to you' and a 'Positive IMPACT on your Professional Development'"

GHD ACTIVITY	VALUE	IMPACT
Your GHD Advisor	89	78
Interaction with other students	89	89
Capstone project	82	81
Other GHD Faculty	78	81
Meet the professor dinners	74	52
M2 mini-field project	67	67
Noon seminars	67	48
Small group seminars	63	52

CENTRALIZED VACCINE REMINDER/RECALL TO IMPROVE ADULT VACCINATION RATES AT AN URBAN SAFETY NET HEALTH SYSTEM Laura P. Hurley[1, 3]; Brenda Beaty[4, 3]; Steven Lockhart[3]; Dennis Gurfinkel[3]; Kristin Breslin[1]; L Miriam Dickinson[2, 3]; Anne Libby[2, 3]; Allison Kempe[3, 2]. [1]Denver Health, Denver, CO; [2]University of Colorado, Aurora, CO; [3]University of Colorado, Anschutz Medical Campus, Aurora, CO; [4]Unviersity of Colorado, Aurora, CO. (Control ID #2702047)

BACKGROUND: Adult vaccination rates are well below Healthy People 2020 goals. Reminder/recall (R/R) is a proven method to increase immunizations, but is underutilized. Centralized R/R using a public health collaborative reduces the burden of an individual practice conducting reminder/recall, and, in prior pediatric trials, has been shown to be effective at increasing immunization rates. However, centralized R/R has not been tested in adult populations. Our objectives were to assess effectiveness and implementation costs of centralized vaccine reminder/recall using the Colorado Immunization Information System (CIIS) vs. usual care for adult vaccine delivery.

METHODS: From September 2015 to April 2016, we randomized 25,039 healthy adults, 16,897 high-risk adults, and 5332 adults ≥ 65 to centralized R/R (R/R) or usual care (TAU) within an urban safety net healthcare system in Denver, CO. In the centralized R/R arm, healthy adults who needed an influenza and/or Tdap, and high-risk adults and seniors who needed an influenza, and/or Tdap, and/or pneumococcal vaccine (PPSV23 or PCV13) were sent up to 3 reminder/recalls by autodialed telephone or mail. Documentation of receipt of any of needed vaccines in CIIS within six months was the primary outcome. We assessed effectiveness of the intervention using multivariable modeling controlling for gender, age, race, ethnicity, insurance type and history of vaccine refusal. Implementation costs were assessed with activity-based accounting for time spent on R/R tasks and supplies in the R/R arm.

RESULTS: In the healthy 19–64 year-old population, 18.6% in the R/R group vs. 17.9% in the TAU group received any needed targeted vaccine (AOR 1.06, 95%CI 0.98-1.14). In the high-risk 19–64 population, 28.1% in the R/R group vs. 26.7% in the R/R group received any needed targeted vaccine (AOR 1.07, 95%CI 1.001-1.15). In the senior population, 33.2% for the R/R group vs. 29.8% for the TAU group received any needed targeted vaccine (AOR 1.15, 95%CI 1.02-1.30). Receipt of influenza vaccine for the 19–64 high-risk and senior populations was the source of the difference in receipt of any needed vaccine in R/R and TAU arms. 26.6% of 19–64 high risk adults in the R/R group received influenza vaccine compared to 25% in the TAU group ($p = 0.02$) and 32% of seniors in the R/R group received influenza vaccine compared to 28.6% in the TAU group ($p = 0.007$). Total R/R resource costs were $14,868.16 for the trial, and the cost per person receiving at least one vaccine was $3.29.

CONCLUSIONS: Centralized R/R was effective at increasing influenza vaccination rates in vulnerable adult populations over a short period of time, without burdening the practices and at a low cost.

CHALLENGES WITHIN INPATIENT ROUNDS: A MULTI-INSTITUTIONAL QUALITATIVE STUDY Raphael Rabinowitz[3]; Oliver Hulland[3]; Jeanne M. Farnan[2]; Lisa Kearns[4]; Michele Long[5]; Bradley Monash[1]; Priti Bhansali[6]; H. Barrett Fromme[2]. [1]University of California, San Francisco, Mill Valley, CA; [2]University of Chicago, Chicago, IL; [3]The University of Chicago Pritzker School of Medicine, Chicago, IL; [4]The Ohio State University, Columbus, OH; [5]University of California San Francisco, San Francisco, CA; [6]Children's National Medical Center, Washington, DC. (Control ID #2701124)

BACKGROUND: Attending rounds is an important activity for both patient care and education at teaching hospitals. There is a relative lack of studies addressing stakeholders' perceptions of challenges and barriers to the rounding experience. This study characterizes perceptions of medical students, pediatrics and internal medicine housestaff and faculty about the challenges faced during inpatient rounds.
METHODS: The authors conducted focus groups with a purposive sample of medical students and internal medicine and pediatrics interns, residents, and faculty at 4 teaching hospitals to determine their perceptions of the purpose of rounds. Participants volunteered unsolicited comments about challenges faced during rounds without directly being asked this question. The constant comparative method was used to identify themes and codes in a secondary analysis of these comments.
RESULTS: The study identified 4 themes: problems with how rounds are run, challenges to teaching, external problems, and problems specific to family-centered rounds (FCR). Problems with how rounds are run related to challenges that emerged from improper or unsatisfactory rounding facilitation by team leaders, and included excessive variability in rounds, poorly defined roles and expectations, and problems with presentations. Challenges to teaching included tension between education and service, decreased physical exam instruction, and decreased role modeling. External problems included systemic issues that impacted rounds such as time pressures and problems with technology. Problems with FCR were exclusively mentioned during pediatrics focus groups, mostly by residents, and encompassed difficulties introduced by the incorporation of patients and families on rounds, including decreased learning, loss of complexity in discussion, and unhelpful for patients and families.
CONCLUSIONS: Challenges described by study participants varied by training level and specialty. Conflicting frustrations with the rounding experience by its participants indicates widespread misunderstanding of the priorities of other stakeholders in the rounding experience. The acknowledgement of problems related to how rounds are run suggests that faculty development initiatives and resident as teacher (RAT) curricular innovations aimed at standardizing a set of best practices may have a significant impact on educational outcomes for new participants on rounds. More research is needed to identify these practices and the best methods to promote them. A tension between teaching objectives and external problems imposed by a compressed and fragmented workday due to duty hours implementation underscores a need for creative innovations in rounding efficiency to maximize their bedside educational value. Finally, resident-specific concerns about FCR indicates the need to better educate residents about the value of patient interactions and family-centered rounds.

CHANGES IN HEALTH AND WELL-BEING AMONG FIRST-YEAR RESIDENTS Christopher Wee[1]; Jacob A. Petrosky[2]; Lauren Mientkiewicz[3]; Krishna K. Patel[4]; Charles Kwon[2]; Allan Siperstein[5]; Xiaobo Liu[2]; Michael Rothberg[2]. [1]Cleveland Clinic Foundation, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH; [3]Akron Children's Hospital, Akron, OH; [4]Mid America Heart Institute, Kansas City, MO; [5]Cleveland, Cleveland, OH. (Control ID #2703204)

BACKGROUND: Training conditions for physicians may affect their ability to serve as healthy role models to patients. There is limited data, however, on how trainees' health and wellness habits are affected by GME training. Our objective was to measure differences in self-reported health and health behaviors at the beginning and end of the PGY-1 year.
METHODS: We invited incoming PGY-1 trainees in all specialties at the Cleveland Clinic during orientation to participate in an anonymous online survey, through a mass e-mail invitation. The 31-question instrument included previously validated questions regarding self-reported health habits, well-being, and nutrition practices, including average hours slept, average days exercising per week, and servings of fruits and vegetables consumed. Self-reported health status was assessed on a scale of 1 (excellent) to 5 (poor). At the end of the year, a follow-up survey was sent to those who had responded initially. Baseline and follow-up measures were compared using paired T-test or Wilcoxon signed rank sum test as appropriate.
RESULTS: Of 170 interns who were sent invitations, 59 (35%) started the initial survey and 34 (58%) of these responded to the follow-up survey. Only the 34 individuals who completed both surveys were included in the longitudinal analyses. Average age was 27, 17 were in internal medicine, 5 in a preliminary year, 4 in pediatrics, and the remainder in other specialties. Twelve were married or in long-term relationships, and 50% lived alone. Only 3 of the respondents had children. Over the course of the year, self-reported weight did not change significantly (157.2 lbs initially v 154.8 lbs at follow-up), number of hours slept decreased (7.3 v 6.3 hrs $p < 0.001$), as did days exercised per week (3.3 v 2.4 days $p = 0.005$), but the length of workouts did not change. There was no change in alcohol consumption. Breakfast and lunch habits changed significantly, with more people skipping breakfast (17.7% v 41.2%) and eating lunch out at follow-up (38.2% v 70.4%). Dinner habits and consumption of fruits and vegetables did not change. Respondents noted feeling less happy and more worn out at follow-up. When asked to rate their general health, at both the initial and follow-up survey, the median answer was 2 (very good). However, when asked to compare their health at the time of the survey to 1 year prior, during the initial survey, the average respondent answered "about the same," while during the follow-up survey, they answered, "somewhat worse than 1 year ago" ($p < 0.001$).
CONCLUSIONS: While training to become health professionals, interns' own health habits deteriorated. Further studies should explore the relationship between health habits and burnout, and whether adherence to constructive habits could mitigate the effects of trainee burnout.

CHANGES IN SELF-REPORTED GENERAL HEALTH, PHYSICAL HEALTH, AND MENTAL HEALTH FOLLOWING THE AFFORDABLE CARE ACT'S MEDICAID EXPANSION Tyler N. Winkelman[1, 2]; Virginia W. Chang[3, 3]. [1]University of Michigan, Ann Arbor, MI; [2]VA Ann Arbor Healthcare System, Ann Arbor, MI; [3]New York University, New York, NY. (Control ID #2699823)

BACKGROUND: The adoption of Medicaid expansion in some states and not others provided a unique natural experiment to study the effects of

Medicaid. Research stemming from this natural experiment suggests that Medicaid expansion increased health insurance coverage, improved access to care, and reduced cost-related barriers to prescription drugs among low income individuals. Findings with respect to health outcomes, however, have been more mixed. Therefore, we analyzed recently released national data from the Behavioral Risk Factor Surveillance System (BRFSS) to assess the relationship between Medicaid expansion and self-reported health measures among low-income individuals.

METHODS: We used 2011–2015 BRFSS data, which provided 3 years of data prior to implementation of Medicaid expansion and 2 years of follow-up data in the majority of expansion states. Our study sample consisted of all individuals age 18–64 with household incomes below $15,000, targeting individuals who would have qualified for Medicaid coverage in expansion states. As in prior work, we excluded five states that had previously expanded Medicaid. Our outcomes were self-reported general health, poor physical health days, poor mental health days, and disability following Medicaid expansion. We used a difference-in-differences approach to estimate the effect of Medicaid expansion on our outcomes of interest. Our key independent variable was equal to 1 for individuals living in states where expansion was in effect during the month of their interview. Estimates were obtained with multivariable linear probability models and adjusted for age, race/ethnicity, sex, education, marital status, and children, as well as state-level and quarter-year fixed effects. We used BRFSS sampling weights and estimated robust standard errors clustered at the state level to account for serial autocorrelation.

RESULTS: In adjusted analyses of the influence of Medicaid expansion, we found that expansion was associated with a significant reduction in fair/poor self-rated health (2.5 percentage points [95% CI, −3.5 to −1.5]). While expansion was not associated with a statistically significant change in the number of poor physical health days (−0.20 days [95% CI, −0.68 to 0.28]), it was associated with a significant reduction in the number of poor mental health days (−0.52 days [95% CI, −0.99 to −0.04]). Change in disability prevalence did not vary between expansion and non-expansion states ($P = 0.73$). Adjusted linear time trends prior to expansion (2011 to 2013) for all outcomes were similar in expansion and non-expansion states ($P > .05$ for all comparisons).

CONCLUSIONS: To our knowledge this is the first national study to report positives changes in self-reported general health following the ACA's Medicaid expansion provision, driven by changes in mental health. Whether these trends continue to improve will likely depend on whether policymakers choose to improve or repeal the ACA in the coming months.

CHANGES TO OUTPATIENT HYPERTENSION AND DIABETES MEDICATIONS IN OLDER ADULTS FOLLOWING UNRELATED HOSPITALIZATIONS

Timothy Anderson[1]; Siqi Gan[1, 2]; Kathy Fung[1, 2]; Ying Shi[1, 2]; Michael A. Steinman[1, 2]. [1]University of California, San Francisco, San Francisco, CA; [2]San Francisco VA Medical Center, San Francisco, CA. (Control ID #2705026)

BACKGROUND: Transient elevations of blood pressure and serum glucose are common in hospitalized older adults. Although these perturbations usually have little long-term significance, they may lead inpatient clinicians to make changes to outpatient regimens, even when patients are hospitalized for conditions that do not typically require aggressive blood pressure or glucose management. Unnecessary changes made to stable outpatient regimens during a hospital stay can easily become over-treatment once patients return home, exposing them to increased risks of serious adverse drug events including hypoglycemia, syncope and falls. We thus sought to evaluate how often patients' diabetes and hypertension regimens are changed following hospitalization for unrelated conditions.

METHODS: We used national VA and Medicare data to assemble a retrospective cohort of veterans age 65 years and older who received regular care in VA outpatient settings, had hypertension and/or diabetes and were hospitalized in a VA medical center in 2011 with pneumonia, urinary tract infection or venous thromboembolism. Using VA pharmacy dispensing records, we identified medications in use prior to hospitalization and medications prescribed in the peri-discharge period. We compared admission medications to medications in use at discharge to identify changes in regimens. Changes were classified as medication additions, discontinuations and dose changes.

RESULTS: 9,795 veterans were included in our cohort of whom 7,635 had hypertension and 4,079 had diabetes. The majority of patients were male (98%) and the median age was 78 (IQR 70–84). Patients were prescribed a median of 7 medications on admission (IQR 5–10). Patients with hypertension were prescribed a median of 2 anti-hypertensives (IQR 1–3) and patients with diabetes a median of 1 hypoglycemic medications (IQR 0–2). 4,836 (63%) patients with hypertension experienced a change to their anti-hypertensive medications, of which 39% experienced at least one anti-hypertensive discontinuation and 38% at least one anti-hypertensive addition. 1,589 (39%) patients with diabetes experienced a change to their diabetes medications, of which 23% experienced at least one hypoglycemic discontinuation and 20% at least one hypoglycemic addition. Overall, medication changes were common, 94% of patients experienced at least one medication change following hospitalization and the median number of medication changes was 5 (IQR 3–7). The majority of patients experienced at least one medication addition (81%) and at least one medication discontinuation (72%).

CONCLUSIONS: Over half of patients in a national cohort of older veterans hospitalized for common medical conditions experienced changes to their outpatient hypertension and diabetes medications at discharge. These high rates of changes have the potential to impact adherence and expose patients to serious adverse drug events upon discharge.

CHOOSING DAILY LABS IN THE HOSPITAL: EVALUATION OF NOVEL MINNESOTA LAB APPROPRIATENESS CRITERIA (MLAB)

Caleb Murphy; Jill Bowman Peterson; Alisa Duran. University of Minnesota, Minneapolis, MN. (Control ID #2703276)

BACKGROUND: Daily lab testing despite patients' clinical and lab stability is identified as an area of inappropriate health care spending in the Society of Hospital Medicine's Choosing Wisely list.[1] Approximately 25% of daily labs are inappropriate, leading to overtreatment and increased spending, yet guidelines for identifying such labs do not exist.[2] The objective of this study was to create and apply the Minnesota Lab Appropriateness Criteria (MLAB) to properly identify inappropriate labs compared to the national average of 25%.

METHODS: MLAB were created by two internists at the University of Minnesota experienced in hospital medicine and high value care, reviewed by the Alliance for Academic Internal Medicine High Value Care Workgroup, and revised. 50 medicine admissions (hospitalization 2–10 days, non-ICU, non-cirrhotic patients) were randomly selected. Using MLAB, two reviewers independently rated appropriateness of basic metabolic panels (BMP) and complete blood counts (CBC) from each hospitalization using both a dichotomous scale (DS; appropriate/inappropriate) and a three-point Likert scale (LS; 1 = inappropriate, 2 = equivocal, 3 = appropriate).

RESULTS: 461 daily labs (253 BMPs, 208 CBCs) from the 50 admissions were reviewed. Using MLAB, 24.1% (95%CI 18.8–29.4%) of BMPs and 25.0% (95%CI 19.1–30.9%) of CBCs were rated inappropriate on the DS. On the LS, 20.2% (95%CI 15.2–25.1%) of BMPs were inappropriate and 7.1% (95% CI 4.0–10.3%) were equivocal, while 16.8% (95%CI 11.7–21.9%) of CBCs were inappropriate and 12.0% (95%CI 7.6–16.4%) were equivocal. When comparing raters on the DS, κ was 0.68 (95%CI 0.58–0.78) for BMPs and 0.77 (95%CI 0.68–0.87) for CBCs. Weighted κ on the LS was 0.58 (95%CI 0.49–0.67) for BMPs and 0.62 (95%CI 0.52–0.72) for CBCs.

CONCLUSIONS: Using MLAB, raters identified 24.1% of BMPs and 25.0% of CBCs as inappropriate, consistent with previously reported figures. This suggests MLAB correctly identifies inappropriate daily lab ordering. When assessed on the LS, inappropriate lab rates dropped as more labs were identified as equivocal. Yet appropriate test rates also dropped; thus, equivocal tests were not just comprised of tests previously identified as inappropriate on the DS. Interrater reliability between raters showed moderate to substantial agreement using both the DS and LS; with more agreement on the DS. MLAB offer an accurate and reliable method of assessing BMP and CBC appropriateness, with potentially important applications in high value care initiatives and medical education. These criteria, when applied prospectively, could potentially translate to cost savings across health systems and help reduce unnecessary daily lab testing in the hospital. References: 1. CLINICAL DECISION SUPPORT (CDS) TOOLS FOR ACE INHIBITOR THERAPY IN HEART FAILURE: HELPFUL OR HASSLE?

Anne Press[2]; Jonathan Austrian[1]; Saul Blecker[2]. [1]NYU, New York, NY; [2]NYU School of Medicine, New York, NY. (Control ID #2706210)

BACKGROUND: Electronic health record (EHR)-based clinical decision support tools (CDS) incorporate individualized data to produce patient-specific recommendations at the point-of-care. However, these tools are often limited in their effectiveness, which may be due to poor consideration of usability. The purpose of this study was to evaluate the utilization of a CDS intervention to increase prescription of Angiotensin Converting Enzyme inhibitor (ACEi) or Angiotensin Receptor Blocker (ARB) for patients with heart failure.

METHODS: We performed a retrospective study of hospitalized patients with heart failure from the time of CDS implementation, 7/10/13, through 11/30/15. The CDS that we investigated offers providers an opportunity to prescribe an ACEi or ARB or report a contraindication to therapy for patients with documented heart failure. All patients with an EF ≤ 40% who were not on an ACEi or ARB at time of discharge were included in the study. We identified the number of patients for whom the CDS triggered; of those, we categorized provider response as: dismissed, ordered an ACEi/ARB, or contraindication reported. We then performed manual chart review to identify the CDS reported contraindication and structured chart abstraction with standard guidelines to identify gold standard contraindications. We compared each CDS contraindication to gold standard contraindications to determine their accuracy.

RESULTS: Out of the 618 subjects who had an EF ≤ 40% but no ACEi or ARB at the time or discharge, 435/618 (70%) had a triggered CDS. Of these 435 subjects for who a CDS was triggered, 180 (41%) were dismissed, 225 (52%) had a contraindication response and 30 (7%) had a prescription for an ACEi/ARB therapy. Overall the accuracy of the documented CDS was 42% (Table 1).

CONCLUSIONS: The CDS that we reviewed was poorly utilized and contraindications documented in the tool poorly correlated with patient clinical status reflected elsewhere in the EHR. These findings identify this CDS as a possible impedance to user workflow. One way to improve CDS tools at the point of care is through thorough usability testing and consideration of physician workflow prior to implementation.

Table 1: Clinical Decision Support (CDS) recorded contraindication to therapy and accuracy of reported contraindication versus gold standard of chart abstraction. Contraindications are listed in order of display in the CDS tool

Contraindication:	CDS	Accuracy
Allergies	4	50%
Aortic Stenosis	4	100%
Patient refusal	9	Not Assessed
Angioedema	0	–
Hyperkalemia	9	78%
Hypotension	43	34%
Renal Artery Stenosis	2	0%
Renal impairment	135	44%

*there were 19 cases with contraindication reported as "other"

CLINICAL DECISION SUPPORT DECREASES VARIABILITY IN CTPA YIELD

Safiya Richardson; Lauren McCullagh; Sundas Khan; Vinodh Mechery; Guang Qui; Salvatore Pardo; Thomas McGinn. Hofstra Northwell School of Medicine, New York City, NY. (Control ID #2705685)

BACKGROUND: Effective clinical decision support (CDS) will be instrumental in bringing the best available evidence to the point of care. Current estimates indicate that only 20–50% of care provided is evidenced based. CDS has demonstrated an ability to improve management and standardize care. Practice variability is a particular challenge in Emergency Rooms (ERs) where overcrowding and medical urgency lead to an overdependence on intuition. Here we focus on the impact of a CDS tool designed to standardize provider estimation of pre-test probability of pulmonary embolism (PE) before computed tomography pulmonary angiogram (CTPA). We measure the change in variability of the percent of tests positive for PE (CTPA yield) after CDS implementation.

METHODS: A CDS tool was built in Allscripts Sunrise Electronic Medical Record at a large academic tertiary care hospital. Tool design was based on previously published work examining ER workflow and usability testing of triggers. Orders for CTPA, V/Q scan or d-dimer are routed to the PE Wells Calculator which presents Wells' Criteria, calculates risk of PE and offers an order set based on risk. We performed a before and after analysis. To avoid potential seasonal variation, due to the start of new trainees in July, we determined the pre-intervention control period to be April to June, 2014 and the post-intervention period to be April to June, 2016. The primary outcome event was CTPA yield, a validated measure of CTPA ordering accuracy. Only providers who ordered CTPAs during both the pre- and post-intervention period were included in the analysis. Variability was assessed using the coefficients of variation.

RESULTS: A total of 45,105 patients were seen in the ER during the analysis periods, resulting in 910 CTPA orders completed to evaluate for PE. During the pre-intervention period monthly CTPA yield varied from 4 to 9%, demonstrating wide variability in accuracy of provider assessment of pre-test probability for PE. During the post-intervention period the yield demonstrated less variability, varying from 10 to 12%. The coefficient of variation was 0.67 during the pre-intervention period vs 0.06 during the post-intervention period. These

were significant results as there was non-overlap of the 95% CI for the coefficients of variation for pre- and post- intervention.

CONCLUSIONS: CDS designed to assist provider estimation of pre-test probability of PE decreased monthly variability in CTPA yield in the ER. Thoughtfully designed and extensively usability tested CDS can improve quality and standardize care.

CLINICAL MEDICAL STUDENT RESILIENCE AND EXPERIENCES WITH STRESSFUL CLINICAL EVENTS Jennifer Houpy; Wei Wei Lee; James N. Woodruff; Amber Pincavage. University of Chicago, Chicago, IL. (Control ID #2693005)

BACKGROUND: Although medical students face numerous stressors during their clinical years, little is known about their resilience. The objective of this study was to characterize medical student resilience and experiences with difficult clinical events.

METHODS: Anonymous electronic surveys were provided to all third year (MS3) and fourth year (MS4) medical students at the University of Chicago in the spring of 2016 to assess resilience (10 item Connor Davidson Resilience Scale (CD-RISC 10)), experiences with difficult clinical events, and burnout (non-proprietary single-item burnout measure).

RESULTS: 62 MS3s and 55 MS4s (response rate 66%) completed surveys. The mean CD-RISC 10 score was 28.2 ± 6.37 (range 10–40, possible range 0–40, 40 indicating most resilient) and lower than in a general population sample (32.1 ± 5.80, $p < 0.001$). Mean resilience was higher in males (30.47 ± 6.14 vs. 26.43 ± 6.02, $p = 0.001$), MS4s (29.68 ± 5.98 vs. 26.91 ± 6.47, $p = 0.023$), and those reporting no burnout symptoms (30.44 ± 5.44 vs. 25.00 ± 6.29, $p < 0.001$). There was no significant difference based on age, undergraduate major, or path to medical school. Over 80% of students had experienced the following clinical events: dealing with difficult patients, difficult family discussions, systems issues, poor team dynamics, chronic narcotic patients, and difficult encounters with other staff. 55% had experienced medical errors. Students found poor team dynamics most stressful. After difficult clinical events, 71% of students reflected on them often, 62% would prefer to discuss them with their team that same day, and only 5% of would prefer not to discuss them. Most students had talked to peers (91%) about difficult clinical events, while only 37% discussed them with their attending and 60% with the team resident. MS4s spoke with attendings (48% vs. 27%, $p = 0.043$) and residents (72% vs. 49%, $p = 0.017$) more than MS3s did. Resilience was higher in students who reported having skills to cope with difficult clinical events (29.47 ± 5.91 vs. 22.98 ± 5.93, $p < 0.001$) and who were comfortable discussing medical errors with peers (30.48 ± 5.99 vs. 25.14 ± 5.64, $p < 0.001$). Most students (64%) believed resilience training would be helpful and best delivered during third year (66%). Only 27% believed they had sufficient training. The top topics identified included difficult team interactions, finding meaning in daily work, and dealing with disappointment.

CONCLUSIONS: Resilience in clinical medical students was lower than in the general population. Students had some insight into their resilience. Although students wanted to discuss difficult clinical events with their team, most students discussed them with peers. Students endorsed a need for resilience training during the third year. More curricula promoting resilience are needed.

CLINICIAN BURNOUT IN SMALL NORTH CAROLINA PRIMARY CARE PRACTICES APPEARS LOWER THAN EXPECTED: AN INITIAL SNAP SHOT FROM EVIDENCE NOW. Samuel Cykert[2]; Darren A. DeWalt[1]; Bryan Weiner[3]; Janet Freburger[4]. [1]UNC School of Medicine, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, NC; [3]University of Washington, Seattle, WA; [4]University of North Carolina Chapel Hill, Chapel Hill, NC. (Control ID #2706811)

BACKGROUND: Given the rapid implementation of electronic health records (EHR), new reporting programs, and the looming changes anticipated from the Merit-based Incentive Payment System and alternative payment models, healthcare leaders and policymakers fear that clinicians, especially in small practices, will experience severe burnout. Evidence Now is a national initiative funded by AHRQ designed to reduce cardiovascular risk among adult patients in small primary care practices and study the effect of practice facilitation as a means of accelerating this effect. We report initial results of a baseline survey of North Carolina (NC) clinicians who are participating in the project. We focus on a validated, single item measure of burnout. Prior studies using national samples documented 60% of the workforce experiencing burnout.

METHODS: The full practice member survey was sent to clinicians from 186 practice sites between February and November of 2016. The items include a validated single item burnout question, an adaptive reserve scale (ARS), and multiple questions concerning the use of evidence-based guidelines. The burnout item consisted of 5 possible responses: 1) I enjoy my work. I have no symptoms of burnout. 2) Occasionally I am under stress and I don't always have as much energy as I once did but I don't feel burned out. 3) I am definitely burning out and have one or more symptoms of burnout such as physical and emotional exhaustion. 4) The symptoms that I'm experiencing won't go away. I think about frustrations a lot. 5) I feel completely burned out and often wonder if I can go on. I am at the point where I may need some changes or may need to seek some sort of help. We also obtained information on payer mix, personnel, and EHR satisfaction.

RESULTS: 158 practice member surveys were received from the practice sites. The mean burnout score was 1.87 (SD +/− 0.5). 18% reported no burnout while 60% agreed with response 2. 20% of clinicians admitted to burnout described in response 3 while 1% said the symptoms were persistent (response 4). No one agreed to the most severe response (5). A negative correlation between ARS and burnout was strong ($r = -.57$, $p < 0.001$). Linear regression was performed to identify factors associated with worse burnout including EHR satisfaction, FTE clinicians, FTE staff, provider visits per day, practice ownership, payer mix, PCMH status, regular data discussions, and ARS. The r-squared for the model was 0.38. PCMH recognition and FQHC status were associated with higher burnout while high adaptive reserve and more visits per provider were associated with less.

CONCLUSIONS: Burnout was lower than expected in a large cross section of clinicians in small NC primary care practices suggesting a resilient workforce in these practices. While the associations of higher burnout in FQHC's and lower burnout with high adaptive reserve were expected, associations with PCMH recognition and higher provider volume were somewhat paradoxical and need further exploration.

CLOSING THE SPECIALTY REFERRAL LOOP: AN IMPERATIVE FOR A RESILIENT PRIMARY CARE NETWORK Malhar Patel; Colin O'Leary; Priscille Schettini; Kevin Shah. Duke University School of Medicine, DURHAM, NC. (Control ID #2702417)

BACKGROUND: A critical function of large primary care practices is connecting patients with specialists. Consistently closing the loop on all patient referrals is a patient safety imperative as identified by The Joint Commission. Our project sought to identify referral completion rates, gaps in referral documentation, and how wait times of referrals affect completion rates.

METHODS: From a large primary care network, we analyzed specialty referrals ($N = 106{,}885$) in FY2016 across 22 high volume subspecialties, excluding procedural and ancillary service referrals. For referrals with appointment scheduling data, we characterized appointment completion, cancellation rates, and wait times. We stratified these referrals into three categories of wait times (<30 days, 31–60 days, and >60 days) and analyzed each category's completion rates.

RESULTS: For 93,584 referrals, a total of 106,885 appointment scheduling attempts were made in FY2016. Some unique referrals had multiple scheduling attempts. Of the 106,885 appointment scheduling attempts, 63,360 (59.3%) had known appointment dates, while 43,525 (40.7%) referrals had no recorded appointment date. Of the referrals without appointment dates, 40.3% were indicated as scheduled (although no date was provided) and 59.7% were not scheduled for reasons including patient self-scheduling or declining. We restricted our analysis further to the 63,360 appointments with documented appointment dates. Of these, 56.9% resulted in completed appointments, 29.3% in cancelled appointments, 7.3% in appointments scheduled after FY2016, and 6.5% in patient no shows. Of canceled referrals, 53.6% were rescheduled, while 46.4% were not. Almost a third of referrals (30.9%) had wait times longer than 30 days. Average wait times for each specialty ranged from 10.6 to 84.7 days. Referrals in wait time categories <30 days, 31–60 days, and >60 days had appointment completion rates of 65.8%, 43.3%, and 29.3%, $p < .001$, respectively. Sub-analyses of 3 specialties (endocrinology, nephrology, and urology) demonstrated that, while wait times varied by specialty, the rate of appointment completion consistently decreased as wait times increased.

CONCLUSIONS: Our analysis of specialty referrals in a large academic primary care practice demonstrates opportunities to close the loop on specialty referrals. Specifically, we found numerous referrals that were not scheduled, did not have appointment dates, or did not have documented completion. Our analysis showed a correlation between increasing wait time and decreasing referral completion rate, as well as wait time variability by specialty. These analyses are likely generalizable to primary care practices making a large number of referrals. This study underscores the need for methods to track patients and ensure the loop is closed between primary and specialty care. This would not only improve patient safety and care, but also advance the Quadruple Aim by reducing burnout in health care providers frustrated by incomplete care for their patients.

CLUSTER ROUNDS: A NEW TECHNIQUE IN BEDSIDE MEDICINE

Nousha Hefzi; Emmanuel Akintoye; Courtney M. Moore; Sajith Matthews; Diane L. Levine. Wayne State University School of Medicine, Detroit, MI. (Control ID #2707041)

BACKGROUND: Proficient physical examination (PE) skills are critical tools in physical diagnosis. A decline in the ability to correctly perform the PE has led to adverse preventable medical errors including missed or delayed diagnosis and incorrect diagnosis.[1] To strengthen the PE skillset of junior medical students on the Internal Medicine clerkship, we utilized an innovative method to teach PE and diagnosis. "Cluster rounds" involves an attending physician gathering multiple patients with the same disease to demonstrate the variability of findings in patients with the same diagnosis. The goal of cluster rounds is to 1) improve PE skills, 2) improve diagnostic skills through the PE, 3) provide an opportunity for direct observation of bedside skills, and 4) increase the confidence of medical students when performing a history and PE on their own.

METHODS: Cluster rounds involve a 5 min history and a 10–15 min PE per patient for a given diagnosis. 11 sessions with 4 patients per a session were conducted. Each session focused on a single diagnosis (endocarditis, congestive heart failure, inflammatory bowel disease, breast cancer, osteomyelitis, arthritis/gout, lead toxicity, opioid toxicity, COPD, and cirrhosis). 8–9 students attended each session with 4 performing the actual PE. Pre- and post-session surveys using a Likert scale were developed to assess 70 student impressions. Impact of the cluster rounds on the students' self-perception was assessed in two ways: first, by percentage increase in perception to at least the level of 'strongly agree' using McNemar's test. Second, by the difference in the median Likert score before and after cluster round using Wilcoxon signed-rank test.

RESULTS: Prior to the cluster round, most participants felt to some degree that they were able to perform the PE on their own without assistance. However, only 2–14% of the participants strongly agreed to each of the questions. Compared to the pre-assessment, there was significant increase in the proportion of participants that moved to the level of 'strongly' or 'very strongly' for able to perform (14% vs 69%, $p < 0.001$), comfortability (12% vs 62%, $p < 0.001$), confidence (7% vs 60%, $p < 0.001$), able to teach (2% vs 52%, $p < 0.001$) and able to use PE finding to make diagnosis (14% vs 67%, $p < 0.001$). In addition, there was significant increase in the median Likert score across all endpoints: 3 vs 4 ($p < 0.001$), 3 vs 4 ($p < 0.001$), 3 vs 4 ($p < 0.001$), 2 vs 4 ($p < 0.001$), and 3 vs 4 ($p < 0.001$) respectively.

CONCLUSIONS: All participants agreed that cluster rounds complemented their IM clerkship curriculum and was valuable in enhancing their PE skillset. This preliminary data illustrates the potential for this innovative method to enhance students' clinical practice skills in comfortably performing a PE and utilizing its findings to make a diagnosis, as well as teaching the exam to peers. With further studies, cluster rounds can potentially be a critical educational experience with regards to students' comfort in PE.

COLLABORATE AS A MEASURE OF PATIENT-CENTERED CARE: A VALIDATION OF A POTENTIAL POINT-OF-CARE ASSESSMENT IN THE VA.

Barbara G. Bokhour[1, 3]; Laurel Radwin[2]; Glyn Elwyn[4]; Mark Meterko[5]. [1]ENRM Veterans Affairs Medical Center, Bedford, MA; [2]VA Boston Healthcare System, Boston, MA; [3]Boston University School of Public Health, Boston, MA; [4]Dartmouth Medical School, Hanover, NH; [5]US Department of Veterans Affairs, Bedford, MA. (Control ID #2705971)

BACKGROUND: Many organizations have identified patient-centered care as a critical aspect of quality. Yet it is unclear how and when to best measure patients' perceptions of the extent to which their care meets the criteria of patient-centeredness. The objective of this paper was to assess the validity of the CollaboRATE, a brief measure of patient-centered communication (PCC) with potential for point-of-care administration. The CollaboRATE asks respondents to evaluate their providers' efforts to (1) help them understand their health issues, (2) listen to the things that matter most to them about their health issues, and (3) include what matters most in choosing what to do next in the patient's care.

METHODS: We conducted a mail survey of outpatients ($n = 1019$) and inpatients ($n = 767$) at 8 Department of Veterans Affairs medical centers, half of which were designated as leaders in patient-centered care. Surveys included 1) the CollaboRATE; 2) the Communication Assessment Tool (CAT), an

established, longer measure of patient-centered communication; 3) measures of patient satisfaction; 4) self-reported health and functional status (PROMIS −29); and 5) the Lorig measure of healthcare self-efficacy. We calculated Cronbach's alpha to assess reliability, and Pearson correlations to assess concurrent validity with the CAT and construct validity with the various proximal and distal patient-reported outcomes.

RESULTS: Internal consistency reliability of the CollaboRATE was excellent in both the inpatient and outpatient samples (r = 0.96, 0.97, respectively). Concurrent validity of the CollaboRATE was demonstrated by statistically significant and strong correlation with the CAT (r. = 0.84, 0.85); $p < .001$). Construct validity was demonstrated in both samples by a strong and statistically significant correlation with the proximal outcome of overall care satisfaction in the outpatient and inpatient samples (r = 0.81 and 0.74, respectively; $p < .001$), and by weak to modest but conceptually consistent and statistically significant positive relationships with the more distal outcomes of patient-reported physical health (r = 0.12, 0.15, $p < .001$) and social functioning (r = 0.18, 0.21, $p < .001$) and healthcare self-efficacy (r = 0.23, 0.25, $p < .001$), and negative relationships with anxiety, depression, fatigue, and sleep quality and disturbance (r's −0.10 to −0.27).

CONCLUSIONS: We found strong evidence of reliability and validity for the CollaboRATE in both inpatient and outpatient samples of Veterans. These findings support the use of the CollaboRATE as a brief measure of patient-centered communication. In the outpatient setting, CollaboRATE could be administered immediately following an outpatient visit using any of a variety of modes of administration such as, a Kiosk check-out stop, hand-out postcard-size survey with drop-off box, or using a survey application on a tablet or laptop computer. In the inpatient setting this could be conducted at bedside or immediately prior to discharge.

COLLABORATIVE CARE FOR DEPRESSION AMONG PATIENTS WITH LIMITED ENGLISH PROFICIENCY: A SYSTEMATIC REVIEW Maria E. Garcia[3]; Lisa Ochoa-Frongia[3]; Nathalie Moise[1]; Adrian Aguilera[4]; Alicia Fernandez[2]. [1]Columbia University Medical Center, New York, NY; [2]UCSF, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA; [4]University of California, Berkeley, Berkeley, CA. (Control ID #2706421)

BACKGROUND: Individuals with limited English proficiency (LEP) face unique challenges in accessing and engaging in mental health care. While many studies report improvement in depressive symptoms among patients enrolled in collaborative care, few studies have evaluated the effectiveness of this model among LEP individuals, whose depression rates are high.

METHODS: To investigate the effectiveness of collaborative care in the treatment of depressive symptoms among individuals with LEP, a systematic review of English articles was performed using online PubMed, PsychINFO, CINAHL and EMBASE databases thru September 15, 2016. Studies were included if they were RCTs, cohort, or case–control studies evaluating collaborative care for depression in primary care among LEP patients. Included studies described the 3 key components of collaborative care: 1) care coordination and care management, involving multi-professional patient care with a social worker or therapist, primary care providers, and a consulting psychiatrist, 2) regular/proactive monitoring and treatment to target using validated clinical rating scales by a designated care manager, and 3) regular, systematic psychiatric caseload reviews and consultation for patients demonstrating no clinical improvement. Two reviewers independently examined titles and abstracts and extracted information on participants' characteristics, type of intervention, features of collaborative care, preferred participant language, and outcome measures.

RESULTS: The search yielded 15 papers, representing 9 studies: 5 RCTs, 3 cohort studies and 1 case–control study. The studies had 4885 total participants and 2564 LEP participants (52%). The majority of LEP participants (2335, or 91%) spoke Spanish. The heterogeneity in study design and outcome definitions precluded a meta-analysis; only 2 studies had the same outcome definition. Follow-up times varied greatly, and ranged from 3 months to 2 years. Four of five RCTs reported more improvement in depressive symptoms among individuals in the intervention group compared to the usual care group. The last RCT had similar improvement between intervention and control groups but had high rates of psychiatry follow-up among both groups. Among non-RCTs, 2 studies reported that Spanish language preference was associated with depressive symptom improvement; the last 2 non-RCTs demonstrated improvement in depressive symptoms but had no usual care control groups.

CONCLUSIONS: All but one study reported improved depressive symptoms in LEP individuals treated with collaborative care. While limited by the small number of LEP participants (particularly Asian patients) and the heterogeneity of study designs and outcomes, this systematic review suggests that collaborative care may be an effective model for the treatment of depression among LEP populations. Future studies should more explicitly detail participants' language preference and cultural adaptations made to the model to treat LEP individuals.

COLLABORATIVE CARE TO ALLEVIATE SYMPTOMS AND ADJUST TO ILLNESS (CASA): PRIMARY EFFICACY RESULTS FROM THE CASA RANDOMIZED CLINICAL TRIAL OF A PALLIATIVE SYMPTOM AND PSYCHOSOCIAL CARE INTERVENTION IN HEART FAILURE David Bekelman[5, 4]; Larry Allen[5]; Brack Hattler[4]; Edward P. Havranek[2]; Diane Fairclough[1]; Connor F. McBryde[3]; Paula Meek[5]. [1]Colorado School of Public Health, Auroa, CO; [2]Denver Health Medical Center, Denver, CO; [3]Denver VA Medical Center, Denver, CO; [4]Eastern Colorado Health Care System, Denver, CO; [5]University of Colorado AMC, Aurora, CO. (Control ID #2704174)

BACKGROUND: Palliative care provided by specialists shows promise in improving symptoms and quality of life in patients with chronic heart failure. However, there is limited high-quality data for what works in the outpatient setting. Furthermore, because there are relatively few palliative care specialists, scalable interventions that can be used in routine outpatient care are needed. The CASA trial determined whether a team-based intervention improved health status (i.e., symptoms, function, and quality of life) and other outcomes in outpatients with heart failure compared to usual care.

METHODS: Patients with heart failure and poor self-reported health status were recruited from a VA, an academic health system, and an urban safety net health system. Patients with dementia, metastatic cancer, major mental illness, or active substance abuse were excluded. The CASA intervention included a nurse who addressed persistent symptoms (e.g., shortness of breath, fatigue, pain) and a social worker who provided psychosocial care. Patients were also reviewed with a study primary care provider, cardiologist, and palliative care physician who wrote orders for medications and tests for patients' primary providers to consider. The primary outcome was heart failure-specific health status at 6 months, measured using the Kansas City Cardiomyopathy Questionnaire (range, 0–100, higher is better; the study was designed to have 90% power to detect a clinically meaningful difference of 6). Secondary outcomes included depression (Patient Health

Questionnaire-9), overall symptom distress (General Symptom Distress Scale), specific symptoms (PEG pain, PROMIS fatigue, shortness of breath), hospitalizations, and mortality. Data were analyzed using mixed models.
RESULTS: 314 patients were randomized (157 intervention, 157 control). Participants were generally male (77%), white (63%), with a mean age of 65.5 years, and 57% had reduced ejection fraction. At 6 months, mean KCCQ score improved 5.5 points in the intervention arm and 2.9 points in the control arm (difference, 2.7; 95% confidence interval −1.3, 6.6; $p = 0.19$). Among secondary outcomes, depressive symptoms and fatigue improved at 6 months with CASA (effect sizes of −0.29 and −0.30, respectively, $p = 0.02$ for both). There were no changes in overall symptom distress, pain, shortness of breath, or hospitalizations. Mortality at 12 months was similar (CASA, 10/157; usual care, 13/157; $p = 0.52$).
CONCLUSIONS: This randomized trial of the CASA intervention did not demonstrate a significant improvement in heart failure-specific health status. Secondary outcomes of depression and fatigue, which have been difficult symptoms to address in heart failure, did improve. Alternate or more intensive interventions should be evaluated to improve health status in the symptomatic heart failure population.

COLLECTING DATA ON PATIENTS' SEXUAL ORIENTATION, GENDER IDENTITY, AND SEX ASSIGNED AT BIRTH IN A CLINICAL SETTING: PERSPECTIVES OF PROVIDERS, PATIENTS, AND REGISTRATION STAFF Karey Kenst[2]; Robert Coulter[3]; Aswita Tan McGrory[2]; Lenny Lopez[1]. [1]University of California San Francisco, San Francisco, CA; [2]Massachusetts General Hospital, Boston, MA; [3]University of Pittsburgh, Pittsburgh, PA. (Control ID #2707079)

BACKGROUND: The Institute of Medicine recommends that healthcare organizations collect information about patients' sexual orientation, gender identity, and sex assigned at birth (SOGI). Healthcare organizations are beginning to collect these data. This study investigated providers', registrars', and patients' perspectives to: (1) understand the issues and nuances regarding collecting SOGI data; and (2) elucidate preferred processes for asking about SOGI.
METHODS: We conducted a mixed methods study with participants of diverse sexual orientations and gender identities. Using a random sampling strategy, we conducted surveys with 104 patients and administered follow-up semi-structured interviews with 16 patients. We also conducted surveys with 13 primary care providers and semi-structured interviews with 15 registrars, 13 LGBTQ (lesbian, gay, bisexual, transgender, and queer) providers, and 18 LGBTQ community members. Surveys and interviews covered the following topics: opinions about collecting SOGI data in clinical settings; storing, accessing, and using SOGI data; cognitive testing of previously recommended SOGI questions; and processes for administering questions. Applied thematic analyses were conducted with a grounded theory approach.
RESULTS: LGBTQ community members and patients overwhelmingly wanted healthcare providers to know their SOGI. Patients and providers agreed that knowing SOGI information would help providers avoid making assumptions about LGBTQ patients' identities and health care needs. All participants thought SOGI data could also be used to monitor for disparities. Barriers included: LGBTQ participants feared discrimination or mistreatment and providers were concerned with making patients uncomfortable. Registrars had the most hesitancy and discomfort asking SOGI, fearing they would upset patients and be unable to address patients' distress. However, they thought that ongoing training would be required to appropriately support registrars. LGBTQ participants wanted additional response options that were inclusive of a wide range of identities (e.g., non-binary, asexual). Transgender participants wanted to be asked about current gender identity first followed by sex assigned at birth. A private setting for registration was recommended and patients and providers thought SOGI data should be stored in their medical records and be accessible to clinical providers. Participants believed ongoing education of patients, providers, and registrars about SOGI data collection and usage was necessary for successful implementation.
CONCLUSIONS: Participants thought that collecting SOGI was important and that staff training and policies were essential to assure appropriate implementation and equitable use of these data. There are many nuances to collecting SOGI data but collecting it allows healthcare organizations to identify disparities and implement targeted initiatives to improve care and achieve health equity for LGBTQ populations.

COMMUNICATION GAPS BETWEEN PCPS AND HOSPITALISTS AROUND TESTS PENDING AT THE TIME OF DISCHARGE Karen J. Blumenthal; Megan M. Meehan; Ryan Thompson. Massachusetts General Hospital, Boston, MA. (Control ID #2703692)

BACKGROUND: Effective communication and care coordination between primary care physicians (PCPs) and hospitalists are essential for safe care transitions between inpatient and outpatient settings. Inadequate care coordination at discharge can result in a lack of necessary follow-up, and in some cases may lead to patient harm. Previous work has suggested that as many as 41% of patients discharged from a medicine service are discharged with one or more test results pending. Standardizing communication between PCPs and hospitalists, particularly around follow-up of tests results pending at discharge, could result in fewer missed test results, less delay in action on these results, and improved patient outcomes. The objective of this study was to determine current communication practices between PCPs and hospitalists at our institution with regard to test results pending at discharge from the inpatient medicine service.
METHODS: We administered a cross-sectional web-based survey to all PCPs ($n = 165$) whose patients are admitted to a hospitalist/inpatient medical team, and all hospitalists ($n = 96$) working at a single, large academic medical center. The survey asked about frequency and perceived efficacy of communication between hospitalist and PCP with regard to pending test results. We summarized survey responses using frequencies to compare communication practices between PCPs and hospitalists.
RESULTS: Fifty-two percent of PCPs and 46% of hospitalists responded to the survey. Our survey found significant differences between hospitalists and PCP regarding knowledge about tests pending at discharge. Seventy-five percent of hospitalists reported "always" (34%) or "usually" (41%) making the PCP aware of tests that need follow-up after discharge, while only 26% of PCPs reported "always" (4%) or "usually" (22%) being made aware by hospitalists of pending tests that need follow-up after discharge ($p < 0.001$). Additionally, 77% of hospitalists reported that they expect that the PCP will follow-up the results of pending tests after discharge. In contrast, only 22% of PCPs report that it is "always" or "usually" clear who is responsible for following-up test results pending at discharge.
CONCLUSIONS: Our study suggests that there is a large gap in perceptions and expectations between PCPs and hospitalists around pending tests at discharge. Our study also revealed ambiguity around who is responsible for following-up pending test results after discharge. These results highlight the need for interventions to develop and standardize the communication of pending tests at the time of discharge as a step to improving patient safety and outcomes following discharge.

COMMUNICATION SKILLS AND VALUE-BASED MEDICINE: UNDERSTANDING RESIDENTS' VARIATION IN CARE USING UNANNOUNCED STANDARDIZED PATIENT VISIT

Kathleen Hanley[1, 3]; Amanda Watsula-Morley[1]; Lisa Altshuler[1]; Heather Dumorne[1]; Adina Kalet[1]; Barbara Porter[2, 3]; Andrew B. Wallach[2, 3]; Colleen Gillespie[1]; Sondra Zabar[1]. [1]NYU School of Medicine, New York, NY; [2]Bellevue Hospital, New York, NY; [3]Gouverneur Healthcare Services, New York, NY. (Control ID #2705415)

BACKGROUND: Training residents to effectively practice value-based care is challenging. We hypothesized that residents with better communication skills would order fewer unnecessary tests and prescribe more appropriate care. We used a USP case of a patient with uncontrolled asthma to examine the relationship between value-based care and communication skills.

METHODS: A 25 year-old female USP presented as a new patient to a medicine resident's clinic, reporting asthma since childhood with worsening symptoms over the past few months. At the time of the visit, she was using her albuterol inhaler multiple times daily, without any additional asthma treatment, and was unsure whether she was using it properly. Data was collected using two forms of assessment: a post-visit USP checklist and a systematic review of the corresponding clinic note to examine treatment recommendations including referrals and quality of documentation. The USP checklist measured communication, patient education, and assessment skills. Each response option included descriptive behavioral anchors and was rated as not done, partly done, or well done. Domain scores were calculated as percent items rated well done.

RESULTS: 141 USP visits were made from 2009 to 2016 with a mean visit length = 88 min, SD = 28 min (range: 40 to 180 min). Almost all residents (92%) evaluated the patient's asthma with a pulmonary examination. The most common treatment prescribed was albuterol and an inhaled steroid, with or without a spacer (79%). The majority of residents (53%) did not order any additional studies; 21% ordered one study, and 26% ordered two or more studies. Study orders fell into one of three categories: gold (appropriate/recommended: PFTs, flu shot, HIV), grey (pulmonary consult, HCG), or inappropriate (TSH, A1C). Across the 141 visits, 129 studies were ordered; 46% were gold, 5% were grey, and 49% were inappropriate. The most common study ordered was a PFT (31%). 87% of single study orders were gold, but 92% of multiple orders included at least one inappropriate study. Residents who did not order any studies had significantly higher patient education and counseling skills than residents who ordered one or more studies (54% vs 34%, $p = 0.00$) and were more likely to explain how to correctly use an inhaler than residents who ordered one or more studies (48% vs 27%, $p = 0.01$). These residents also had significantly higher management and treatment skills (61% vs 39%, $p = 0.00$) and overall communication skills (68% vs 55%, $p = 0.01$). There were no significant differences between groups in medications prescribed or in quality of documentation.

CONCLUSIONS: Effective communication skills may contribute to value-based care through appropriate patient education and ordering of fewer inappropriate studies. Rigorous curricula and assessment of resident's patient education skills should be in place to help both patients and health care system achieve value-based care.

COMMUNITY HEALTH SPECIALIST TRAINING FOR LIBRARIANS: IMPROVING KNOWLEDGE AND CONFIDENCE IN ADDRESSING THE SOCIAL DETERMINANTS OF HEALTH

Anna U. Morgan[2]; Bernadette A. D'Alonzo[2]; Roxanne Dupuis[2]; Alexander Reisley[2]; Heather Klusaritz[1]; Carolyn C. Cannuscio[1]. [1]Perelman School of Medicine, U. of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA. (Control ID #2706512)

BACKGROUND: Hosting over 1.5 billion in-person visits annually, and often serving as a lifeline for the highly vulnerable, public libraries can be partners in population health. Public library staff, however, report feeling ill-equipped to address the health and social challenges facing many of their patrons. The aim of this study was to train public library staff in pertinent health-related topics and evaluate their comfort, confidence, and preparedness in assisting vulnerable patrons.

METHODS: Our interdisciplinary team of individuals with medical, social work, and public health backgrounds conducted a needs assessment of library staff and local residents in Philadelphia to determine the most pressing challenges facing the community. We then developed a 12-hour, case-based training curriculum for library staff. Topics addressed in the training–homelessness, mental illness and substance use, immigration, and trauma–were selected based on findings from the needs assessment. Each case was designed to help staff "recognize" high-risk patrons, "engage" them in conversation, and "refer" them to appropriate community-based services. Participants were surveyed before and after each session and asked to rate on a scale of 1–10 how "comfortable," "confident," and "prepared" they felt when presented with each case. Responses (before and after) were compared using a paired t-test. Participants were also interviewed 4 months post-training about their daily work, how they had used the training, and for additional feedback. Interviews were transcribed and analyzed for key themes using an iterative process.

RESULTS: 11 individuals participated in the training (81% female, age 26–65, 45% African-American, 45% white, 9% Asian). Staff included managers, adult and children's librarians, library assistants, and security guard. Participants reported a significant improvement in comfort, confidence, and preparedness in almost all cases. Nine (81%) of the library staff completed semi-structured interviews. Overall, participants were positive, stating that the curriculum boosted their confidence about their current work. They also reported feeling more capable of assisting vulnerable patrons. However, several had not yet used many of the resources presented because they had not encountered patrons whom they identified as needing extra assistance.

CONCLUSIONS: A 12-hour case-based training curriculum to teach public library staff to "recognize, engage and refer" patrons to appropriate resources significantly increased the preparedness, comfort, and confidence of staff in assisting vulnerable patrons with health and social needs, thereby increasing the capacity for public libraries to serve as partners in improving population health. Future training programs should strive to provide resources in a more accessible format, continue to assist staff in defining their role as public health partners, and assess the impact such training programs have on vulnerable patrons.

COMMUNITY HEALTH WORKER SUPPORT VERSUS COLLABORATIVE GOAL-SETTING FOR DISADVANTAGED PATIENTS WITH MULTIPLE CHRONIC DISEASES: A RANDOMIZED CLINICAL TRIAL

David Grande[1]; Judith A. Long[1, 3]; Nandita Mitra[2]; Hairong Huo[1]; Robyn A. Smith[1]; Shreya Kangovi[1]. [1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]Corporal Michael J. Crescenz VAMC, Philadelphia, PA. (Control ID #2707904)

BACKGROUND: A growing number of Americans have multiple chronic conditions. Collaborative goal-setting between patients and providers can improve

chronic disease control, but may be insufficient in patients with unaddressed socioeconomic needs. Community health workers (CHWs), trained laypeople who share socioeconomic background with patients, can effectively improve chronic disease outcomes. Unfortunately, most prior CHW interventions have been disease-specific. The study team created IMPaCT (Individualized Management for Patient-Centered Targets), a standardized CHW intervention that addresses 'upstream' socioeconomic and behavioral barriers *across* diseases. In a prior randomized clinical trial of hospitalized patients with a variety of diagnoses, this intervention improved post-hospital access to primary care, mental health and quality of care while decreasing recurrent hospital readmission. For this study we adapted the IMPaCT intervention for use in the outpatients with multiple chronic conditions. Our objective was to compare the effects of collaborative goal-setting versus goal-setting plus CHW support on chronic disease control.

METHODS: We performed a single-blind, randomized clinical trial in two urban academic adult internal medicine clinics. We enrolled 302 participants who were residents of high-poverty neighborhoods, uninsured or publicly insured, and diagnosed with ≥2 chronic diseases (diabetes, obesity, tobacco dependence, hypertension). All participants met with their primary care provider to collaboratively set a chronic disease management goal for one of their multiple conditions. Patients randomly assigned to CHWs also received six months of tailored support.

RESULTS: The mean age of the cohort was 56.3 years (SD 13.1), 94.7% were black and 96.3% had a history of a traumatic event. Participants were diagnosed with an average of 2.5 of the eligibility chronic conditions. We found differences in the six-month change in chronic disease control between CHW support vs goal-setting alone arms (△HbA1c −0.4 vs 0.0, △BMI −0.3 vs. -0.1, △CPD −5.5 vs. -1.3, △SBP −1.8 vs. -11.2, overall $p = 0.08$). Patients receiving CHW support also showed greater improvements in mental health (2.3 vs. -0.2, $p = 0.008$) and reported higher quality primary care that was comprehensive (49.2% vs. 39.7%, $p = 0.01$) and supportive of disease self-management (62.9% vs 38%, $p = 0.0002$). Thirty-two percent of patients in the goal-setting arm were hospitalized at one-year versus 23% in the CHW support arm ($p = 0.11$). There were no differences in patient activation or self-rated physical health.

CONCLUSIONS: CHW support led to modest improvements in diabetes, obesity and smoking, but not in hypertension. CHW support improved mental health and quality of primary care, and may have reduced hospitalizations. Standardized CHW interventions can improve key health outcomes *across* multiple diseases for high-risk patients.

COMPARING LIFE-YEARS LOST VS. NUMBER OF DEATHS IN THE US OVER THE PAST 20 YEARS Glen B. Taksler; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Control ID #2698725)

BACKGROUND: Leading causes-of-death are typically reported by number of deaths. Assessing life-years lost to each cause may provide better context.

METHODS: We assembled national data on life-years lost to each cause-of-death and analyzed changes over the past 20 years, using all death certificates filed with the National Vital Statistics System for 2015 and 1995. Specifically, we defined "life-years lost" as remaining life expectancy for each decedent's age, sex and race. We summed life-years lost across all individuals in 2015 and 1995, and calculated the share of life-years lost to each cause-of-death. To better understand reasons for the change in life-years lost between 1995 and 2015, we redefined life-years lost as the product of 3 terms: the mortality rate, population size and life expectancy. We employed a first-order Taylor series expansion for each age (single-year increments), sex, race and cause-of-death subgroup, allowing us to approximate the change in life-years lost by a weighted average of the change in disease-specific mortality rates, the change in population size and the change in life expectancy.

RESULTS: Heart disease caused the most deaths in both years, but cancer was responsible for 23% more life-years lost in 2015. Life-years lost to heart disease declined 6% since 1995, led by a 42% decline for acute myocardial infarctions, whereas life-years lost to cancer increased 16%. Accidents caused twice the share of life-years lost as deaths in 2015 (10.6% vs. 5.4%), and rose in importance since 1995 because of a 4.5-fold increase in life-years lost to accidental poisonings, primarily overdoses. The entire gains of the past 20 years in preventing and treating HIV were offset by the increase in accidental deaths. Suicides and homicides disproportionately burdened younger individuals. Improvements in disease-specific mortality rates contributed to a 28% reduction in life-years lost since 1995, and saved 1.5 million more life-years for heart disease than cancer. However, total life-years lost increased by 17%, due to population growth (mostly for ages 50–64 y, 16.1% contribution) and longer life expectancy (mostly for white males, 5.0% contribution). Among elders aged ≥80 y, increases in disease-specific mortality rates for Alzheimer's disease caused more growth in life-years lost than all other increases combined. Measuring life-years lost highlighted racial disparities in heart disease (+20.8% for black males vs. -4.6% for white males), homicides and perinatal conditions.

CONCLUSIONS: Life-years lost may provide better context than number of deaths for understanding mortality trends. Focusing on life-years provides a better estimate of the societal burden of disease (e.g., cancer has already surpassed heart disease as the leading cause of life-years lost) and highlights racial disparities. Based on current trends, future progress in secondary prevention and treatment of chronic heart conditions, cancer, addiction and neurodegenerative disease appear critically important.

COMPARING PATIENTS' EXPERIENCES WITH ECONSULT AND REFERRAL FROM PRIMARY TO SPECIALTY CARE: RESULTS FROM A NATIONAL SURVEY Sara L. Ackerman[3]; Scott Shipman[4]; Drayton Moody[1]; Meaghan Quinn[4]; Ariana Afshar[2]; Nathaniel Gleason[1]. [1]UC San Francisco, Nathaniel Gleason, CA; [2]UCSF, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA; [4]American Association of Medical Colleges, Washington, DC. (Control ID #2706848)

BACKGROUND: eConsults enable primary care providers (PCPs) to request advice from specialists via an electronic health record. Research has demonstrated high clinician satisfaction with eConsults as well as their potential to improve specialty care access. However, to date there has been no large-scale assessment of patients' experience with eConsult. As part of a national dissemination of an eConsult model developed at the University of California, San Francisco, we sought to compare the experiences of eConsult patients with patients referred for an office appointment with a specialist.

METHODS: An email-initiated online survey was administered at 9 academic medical centers in 2016. We identified all referral and eConsult orders to participating specialties from primary care visits with adult patients. We filtered out patients with: a) orders from PCPs who did not submit at least one eConsult in the prior month, to control for provider influences on patient experience; and b) more than one order in the prior month, to reduce confusion about which referral or eConsult was the subject of the survey. A total of 28,160 patients (eConsult/ref) were invited to participate during the nine-month study.

RESULTS: 7,264 patients responded (14% eConsult; 86% referral), a 26% response rate. Respondents' mean age was 57, 66% were women, and on average they reported more formal education and less ethnic diversity than the general population (83% identified as white). Referral patients were more likely than eConsult patients to identify the correct order type resulting from their primary care visit (72% vs. 40%; $p < 0.001$). Nearly all respondents (96% eConsult; 99% referral) agreed with their PCP's order decision. Approximately 82% of both referral and eConsult patients were satisfied with the specialist's recommendations. Among patients who had received information from a PCP about their recent eConsult (84%), 96% agreed that the PCP's communication of the specialist's recommendations was prompt; 97% agreed that the PCP clearly explained the specialist's advice; and 79% agreed they had an opportunity to ask questions. 52% of communications from PCPs to patients about eConsult results took place via secure email; 33% were by phone or in-person. 32% of referral patients and 77% of eConsult patients would prefer an eConsult rather than an in-person appointment with a specialist for a similar problem in the future.

CONCLUSIONS: Across nearly all measures, eConsult patients were as satisfied as standard referral patients with their consultation experience. The high proportion of referral patients who expressed a preference for eConsult for a similar problem in the future also suggests acceptability among patients previously unfamiliar with the service. The lack of awareness of eConsult orders among many respondents, and delays in conveying the specialist's advice, suggest room for improvement in patient involvement in eConsult decision making and communication.

COMPARING THE VALUE OF CARE DELIVERED BY U.S. NURSE PRACTITIONERS, PHYSICIAN ASSISTANTS, AND PHYSICIANS IN THE EMERGENCY DEPARTMENT John N. Mafi[1, 2]; Peter Smulowitz[3]; Robert Brook[2, 1]; Bruce E. Landon[4, 5]. [1]David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]RAND Corporation, Santa Monica, CA; [3]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; [4]Harvard Medical School, Boston, MA; [5]Beth Israel Deaconess Medical Center, Boston, CA. (Control ID #2706948)

BACKGROUND: Prior research has found that nurse practitioners and physician assistants (NPs, PAs) provide similar quality and efficiency of care to physicians for routine and low-complexity care in the ambulatory setting. Few studies, however, have compared the value of care between NPs/PAs and physicians managing potentially higher acuity cases in the emergency department (ED) setting.

METHODS: Using nationally representative data from the National Hospital Ambulatory Medical Care Survey on visits to ED providers, we compared utilization of health services among NPs/PAs and physicians from 2009–2013. Outcomes included overall use of hospital admissions, imaging studies, diagnostic tests, procedures (e.g., suturing), and medications given in the ED or upon discharge. We also evaluated use of 4 low value services recently highlighted by the Choosing Wisely Campaign for 5 common conditions: use of (1) CT/MRI for back pain, headache, or syncope, (2) plain x-rays for back pain, (3) antibiotics for upper respiratory infection or skin abscess after drainage, (4) opioids for back pain or headache, as well as hospital admissions for each of the 5 conditions. We excluded red flags for each condition (e.g., hypotension on presenting vital signs for skin abscess) and estimated weighted logistic regression models adjusting for age, sex, race/ethnicity, triage severity assigned by a triage nurse, whether the patient came from a nursing home, primary diagnosis category (e.g., cardiovascular, neurological), chronic comorbidities (e.g., diabetes, HIV), insurance status (e.g., Medicare), urban location, geographic region, and year.

RESULTS: We identified 100,535 physician visits and 20,387 NP/PA visits (39% of NPs/PAs saw patients alone vs. 61% of NPs/PAs saw patients alongside a physician), representing ~515 million ED visits during the study period. Compared with physicians, NP/PA patients were younger (mean age 42.7 vs. 46.5 years, $p < 0.001$) and had lower triage severity (6.7% vs. 12.2% immediate or emergent cases, $p < 0.001$). In adjusted analyses, NPs/PAs utilized similar amounts of hospital admissions (~10%, aOR 0.97 [0.84-1.11], imaging (~50%, aOR 0.96 [0.90–1.02]), diagnostic tests (~79%, aOR 0.92 [0.84–1.01]), and procedures (~49%, aOR 1.04 [0.95–1.15]), but used more medications (83.9% vs. 81.5%, aOR 1.18 [1.04–1.33]) compared with physicians. When focusing on use of low value services, utilization patterns were largely similar except for use of antibiotics: 59.7% for NPs/PAs vs. 53.7% for physicians, aOR 1.28 [1.03–1.58].

CONCLUSIONS: In this large and nationally representative analysis, NPs/PAs prescribed more medications and low value antibiotics than physicians after controlling for patient characteristics, although practice patterns for other services remained otherwise equivalent between the two groups. These findings suggest that aside from greater medication and antibiotic use, NPs/PAs seem to provide similar value and efficiency of care compared with physicians among the measures we studied.

COMPARING THE VISIT CHARACTERISTICS AMONG PHYSICIANS AND ADVANCED CARE PRACTITIONERS Aditi Patel; Parth Parikh; Xiaobo Liu; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Control ID #2707362)

BACKGROUND: To reduce physician burden and decrease costs, health systems are increasingly employing advanced care practitioners, including nurse practitioners (NP) and physician assistants (PA). Studies have shown that patient satisfaction and quality of care are similar between primary care physicians (PCP) and NPs. These comparisons generally focus on specific problems and have not assessed the complexity of the patient or the visit. Our objective was to understand patient and visit characteristics of same day visits among the three provider types.

METHODS: A retrospective analysis of adult patients with same day office visits to either a physician, PA or NP was performed. Of the 19,864 patients screened, 400 patients seen by each provider were randomly selected. Patient demographics (age, race, sex and insurance type) were extracted electronically. Two team members manually extracted the following visit-related variables: visit complexity (simple problems addressed by following algorithms or complex problems requiring diagnostic acumen), duration of complaint (acute vs. chronic), number of additional problems addressed, number of prescription and non-prescription medications prior to the visit and groups requiring extra attention (i.e. patients on insulin, opiates, warfarin and oral hypoglycemic). The ANOVA F-test or Kruskal-Wallis test was used to evaluate relationships between continuous measures and setting (described as Median, IQR). Pearson's chi-square test or Fisher's exact test was used to assess associations between categorical measures.

RESULTS: After excluding 9 repeat visits within the study period, our sample contained 1191 unique visits. Physicians were less likely to see patients compared to PAs and NPs who were female (60.6% vs 70.7% vs 66.9% $p = 0.01$), African American (3.8% vs 14.3% vs 14.1% $p < 0.001$) or who had commercial insurance (59.3 vs 72.2 vs 62.4 $p < 0.001$). There was no difference in frequency of acute problems (84.1% vs 88.7% vs 85.4% $p = 0.69$). Physicians were more likely to address additional problems compared to PA

and NP's (35.6% vs 25.8% vs 25.3% $p = 0.001$), and problems that require diagnostic acumen (44.9% vs 33.8% vs 30.3% $p < 0.001$), At the time of the visit, patients of NPs took more prescription medications (Median 4, IQR 2–6) than patients of physicians (3,1-5) or PAs (2,1–4) ($p < 0.001$).

CONCLUSIONS: The patients seen by physicians, PAs and NPs differ in a number of ways that suggest they are not interchangeable..Patients of NPs take more prescription medications but physicians see more complex medical complaints. Physicians also address additional problems more often.

COMPARISON OF MEDICAL STUDENT SELF ASSESSMENT AND FACULTY ASSESSMENT OF PERSONAL AND PROFESSIONAL DEVELOPMENT SKILLS Christopher Mattson; Jeanne M. Farnan; James N. Woodruff; Wei Wei Lee. University of Chicago, Chicago, IL. (Control ID #2706759)

BACKGROUND: In 2013, the Association of American Medical Colleges (AAMC) included "Personal and Professional Development (PPD)" as a competency domain to be taught in medical school. While most schools have elements of PPD programming in place, assessment of student progress towards competency attainment has not been well studied. In addition, little research has focused on assessing differences between student self assessment and faculty assessment of PPD skills.

METHODS: After conducting a literature review on core PPD competencies, we developed a 48-question survey consisting of Likert scale questions and open-ended questions assessing PPD goals that was given to MS2 students in February 2016. A parallel 8-item survey was developed for faculty to evaluate relevant PPD domains during the MS2 clinical skills (CS) course and Scholarship and Discovery (S&D) experience in the spring and summer of 2016. For our data analysis, we compared the student self-assessments to matched faculty assessments from their CS preceptors and S&D mentors. Using paired t-tests, we analyzed the data for agreement between student self-ratings and faculty ratings. We also analyzed the data for agreement between the two different faculty raters.

RESULTS: There were 28 students for whom there was a self-assessment, a CS assessment and a S&D assessment. Self-assessment scores were significantly lower than CS assessments for each of the 8 PPD competencies assessed. Self-assessments were significantly lower than S&D assessments for 7 of the 8 competencies. There was no statistically significant difference found for "Complying with rules and regulations". There was also no statistically significant difference between CS assessments and S&D assessments for any of the 8 PPD competencies. Of the 28 S&D mentors included in the data set, 17 (60.7%) rated the student as being "Highest performance (top 10%)" in comparison to other medical students with whom the mentor had worked previously. Eight (28.6%) rated the student as being "Above average performance (11-25%)", 1 (3.6%) rated the student as being "Average performance (26-50%)" and 2 (7.1%) said they had never before mentored a medical student on a scholarly project. Thirty-five out of fifty six (62.5%) total faculty assessments gave a rating of 5 out of 5 for all competencies.

CONCLUSIONS: Over half of the S&D mentors rated their students as being in the top 10% of students which suggests that grade inflation contributes to the discrepancy in student and faculty assessments. This is supported by the fact that the majority of CS and S&D faculty uniformly rated students 5/5 for all domains. The data is consistent with trends in the literature, which have shown grade inflation in other aspects of medical education. The data also makes it difficult to provide meaningful PPD feedback to students. Future work should focus on faculty training to improve PPD assessment skills and also on providing opportunities for students and faculty to review and discuss discordant scores.

COMPARISON OF PERICARDIAL EFFUSION SIZE AND PHYSIOLOGY AS ASSESSED BY ECHOCARDIOGRAPHY AND COMPUTED TOMOGRAPHY Samuel Huxley; Joshua Meskin. Medical College of Wisconsin, Milwaukee, WI. (Control ID #2693780)

BACKGROUND: While literature supports usage of computed tomography (CT) to assess pericardial thickness and presence of pericardial effusion (PE), how CT compares to echocardiography (echo) in determining PE size or findings of tamponade physiology (TP) is unknown. Our goal is to compare echo and CT in sizing a PE and determining TP.

METHODS: A retrospective chart review was performed using 122 patients who had an echo that showed a PE and who had a chest CT within three days of the echo. The presence of TP and qualitative sizes of PE on CT and echo were obtained and compared (Table 1).

RESULTS: Patients with TP on echo had a range of PE sizes on CT from trace to large, but 90% of those with TP on echo had a PE of at least moderate size on CT. All patients with large PE by CT had TP on echo. TP by CT did not predict with significance TP by echo [Odds ratio 2.09; 95% confidence interval (CI): 0.58 to 7.09, $p = 0.24$]. The correlation of sizing between echo and CT was variable, being strongest at the size boundaries [Spearman's $\rho = 0.784$, $p < 0.0001$]. If a PE was trace or absent on CT, 84% of PEs were sized similarly on echo. If a PE was moderately large to large on CT, 86% of PEs were sized similarly on echo. If a PE was sized between small and moderate on CT, only 66% of PEs were sized similarly on echo.

CONCLUSIONS: Our data suggest that identifying TP by CT does not correlate with those findings on echo and that sizing between modalities does not correlate well for mid-range sized PEs.

		Qualification by CT				
		None+ trace	Small	Moderate	Large	Total
Qualification by echocardiogram	None+trace	36	11	3	0	50
	Small	3	9	4	0	16
	Moderate	4	7	22	2	35
	Large	0	0	9	12	21
	Total	43	27	38	14	122

Table 1: Frequencies of qualitative PE size by CT and echocardiogram

COMPLEMENT OR CONFLICT: RESIDENT AND FACULTY PERCEPTIONS OF SERVICE AND EDUCATION AT A COMMUNITY-BASED INTERNAL MEDICINE TRAINING PROGRAM Stacie K. Nishimoto. California Pacific Medical Center, San Francisco, CA. (Control ID #2707244)

BACKGROUND: Service is intrinsic to patient care. However, recent ACGME resident survey questions about service and education imply a conflicting relationship between the two and seem to equate "service" with "scut". This study uses clinical vignettes to investigate this question and aims to (1) investigate resident and faculty perceptions of service and education (2) ascertain what aspects of patient care positively and negatively affect perceptions, and (3) evaluate perceptions of how the program balances service and education."

METHODS: This cross-sectional study design used clinical vignettes to investigate resident and faculty perceptions of service and education at a

medium-sized university-affiliated community internal medicine program. We used an anonymous electronic survey instrument to collect qualitative and quantitative data responses. Participants for the study were recruited from the following groups: Internal Medicine Trainees (IMT) (81 residents, chief residents and fellows) and Teaching Faculty (TF) (50 core faculty and program leaders). Analyses included quantitative and qualitative assessments. Main themes were identified from vignette comments and multiple choice questions to showcase how residents and faculty conceptualize "service" and "education." Likert scale data were collapsed into a 4-point scale (strongly disagree/ disagree, neutral, agree/strongly disagree, not applicable).

RESULTS: Eighty participants completed surveys for an overall response rate of 61% ($N=45$; 56% IMT; $N=35$; 70% TF). Overall, 21% of respondents perceived that excessive service obligations negatively impacted the learning environment, with trainees being significantly more likely than faculty to report agreement with this statement (33% vs 6%, respectively; $p=.001$). Trainees were also significantly more likely than faculty to agree that excessive service obligations contributed to duty hour violations (21% vs 6%, respectively; $p=.03$) in their program. With some notable exceptions, faculty and trainees generally agreed on the relative service and educational values of vignette activities. Several activities ranked high in terms of both service and educational value, such as running a family meeting and seeing an urgent care clinic patient. Both quantitative and qualitative responses suggested that high "service" activities fell into two main categories: tasks that could easily be completed by non-physicians and patient care with little autonomy. For example, the top 4 reported choices in a list of activities that constituted "inappropriate or excessive service obligations" were: "calling insurance companies for prior authorizations ($N=56$)", "caring for pts when you have little autonomy (33)", "completing forms for patients (30)", and "making clinic appointments for patients at discharge (29)".

CONCLUSIONS: Service and education are not mutually exclusive. Residents perceive maximal education and service value in situations involving both complexity and connection.

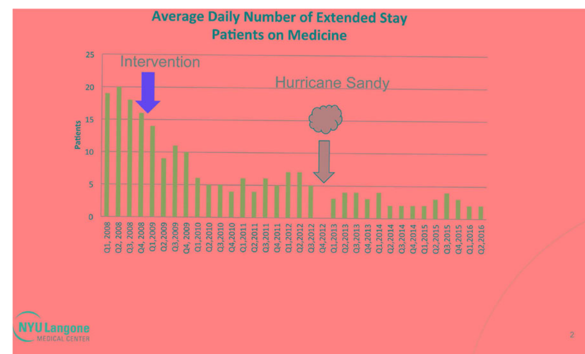
COMPLEX CARE ROUNDS: A COORDINATED INTERDISCIPLINARY STRATEGY FOR CARING FOR OUR SICKEST PATIENTS Katherine A. Hochman[2]; Anne Meara[2]; Regina Presa[2]; Thomas Sedgwick[2]; Ramon Jacobs[1]. [1]New York University School of Medicine, New York, NY; [2]NYU Langone Medical Center, New York, NY. (Control ID #2700019)

BACKGROUND: Extended stay (>30 day stay) cases strain hospital resources, psychologically burden staff, increase average length of stay (ALOS) and ultimately are not patient-centric. In 2008, extended stay patients represented 15% of the average daily census on the Medicine service. The objective of our intervention was to devise a sustainable strategy to reduce the number of extended stay patients on the medicine service and overall ALOS.

METHODS: In 2008, we convened a proactive interdisciplinary team to engage in addressing barriers to care progression and discharge. The goal was to reduce the number of extended stay patients on the medicine service and overall ALOS. The team was comprised of a hospitalist physician and leadership from Care Management, Social Work, Ethics, Finance and post-acute care. Complex Care rounds occurred twice weekly. All patients with LOS of 5 days or more were presented in a standardized format, "The Four Questions", to ensure a shared mental model. These questions are 1.) Why is the patient hospitalized? 2.) Why is the patient STILL hospitalized? 3.) What has to happen for this patient to be discharged? and 4.) When and where is this patient being discharged to safely? A special emphasis was placed on barriers to discharge (ranging from medical, social, financial, psychological), advanced care planning and contingency planning. The hospitalist physician served as a liaison to the medical staff regarding clarification of endpoints to admission.

RESULTS: Since the initiation of Complex Care Rounds, the percent of extended stay patients on the average daily census dropped from 15 to 1.5% (Figure 1). Our ALOS dropped from 6.81 days (2008) to 5.69 days (2016). It is important to note this decrease in ALOS occurred despite two important factors: 1.) our case mix index has increased dramatically from 1.47 to 1.81 during that same period and 2.) the initiation and vast expansion of our observation program siphoned off the short stay cases.

CONCLUSIONS: We have demonstrated a strategic and sustainable approach for reducing and managing patients with extended stays. Since we have achieved our initial goals, it is time to reinvent these rounds. Our new focus is mobilizing resources within the community based on disease entity and psychosocial needs.



COMPREHENSIVE OSCES AS OPPORTUNITIES FOR FACULTY TO MAKE ENTRUSTMENT JUDGMENTS: HOW ARE STANDARDIZED PATIENT ASSESSMENTS OF SKILLS PERFORMANCE ASSOCIATED WITH FACULTY ENTRUSTABILITY JUDGMENTS? Colleen C. Gillespie[1]; Kathleen Hanley[1, 2]; Jasmine A. Ross[1]; Jennifer Adams[1, 2]; Sondra Zabar[1, 2]. [1]NYU School of Medicine, New York, NY; [2]Gouverneur Healthcare Services, New York, NY. (Control ID #2705883)

BACKGROUND: Entrustable Professional Activities (EPAs) and milestones are expert judgments made based on many formative assessments. Their validity is dependent on the number of assessments but attention is increasingly being paid to having a "fair" sample of observations equally distributed across residents and contexts. OSCEs provide such a consistent, fair sample of behavior assessed under controlled conditions but have mostly used been used to provide granular skills feedback. We explore how faculty judge the "entrustability" of residents based on observing OSCE cases and then how these entrustments relate to OSCE skills performance.

METHODS: In an 11-case OSCE for primary care residents ($n=25$; PGY1-3), SPs rated skills in communication (information gathering, relationship development, education/counseling), assessment, patient education (case-specific), physical exam, professionalism, treatment plan, patient satisfaction and patient activation. Summary scores were calculated as % items rated well done (vs not or partly done; internal consistency > .72). Faculty observers then judged how much supervision

the resident would need in actual practice to handle the case: 1-requires direct supervision, 2-requires indirect supervision, 3-ready for unsupervised practice, or 4-can supervise others. Mean entrustment rating across cases was correlated with clinical skills.

RESULTS: Mean entrustment =2.46 (SD .37), falling between *requires indirect supervision* and *ready for unsupervised practice*. On average, residents were judged to need direct supervision in .40 cases (SD .65), indirect supervision in 4.76 (SD 2.03), ready for unsupervised practice in 2.92 (SD 1.80), and able to supervise others in 1.07 cases (SD 1.15) with PGY1 residents needing direct and indirect supervision in more cases than PGY2 and 3 ($p = .037$). Associations between OSCE performance and faculty entrustment ranged from essentially zero (communication sub-domains of information gathering and education/counseling; case-specific patient education; patient satisfaction) to negative (communication sub-domain of relationship development $r = -.25$, $p = .16$; professionalism $r = -.21$, $p = .22$) to positive (case-specific assessment, $r = .35$, $p = .07$; physical exam $r = .30$, $p = .13$; treatment plan $r = .40$, $p = .04$; patient activation $r = .51$, $p = .008$). Associations between skills performance and entrustment ratings varied by case.

CONCLUSIONS: OSCEs provide a valuable opportunity for faculty to make entrustment judgments based on observing the same, complete encounter across many trainees. Entrustment judgments appear to be capturing elements of competence related to but different from SP assessments of performance, including especially “bottom line” aspects of practice such as assessment, physical exam, treatment plans and patient activation. Interestingly, we consider patient activation skills to be an “educationally sensitive patient outcome” i because both teachable and associated with patient outcomes and our results support the importance of this skill set.

CONDITION-RELATED SIDE EFFECTS AND BELIEFS ABOUT CANCER AND DIABETES Chloe Soukas[1]; Kimberly A. Muellers[1]; Juan Wisnivesky[2]; Jenny J. Lin[1]. [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Mount Sinai School of Medicine, New York, NY. (Control ID #2707558)

BACKGROUND: Urinary dysfunction is a side effect of both prostate cancer treatment and as some diabetes medications. In patients with both newly diagnosed and chronic conditions, it is important to consider how symptoms impact patient beliefs about illness. We undertook this study to assess the effect of cancer diagnosis on experience of urinary symptoms in patients with diabetes. We also evaluated how differential experience of side effects impacts patients’ beliefs about diabetes among diabetes patients with or without cancer.

METHODS: We recruited patients with diabetes and early-stage prostate cancer and enrolled age-, gender- and hemoglobin A1c-matched patients with no cancer history. All patients were prescribed an oral hypoglycemic agent, and all cancer patients began treatment in the past 6 months. Urinary symptoms were assessed using the EPIC short form and dichotomized by no symptom versus any symptom during the past four weeks. Patient beliefs were assessed by the Beliefs and Illness Perceptions Questionnaire. We used chi-squared tests to assess differences in cancer and non-cancer patients’ symptoms, reported beliefs about diabetes, and symptom experience and itemized beliefs stratified by cancer status.

RESULTS: We surveyed 31 prostate cancer and 89 diabetic non-cancer patients. We found no overall difference in cancer and non-cancer patients’ beliefs (all items $p > 0.05$). Cancer patients were more likely to report urine leakage, poor urinary control, poor overall urinary function, painful urination, and frequent urination in the past 4 weeks. There was no difference in experience of weak urine stream. Non-cancer patients had associations between urine leak and more emotional impact (55% vs. 25%, $p = 0.045$; $p > 0.1$ for cancer); between poor urinary function and less emotional impact (23% vs. 50%, $p = 0.025$; $p > 0.05$ for cancer); and weak urine stream and concern (100% vs. 71%, $p = 0.032$; $p > 0.1$ for cancer). Among cancer patients, there were associations between poor urinary control and concern (87% vs. 38%, $p = 0.013$; $p = 1.0$ for non-cancer); between painful urination and emotional impact (67% vs. 20%, $p = 0.043$; $p = 1.0$ for non-cancer); and between frequent urination and impact on daily life (35% vs. 0%, $p = 0.033$ for cancer; $p > 0.05$ for non-cancer). Both cancer (45% vs. 0%, $p = 0.026$) and non-cancer (45% vs. 21%, $p = 0.012$) patients reported more emotional impact with frequent urination.

CONCLUSIONS: Patients with diabetes and prostate cancer were more likely to experience urinary problems in the past 4 weeks than other diabetes patients. There was no difference between cancer and non-cancer patients’ beliefs about diabetes. Although urinary symptoms appeared to differentially affect cancer and non-cancer patients’ beliefs about diabetes, the results of this analysis reveal a complex relationship between cancer, symptom experience and disease belief. Further exploration of symptom attribution and beliefs about illnesses in patients with multiple conditions may be valuable to improving disease management.

CONFLICTING MAMMOGRAPHY SCREENING GUIDELINES: WOMEN’S PERCEPTIONS OF SCREENING EFFICACY Michael G. Knight[2, 3]; Carmen E. Guerra[1]; Marilyn M. Schapira[2]. [1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]Crescenz VA Medical Center, Philadelphia, PA. (Control ID #2707227)

BACKGROUND: Breast cancer continues to be the second leading cause of cancer death, and has the highest rate of new cancer cases, among US women. National initiatives have worked to combat these persistent rates through community health education, and increasing access to mammography. However, such initiatives now face the challenge of conflicting recommendations surrounding mammography. In this study, we sought to describe the awareness of conflicting mammography guidelines, and its association with perceptions about mammography among a group of women who had previously undergone screening mammography.

METHODS: A survey was designed with questions, adapted from the Theory of Planned Behavior, to assess the awareness of conflicting mammography guidelines and attitudes about mammography. A convenience sample of women over the age of 21, who had previously undergone mammography, was used. Participants were recruited from community events in the New York area. Awareness of conflicting mammography guidelines was defined by a response of “strongly disagree”, “disagree”, or “neither agree or disagree” for one or more statements that experts agreed on the age of initiation, screening interval, or age of discontinuation of routine mammography. Beliefs that having a mammogram would prolong life or prevent breast cancer were measured on a 5-point Likert scale from 1 (Strongly Disagree) to 5 (Strongly Agree). Descriptive statistics were used to define the study population, and generate response distributions for survey items. Bivariate analysis using chi-square or t-tests was used to examine the relationship between awareness of conflicting guidelines and attitudes about mammography.

RESULTS: There were 70 study participants; 87% were Black, 15% had a family history of breast cancer, and 2% had a personal history of breast cancer. Sixty-one percent (61%) were aware of conflicting mammography screening

guidelines. When compared to participants who were not aware of conflicting guidelines, these women were less likely to agree with the following: Having a mammogram would "..help me to live longer" mean (SD), 3.4 (1.2) vs. 4.1 (1.0) ($p = 0.013$) and "..help me in the prevention of breast cancer" 3.3 (1.4) vs 4.1(1.1) ($p = 0.012$). Participants who were aware of the conflicting guidelines were also more likely to believe that private insurance companies made recommendations for mammography screening 25.6% vs 7.4% ($p = 0.057$). There was no difference in other perceived barriers, behavioral control, or intentions to have a mammogram.

CONCLUSIONS: Awareness of conflicting mammography guidelines in women who have undergone mammography is associated with perceptions of decreased efficacy of mammography with respect to breast cancer prevention and mortality reduction. These results warrant further study and consideration by healthcare providers and guideline generating organizations on the possible association that the ongoing controversy on mammography guidelines may have with patient perceptions about mammography.

CONSUMERS AND USE OF A LARGE NATION-WIDE PRIMARY CARE TELEMEDICINE SERVICE Kathryn A. Martinez; Mark Rood; Nikhyl Jhangiani; Adrienne Boissy; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Control ID #2702041)

BACKGROUND: Advancements in mobile technology have ushered in a new area of consumer-directed health applications. Interest is high, however, little is currently known about the provision of primary care via telemedicine. The objective of this study was to characterize consumers and their use of a large nation-wide telemedicine service.

METHODS: We analyzed all completed primary care encounters between January 2013 and August 2016 from the Online Care Group primary care telemedicine service, one of the largest telehealth companies in the U.S. Patient characteristics, including age, sex, and geographic region were provided by the user. Encounter characteristics, including time of day, wait time, visit length, connection type (mobile device, computer, or telephone), and whether patients used a coupon were recorded by the telemedicine system. Patient diagnosis and prescription receipt were recorded by the visit provider. At encounter conclusion, users rated their satisfaction with their visit provider and with the telemedicine system, on scales of 0 to 5 stars. They were also asked where they would have sought care otherwise (doctor's office, emergency department, urgent care/retail clinic, or done nothing). We generated descriptive statistics regarding users and use of the telemedicine service.

RESULTS: There were 56,863 completed telemedicine encounters during the study period by 601 providers; 60% of patients were female, mean age was 35.2 years (Interquartile Range (IQR): 27–45 years) and 9% were <18 years. Most were from the South (34%), followed by Midwest (29%), West (23%), and Northeast (14%). The majority (62%) accessed the system via mobile device and a third (32%) by computer. Twenty-two percent used a coupon. Mean wait time was 5.1 min (IQR: 1.2-6.1 min) and mean visit length was 7.1 min (IQR: 3.4-8.8 min). Most accessed the service during working hours: 27% called between 7 am and noon and 34% called between noon and 5 pm. Only 6% of users called between midnight and 6 am. Eighty-five percent rated their visit provider 5 stars, and 78% rated the telemedicine service 5 stars. Thirty percent were diagnosed with upper respiratory infections, followed by urinary conditions (8%), dermatological conditions (5%), and mental health/lifestyle issues (4%). Overall, 57% of users received a prescription. Had they not used the telemedicine service, 44% reported they would have visited an urgent care/retail clinic, 28% would have sought care at a doctor's office, 21% would have done nothing, and 6% would have gone to the emergency department.

CONCLUSIONS: Users were young and most accessed the system via mobile device. Both average wait time and visit length were short. Use of the telemedicine service appears to serve primarily as a substitute for urgent care/retail clinics, and to a lesser extent physician visits. However a significant number of users would have forgone care entirely were the service not available.

CONTRACEPTIVE COUNSELING QUALITY AND EFFECTIVE CONTRACEPTIVE USE AMONG WOMEN VETERANS: DATA FROM THE ECUUN STUDY Lisa S. Callegari[3, 6]; E. Bimla Schwarz[1]; Xinhua Zhao[5]; Maria K. Mor[4]; Sonya Borrero[2]. [1]University of California, Davis, Sacramento, CA; [2]University of Pittsburgh and VA Pittsburgh, Pittsburgh, PA; [3]VA Health Services Research & Development, Seattle, WA; [4]VA Pittsburgh Healthcare System, Pittsburgh, PA; [5]VA Puget Sound Health Care System, Pittsburgh, PA; [6]University of Washington, Seattle, WA. (Control ID #2706328)

BACKGROUND: Nearly half of pregnancies in the US are unintended, and the majority of these occur in women not using or inconsistently using contraception. Understanding associations between contraceptive counseling quality and effective contraceptive method use could inform efforts reduce unintended pregnancy.

METHODS: We analyzed data from the "Examining Contraceptive Use and Unmet Need among Women Veterans" (ECUUN) study, a national telephone survey of women veterans ages 18–45 years who received primary care in VA in the past year. This analysis was limited to women at risk of unintended pregnancy (heterosexual intercourse within the past year; not pregnant or trying to conceive; no history of hysterectomy, sterilization, or infertility) who reported receiving contraceptive counseling in the past year. Counseling quality was measured using six Likert-scale questions assessing whether patients' concerns were addressed, risks/benefits of options were discussed, and patients' views were elicited regarding which method they thought was best for them. Composite scores of how many items to which participants responded "agree" or "strongly agree" were calculated (0–6) and categorized as high (score = 6), moderate (score 3–5), and low (score < 3) quality. Our outcome was contraceptive method used at last sex, categorized as highly effective (intrauterine device, implant), moderately effective (injection, pill, patch, ring), and less effective (barrier, withdrawal)/no method. Logistic regression assessed associations between counseling quality and use of effective methods (moderately or highly effective) and, among those using effective methods, use of highly effective methods, controlling for age and race.

RESULTS: Of the 365 women veterans in our sample, 42 (12%) reported low quality counseling, 144 (40%) moderate quality, and 179 (49%) high quality. In unadjusted analyses, women reporting low quality counseling were less likely to use highly effective methods compared to women reporting high or moderate quality counseling (2% vs 20 and 18%, respectively) and more likely to use less effective methods/no method (36% vs 21 and 19%, respectively), with similar proportions (60-63%) using moderately effective methods across counseling quality groups [overall $p = 0.02$]. In adjusted analyses, women

reporting low quality counseling were less likely to use effective methods than women reporting high quality counseling (adjusted OR[aOR]:0.42, 95%CI 0.20, 0.89). Among the 286 women using effective methods, women reporting low quality counseling were less likely than women reporting high quality counseling to use a highly effective method (aOR:0.12, 95%CI 0.003, 0.81).

CONCLUSIONS: Quality of contraceptive counseling is associated with effective contraceptive method use among women Veterans. Facilitating higher quality contraceptive counseling may represent an opportunity to improve contraceptive outcomes and reduce unintended pregnancy.

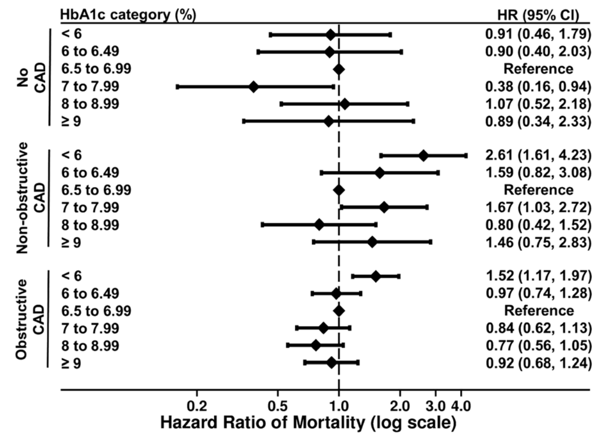
CORONARY ARTERY DISEASE SEVERITY MODIFIES THE ASSOCIATION BETWEEN GLYCEMIC CONTROL AND MORTALITY AND INFORMS PERSONALIZED DIABETES MANAGEMENT TARGETS Sridharan Raghavan[3, 4]; Wenhui G. Liu[3]; Michael Ho[1]; Margaret E. Plomondon[3]; David Magid[3]; David Saxon[2, 3]; Steven M. Bradley[5, 3]; Thomas M. Maddox[1]. [1]Eastern Colorado Health Care System, Denver, CO; [2]University of Colorado, Aurora, CO; [3]VA Eastern Colorado Health Care System, Denver, CO; [4]University of Colorado School of Medicine, Denver, CO; [5]Minneapolis Heart Institute, Minneapolis, MN. (Control ID #2702512)

BACKGROUND: While professional society guidelines recommend a personalized approach to diabetes management that takes into account an individual's comorbidities and diabetes-related complications, there is little evidence to guide individualization of diabetes treatment targets. We examined whether the severity of coronary artery disease (CAD) modifies the association between glycemic control and mortality and thus provides guidance in personalizing diabetes treatment.

METHODS: We studied 17,394 veterans with type 2 diabetes who underwent elective cardiac catheterization in the Veterans Affairs (VA) health care system between 2005 and 2013. The primary exposure was HbA1c level over 2 years of follow-up after index catheterization. The primary outcome was 2-year all-cause mortality, and cardiovascular versus non-cardiovascular mortality was a secondary outcome. CAD severity was categorized as no CAD, non-obstructive CAD, or obstructive CAD based on angiographic findings. Using multivariable Cox proportional hazards regression, adjusting for demographic and clinical covariates, we estimated the association between time-varying HbA1c and mortality, with an interaction term to determine effect modification by CAD severity.

RESULTS: Mean HbA1c at baseline was 7.5%; 61% had obstructive, 22% had non-obstructive, and 17% of participants had no CAD. Relative to a reference HbA1c of 6.5-7%, HbA1c <6% was associated with increased mortality risk (HR 1.55 [1.25, 1.92]), whereas HbA1c categories above 7% were not. We observed a significant interaction between HbA1c and CAD severity (interaction $p = 0.0005$). HbA1c <6% was associated with increased risk of mortality among individuals with obstructive and non-obstructive CAD, but not in those with no CAD (Figure). In secondary analysis, HbA1c <6% was associated specifically with increased risk of non-cardiovascular but not cardiovascular mortality.

CONCLUSIONS: CAD severity may inform diabetes treatment goals. In particular, the short-term risk of harm associated with lower glycemic control targets was limited to individuals with CAD on angiography. Measures of cardiovascular disease burden may help physicians optimize individualized glycemic control targets, especially with respect to minimizing harm.



CORRELATES OF OPIATE MISUSE OF PATIENTS ON CHRONIC OPIATE THERAPY FOR CHRONIC NON-CANCER PAIN IN AN ACADEMIC, SAFETY-NET PRIMARY CARE CLINIC Smita Y. Bakhai[1]; Bright Thilagar[1]; Jessica Reynolds[1]; Kenneth Leonard[2]. [1]SUNY at Buffalo, Williamsville, NY; [2]SUNY at Buffalo, Buffalo, NY. (Control ID #2690370)

BACKGROUND: Misuse and deaths associated with prescriptions opiates has increased dramatically. Efforts to curb the misuse of prescription opiates have focused on recognizing inappropriate use by patients in treatment for chronic non-cancer pain (CNCP). The primary objective of this study was to evaluate the correlates of opiate misuse based on a failed urine drug test (UDT) among patients on chronic opiate therapy (COT) for CNCP in a primary care setting.

METHODS: Utilizing medical records, we conducted a cross-sectional study of 206 subjects, between April 2011-April 2012, who were prescribed COT for at least 3 months' duration for CNCP. UDT results were used to classify subjects into three groups: 1) No Misuse, positive UDT for prescribed opiate and negative for illicit drugs and non-prescribed control substances; 2) Misuse, positive UDT for illicit drugs or non-prescribed control substances and positive or negative for prescribed opiates or overdose; 3) Potential diversion, negative for prescribed opiates and negative for illicit/un-prescribed controlled substances. Variables of interest were UDT results, patient demographics and medical, psychiatric and substance abuse history, missed medical appointments and non-adherence to non-opiate medications for other chronic diseases. Non-adherence was defined as physician documentation of medication non-adherence in medical records during clinic visit. We conducted an initial analysis comparing all groups using chi square analyses for categorical variables. Continuous variables were analyzed with ANOVA with Bonferroni corrected post hoc tests. We conducted two logistic regression analyses, one comparing groups using only those variables that were predictive of group status in the initial analyses.

RESULTS: The most commonly prescribed opiate was hydrocodone. The most commonly misused substances were marijuana, cocaine, benzodiazepines and non-prescribed opioids. Of the 206 records analyzed, 80 (38%) had a no misuse, 91 (44%) had misuse and 35 (17%) had potential diversion. In bivariate analyses, positive history of smoking (OR 3.90, 95% CI 1.69–9.03), substance use (OR 7.02, 95% CI 2.56–19.20), missed medical appointments (OR 2.85, 95% CI 1.44–5.63), and non-adherence to other medications correlated with opiate misuse group (OR 18.86, 95% CI 8.73–40.74). In logistic regression, only substance use history (OR 4.32, 95% CI 1.27–14.64) and non-adherence with non-opiate medications (OR 13.22, 95% CI 5.81–30.10) correlated with opiate misuse.

CONCLUSIONS: Non-adherence with non-opiate medications and missed appointments were significant correlates of opiate misuse based on failed UDT in a primary care setting. This study highlights the significance of reviewing medication and appointment adherence, in addition to substance abuse and smoking history.

COST OF RETRIEVING PRESCRIPTION DRUG MONITORING PROGRAM REPORTS: COMPARISON OF PHYSICIAN VERSUS DELEGATE MODELS Marcus Bachhuber[2]; Marc Larochelle[1]; Jessica Merlin[3]; Sean M. Murphy[4]. [1]Boston University School of Medicine and Boston Medical Center, Boston, MA; [2]Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY; [3]University of Alabama Birmingham, Birmingham, AL; [4]Washington State University, Pullman, WA. (Control ID #2705307)

BACKGROUND: Prescription drug monitoring programs (PDMPs) are state-level databases of dispensed controlled substances. Clinical guidelines recommend, and an increasing number of states mandate, periodically obtaining PDMP patient reports prior to writing controlled substance prescriptions. Although the task of retrieving reports is a clerical function, it often falls to the prescribing physician. While delegates such as administrative staff members have access to PDMPs in many states, no study has compared the costs of delegates assisting physicians to obtain PDMP reports to the costs of relying solely on physicians to obtain them.

METHODS: We conducted a cost analysis with a 1 year time horizon, from the perspective of physicians (if self-employed) or their employers. We obtained estimates of the frequency of controlled substance prescribing by primary care providers from the 2011–2013 National Ambulatory Medical Care Survey. We measured time to retrieve PDMP reports by calculating the mean of 64 query attempts by 13 physicians in 5 states (30s to log in and 40s to retrieve a PDMP report). We defined two PDMP usage cases based on the frequency of queries: comprehensive (before every Schedule II-IV prescription), selective (before new Schedule II- IV prescriptions and only every 6 months for continuing prescriptions), and minimal (limited to before new Schedule II or III prescriptions and annually for continuing prescriptions). For each PDMP usage case, we calculated the labor costs (monetary value of physician or delegate time) and media costs (paper and ink).

RESULTS: Nationally, primary care providers write a new Schedule II-IV controlled substance prescription at 5.0% of visits and write a continuing Schedule II-IV controlled substance prescription at 17.8% of visits. For comprehensive, selective, and minimal PDMP usage, primary care providers spend an annual mean of 12, 11, and 6 hours, respectively, retrieving PDMP reports. The mean annual cost of this activity is an estimated $1509, $1387, and $762, respectively. The mean annual cost of the delegate model is $1105, $1023, and $710, respectively. Compared to the physician model, the delegate model results in a cost savings of $404 (27%), $364 (26%), and $52 (7%).

CONCLUSIONS: Retrieving PDMP patient reports—a clerical function—represents an opportunity cost to the payer of physician services in that it may result in forgone patient care. Alternatively, physicians may perform this activity after work hours, which could contribute to burnout. A model where delegates assist physicians can only reduce costs by up to one quarter. Ultimately, automation and integration of PDMP data into electronic health records may further reduce physician labor costs. Physicians, health care systems, and states should collaborate to ensure that PDMPs are employed in a manner that maximizes their benefit to patients and society, while minimizing their associated costs.

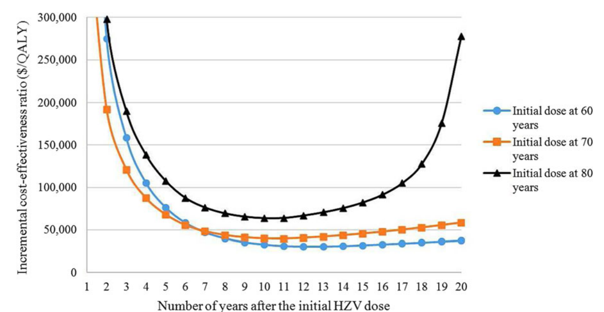
COST-EFFECTIVENESS OF A SHINGLES VACCINE BOOSTER FOR CURRENTLY VACCINATED PERSONS Phuc H. Le; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Control ID #2705585)

BACKGROUND: The Advisory Committee on Immunization Practices recommends a single dose of the live attenuated herpes zoster vaccine (HZV) in persons aged ≥60 years. Because the efficacy decreases to zero after 10 years, many vaccinated patients will soon be subject to an increased risk of herpes zoster and post-herpetic neuralgia. A booster might be necessary to extend protection but its cost-effectiveness is unknown. We aimed to determine the cost-effectiveness of a HZV booster and its optimal timing in immunocompetent adults first vaccinated at aged ≥60 years.

METHODS: We updated a validated Markov model to follow patients lifetime. From the societal perspective, we compared costs and quality-adjusted life years (QALYs) for no booster versus booster options. We examined a booster anytime between 1–20 years after the first dose, and conducted the analysis for persons having the first dose at different ages: 60, 70, and 80 years. The model started with the 'Healthy' state and patients could move between health states over time. Compared to no booster group, patients with a booster had an additional reduction in disease incidence and complications proportional to vaccine efficacy. Because patients entered the model already vaccinated, costs and side effects of the first dose were not included. We assumed the booster had the same efficacy and waning rate as the initial vaccination. Transition probabilities and other model inputs were based on published literature. We derived vaccine efficacy from the Shingles Prevention Study and its long-term data. All costs were expressed in 2015 US dollars ($). Costs and QALYs were discounted at 3%/year. Results were presented as incremental cost-effectiveness ratio (ICER) ($/QALY) and a threshold of $100,000/QALY was used to determined cost-effectiveness.

RESULTS: Cost-effectiveness of the booster varied by age and time since vaccination. The booster cost less than $100,000/QALY for all patients at least 5 years after the initial dose, but was most cost-effective at around 10 years. In one-way sensitivity analysis, none of the variables caused the ICER to exceed $100,000/QALY. In probabilistic sensitivity analysis, a booster at 10 years had >80% the probability of being cost-effective.

CONCLUSIONS: Under current assumptions, a booster dose of HZV could be cost-effective for vaccinated patients 10 years after initial vaccination. Future data on booster's efficacy could change the conclusion.



CREATING CONTINUITY ON A 7 ON 7 OFF HOSPITALIST STAFFING MODEL Christopher M. O'Donnell; Marsha Stern; Traci Leong; Ethan Molitch-Hou; Bruce Mitchell. Emory University, Atlanta, GA. (Control ID #2702955)

BACKGROUND: Transitions of care are a potential pitfall for miscommunication and an area of increased risk for patients. This study implemented a novel staffing model in a 7 on 7 off shift-based staffing system that focused on continuity of care on an urban academic hospitalist service. The purpose of the model was to allow hospitalists more continuity with their patients and to measure how this is associated with mortality, length of stay (LOS), and readmissions.

METHODS: This was a retrospective cohort in which matching 6 months of patient data were compared pre and post implementation of a new staffing model in 2016. The model changed from a drip system of admissions with dedicated rounders and admitters to one where rounding hospitalists admitted their own patients for daytime hours on the first four days of their week. They did not admit on their last three days. Total hospitalists involved in care were assessed as a measure of handoffs. Outcome measures included mortality, length of stay, and 30-day readmission rate.

RESULTS: We identified 2,102 patients admitted to the hospital medicine service from January 1st 2015 to June 30th 2015 and 1,870 patients admitted during the same time in 2016. Patient characteristics were found to be similar between years. There was on average 2.76 hospitalists per patient encounter in 2015 versus 2.19 in 2016 [$p < 0.001$]. Average length of stay was significantly reduced by over a half day from 6.34 days in 2015 to 5.7 days in 2016 [$p = 0.002$]. Of patients admitted prior to intervention, 46.52% had just one rounder during the hospital course while 57% had one rounder in the intervention group [$p < 0.001$]. In 2016, 23% of patients had one provider from admission to discharge compared to none in 2015 [$p < 0.001$]. There was no difference in mortality between groups. There was a direct relationship between the number of hospitalists and death in both groups with an increase odds ratio of 1.37 with each additional hospitalist added to the patient's care [$p < 0.001$]. There was no statistical difference in 30-day readmissions between years.

CONCLUSIONS: Improvement in hospitalist continuity significantly decreased patient LOS in this novel seven day staffing model. There was not a significant difference in mortality or 30-day readmission rate between groups, but there were increased odds of death with additional hospitalist handoffs. Implementing a new staffing model focusing on continuity is an inexpensive and potentially cost effective intervention for a hospitalist service.

Team	M	T	W	Th	F	Sa	Su
A	Day 1	2	3	4	5	6	7
B	Day 1	2	3	4	5	6	7
C	Day 1	2	3	4	5	6	7
D	4	5	6	7	Day 1	2	3
E	4	5	6	7	Day 1	2	3
F	4	5	6	7	Day 1	2	3
G	7	Day 1	2	3	4	5	6

Days 1-4, teams see patients newly admitted to the hospitalist service and patients signed out to them from the previous block. Days 5-7, teams continue to care for their remaining patients and do not receive any new admissions. Day 7, the team turns over to an oncoming physician through verbal and electronic sign-out.

CUSTOMIZING EMR REGISTRY REPORTING: USING DISEASE MANAGEMENT REGISTRY DATA TO IMPROVE COMMON ACO DIABETES METRICS

John Voss; William Clay; Douglas Thaggard; Ira Helenius; Katharine Schlag. University of Virginia, Charlottesville, VA. (Control ID #2703575)

BACKGROUND: Electronic medical records (EMRs) offer promise to facilitate chronic illness care quality improvement (QI) but the data may be difficult to access in readily usable form for individual clinician QI efforts. To improve diabetes mellitus (DM) control in an internal medicine resident (IMR) clinic, we developed and disseminated customized outcomes reports using EMR disease management registry data for 61 2nd & 3rd year IMRs in an internal medicine residency clinic.

METHODS: Using a locally developed structured PDSA tool, IMRs self-designed HbA1c or HBP control or foot exam QI projects for implementation over 6 months (3rd year IMRs) or 12 months (2nd year IMRs). Each IMR received a monthly report for their own clinic DM patients displaying summary run charts of HbA1C control, HBP control, and foot exam completion as well as a list of individual patients and their respective clinical values. Residents were instructed to use customary available clinic resources to achieve their project goals. To create reports, DM registry data were downloaded biweekly and processed via an R script to generate reports displaying run charts of HbA1C control (mg/dL, proportion <8%, proportion >9%), HBP control (mm Hg systolic and diastolic, % < 140/90, % < 150/90), foot exam completion (% requiring) and lists of unique patient values and individual clinician versus clinic population means. After 12 months, DM outcomes were assessed using mixed model linear or logistic regression controlling for IMR, IMR project selection, and elapsed time.

RESULTS: IMRs selecting HbA1c control projects reduced their patient's HbA1c values from a mean of 8.33 (sd = .43) to 8.07 (sd = .31) compared to 7.82 (sd = .38) to 7.84 (sd = .57) for all other residents (b coefficient for trend = 0.005 mg/dL per week, overall $p < 0.001$.) No initial meaningful difference existed in the mean proportion of patients needing a foot exam between foot exam (FE) IMRs (0.67) and non-foot exam (NFE) IMRs (0.68). Although this proportion decreased significantly over time for all residents, the proportion of patients needing a foot exam at the end of the project for FE IMRs (0.38) was substantially lower relative to NFE IMRs (0.49), and the difference in this change over time was marginally significant, $p = 0$ .08. IMRs electing to improve HBP control were unable to demonstrate improvement over time. A contributing factor may be a significantly higher proportion of patients with a BP > 150/90 at baseline (0.35) for the HBP control residents relative to non-HBP control residents (0.25), $p = 0$ .02.

CONCLUSIONS: Structured tools and custom EMR reports can be developed using free and readily available software to assist clinicians to improve chronic illness care metrics of interest in the era of value-based purchasing. These tools alone may be insufficient to improve more challenging outcomes like hypertension control without additional resources beyond individual clinician effort.

DAILY MARIJUANA USERS IDENTIFIED IN PRIMARY CARE AND EMERGENCY SBIRT SETTINGS: CHARACTERISTICS AND SCREENING RESULTS

Sandeep Kapoor[1, 3]; Jeanne Morley[2, 3]; Kristen Pappacena[4]; Cherine Akkari[4]; Camila Bernal[4]; Charles Neighbors[4, 5]; Mark Auerbach[1, 3]; Nancy Kwon[1, 3]; Jonathan Morgenstern[2, 3]; Joseph Conigliaro[2, 3]; Megan O'Grady[4, 5]. [1]Northwell Health, New Hyde Park, NY; [2]Northwell Health, Great Neck, NY; [3]Hofstra Northwell School of Medicine, Hempstead, NY; [4]The National Center on Addiction and Substance Abuse, New York, NY; [5]Yale Univeristy, New Haven, CT. (Control ID #2705043)

BACKGROUND: Marijuana is the most widely used illicit substance in the US. Its rates of use as well as rates of daily users have steadily increased over the past several years. Within primary care settings, individuals who screen positive for drugs most commonly use marijuana. An estimated 25–50% of daily users will develop cannabis use disorder, making them a potentially important focus in healthcare settings.

METHODS: This study examined the characteristics and screening results of daily marijuana users identified in healthcare settings as part of an interdisciplinary Screening, Brief Intervention, and Referral to Treatment (SBIRT)

program. Patients presenting to a Primary Care Practice (PCP) or an Emergency Department (ED) were screened for risky substance use with the AUDIT and DAST-10 and, if positive, were further assessed on psychosocial factors, substance use severity, and demographics ($n = 1604$).

RESULTS: Of the patients who screened positive and participated in the assessment, 44% used marijuana at least one day in the past 30 and 15% used marijuana 25 or more days. These daily users ($n = 239$) had relatively low DAST-10 scores (M = 3.02) and 42% screened into the moderate or higher risk category on the DAST-10 (3+). Using multivariate logistic regression analyses, we identified significant predictors of 1) being a daily user (vs. non-daily) and 2) screening as moderate/high risk (vs. low) on the DAST-10. Among the marijuana users ($n = 739$), daily use was significantly predicted by being male, Latino, and an ED patient. Among daily users, significant predictors of screening moderate/high on the DAST-10 were: younger age, being a user of other drugs, and more frequent alcohol use.

CONCLUSIONS: Findings suggest that while SBIRT programs in healthcare settings are likely to encounter daily marijuana users, the majority may screen at low risk for health or psychosocial problems. Patients who screen into higher risk categories are likely to be younger and using other substances. Therefore, interventions for daily marijuana users may need to be tailored such that interventions for lower risk patients focus on reducing marijuana use, while interventions for higher risk patients be adapted for multiple substances and younger users.

Predictors of daily marijuana use (using ≥ 25 days/month) among all marijuana users ($n = 739$)

DAY OF THE WEEK AND PHYSICIAN DECISION MAKING Michael L. Barnett[4, 1]; Jeffrey A. Linder[2]; Hannah Neprash[3]; Anupam B. Jena[3]. [1]Brigham and Women, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA; [4]Harvard T. H. Chan School of Public Health, Boston, MA. (Control ID #2705781)

BACKGROUND: Physicians make dozens of clinical decisions daily, which may create the potential for "decision fatigue," whereby decision-making effort slumps over time. However, little evidence has explored this phenomenon across the week for multiple clinical decisions. We hypothesized that full-time, but not part-time, physicians would display increasing decision fatigue during the workweek for effort-intensive decisions such as avoiding narcotic prescribing and counseling on smoking cessation.

METHODS: We performed a cross-sectional analysis of the nationally representative National Ambulatory Medical Care Survey of office visits by adults from 2000–2012. The main analysis was restricted to "full-time" physicians who saw patients for ≥4 weekdays in the surveyed week. The key exposure was a visit occurring the beginning of the week (Monday/Tuesday) versus the end of the week (Thursday/Friday). We measured the rates of 3 clinical measures potentially vulnerable to decision fatigue: antibiotics for upper respiratory infections (URIs), narcotics for acute low back pain (LBP) and smoking cessation counseling for active smokers. We estimated the rates of each outcome in the beginning vs. the end of the week using logistic regression adjusting for patient and visit characteristics. We compared results for "full time" physicians with a sample of "part-time" physicians seeing patients for ≤3 weekdays in the week who should be less vulnerable to decision fatigue across the week. All estimation of results took account of the multistage probability design of the surveys.

RESULTS: From 2005–2012, the study sample contained 82,725 office visits eligible for at least one of the outcomes examined. Office visits in the beginning versus end of the week were similar across all patient characteristics measured (all $p > 0.20$). Comparing the end of the week to the beginning, after adjustment physicians were significantly more likely to prescribe narcotics for LBP (OR 1.18, 95% CI 1.05-1.32, $p = 0.006$). In contrast, physicians were less likely to perform smoking cessation counseling at the end of the week (OR 0.78, 95% CI 0.67-0.92, $p = 0.002$). Neither of these measures had statistically significant differences across the week among physicians working ≤3 days in the week ($p > 0.17$). There was no significant difference in antibiotic prescribing for URIs by day of the week for either group ($p = 0.83$).

CONCLUSIONS: We observe evidence consistent with decision fatigue among physicians over the workweek for 2 of 3 measures examined: increased rates of narcotic prescribing for LBP and decreased rates of time-intensive smoking cessation counseling. We observed these differences for full-time, but not part-time, physicians, arguing against patient selection in the end of the week driving these findings. These results suggest that strategies to improve the quality of care delivery should also address the potential contribution of decision fatigue for full-time clinicians.

DE-ESCALATION OF BROAD SPECTRUM ANTIBIOTICS FOLLOWING NEGATIVE CULTURES IN PNEUMONIA: RATES AND OUTCOMES Michael B. Rothberg[2]; Abhishek Deshpande[2]; Peter B. Imrey[2]; Pei-Chun Yu[2]; Peter K. Lindenauer[1]. [1]Baystate Medical Center, Springfield, MA; [2]Cleveland Clinic, Cleveland, OH. (Control ID #2707495)

BACKGROUND: For patients at risk for multidrug resistant organisms, including those with healthcare associated pneumonia and other severe pneumonias, recommended empirical therapy includes one agent with activity against methicillin-resistant *Staphylococcus aureus* (MRSA) and another with activity against *Pseudomonas*. Following negative blood and respiratory cultures, guidelines are unclear as to whether antibiotics should be de-escalated. We assessed the rate of de-escalation and associated outcomes among a large cohort of pneumonia patients.

METHODS: This retrospective cohort study assessed adult patients admitted with pneumonia from 2010–2015 to 168 US hospitals that participate in the Premier data base, providing administrative and microbacteriological data. We included only patients who had blood or respiratory cultures and were begun on vancomycin together with an antipseudomonal drug other than a quinolone by hospital day 1. Patients with any positive culture or who died or were discharged before hospital day 4 were excluded. De-escalation was defined as stopping vancomycin and the antipseudomonal drug by the 4th hospital day after cultures were obtained, but continuing another antibiotic. Patients were matched on propensity for de-escalation and compared on subsequent transfer to intensive care (ICU), inpatient mortality, length of stay (LOS), cost and 30-day readmission. The propensity model included patient demographics, co-morbidities and treatments received on day 4 after cultures. Certain treatments

(e.g. mechanical ventilation, vasopressors) served as proxies for severity of illness. We also compared patient outcomes across quartiles of de-escalation at the hospital level.

RESULTS: We identified 22,400 patients who met inclusion criteria. Following cultures, 4114 (18.4%) had both drugs stopped within 4 days. Hospital rates of de-escalation ranged from 0 to 67%. Median age was 72 years, 54% were male, and 39% were admitted to the ICU. Compared to patients without de-escalation, those de-escalated had similar demographics, but fewer co-morbidities and less severe disease at 1 and 4 days after culture. After propensity-matching, there were no significant differences in any of 83 measured variables. In the matched sample, patients who were de-escalated had 21% shorter LOS, 21% lower costs, and lower odds of subsequent transfer to ICU (OR 0.28; 95% CI 0.17 - 0.47)) and inpatient mortality (OR 0.71, 95% CI 0.60 - 0.83). There were no significant associations between hospital quartile of de-escalation and inpatient mortality, cost, LOS or readmission.

CONCLUSIONS: In a large US inpatient database, <20% of pneumonia patients had antibiotic coverage de-escalated following negative cultures, but there was wide variation by hospital. De-escalated patients and hospitals with high rates of de-escalation did not have worse outcomes. Following negative cultures, de-escalation appears safe in selected patients.

DECEDENTS OF OPIOID OVERDOSE: INJECTION-RELATED OVERDOSE DEATHS DIFFER FROM NON-INJECTION RELATED DEATHS. Emily E. Hurstak[1, 2]; Christopher Rowe[3]; Emily Behar[3]; Caitlin Turner[3]; Rachel Cabugao[3]; Phillip Coffin[3]. [1]UCSF, San Francisco, CA; [2]San Francisco Free Clinic, San Francisco, CA; [3]San Francisco Department of Public Health, San Francisco, CA. (Control ID #2703722)

BACKGROUND: Opioid overdose is the leading cause of unintentional injury death in the United States. Death certificates often exclude details on individual causative drugs and may underestimate heroin-related overdose deaths due to challenges in relying on toxicology alone. We propose a strategy to differentiate overdose deaths related to injection drug use (IDU) from non-injection related opioid overdoses in order to improve understanding of opioid overdose epidemiology and to guide prevention efforts.

METHODS: We reviewed all accidental drug overdose cases occurring in San Francisco County from 2006–2012 using information from the California Electronic Death Reporting System. We included cases if the death occurred in San Francisco County, was attributed to intoxication from heroin or opioid analgesics, and was not determined to be a suicide or homicide. We extracted descriptive data from decedent case narratives from the San Francisco Office of the Chief Medical Examiner (OCME), including death scene details and health history. We created a definition for injection-related overdose deaths based on review of toxicology, decedent history, and death scene details. We compared opioid analgesic overdose cases to cases involving injection drug use.

RESULTS: Between 2006–2012, we identified 255 deaths that involved IDU and 552 deaths attributed to opioids without evidence of IDU. Sixty-percent (59.6%) of IDU-related deaths could be designated as definite heroin-overdoses. Decedents of IDU-related overdose were younger (45.2 vs. 48.6 years, $p < 0.001$) and more likely to be male (76.9% vs. 67.2%, $p = 0.005$). Decedents of IDU-related overdose were more likely to be found in a single room occupancy hotel (38.4% vs. 25.3%, $p < 0.0001$) or a public space (14.5% vs. 8.2%, $p = 0.005$), compared to a private residence (40.0% vs. 56.9%, $p < 0.001$). IDU-related overdoses were more likely to be discovered by a passerby (8.6% vs. 4.5%, $p = 0.02$) or a program staff member (37.3 vs. 29.9, $p = 0.04$), rather than by a cohabitant (35.3% vs. 45.2%, $p = 0.02$). Fifty percent (49.8%) of IDU-related overdose decedents had a known prior history of IDU, compared to 10.3% of non-IDU overdose deaths. Benzodiazepines contributed to the cause of death in 8.2% of IDU-related overdoses compared to 24.3% of non-IDU deaths ($p < 0.001$).

CONCLUSIONS: We created a definition for IDU-related opioid overdose by incorporating historical details about the decedent and death scene. Using this definition, we identified differences in overdose cases that involved injection drug use compared to those that did not. Traditional opioid overdose prevention efforts target people with injection drug use. However, only a small proportion of decedents of opioid analgesic overdose have histories of injection drug use and our results suggest differences in the drug use patterns of injection-related and non-injection related overdoses. Increasing our understanding of opioid overdose will improve overdose education programs and outreach efforts to populations at risk.

DECREASING INAPPROPRIATE FRESH FROZEN PLASMA TRANSFUSIONS BY INCORPORATING EVIDENCE-BASED TRANSFUSION INDICATIONS IN THE ELECTRONIC ORDERING SYSTEM Salima Vasani[1]; Daniel Goldsmith[1]; Joseph J. Thomas[2]. [1]Capital Health Regional Medical Center, Trenton, NJ; [2]Accumen, Trenton, NJ. (Control ID #2700579)

BACKGROUND: Fresh Frozen Plasma (FFP) is a major source of coagulation factors, often indicated in bleeding due to coagulopathy. It is frequently transfused inappropriately, especially due to inadequate adherence to evidence-based transfusion guidelines. Like any other blood product, FFP transfusion is expensive and associated with serious transfusion reactions. Studies have shown that interventions that emphasize transfusion guidelines can significantly decrease inappropriate utilization of FFP. Aim of this project was to evaluate current FFP transfusion practices at our community hospital and improve utilization by reinforcing transfusion guidelines via the Computerized Physician Order Entry (CPOE) system in addition to training sessions.

METHODS: Stage I included review of FFP transfusion orders over a period of six months from April 2015 to September 2015. Evaluation included number of patients, units of FFP transfused and indications. Indications were deemed appropriate or inappropriate in accordance with institutional transfusion guidelines. Massive transfusion protocols and plasmapheresis were excluded. In October 2015, a new ordering system was incorporated in CPOE which required ordering physicians to choose from a menu of evidence-based indications for FFP transfusion. Training sessions were conducted for residents and attending physicians to reinforce transfusion guidelines. Stage II commenced after implementation of the new system, from November 2015 to May 2016. Records from the new ordering system were evaluated using the same parameters as Stage I.

RESULTS: In Stage I, total of 310 units of FFP were transfused to 101 patients. During Stage II, total of 251 units of FFP were transfused to 80 patients. A 19.04% decrease in number of units transfused and 20.8% decrease in number of recipients, after implementation of the new ordering system. Inappropriate transfusions that did not meet institutional guidelines decreased from 61 units to 25 units (from 19.6 to 9.9%). Most common indications for FFP transfusion were Gastrointestinal and Intracranial bleeding with coagulopathy. Most common inappropriate indications were bleeding without coagulopathy and elevated INR without evidence of bleeding.

CONCLUSIONS: Incorporation of transfusion indications in the electronic ordering system has the potential to decrease inappropriate Fresh Frozen Plasma transfusions by prompting ordering physicians to select evidence-based indications. This may in turn reduce cost and potentially reduce adverse transfusion reactions. This is a continuing project which will assess several other parameters in the upcoming months including number of transfusion reactions before and after implementation of the new system, reasons for inappropriate orders, and affect on pre and post-transfusion INR. Our goal is to continue education and awareness about evidence-based transfusions in order to improve quality of patient care.

DEPRESCRIBING IN POLYPHARMACY PATIENTS: A PILOT STUDY OF PRESCRIBING PRACTICES IN AN ACADEMIC PRIMARY CARE CLINIC. James L. Wofford[4]; Carolyn F. Pedley[2]; Claudia L. Campos[4]; Feben Girma[3]; Melanie Martin[1]. [1]Wake Forest, Greensboro, NC; [2]Wake Forest, Winston-Salem, NC; [3]Wake Forest Baptist Medical Center, Winston-Salem, NC; [4]Wake Forest University, Winston-Salem, NC. (Control ID #2704790)

BACKGROUND: "Deprescribing", the process of tapering, or discontinuing of drugs with the goal of minimizing polypharmacy and improving outcomes, has now become a national movement. Whether or not proponents of deprescribing can counter the forces that encourage polypharmacy (pharmaceutical marketing, attention to clinical inertia, consumer demand), a better understanding of prescribing practices in the faced of polypharmacy would be useful for ambulatory education. We explored the prescribing actions of clinicians in a single urban academic primary care clinic to determine the prevalence and types of medication changes and to compare prescribing patterns of senior clinicians with resident physicians

METHODS: We performed a one-week audit of all medication lists for return continuity visits at this community-based, academic primary care clinic, Each EMR medication list was examined for medication additions, changes, and/or deletions during that visit. Patients with polypharmacy were defined as having 10 or more medications documented on their medication list. We compared prescribing actions of senior clinicians with those of resident clinicians, and for patients with and without polypharmacy.

RESULTS: 186 patients who attended a return continuity visit during the designated audit week were seen by one of 34 clinicians (121 patients to 11 senior clinicians, 65 to 21 resident physicians) Patients had a mean age of 56.8 (+12.8) years, and 24% (46/187) were aged 65 or older. 18% (33/186) were seen by a clinician other than their designated PCP during the return clinic visit. The number of medications listed in the EMR averaged 10.0 + 5.4, but did not significantly differ by age group (mean 11.6 (+0.8) for >65 years versus 9.4 (+0.5) for <65). Fifty percent (93/186) of patients had 10 or more medications. Medication lists were only slightly longer for senior clinicians than for residents (10.3 (+0.5) versus 9.3 (+0.7)). Sixty percent (111/185) of return visits reflected at least one medication change to the list during the clinic visit. At least one medication was added (36.2% (67/185)), changed (34.5% (64/185)), or deprescribed (16.2% (30/185)), respectively, Resident clinicians more often added medications than did senior clinicians (45.3% (24/64) vs 32.3% (39/121), $p = .08$), but there was no significant difference between resident physicians and senior clinicians in medication dosing changes (39.1% (25/64) vs 34.7% (42/121)), or deprescribing of a medication (14.1% (9/64) versus 17.4% (21/121)). There was no signficant difference in deprescribing for polypharmacy patients (>9 medications) versus non-polypharmacy patients (12.9% (12/93) versus 19.6% (18/93) $p = .21$).

CONCLUSIONS: In this academic-affiliated primary care clinic, the rate of medication addition was more than twice the rate of deprescribing. Senior clinicians were no more likely than resident cliniciansto to deprescribe medications.The presence of polypharmacy was not associated with a higher rate of deprescribing.

DEPRESCRIBING: A SURVEY STUDY OF PATIENT ATTITUDES AND EXPERIENCES THAT PREDICT MEDICATION DISCONTINUATION Amy Linsky[1, 3]; Steven R. Simon[1]; Kelly Stolzmann[1]; Mark Meterko[2]. [1]VA Boston Healthcare System, Boston, MA; [2]VHA Office of Analytics and Business Intelligence (OABI), Bedford, MA; [3]Boston Medical Center, Boston, MA. (Control ID #2699348)

BACKGROUND: Polypharmacy is associated with adverse medication effects. One potential solution is deprescribing, which is the intentional, proactive, rational discontinuation of a medication that is no longer indicated or whose potential harms outweigh potential benefits. We sought to characterize patient characteristics, attitudes and healthcare experiences associated with prior medication discontinuation.

METHODS: We conducted a mail survey in August-October, 2015 using the Patient Perceptions of Discontinuation (PPoD) instrument. We randomly sampled 1600 Veterans receiving primary care at Veterans Affairs medical centers nationally with ≥ 5 concurrent prescribed medications, oversampling women. The primary outcome was response to: "Have you ever stopped taking a medicine (with or without your doctor's knowledge)?" We restricted analyses to those who answered "No" or "Yes." The primary predictors of interest were eight validated attitudinal scales, all on a 1–5 scale (Beliefs about Medications Questionnaire - Overuse, Trust-provider, CollaboRATE, Medication Concerns, Provider Knowledge, Interest in Stopping Medicines, Patient Involvement in Decision Making, and Unimportance of Medicines). Other predictors included demographics, health status, and health care experiences. Multivariable logistic modeling associated patient factors with prior medication discontinuation.

RESULTS: Respondents ($n = 803$; adjusted response rate, 52%), were predominantly male (85%); non-Hispanic white (68%), age ≥ 65 years (60%), with generally poor (16%) or fair (45%) health. Participant attitudes toward medications and their providers were generally favorable. Respondents disagreed that medicines were unimportant and overused, with mean scores of 2.39 and 2.91 on the Unimportance of Medicine and the BMQ-Overuse scales, respectively. Respondents held generally positive views of providers, with mean scores of 3.75 on Provider Knowledge and 3.56 on Trust-provider. Concurrently, patients were generally interested in stopping medicines (mean 3.42). Just over 1 in 3 patients (34%) reported having stopped a medicine in the past. In a multivariable logistic regression model ($p < 0.001$, pseudo-R^2 0.31, c-statistic 0.82), factors associated with experiencing discontinuation included being told to stop a medicine or asking to stop a medicine, greater interest in deprescribing and in shared-decision making, and higher education. Factors associated with decreased discontinuation were more prescriptions, higher trust in provider, and seeing a VA clinical pharmacist.

CONCLUSIONS: This study suggests that more highly educated patients who have interest in deprescribing and in shared-decision making may be more receptive to discontinuation discussions. Future research evaluating how to incorporate this survey and its findings into clinical workflow through the design of clinical decision-support interventions may help promote safe, appropriate, and rational use of medications.

DEPRESSION AMONG HEALTHCARE WORKERS—CONTRIBUTION OF PERSONALITY, WORK CHARACTERISTICS, COPING, AND BURNOUT Wei Duan-Porter[2]; Daniel Hatch[3]; Jane Pendergast[1]; Guy Potter[1]. [1]Duke University School of Medicine, Durham, NC; [2]Minneapolis VA Health Care System, Minneapolis, MN; [3]Duke University Center for the Study of Aging and Human Development, Durham, NC. (Control ID #2705619)

BACKGROUND: Relative contributions of individual and work factors to the development of depression remain unclear. There is also debate about the relationship between depression and burnout. We sought to examine the association of individual and work characteristics with depressive symptoms over 12 months. We evaluated the contribution of demographics, personality, work characteristics, and coping to differences in depression between individuals. Then, we investigated how burnout was associated with differences in depression both between and within individuals.

METHODS: Participants were recruited from nurses and associated healthcare staff employed by a large academic health system in the Southeastern U.S. Baseline assessments included demographics, health information, work characteristics, coping, burnout, and depression. Participants then completed monthly surveys on burnout and depression. Selected participants had full baseline data, and a minimum of 3 completed follow-up assessments ($n = 281$, 89% of these had data for at least 9 of 12 months). We used random effects hierarchical linear modeling to examine differences in depression between and within individuals over time. We added categories of predictors in a step-wise fashion to successive models, beginning with only demographics, then personality, work characteristics, coping, and finally burnout.

RESULTS: Most participants were female (92%), white (82%), and nurses (90%). Demographic factors were not significantly associated with depression, but personality, work characteristics, and coping all had significant fixed effects. Personality accounted for 36% of variation between individuals, while work characteristics and coping explained an additional 5 and 8%, respectively. Burnout was significantly associated with depression, but the 2 dimensions—exhaustion and disengagement—had contrasting effects. Whereas baseline exhaustion contributed to differences in depression between individuals (coefficient 2.44, p <0.001), time-varying follow-up exhaustion scores were not associated with further changes in depression within individuals over time (coefficient 0.37, $p = 0.09$). Time-varying disengagement scores were associated with changes in depression within individuals (coefficient 0.52, $p = 0.01$), but baseline disengagement was not significantly associated with differences between individuals (coefficient −0.51, $p = 0.32$).

CONCLUSIONS: Personality, work characteristics, coping, and burnout were associated with depression among healthcare workers. Higher exhaustion was associated with more depressive symptoms when comparing individuals, and higher disengagement over time was associated with increased depressive symptoms within individuals longitudinally. Our findings suggest that interventions to promote wellbeing for healthcare workers should address both work and individual factors. Careful characterization of type and severity of existing burnout may impact the expected benefits and relevant timeframe for evaluating future interventions.

DEPRESSION AND BURNOUT AMONG MEDICAL STUDENTS DURING 4 yearS OF MEDICAL SCHOOL: A SINGLE CENTER STUDY Padmini Ranasinghe[1]; Brandyn D. Lau[2]. [1]Johns Hopkins School of Medicine, Baltimore, MD; [2]The Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #2703533)

BACKGROUND: Previous studies reported that medical students experience symptoms depression and burnout at a higher rate compared to the general population. Medical students also have a higher rates of suicidal ideation. Burnout rate is up to 50% among medical students: 53% of medical students reported experiencing high emotional exhaustion and/or depersonalization. Recent systematic review, estimated that prevalence of depression or depressive symptoms among medical students was 27.2 and that of suicidal ideation was 11.1%. Despite the deleterious consequences of these symptoms, only a small minority (up to 15.7%) of medical students ultimately seek treatment.

METHODS: In this longitudinal single center survey study, health and wellness of medical students across 4 years of medical school were evaluated using a combination of validated and adapted assessment tools. Standardized surveys were administered annually between 2009 and 2014. This study was approved by the Institutional Review Board and consent was obtained at the time each first survey was administered. Students who matriculated in 2009, 2010, or 2011 were included in this report. Each participant completed 5 surveys: one at the beginning of each year of medical school and an exit survey post-graduation. PHQ 9 was used to screen for depression and burnout was assessed based on a single question of "Can you classify your current level of burnout".

RESULTS: Three hundred sixty (360) students matriculated to the undergraduate medical education program between 2009 and 2011. 284 (78.9%) were continuously enrolled during pre-clinical and clinical years, and were eligible for inclusion. In this study 128 medical students (45.1%) completed the health and wellness survey each year. During the first year of medical school, 4.7% of respondents reported symptoms of at least minor depression. During second year 6.6% of respondents reported symptoms of at least minor depression, 24.9% in third year, and 32.7% in fourth year. The proportion of respondents who self-reported at least some symptoms of burnout was low during first year (4.2%), increased in second year (18.8%), and remained high in third year (17.7%) and very high in fourth year (31.3%).

CONCLUSIONS: Medical students' psychological health including depression and burnout are high during medical school: symptoms of at least minor depression and self-reported burnout increased each year in the school. This suggest we as generalist involved in undergraduate medical education should be aware of these subtle changes which have life long implications. We also should be mindful and available for students to become effective and compassionate student centered teaches

DEPRESSIVE SYMPTOMS PREDICT SHORT TERM MORTALITY IN THOSE WHO REPORT EXCELLENT OR VERY GOOD STATE OF HEALTH Nathalie Moise[1]; Yulia Khodneva[3]; Joshua S. Richman[3]; Karina Davison[1]; Ian M. Kronish[1]; Jonathan Shaeffer[4]; Monika M. Safford[2]. [1]Columbia University Medical Center, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]University of Alabama, Birmingham, AL; [4]University of Colorodo, Denver, CO. (Control ID #2704319)

BACKGROUND: The relationship between elevated depressive symptoms, which often relapse and remit, and mortality has been poorly elucidated given the use of single measurements of depressive symptoms, the unclear role of health status and incomplete covariate adjustment. We aimed to determine whether time varying depressive symptoms predict all-cause and cause-specific mortality in those with self-reported excellent or very good health.

METHODS: The Reasons for Geographic and Racial Differences in Stroke (REGARDS) is a national, population-based longitudinal study conducted from 2003–2007 in general continental U.S. communities. 29,491 black and

white U.S. adults aged 45 years and older randomly sampled within race-sex-geographic strata with available baseline depressive symptoms. Elevated depressive symptoms were defined as CES-D-4 ≥ 4 measured at baseline and on average 5 and 7 years later. Cox proportional hazard regression models were constructed to assess cancer, non-cardiovascular (CVD), CVD and all-cause mortality. All analyses were stratified by baseline self-reported health status.
RESULTS: Overall, 11.0% had elevated depressive symptoms; the average age was 64.9 years, 55% were female, 41% black, 54% had poor, fair or good health, and 16% died in the follow up period. Time-varying depressive symptoms were significantly associated with nonCVD (aHR = 1.29, 95% CI 1.16–1.44) and all-cause (aHR = 1.24, 95%CI 1.14–1.39), but not cancer (aHR = 1.15, 95%CI 0.96–1.38) or CVD (aHR = 1.13, 95%CI 0.98–1.32) death adjusting for age, gender, race, education, income, insurance status, region, diabetes, blood pressure, body mass index, kidney disease, hyperlipidemia, CVD, cognitive impairment, lung disease, aspirin, antidepressant, statin or antihypertensive use, smoking, physical inactivity, alcohol, medication non-adherence, C-reactive protein, physical health, and perceived stress. Depressive symptoms were particularly related to all-cause (aHR = 1.48, 95%CI 1.27–1.78), CVD (aHR = 1.37, 95%CI 0.99–1.91), nonCVD (aHR = 1.54, 95%CI 1.24–1.92) and cancer (aHR = 1.36 95% 0.97–1.91) death in those who reported excellent or very good health. Baseline analyses yielded similar results.
CONCLUSIONS: Depressive symptoms confer both a short-term risk for all-cause mortality, CVD, non-CVD death and cancer death, particularly in those with excellent or very good health. These findings may have implications for timely treatment, regardless of health status.

DERIVATION OF A CLINICAL PREDICTION MODEL TO PREDICT UNCHANGED INPATIENT ECHOCARDIOGRAMS

Craig G. Gunderson[1, 3]; Elizabeth S. Gromisch[2, 3]; John J. Chang[1, 3]; Brian Malm[2, 3]. [1]Yale Medical School, West Haven, CT; [2]Yale University School of Medicine, New Haven, CT; [3]VA Connecticut Healthcare System, West Haven, CT. (Control ID #2705132)

BACKGROUND: Transthoracic echocardiography (TTE) is one of the most frequently ordered tests in healthcare. Repeat TTE defined as TTE done within 1 year of a prior TTE represent 24–42% of all studies. In the present study we derive a clinical prediction model to predict unchanged repeat TTE with the goal of defining a subset of studies that are potentially unnecessary.
METHODS: Single-center retrospective cohort study of all hospitalized patients who had a repeat TTE between October 1, 2013 and September 30, 2014. Patients with repeat TTEs within the past year were grouped into those with major changes on repeat TTE and those with mild or no change. Logistic regression was used to define variables that were independent predictors of major changes and a score was constructed based on the regression coefficients.
RESULTS: During the study period 601 patients had at least one inpatient TTE. Of these 601 patients, 211 (35%) had a prior TTE within the past year. Of those 211 patients, 67 (32%) had no change, 66 (31%) had minor changes and 78 (37%) had major changes. On logistic regression, 5 variables were independent predictors of major new TTE changes, including history of intervening acute myocardial infarction, intervening cardiothoracic surgery, major new EKG changes, prior valve disease, and prior chronic kidney disease. Using the β-coefficient for each of these variables we defined a clinical prediction model which we named the CAVES score. The prevalence of major TTE change for the full cohort was 35%. For the group with a CAVES score of −1 that probability was only 5.6%, for the group with a score of 0, the probability was 17.7%, and for the group with a score ≥1 the probability was 55.3%.The bootstrap corrected c-statistic for the model was 0.78 (95% CI, 0.72–0.85) indicating good discrimination.
CONCLUSIONS: We report on the derivation of a 5 variable clinical prediction model called the CAVES score to predict major changes in repeat TTEs. Overall the CAVES score had good discrimination and calibration. If further validated it may be useful to predict repeat TTEs that are unlikely to have major changes.

Table 4. Results from multivariate analysis of risk factors for changed TTE and the corresponding score assigned for each significant variable.

Covariate	Odds Ratio (95% CI)	P value	B coefficient	Score
Intervening AMI	9.3 (3.3-25.6)	.000	2.2	2
Intervening CT Surgery	3.8 (1.6-8.8)	.002	1.3	1
Valvular heart disease	3.4 (1.7-7.1)	.001	1.2	1
Major new ECG change	2.7 (1.3-5.4)	.006	1.0	1
CKD	0.4 (0.2-0.9)	.032	-0.9	-1

Abbreviations: TTE, transthoracic echocardiogram; AMI, acute myocardial infarction; CT, cardiothoracic; ECG, electrocardiogram; CKD, chronic kidney disease.

Table 5. CAVES Score Frequencies and Associated Rates of Major TTE Changes.

CAVES* Score	Number (%) N=211	Major TTE Change (%) N=78
-1†	18 (8.5)	1 (5.6)
0	79 (37.4)	14 (17.7)
1	60 (28.4)	24 (40.0)
2	33 (15.6)	20 (60.6)
3	12 (5.7)	11 (91.7)
4	8 (3.8)	7 (87.5)
5	1 (0.5)	1 (100)
Simplified CAVES Score		
-1	18 (8.5)	1 (5.6)
0	79 (37.4)	14 (17.7)
≥1	114 (54.0)	63 (55.3)

Abbreviations: TTE, transthoracic echocardiogram.

*The letters in the acronym CAVES stand for: C, Chronic kidney disease (CKD); A, Acute myocardial infarction since the prior TTE; V, Valvular heart disease on the prior TTE; E, ECG with major new changes since prior study; S, Surgery on the heart since prior TTE.
†Patients with chronic kidney disease subtract one point on the CAVES score.

DETERMINING THE APPROPRIATENESS OF MEDICATION ALERTS OVERRIDDEN AS INACCURATE WARNINGS

Christine Rehr[1, 2]; Adrian Wong[1, 4]; Diane L. Seger[2]; David W. Bates[1, 3]. [1]Brigham and Women's Hospital, Boston, MA; [2]Partners Healthcare, Wellesley, MA; [3]Harvard Medical School, Boston, MA; [4]MCPHS University, Boston, MA. (Control ID #2704776)

BACKGROUND: Medication clinical decision support has shown progress in reducing adverse drug events and costs, and improving patient outcomes (1). However, research has also shown that many of these warnings are frequently overridden, and often inappropriately, likely because of alert fatigue and poor alert design (2). This study was performed to evaluate the alerts providers have overridden with the reason "inaccurate warning" in order to learn more about the alerts perceived to be erroneous.
METHODS: The data for this study were overrides occurring in the intensive care units (ICU) at a major academic medical center between June 15 and November 15, 2016. The overrides were analyzed by two independent reviewers using predetermined criteria for appropriateness. The three alert types analyzed were chosen based on clinical significance and frequency for ICU patients: drug-drug interactions (DDI), drug-allergy interactions (DAI), and dose alerts.
RESULTS: There were 26501 overridden alerts in the ICUs, 268 of which were documented with the reason "inaccurate warning" (1.0%). Of the 15 DDIs, all were inappropriate overrides, and all but one were for QT prolongation. Eight of the 48 DAIs (16.7%) were inappropriate overrides, as the patient had a true allergy and had not tolerated the medication before. Two of the 13 renal dose overrides (15.4%) were found to be inappropriate, whereas the 11 appropriate overrides were for correct renal replacement therapy doses or for patients without

renal insufficiency. Two of 4 weight-based dose overrides (50%) were inappropriate, as the provider should have used the patient's weight to calculate the correct dose. Five of 13 overdose overrides (38.5%) were inappropriate, whereas some of the appropriately overridden alerts had incorrect overdose thresholds (23.1%) or were alerts on correct electrolyte protocols (23.1%), meaning 46.2% of these overdose alerts should never be fired.

CONCLUSIONS: This study shows that DDIs are not appropriately overridden with the "inaccurate warning" reason, whereas some dosing and DAI alerts are. The appropriate DAI overrides indicate that there should be a better mechanism for showing only accurate alerts, such as removing documented allergies based on prior tolerance or incorrect ingredient match. The appropriate dose overrides indicate that the alerts need to better identify patient conditions, dosing mechanisms, and protocols, in addition to altering thresholds and cancelling certain electrolyte alerts. DETERMINING THE OPTIMAL SCREENING INTERVAL FOR TYPE 2 DIABETES MELLITUS USING A RISK PREDICTION MODEL Andrei Brateanu[1]; Thomas Barwacz[2]; Lei Kou[1]; Sihe Wang[1]; Anita D. Misra-Hebert[1]; Bo Hu[1]; Abhishek Deshpande[1]; Nana Kobaivanova[1]; Michael B. Rothberg[1]. [1]Cleveland Clinic, Cleveland, OH; [2]University Hospital, Cleveland, OH. (Control ID #2703815)

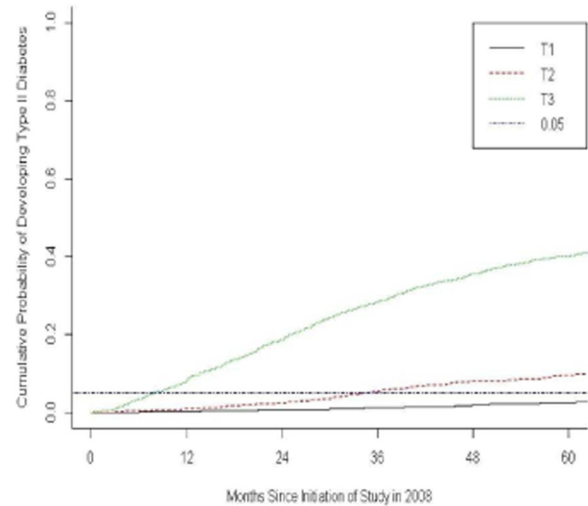
BACKGROUND: Progression to diabetes mellitus (DM) is variable and the screening time interval not well defined. The American Diabetes Association and US Preventive Services Task Force suggest screening every 3 years, but evidence is limited. The objective of the study was to develop a model to predict the probability of developing DM and suggest a risk-based screening interval.

METHODS: We included non-diabetic adult patients screened for DM in the Cleveland Clinic Health System if they had at least two measurements of glycated hemoglobin (HbA1c), an initial one less than 6.5% in 2008, and another between January, 2009 and December, 2013. Cox proportional hazards models were created. The primary outcome was DM defined as HbA1C greater than 6.4%. The optimal rescreening interval was chosen based on the predicted probability of developing DM.

RESULTS: Of 5084 participants, 100 (4.4%) of the 2281 patients with normal HbA1c and 772 (27.5%) of the 2803 patients with prediabetes developed DM within 5 years. Factors associated with developing DM included HbA1c (HR per 0.1 units increase 1.20; 95%CI, 1.13–1.27), family history (HR 1.31; 95%CI, 1.13–1.51), smoking (HR 1.18; 95%CI, 1.03–1.35), triglycerides (HR 1.01; 95%CI, 1.00–1.03), alanine aminotransferase (HR 1.07; 95%CI, 1.03–1.11), body mass index (HR 1.06; 95%CI, 1.01–1.11), age (HR 0.95; 95%CI, 0.91–0.99) and high-density lipoproteins (HR 0.93; 95% CI, 0.90–0.95). Five percent of patients in the highest risk tertile developed DM within 8 months, while it took 35 months for 5% of the middle tertile to develop DM. Only 2.4% percent of the patients in the lowest tertile developed DM within 5 years (figure 1).

CONCLUSIONS: A risk prediction model employing commonly available data can be used to guide screening intervals. Based on equal intervals for equal risk, patients in the highest risk category could be rescreened after 8 months, while those in the intermediate and lowest risk categories could be rescreened after 3 and 5 years respectively.



DEVELOPING A PEER SUPPORT PROGRAM TO TARGET HIGH RISK PRIMARY CARE PATIENTS Karin M. Nelson[1, 2]; Jennifer L. Williams[1]; Marie C. Lutton[1]; Julie Silverman[1, 2]; Kamala B Jain[1, 2]; Tiffanie Fennell[1, 2]; Matthew R. Augustine[1, 2]; Kristen E. Gray[1, 2]; Walter Kopf[1, 2]; Christopher Vanderwarker[1, 2]. [1]VA Puget Sound Health Care System, Seattle, WA; [2]University of Washington, Seattle, WA. (Control ID #2701160)

BACKGROUND: Cardiovascular disease (CVD) is the leading cause of mortality in the US and among Veterans, and CVD risk factors remain sub-optimally controlled. The objective of the current study is to describe a novel strategy using patient-level geographic information systems (GIS) data to identify areas of highest CVD risk and recruit Veterans with well-controlled hypertension living in these areas to become peer health coaches as part of the "Veteran peer Coaches Optimizing and Advancing Cardiac Health (Vet-Coach)" study.

METHODS: We spatially joined Veteran addresses of patients enrolled in VA Puget Sound primary care or women's clinic from VHA administrative data to the 2010 Census Tract Boundary file to obtain the census tract code. Using these data, we generated spatial distributions of hypertension prevalence by census tract within a 5-mile and 10-mile radius of our clinic. We then selected 60 census tracts (from total of $n = 398$ in King County, WA) with the highest rates of hypertension: 38–44% of patients with a diagnosis of hypertension ($n = 24$ census tracts), 45–50% ($n = 25$ census tracts), and 51–65% ($n = 11$ census tracts). To identify potential peer health coaches, we provided each primary care clinic team ($n = 41$ MDs, $n = 35$ nurses) with a list of their patients from the target areas who had a diagnosis of hypertension ($n = 964$ patients) and at least one clinic visit during the prior year. During a clinic staff meeting, we asked primary care providers and team nurses to review their list and nominate Veterans they felt might be a good peer health coach, based on the following criteria: successful use of VA services; successful management of hypertension or other chronic conditions; and experience utilizing clinic and community resources. We used data from the 2006–2010 U.S. Census Bureau American Communities Survey to characterize census tract demographics.

RESULTS: Using this method, primary care clinic teams nominated $n = 73$ Veterans living in the 60 targeted census tracts. We then sent the nominated patients an introductory letter prior to conducting follow-up calls to assess interest in becoming a Vet-Coach, which provides reimbursement based on an hourly rate. We interviewed $n = 12$ Veterans for the position and selected 5 peer coaches. Compared to other census tracts in King County, the targeted census tracts had higher rates of poverty [% of residents under 200% of federal

poverty, 32% vs. 22%, $p < 0.001$] and a higher percentage of non-white residents [49.4% vs. 33.8%, $p < 0.001$].

CONCLUSIONS: Using this area-based method, we successfully recruited patients from low-income neighborhoods with high rates of hypertension. Results of the Vet-Coach recruitment will be discussed along with lessons learned, with a specific focus on developing a peer support program targeted to high risk patients that is integrated into primary care clinic work flow.

DEVELOPING A PREDICTIVE MODEL FOR MEDICINE READMISSIONS

Michael R. Trautwein[1]; Stacy Schwartz[2]; Karen M. Freund[3]; Saul N. Weingart[1]; Geneve Allison[1]; Phanicharan Sistla[1]; Lori Lyn Price[1]; Jana C. Leary[1]; Alexander Pavoll[1]. [1]Tufts Medical Center, Boston, MA; [2]Tufts Medical center, Boston, MA; [3]Tufts University School of Medicine, Boston, MA. (Control ID #2706110)

BACKGROUND: 30-day preventable hospital readmissions are a measure of resource utilization and an indicator of health care quality. We compared attributes of patients who were readmitted within 30 days to those who were not in order to develop a predictive model that could inform interventions to prevent unnecessary readmissions.

METHODS: We abstracted electronic medical and billing records for patients admitted to the medicine service at Tufts Medical Center from 9/5/13 - 8/31/16. We included potential predictors of readmission included demographic characteristics, primary language, discharge unit, hospital service, number of medications, zip code (to determine distance to Tufts and as a proxy for income), discharge disposition, physical therapy evaluation, any ICU stay, number of admissions, observations and emergency department encounters in the previous 6 months, primary insurance, warfarin use, alcohol and substance abuse, diabetes, opioid use, Charlson comorbidity score, and day of discharge (weekday vs. weekend). Variables associated with readmission in bivariate analyses ($p < 0.05$) were used to create a multivariate logistic regression model with backward elimination based on a derivation cohort of discharges from 1/1/14 - 11/30/15. We validated the model using a validation cohort that included discharges 1/1/16 - 8/31/16, using the C-statistic to evaluate the models. We used beta coefficients from the derivation model to develop a scoring system to predict risk of readmission. We compared our model with the LACE predictive model.

RESULTS: The development dataset consisted 7971 admissions; mean age of the patients (SD) was 61 (18), 55% were men, 70% were white, 10% black, 13% Asian and 6% Hispanic. There were 3214 admissions in the validation cohort. In bivariate analysis, factors associated with readmission were Charlson comorbidity score, ICU use, number of medications, admissions, observations and emergency department encounters in the previous 6 months, discharge disposition, opioid use, diabetes, insurance, discharge service, and physical therapy consultation. In the multivariate analysis, 6 variables associated with unplanned readmissions included Charlson comorbidity score, any ICU stay, number of medications, prior admission/observation encounters within 6 months, discharge disposition, and hospital service. Discharges to skilled nursing and long term care facilities had the greatest odds of readmission. The C-statistic for the predictive model from the development dataset was 0.67 and 0.66 for the validation dataset, both higher than $c = 0.63$ using the LACE model.

CONCLUSIONS: We developed a model with moderate ability to predict unplanned readmissions. In our setting, variables predicting readmission were related to medical complexity, and pointed to the importance of ensuring vulnerable patients' safe transitions to skilled nursing and longterm care facilities.

DEVELOPMENT AND PRELIMINARY FINDINGS OF DIABETESSISTERSVOICES - AN ONLINE COMMUNITY TO ENGAGE WOMEN WITH DIABETES ABOUT RESEARCH AND HEALTHCARE PRIORITIES

Peijin Han[1, 5]; Wanda Nicholson[2]; Anna Norton[3]; Richard Singerman[4]; Aditi Sundaresan[2]; Wendy L. Bennett[1]. [1]Johns Hopkins School of Medicine, Baltimore, MD; [2]University of North Carolina, Chapel Hill, NC; [3]DiabetesSisters, Bolingbrook, IL; [4]TrustNetMD, San Diego, CA; [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. (Control ID #2705252)

BACKGROUND: Women with or at high risk of diabetes are an important clinical group with unique health concerns across the life course- from pre-conception health and pregnancy to middle age and the menopause transition. Engaging women with diabetes is critical to efforts to inform a patient-centered research agenda to improve health outcomes. Our objective was create an online community for women with any type of diabetes (type 1, type 2, gestational or pre-diabetes) to engage about research priorities to address their health care needs and improve diabetes management, use in-person and web-based strategies for recruitment to the on-line site and measure trends in engagement and re-engagement of site participants.

METHODS: In phase 1, we partnered with DiabetesSisters, a national advocacy organization for women with diabetes, and a diverse stakeholder advisory board to develop the online community, termed DiabetesSistersVoices (aka DSVoices). In phase 2, we employed several recruitment strategies, including social media (e.g. email, Twitter, Facebook), web-based newsletters and printed media to engage women with diabetes. Eligibility included women living with or at risk for diabetes who were age 18 years and older and currently living in the U.S. Participants completed an on-line consent process and survey questions about socio-demographic characteristics, self-reported health status, technology use and social support. Once enrolled, trends in participants' activities, including posting questions, sharing experiences of living with diabetes and searching for educational resources are monitored and tracked by an on-line moderator.

RESULTS: To date, 94 women have enrolled (83% type 1, 86% Caucasian, median age = 46), from 31 states in the U.S. Most learned about DSVoices from Facebook, Twitter, friends and relatives. More than 90% of participants regularly use social networking sites (mainly Facebook and Twitter) and 80% of them use every day. The most popular discussion topics are: "type 1 and lada (latent autoimmune diabetes in adults)", "type 2", "popular websites", "healthy living" and "physical activity and exercise". Priority topics for research and healthcare have focused on (1) medication management (2) eating disorders (3) meal planning (4) mental health (5) exercise.

CONCLUSIONS: This formative data describes the refinement and formal testing of an on-line community for women with diabetes to set research priorities. Additional engagement strategies to enroll minority or low-income women and those in rural areas are underway. Our efforts can contribute to the development of novel engagement methods and the identification of patient-centered priorities for research and care for women with or at risk for diabetes.

DEVELOPMENT AND VALIDATION OF AN ELECTRONIC HEALTH RECORD MODEL FOR PREDICTING 30-DAY READMISSIONS IN ACUTE MYOCARDIAL INFARCTION: THE AMI READMITS SCORE

Oanh K. Nguyen[1, 1]; Anil N. Makam[1, 1]; Christopher Clark[2]; Song Zhang[1]; Sandeep R. Das[1]; Ethan Halm[1, 1]. [1]UT Southwestern Medical Center, Dallas, TX; [2]Parkland Health & Hospital System, Dallas, TX. (Control ID #2694487)

BACKGROUND: Readmissions after hospitalization for acute myocardial infarction (AMI) are common, but the few available risk prediction models have poor predictive ability and are not readily usable in real-time. We sought to develop and validate an AMI readmission risk prediction model from electronic health record (EHR) data available on the first day of hospitalization, and to compare model performance to the Centers for Medicare and Medicaid Services (CMS) AMI model and a validated multi-condition EHR model.

METHODS: EHR data from AMI readmissions from 6 diverse hospitals in north Texas from 2009–2010 were used to derive a model predicting all-cause non-elective 30-day readmissions to any of 75 hospitals in the region, which was then validated using five-fold cross-validation.

RESULTS: Of 826 consecutive index AMI admissions, 13% were followed by a 30-day readmission. The AMI READMITS score included seven predictors, all ascertainable within the first 24 hours of hospitalization (Table 1A). The AMI READMITS score was strongly associated with 30-day readmission in our cross-validation cohort: ≤13 points = extremely low risk (bottom quintile, mean predicted risk 3%); 14–15 points = low risk (4th quintile, predicted risk 7%); 16–17 points = moderate risk (3rd quintile, predicted risk 11%); 18–19 points = high risk (2nd quintile, predicted risk 16%); and ≥20 points = extremely high risk (top quintile, predicted risk 35%). The READMITS score had good discrimination with comparable performance to the CMS model in our cohort; it had improved discrimination, reclassification, and calibration compared to a multi-condition EHR model (Table 1B).

CONCLUSIONS: The AMI READMITS score accurately stratifies patients hospitalized with AMI into groups at varying risk of 30-day readmission. Unlike claims-based models which require data not available until after discharge, READMITS is parsimonious, easy to implement, and leverages actionable real-time data available from the EHR within the first 24 hours of hospitalization to enable early prospective identification of high-risk AMI patients for targeted readmissions reduction interventions.

Table 1A. AMI READMITS Score

Predictors within First 24 Hours of Admit	Adjusted OR (95% CI)	Points
Renal function (Cr>2 mg/dL)	2.56 (2.52-6.08)	6
Elevated BNP (BNP≥50, NT-proBNP≥125 pg/mL)	6.36 (1.65-24.47)	8
Age (per decade greater than 18 years)	1.26 (0.98-1.61)	1 per decade
Diabetes history	2.41 (1.37-4.24)	4
Not Male (i.e. female sex)	1.53 (0.92-2.57)	2
No Intervention with Timely PCI	1.31 (1.02-1.69)	1
Systolic blood pressure < 100 mmHg	2.18 (1.68-2.82)	3

Table 1B. Model Performance and Comparison of AMI READMITS Score Versus Other Models

Model	C-statistic	p-value*	NRI† (95% CI)	Average Predicted Risk % Lowest Decile	Average Predicted Risk % Highest Decile
READMITS score for AMI	0.75 (0.70-0.80)‡	[Ref]	[Reference]	2.1	41.1
EHR multi-condition model	0.70 (0.65-0.75)	0.04	-0.19 (-0.30 to -0.18)	6.6	25.7
CMS model for AMI	0.74 (0.69-0.79)	0.57	-0.01 (-0.11-0.09)	7.2	24.3

Abbreviations: AMI, acute myocardial infarction; CI, confidence interval; EHR, electronic health record; NRI, net reclassification index

* p-values shown are for each model compared to the respective reference model

† The categorical NRI compares reclassification between the highest top risk quintile and the lowest four risk quintiles

‡ Optimism-corrected C-statistic 0.73 (95% CI 0.71-0.74) for READMITS score

DEVELOPMENT OF AN ELECTRONIC SCREENING DEVICE TO IDENTIFY UNDIAGNOSED MODERATE-TO-SEVERE CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD) IN PRIMARY CARE SETTINGS Julien J. Dedier[1]; George O'Connor[2]; Timothy Heeren[1]. [1]Boston University, Boston, MA; [2]Boston Medical Center, Boston, MA. (Control ID #2705006)

BACKGROUND: COPD is a leading cause of morbidity and mortality, and is underdiagnosed in primary care settings. Though benefits of COPD screening in asymptomatic adults with mild disease are unproven, COPD therapies reduce exacerbations and improve health status in symptomatic individuals with more severe COPD. Feasible screening approaches to identify undiagnosed cases of more severe COPD in primary care settings may reduce the clinical burden of COPD. We created a screening tool to identify patients with moderate-to-severe (mod-sev) COPD and assessed its performance in a diverse sample of adult primary care patients at a large safety-net hospital. The tool consisted of a tablet-based questionnaire linked to an electronic peak expiratory flow (PEF) meter.

METHODS: We used data from the Framingham Heart Study (FHS) 8th Offspring Exam to derive 2 multiple logistic regression models for predicting mod-sev COPD in men and women. Candidate predictor variables included demographics, smoking status, selected symptoms from the ATS-DLD-78 Respiratory Disease Survey, and PEF. We used backward selection to identify variables that independently predicted mod-sev COPD at $p < 0.2$. We then loaded questions to capture final predictors onto a tablet computer which also contained a brief video on how to use a PEF meter. The system was refined using input from user-consultants. Its performance was then validated in 188 clinic patients at Boston Medical Center (BMC) who had a clinical diagnosis of COPD or no known lung disease. Next, we prospectively assessed the system in a 'testing' cohort of primary care patients without known COPD. The system classified predicted risk of mod-sev COPD as low (0–4%), medium (5–19%) or high (≥20%). In each study cohort COPD status was established by spirometry, and we calculated the system's ability to discriminate between mod-sev and no or mild COPD (c-statistic). In the testing cohort we determined system sensitivity and specificity at 2 cut points.

RESULTS: The final model for men and for women both had 8 variables: 3 demographic, PEF, smoking status, and 3 relating to respiratory history. The table describes the 3 study cohorts and shows the system's c-statistic in each. In the 'testing' cohort, system sensitivity and specificity were 0.94 and 0.36 when a positive test was defined as a predicted risk of ≥ 5%, and 0.81 and 0.55 when set at ≥ 20%.

CONCLUSIONS: Our system to identify undiagnosed mod-sev COPD showed good discrimination, sensitivity and specificity in a diverse group of primary care patients, particularly at a positivity criterion of ≥ 20%. Screen-positive patients would then require spirometry for confirmation.

	Cohort Derivation (FHS) $N = 2{,}574$	Validation (BMC) $N = 190$	Testing (BMC) $N = 399$
Age (yrs), mean [SD]	66 [8.8]	59 [7.2]	56 [9.4]

Women	0.91	0.83	0.67

DEVELOPMENT OF AN INTERNAL MEDICINE "BOOT CAMP" FOR MEDICAL STUDENTS David C. Chu[1]; Rachel S. Casas[1]; Laura D. Hallett[3]; Frank Schembri[4]; Ryan Chippendale[2]. [1]Boston Medical Center, Boston, MA; [2]boston university, Boston, MA; [3]University of Massachusetts, Worcester, MA; [4]Boston Medical Center, Bostn, MA. (Control ID #2689273)

BACKGROUND: Internal medicine "boot camps" are an emerging strategy to ease the challenging transition from fourth year of medical school to internship, but prioritized topics vary by institution. We aimed to determine the most important content for a boot camp curriculum though a needs assessment at the Boston University School of Medicine (BUSM).

METHODS: Fourth year medical students applying to internal medicine residency programs ($N = 47$) and first year internal medicine interns ($N = 40$) at BUSM were anonymously, electronically surveyed about managing 27 clinical scenarios, skills, and procedures. We chose these topics based upon existing medicine boot camp curricula and internal discussion. Responses were ranked on 4 point scales of importance or interest. Participants were also asked open-ended questions about their concerns for intern year and the most important topics for inclusion in a boot camp elective.

RESULTS: Survey response rates were 51% ($N = 24$) for medical students and 58% ($N = 23$) for interns. Of clinical scenarios, medical students prioritized chest pain ($N = 21$, 88%), shock ($N = 21$, 88%), and severe electrolyte disturbances ($N = 18$, 75%) as 'very important' for inclusion. Current interns ranked chest pain ($N = 19$, 83%), acute hypoxemia ($N = 15$, 65%) and altered mental status ($N = 15$, 65%) as 'very important' for inclusion. Both medical students and interns rated time management and ECG interpretation among the most important clinical skills. Medical students were 'very interested' in almost all procedures, with thoracentesis, paracentesis, and arterial blood gases ranking highest ($N = 17$ for each, 71%). Interns expressed lower interest in procedures than medical students, with only arterial blood gases ($N = 12$, 52%) receiving more than three 'very important' responses. In open-ended responses, medical students and interns were most concerned about managing acutely decompensating patients ($N = 7$ and $N = 5$ respectively) and time management ($N = 6$ and $N = 3$ respectively). Additionally, medical students stated concerns about procedural skills ($N = 3$).

CONCLUSIONS: Medical students and interns have similar priorities in acute clinical scenarios and skills for inclusion in an internal medicine boot camp. However, medical students expressed more interest and concern about learning procedures compared to interns. This needs assessment will guide development of a boot camp curriculum at BUSM, and can inform similar electives at other institutions.

DEVELOPMENT OF PREDICTIVE SCORING SYSTEM OF FALLS IN ADULT INPATIENTS USING DEGREE OF BED-RIDDEN AND COGNITIVE FUNCTION Masaki Tago[1]; Naoko E. Furukawa[1]; Yoshimasa Oda[2, 1]; Shu-ichi Yamashita[1]. [1]Saga University Hospital, Saga, Japan; [2]Yuai - Kai Foundation & Oda Hospital, Kashima, Japan. (Control ID #2690741)

BACKGROUND: Falls among elderly can degrade their quality of life and worsen prognosis. The incidence rate of falls in inpatients is higher than that of community-dwelling persons aged ≥65 years. Various factors, such as previous falls, lower-extremity weakness, age, female gender, had been reported as risk factors of falls. Some predictive formulas of falls have been developed; however, they used complicated factors, which make them hard-to-use. In the present study, we developed and validated a new formula predictive model of risk of falls of about our adult inpatients using the scales of the degree of bed-ridden and decline of cognitive function in daily living before admission. Both scales are widely used in the Japan's public certification of long-term care need.

METHODS: We retrospectively analyzed the adult patients admitted to Yuai-kai Foundation Oda Hospital, Japan, from April 2012 to January 2015. The data (including age, sex, activity of daily living, the degree of bed-ridden and decline of cognitive function in daily living before admission, past medical history, medications, presence or absence of past history of falls and the route of admission) were derived from the charts. Multivariable analysis was performed with the variables gathered on admission, which had significant difference between patients with or without falls during the hospital stay, in the univariate analysis. We developed a new predictive formula with the independent variables selected by the multivariate analysis. The model was validated.

RESULTS: There were 371 falls of all 8031 admitted adult patients during the period of present survey. The median age of all patients was 77 years (20–104), 49% were men, and the median hospital stays was 9 days (1–189). In the univariate analysis, the proportion of patients with the age older than 75, emergency admission, referral forms, the use of hypnotic medications, hospital stay longer than 9 days, visual impairment, undergoing surgical operation, undergoing rehabilitation, sequels of cerebral infarction disturbing everyday life, and history of previous falls occupied higher percentages in fallen patients. There were also significant differences in the degree of bedridden, cognitive decline, and the necessity of assistance in daily living between patients with or without falls. The new prognostic formula is shown bellow: y = (older than 75 years) × 6 + (male) × 4 + (emergency admission) × 5 + (previous fall) × 3 + (the degree of bedridde$n$ = J) × 12 + (the degree of bedridde$n$ = A) × 18 + (the degree of bed-ridde$n$ = B) × 20 + (the degree of bedridde$n$ = C) × 17 + (the degree of cognitive decline = 2) × 4 ($0 \leq y \leq 42$, be apply to each conditio$n$ = 1). The test of goodness of fit by ROC curve showed AUC of 0.789 (95%CI: 0.770 - 0.808, $p < 0.001$).

CONCLUSIONS: We developed a new and accurate predictive scoring system of falls in adult inpatients using degree of bed-ridden and cognitive function, which are much more easily gathered than those used in the previous reported models.

DIABETES AMONG WOMEN VETERANS FOUR DECADES AFTER WAR: THE HEALTHVIEWS STUDY Eric M. Schmidt[1]; Eileen M. Stock[2]; Tracey Serpi[2]; Yasmin Cypel[3]; Kathryn M. Magruder[4]; Amy M. Kilbourne[5]; Suad El Burai Felix[2]; Avron Spiro[6]; Rachel Kimerling[7]; Beth Cohen[8]; Susan M. Frayne[1]. [1]VA Palo Alto Health Care System/Stanford, Menlo Park, CA; [2]VA Perry Point, Perry Point, MD; [3]VA Central Office, Washington, DC; [4]VA Charleston, Charleston, SC; [5]VA Ann Arbor, Ann Arbor, MI; [6]VA Boston, Boston, MA; [7]VA Palo Alto, Palo Alto, CA; [8]VA San Francisco, San Francisco, CA. (Control ID #2702859)

BACKGROUND: Military service can affect health through injuries, exposures, trauma, and physical demands. Less is known about the effects of war zone service on later-life risk for chronic diseases such as diabetes, particularly in women. In a national, population-based sample of Vietnam-era women Veterans, we examined whether incidence of diabetes following wartime service was greater among those who served in Vietnam compared to those who served in a non-combat location.

METHODS: In HealthVIEWS, a large epidemiologic study of Vietnam-era (1965–1973) women Veterans, those who were alive and locatable in 2011 were invited to complete a survey and telephone interview to characterize their health status (response rate 67%); sampling was stratified based on wartime location of service: in Vietnam (VN), near Vietnam (NV), or in the U.S. (US). An extended Cox regression model tested differences, by wartime location, in time from the start of Vietnam-era wartime service to self-reported diabetes onset. A time-varying effect of Vietnam service was entered to meet model assumptions before adjusting for demographics and military service factors.

RESULTS: Of 4,503 women in the analytic cohort, 17.7% developed diabetes; for them, mean time to diabetes onset differed for VN vs NV vs US (32.9 vs 33.2

vs 31.2 years; $p < 0.01$). Following enlistment into military service, those who served in VN (vs in US) were at three-fold lower relative risk of diabetes, and this difference persisted after adjustment (HR = 0.33, $p < 0.01$ at T0). The time-varying effect of Vietnam service was also significant, indicating diabetes risk accumulated faster in the VN group (vs US); diabetes risk was essentially the same in the VN vs US groups after 30 years (HR = 0.99, p = ns). The NV (vs US) group did not have excess in diabetes risk. Older age, non-white race/ethnicity, service in the Army or Marine Corps, lower military rank, and enlisting at the start of heightened periods of combat were associated with increased risk for diabetes.
CONCLUSIONS: War zone service was associated with lower risk for diabetes early in wartime military service but faster subsequent accumulation of diabetes risk, leading the VN and US groups to have nearly identical diabetes risk by three decades after military service. This more rapid accumulation of risk after war zone service, despite superior initial health, could potentially result from factors such as weight gain or mental health conditions, which might manifest in unique ways among women. Attention to preventive medicine and healthy lifestyle during military service among women currently in the armed forces may help to avert or delay diabetes onset later in life.

DIABETIC KETOACIDOSIS RISK AFTER INITIATING AN SGLT2 (SODIUM-GLUCOSE COTRANSPORTER 2) INHIBITOR: A POPULATION-BASED COHORT STUDY Michael Fralick; Sebastian Schneeweiss; Elisabetta Patorno. Brigham and Women's Hospital, Boston, MA. (Control ID #2697981)

BACKGROUND: Recent case reports to the FDA suggest sodium-glucose cotransporter 2 (SGLT2) inhibitors might increase a patient's risk of diabetic ketoacidosis (DKA). The objective of this study was to assess and quantify this risk.
METHODS: We conducted a population-based new initiator cohort study using the Truven MarketScan database. Patients who newly initiated either an SGLT2 inhibitor or a dipeptidyl peptidase-4 (DPP4) inhibitor, a medication not associated with DKA, between April 1, 2013 and December 31st, 2014 were included. We excluded patients with type 1 diabetes, past DKA, or end-stage renal disease. The primary outcome was hospitalization for DKA within 180 days of initiating an SGLT2. We matched new initiators of SGLT2 inhibitors with new initiators of DPP4 inhibitors using 1:1 propensity score (PS) matching. The PS was calculated through a logistic regression model including covariates related to demographics, diabetes severity, comorbid conditions, and healthcare utilization. The primary time-to-event analysis used Cox proportional hazard model to examine the incidence rate and hazard ratio of DKA.
RESULTS: We identified 61,708 patients who newly initiated an SGLT2 inhibitor and 94,285 who newly initiated a DPP4 inhibitor. After PS-matching, our study included 45,789 new users of SGLT2 inhibitors and 45,789 new users of a DPP4 inhibitors. Differences in baseline demographics, comorbid conditions, diabetes severity, and healthcare utilization were well balanced amongst these two groups. Of the patients included, half were male, the average age was 60, 65% had hypertension, 9% had coronary artery disease, 57% were prescribed metformin, 19% were prescribed insulin, and most were being managed by a primary care physician. There were 58 DKA events (4.23 events per 1,000 person-years) among initiators of an SGLT2 inhibitor compared to 29 DKA events (2.01 per 1,000 person-years) among initiators of DPP4 inhibitors. The unmatched/unadjusted risk of DKA within 180 days of initiating an SGLT2 inhibitor was 1.9 times (HR 1.9, 95% CI 1.4 to 2.6) greater than the risk for those initiating a DPP4 inhibitor and the risk heightened after PS matching (HR 2.1, 95% CI 1.3 to 3.3). The risk was further heightened within 60 days of initiating an SGLT2 inhibitor (PS matched HR 3.0, 95% CI 1.6 to 5.5) and the increased risk of DKA was not specific to the elderly (age < 65, PS matched HR 2.3, 95% CI 1.4 to 3.6).
CONCLUSIONS: SGLT2 inhibitors were associated with an increased risk of DKA. Physicians should counsel their patients accordingly and consider ordering bloodwork when patients present with symptoms suggestive of DKA (e.g., nausea, vomiting, polyuria, etc.).

DIET AND EXERCISE DO WORK FOR WEIGHT LOSS: THE SUCCESS OF AN INTERDISCIPLINARY OBESITY CLINIC IN A PRIMARY CARE SETTING Abigail Lawson; Christina Fahey; Garrett Oberst; Dylan Woolum; David Rudy; Stephanie A. Rose. University of Kentucky, Lexington, KY. (Control ID #2700120)

BACKGROUND: Despite efforts, obesity continues to be a problem in the United States. Since 2011 Medicare has recognized obesity as a disease. This change has purported to remove the stigma behind obesity and has encouraged its treatment in the medical setting as opposed to commercial settings alone. The aim of our study is to assess relevant weight loss in an outpatient primary care-based weight loss program. We hypothesize that relevant weight loss, defined as loss of 5 or 10% of body weight or loss of ≥3 kg at 6 months, can be achieved in the primary care setting.
METHODS: Patients with a BMI ≥30 kg/m^2 or a BMI ≥25 with comorbidities related to obesity were enrolled in a weight loss program located at a large university-based Internal Medicine clinic. Most weight loss was achieved using diet and behavioral motivation, with a few patients also trying weight loss medications. Visits were covered by insurance similar to a primary care physician visit. Patients were seen by an Obesity Medicine-certified physician each visit and sometimes by a dietitian. Visits lasted 1 hour the first visit and ½ hour on subsequent visits. Information obtained for patients included diet history, family weight history, dietary assessment, 24-hour food recall. Visits typically occurred monthly. Demographic information, weight, waist/hip/neck circumferences, lab values, medications, and medical history were obtained on each patient. Mean weight loss, number of patients losing ≥ 5 and ≥10% of body weight, and number of patients who lost ≥3 kg at 6 months were measured. Comparisons were analyzed using t-tests that compared differences among male and female patients for continuous variable characteristics. Only those patients who consented to the study were analyzed.
RESULTS: 115 patients consented to be in the study. Patients were a mean age of 47.5 years, 76% female, and a mean BMI of 41 kg/m^2. Patients lost an average of 10lbs (SE = 1.6), with men (M) losing slightly more weight than women (F) (14.2 vs. 8.8lbs). 21.7% of patients (M = 5, F = 20) lost ≥5% of their initial body weight, 8.7% of patients (M = 2, F = 8) lost ≥10% of their initial body weight, and 56.5% of patients (M = 17, F = 48) lost at least 3 kg at 6 months of program participation. Patients lost an average of 2.9lbs after 1 month, 5.4lbs after 3 months, and 7.2lbs after 6 months. More weight lost was positively correlated with more clinic visits, with patients who attended ≥6 visits losing an average of 17.3lbs.
CONCLUSIONS: This study demonstrates that behavioral modification and dietary change can promote relevant weight loss, and that this success can be achieved in the outpatient primary care setting. Patients continued to lose weight the longer they participated in the program, unlike many programs where weight plateaued or was regained over time. Future goals include the study of medication changes, changes in disease states and labs, and methods to make this program easier for primary care physicians to deliver.

DIFFERENCES IN EMERGENCY DEPARTMENT CARE FOR PATIENTS WITH LIMITED ENGLISH PROFICIENCY lucy schulson[1]; Victor Novak[1]; Peter Smulowitz[1]; Bruce E. Landon[2]. [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Harvard Medical School, Boston, MA. (Control ID #2706552)

BACKGROUND: The United States is becoming more culturally and linguistically diverse. Research has focused on disparities in care for such patients, however little is known about how limited English proficiency (LEP) impacts care in the emergency department (ED). LEP patients may be particularly vulnerable in the ED because of its faster paced and higher acuity nature, which might lead to differences in the care received when there are language barriers.
METHODS: We used administrative data from a single academic ED to study all patients 18 years or older who presented to the ED between September 1, 2013 and September 1, 2015. We excluded patients presenting with a psychiatric or substance related complaint, who died in the ED, who were not charged for their visit, who left without being seen, or who refused treatment. Patients with > 5 ED visits in the calendar year were also excluded from analysis. The primary exposure of interest was whether the patient had identified a language other than English as their preferred language during registration. Our primary outcomes of interest were the number of diagnostic studies (laboratory studies, imaging tests, and cardiac tests) performed during the patient's initial visit, whether the patient was admitted to the hospital, and, for those discharged from the ED, the rate of 72-hour unscheduled return visits. We estimated multivariable logistic regression or Poisson or negative binomial modeling as appropriate controlling for age, sex, insurance type, triage acuity score, time of presentation, and discharge diagnosis category.
RESULTS: We studied ED visits for 54,417 EP and 5415 LEP individuals. LEP patients were older (50.3% 60 and older vs 33.2% for EP, $p < .0001$), more likely to be female (57.6% vs. 54.6%, $p < .0001$), less educated (18% vs. 0.9% with 8th grade or less, $p < .0001$), and more likely to have public insurance (29.6% vs. 11.7%, $p < .0001$). In unadjusted analysis, LEP patients were more likely to have a laboratory test (80.6% vs. 75.4%, $p < .0001$), plain x-rays (71.8% vs. 64.7% $p < .0001$), and CT scans (5.9% vs. 5.2% $p = .0417$), but less likely to undergo MRI testing (0.8% vs. 1.1% $p = .03$). LEP patients were also more likely to have an EKG (52.4% vs. 45.1% $p < .0001$) or a stress test (4.1% vs. 2.9% $p < .0001$). Finally, LEP patients were also more likely to be admitted, (38.8% vs. 34.2%, $p < .0001$) and to have an unscheduled 72-hour return visit (1.8% vs. 1.6% $p < .0001$). Preliminarily, in adjusted analyses the findings were consistent.
CONCLUSIONS: LEP patients receive more care in the emergency department than EP patients. They also are more likely to be admitted and to return to the ED within 72 hours of discharge. These disparities may be due to communication challenges, and suggest that interventions be targeted to improve the value of care they receive.

DIFFERENCES IN GOALS DURING RESIDENCY TRAINING BETWEEN THE UNITED STATES AND JAPAN: TIME TO ADDRESS GAPS BETWEEN COMPETENCIES AND TRAINEE SELF-IDENTIFIED GOALS Hirotaka Kato[3]; Alfred Burger[4]; Ken Emoto[5]; Reiko Sakama[2]; Yuki Uehara[2]; Ankur Segon[3]; Jenny J. Lin[1]. [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Juntendo University School of Medicine, Tokyo, Japan; [3]Medical College of Wisconsin, Milwaukee, WI; [4]Mount Sinai Beth Israel, Icahn School of Medicine at Mount Sinai, New York, NY; [5]Aso Iizuka Hospital, Iizuka, Japan. (Control ID #2698472)

BACKGROUND: Medical educators worldwide aspire to transition from time based training to a competency based medical education model. The degree of alignment between competencies and residents' self-identified training goals, as well as variations in different countries have not been studied. This study sought to examine (1) how residents' goals match proposed universal competencies, (2) differences in residents' self-identified training goals between the United States (US) and Japan, and (3) prevalence of fatigue among residents.
METHODS: An online survey targeting postgraduate trainees in both the US and Japan was conducted between January and June 2016. The authors recruited two internal medicine residency programs at an urban university program and an affiliated medical center in New York City as well as one university based and four non-university based programs in Japan. The survey questions included demographics, milestones across eight competency areas proposed as universal, and eleven Iowa Fatigue Scale (IFS) questions. A 4-point scale was used (not important, a little bit important, somewhat important, very important) and responses were dichotomized into 1 (very important) and 0 (others) to compute statistical significance with Chi-Square or Fisher's exact test. Presence of fatigue and severe fatigue were defined as IFS >30 and IFS > 40, respectively. Chronbach alfa (0.79) confirmed internal consistency for IFS.
RESULTS: 165 out of 393 potential respondents (42%) completed the survey. 58% were US trainees. The proportions of "very important" in systems-based practice milestones were generally low in both countries (<70%). Significant differences were observed across all competency areas due to lower rating by postgraduate year (PGY) 1 respondents in Japan. Among the PGY 2 and 3 respondents, the statistically significant items ($p \leq .05$) included (a) Qualified handoff (US 86% versus Japan 59%), (b) Supervision for team members (80% vs. 41%), (c) Symptom relief (88% vs. 50%), (d) Evidence-based practice (94% vs. 69%), (e) Education for team members (71% vs. 48%), (f) Continuous learning (94% vs. 48%), (g) Communication with health professionals (92% vs. 71%), (h) Difficult conversations (96% vs. 74%), (i) Administrative responsibilities (36% vs. 68%), (j) Compassion and respect (100% vs. 84%), and (k) Sensitivity to diversity (91% vs. 58%). The prevalence of fatigue (42% vs. 81%), and severe fatigue (4% vs. 19%) was significantly higher in Japan ($p < .01$).
CONCLUSIONS: There were significant differences in training goals between resident physicians in the US and Japan. US trainees were more likely to see competencies as their own goals during residency compared to their Japanese counterparts. GME training should ideally be designed so that resident physicians can align their goals with milestones and competencies.

DISCHARGING THE DATA: UNDERSTANDING THE STRUCTURE OF THE HOSPITAL DISCHARGE SUMMARY IN DELIVERING PATIENT CARE Nancy T. Skehan; Bruce Barton; Sheri Keitz. University of Massachusetts Medical School, Worcester, MA. (Control ID #2700517)

BACKGROUND: Major clinical errors, increased emergency visits, and hospital readmissions can all result from poor communication between providers as patients transition from inpatient to ambulatory settings. Lapses can include medication errors, pending test results, or lack of critical information at discharge. The hospital discharge summary has been identified as a vital tool for relaying information at discharge and its content has been well defined by numerous national organizations. However, there is no standard structure for the discharge summary. We conducted a survey of residents, hospitalists and primary care providers (PCPs) in Internal Medicine, Pediatrics and Family

Medicine to determine if they identify and share a definition of an accepted structure for the discharge summary, as compared to a History and Physical (H&P). We also assessed prior discharge summary training and providers' comfort in discharge communication. The goal was to conduct a needs assessment of existing knowledge and attitudes about discharge summaries, ultimately to develop systems and educational interventions.

METHODS: A single-site cross-sectional survey of the target population was conducted at a tertiary care academic center and its community affiliates from April-May 2015. Providers were asked to identify the expected location of key clinical components in the discharge summary, as well as components of an H&P. Study data were collected and managed using REDCap electronic data capture tools. The statistical analyses generated the frequencies and percentages for each location by the specified subgroup. All analyses were conducted using SAS Version 9.3 (SAS Institute, Cary, NC).

RESULTS: 415 participants were surveyed, with 220 respondents. Respondents identified the location of the H&P elements with 80-96% concordance, compared to 42–82% in discharge summaries. In assessing knowledge, 72% of respondents felt they had not received formal training. 50% reported observing an adverse patient outcome with 77% citing difficulty in locating information as a primary cause. A subgroup analysis of hospitalists and PCPs revealed that hospitalists expect the final diagnoses at the beginning, where PCPs expect it to be at the end ($p < 0.001$).

CONCLUSIONS: Compared to the H&P, physicians do not identify a common sequence for the key components in discharge summaries. Moreover, hospitalists who generate the discharge summary do not have the same definition of its structure compared to PCPs, who receive the document. This may lead to difficulty in locating information within the document, and may contribute to medical error. These data show a need for standardized structure for the discharge summary with an accompanying educational and systems interventions to decrease the likelihood of major clinical errors.

DISPARITIES IN QUALITY OF PRIMARY CARE BY RESIDENTS AND STAFF PHYSICIANS: IS THERE A CONFLICT BETWEEN TRAINING NEEDS AND EQUITY IN CARE? Utibe R. Essien[1, 2]; Jonathan R. Abraham[1]; Alaka Ray[1]; Wei He[1]; Yuchiao Chang[2]; Daniel E. Singer[1]; Steven J. Atlas[1]. [1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA. (Control ID #2694122)

BACKGROUND: Ambulatory education for internal medicine (IM) residents is vital to training. As a majority of training is spent on the inpatient wards, concern remains about the quality of outpatient care residents provide. Prior studies compared patient outcomes of resident and staff primary care physicians (PCPs) but few examined quality of care following mandated increases in ambulatory time. We compared outcomes of patients seen by resident and staff PCPs controlling for patient characteristics and time in network.

METHODS: We compared cohorts of patients receiving care from IM residents and staff PCPs at 16 primary care clinics (PCCs) affiliated with Massachusetts General Hospital from 2005–2015. A validated algorithm was used to attribute patients to resident and staff PCPs. We assessed diabetes and CAD outcome measures, cancer screening rates and resource utilization in 2015. We report outcomes adjusted for age, gender, race, language, insurance, education, area-based median household income, clinic site, Charlson score and physician-defined complexity using generalized linear regression models. To further control for confounding between resident and staff patients including time in network, we compared outcomes from 1:1 propensity score matched subgroups.

RESULTS: Among all PCC patients, 10,538 (7.5%) were attributed to resident and 130,706 to staff PCPs. Compared to staff patients, resident patients were more likely to be male, African-American, receive Medicaid or be uninsured, live in low-income areas and have higher comorbidity scores (all $p < 0.05$). Resident patients were less likely to speak English and completed less education. Compared to staff patients, resident patients had lower chronic disease outcomes, cancer screening rates and higher rates of admission and ED visits (Table 1). The differences in all outcomes remained significant in propensity score-matched subgroups (data not shown).

CONCLUSIONS: In this single primary care network, major differences in sociodemographics and comorbidities exist among patients seen by resident and staff PCPs. After controlling for confounding using multivariable modeling and propensity matching, resident patients still had poorer chronic disease, cancer screening and resource utilization outcomes. Unmeasured confounders may partially account for the outcomes observed. Novel approaches to engage trainees in team-based practice and population health management may be needed to prevent disparities in quality of care in academic PCCs while meeting resident educational needs.

Quality of Care between Resident and Staff PCP Patients

Quality of Care and Resource Utilization Measures	Resident PCP Patients $n = 10{,}538$	Staff PCP Patients $n = 130{,}706$	Adjusted Relative Risk (95% CI)	Adjusted p-value
Coronary Artery Disease (CAD) - LDL Level <100 mg/dL	49.6%	61.8%	0.82 (0.74, 0.89)	<.0001
Diabetes - HbA1c Level < 9%	74.2%	81.1%	0.95 (0.91, 0.98)	0.0001
Breast Cancer Screening	70.4%	83.6%	0.89 (0.87, 0.92)	<.0001
Cervical Cancer Screening	69.6%	82.8%	0.92 (0.89, 0.94)	<.0001
Colorectal Cancer Screening	65.9%	77.8%	0.93 (0.90, 0.95)	<.0001
Admissions (per 100 pts)	15.5	6.5	1.75* (1.59, 1.93)	<.0001
Emergency Department (ED) Visits (per 100 pts)	25.8	11.9	1.47* (1.35, 1.60)	<.0001

*Risk Ratio

DO DIABETES GROUP VISITS IMPROVE HEALTH OUTCOMES AMONG PATIENTS IN COMMUNITY HEALTH CENTERS? Arshiya A. Baig[1]; Erin M. Staab[1]; Amanda Benitez[3]; Sarah P. Hermans[1]; Yue Gao[1]; Sandra Ham[1]; Amanda Campbell[4]; Cynthia T. Schaefer[2]; Michael T. Quinn[1]. [1]University of Chicago, Chicago, IL; [2]University of Evansville, Evansville, IN; [3]Enlace Chicago, Chicago, IL; [4]Midwest Clinicians' Network, East Lansing, MI. (Control ID #2705087)

BACKGROUND: Diabetes group visits, shared appointments in which patients receive self-management education in a group setting and have a medical visit,

are an innovative way to deliver diabetes care and have been shown to improve clinical outcomes. Community health centers (CHCs) play a vital role in providing care to patients with diabetes. No studies have systematically implemented diabetes group visits in a network of U.S. CHCs.

METHODS: We designed a group visit intervention in partnership with Midwest Clinicians' Network. We trained staff from six CHCs in five states to conduct six monthly group visits with 8–10 adult patients with uncontrolled diabetes (glycosylated hemoglobin, A1C, ≥ 8%). Primary outcome was change in A1C from baseline to 6- and 12-month follow-up. Secondary outcomes were changes in diabetes self-care (diet, exercise, foot care, blood glucose testing), diabetes-related quality of life (dissatisfaction with diabetes control, diabetes-related social worry), and diabetes distress (emotional burden, physician distress, regimen distress, interpersonal distress). Analysis of secondary clinical outcomes, including LDL, blood pressure, and weight, is in progress, and we are currently collecting data on matched control patients at each site.

RESULTS: Fifty-one patients were enrolled across the six sites (mean age 55 ± 12 years, 67% female, 38% African American, 38% white, 22% Latino, 9% American Indian/Native American). Average baseline A1C was 10.2% ± 1.7%. Patients attended an average of 3.5 ± 1.9 group sessions. Compared to baseline, A1C was significantly lower at 6 months (8.8% ± 2.3%, $p = 0.0002$) and 12 months (9.0% ± 2.0%, $p < 0.0001$). Patients improved in two self-care areas from baseline to 6 months: days per week following a healthful eating plan (3.3 ± 2.4 vs. 4.8 ± 1.4, $p = 0.023$) and testing blood sugar (4.8 ± 2.4 vs. 6.1 ± 1.2, $p = 0.001$). Dissatisfaction with diabetes control decreased significantly (2.3 ± 0.8 vs. 1.8 ± 0.6 [1 = least to 5 = most problematic], $p = 0.029$) at 6 months. Participants experienced significantly less emotional burden (2.6 ± 1.4 vs. 2.0 ± 1.4 [1 = least to 6 = most distressed], $p = 0.049$), regimen distress (3.0 ± 1.5 vs. 2.0 ± 1.2, $p = 0.014$), and overall diabetes distress (2.3 ± 1.2 vs. 1.8 ± 1.1, $p = 0.048$). There were no significant changes in foot care, exercise, physician or interpersonal distress, overall diabetes-related quality of life, or diabetes-related social worry. The intervention was well-received by patients: 93% gained confidence in their ability to manage diabetes, 93% agreed the content was relevant to their lives, and 90% said attending group visits was not a burden.

CONCLUSIONS: Among a sample of adults with uncontrolled diabetes who receive care in CHCs, diabetes group visits improved glycemic control, diabetes self-care, diabetes-related quality of life, and diabetes distress. Future research should assess the cost of group visits and facilitators and barriers to group visit implementation in CHCs.

DO HISPANIC-SERVING HOSPITALS HAVE WORSE PATIENT OUTCOMES? CASE OF ACUTE MYOCARDIAL INFARCTION INPATIENT MORTALITY

Lenny Lopez[5]; Michael Paasche-Orlow[3]; Nancy R. Kressin[4]; Eun Ji Kim[2]; Meng-Yun Lin[1]; Jennifer E. Rosen[6]; Amresh D. Hanchate[3]. [1]Boston Meidcal Center, Boston, MA; [2]Boston University, Boston, MA; [3]Boston University School of Medicine, Boston, MA; [4]Dept of Veterans Affairs and Boston University, West Roxbury, MA; [5]University of California San Francisco, San Francisco, CA; [6]MedStar Washington Hospital Center, Washington DC, DC. (Control ID #2707004)

BACKGROUND: Hospital quality is associated with patient outcomes. Examination of hospital effects on disparities in patient outcomes has been limited to black vs. white comparisons. Our objective was to extend such analyses to include ethnicity and to examine the role of hospitals' ethnic composition and other characteristics on patient outcomes. We estimated inpatient risk adjusted mortality for acute myocardial infarction (AMI) discharges by race/ethnicity and examined variations in mortality by patient and hospital characteristics at high proportion Hispanic-serving hospitals compared to other hospitals.

METHODS: We used patient level data from state inpatient discharge data (2010–11) from 14 states (AZ, CA, CO, FL, IL, MA, MD, NV, NJ, NY, OR, PA, TX, VA) that account for 85% of the US Hispanic population. We obtained hospital characteristics from the American Hospital Association and we applied the Agency for Healthcare Research and Quality's Inpatient Quality Indicators protocol to AMI discharges. Using the proportion of Hispanic patients out of all discharges at each hospital, we stratified all hospitals into deciles. The top 3 deciles served a majority of Hispanic patients (79%), but smaller proportions of white (22%), black (34%) and Asian (53%) patients. We adjusted for patient risk using Elixhauser comorbidity indicators to compare inpatient mortality differences by race/ethnicity (Hispanics, non-Hispanic blacks, Asians and non-Hispanic whites). Using logistic regression models we estimated race/ethnic differences in risk-adjusted mortality and stratified these differences across Hispanic-serving hospital deciles.

RESULTS: There were 513,639 AMI discharges (10.8% Hispanics, 9.5% blacks, 2.9% Asians and 76.8% whites). Overall inpatient mortality rate was 6.1%. Inpatient mortality was higher among Hispanics (odds ratio (OR) = 1.09, $p < 0.05$) and Asians (OR = 1.09, $p < 0.05$), but no different among blacks (OR = 0.97), compared to whites, after adjusting for age, sex and comorbidities. Across hospital deciles by Hispanic-serving proportion, the share of Hispanic patients ranged from 0.1% in the lowest decile to 46.3% in the highest, and the latter were more likely to be safety-net, for-profit, government-owned or have a low annual average AMI volume. Risk-adjusted inpatient mortality exhibited a U-shape with respect to Hispanic-serving hospital deciles with the lowest mortality in the middle, decile 5 hospitals. Relative to decile 5 hospitals, mortality was higher in the top 3 deciles: decile 8 OR = 1.21; decile 9 OR = 1.14; decile 10 OR = 1.29 (all p-values < 0.05).

CONCLUSIONS: Hispanic patients have a higher rate of AMI inpatient mortality than white patients. Hospitals that disproportionately serve Hispanic AMI patients serve a lower portion of white and other minority patients and have higher inpatient mortality compared to other hospitals. Quality improvement at these hospitals could reduce Hispanic disparities in healthcare outcomes.

DO MEDICARE'S PAY-FOR-PERFORMANCE PENALTIES HAVE A BITE? THE CUMULATIVE 2013–2016 EXPERIENCE.

Amresh D. Hanchate[4, 1]; Meng-Yun Lin[2]; Danny McCormick[3]; Ge Bai[6]; Gerard F. Anderson[5]; Souvik Banerjee[1]; Michael Paasche-Orlow[1]. [1]Boston University School of Medicine, Boston, MA; [2]Boston Medical Center, Boston, MA; [3]Harvard Medical School/Cambridge Health Alliance, Cambridge, MA; [4]VA Boston Healthcare System, Boston, MA; [5]Johns Hopkins University, Baltimore, MD; [6]Johns Hopkins University, Washington, DC. (Control ID #2701207)

BACKGROUND: In 2013 the Centers for Medicare & Medicaid Services' (CMS) introduced pay-for-performance programs - the Hospital Readmissions Reduction Program (HRRP) and Hospital Value Based Purchasing (HVBP) program - that instituted Medicare payment penalties (and bonuses) for hospitals based on patient outcome performance measures. However, due to the small size of annual penalties, the potency of the programs to influence quality

improvement has been questioned. Little is known about how often hospitals are subject to repeated penalties, the cumulative penalty size and associated financial loss. Using data from 2013–2016 we assessed the frequency of repeated penalties, revenue loss relative to hospital financial performance indicators, and characteristics associated with higher financial loss.

METHODS: We obtained data on Medicare participating hospitals' penalty/bonus payment rates for the HRRP and HVBP programs (2013–2016) from CMS' Final Impact Rule files. We merged these data with hospital data on acute inpatient care revenues from Medicare patients and overall patients, and net income (operating profits), obtained from CMS' Healthcare Cost Report Information System (HCRIS) files (2013–2014, the program years for which data is available). We used the 2013–2014 annual average of the HCRIS financial performance indicators, adjusted for inflation, as the baseline indicator of hospital financial status. We applied the cumulative penalty (and bonus) payment rates during 2013–2016 to the baseline financial measures to obtain the expected cumulative penalties ($) as a proportion of annual net income (*income share*) and of annual overall inpatient revenues (*revenue share*). Using linear regression models we examined the associations of both income and revenue share with several hospital characteristics: Medicare share of hospital inpatient volume (*Medicare share*), safety-net status, bed size and non-profit status.

RESULTS: Our study cohort included 2,192 hospitals. During 2013–2016, 1,695 hospitals (77%) experienced a cumulative penalty from both programs combined; 72 and 41% hospitals were penalized at least 3 years under HRRP and HVBP, respectively. Among penalized hospitals, the maximum cumulative penalty rate was 9.5% (media*n* = 1.8%), and the maximum penalty amount was $18,869 per bed (media*n* = $1,961). In over half the penalized hospitals, income share exceeded 3.2%, and revenue share exceeded 0.4%. 363 hospitals (16.6%) experienced penalties exceeding 2% of income share and 1% of revenue share. Income and revenue shares were higher in hospitals with higher Medicare share of total discharge volume; hospitals with >50% Medicare share experienced higher penalties amounting to 6.5% income share and 0.6% revenue share. Safety-net status, larger bed size and non-profit status were also associated with higher financial loss.

CONCLUSIONS: Repeated penalties from HRRP and HVBP programs are common, and for many hospitals the cumulative penalties represent a sizable share of net income and revenues.

DO PRESCRIBED OPIOIDS INCREASE RISK OF COMMUNITY-ACQUIRED PNEUMONIA REQUIRING HOSPITALIZATION? E. J. Edelman[1]; Kirsha S. Gordon[2]; Janet P. Tate[1]; William Becker[2, 1]; Kendall Bryant[3]; J. R. Gaither[1, 2]; Cynthia Gibert[4]; Adam Gordon[5]; Brandon D. Marshall[6]; Maria Rodriguez-Barradas[7]; Jeffrey H. Samet[8]; Kristina Crothers[9]; Amy C. Justice[1, 2]; David A. Fiellin[1]. [1]Yale University, New Haven, CT; [2]VA Connecticut Healthcare System, West Haven, CT; [3]National Insitutes of Health (NIH), Bethesda, MD; [4]Veterans Affairs Medical Center, Washington, DC; [5]University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA; [6]Brown University, Providence, RI; [7]Michael E. DeBakey VAMC, Houston, TX; [8]Boston University School of Medicine, Boston, MA; [9]University of Washington, Seattle, WA. (Control ID #2707005)

BACKGROUND: As opioids have respiratory and immunosuppressive properties, we aimed to determine whether prescribed opioids impact risk of community-acquired pneumonia requiring hospitalization (CAP) among patients with (HIV+) and uninfected individuals.

METHODS: We conducted a longitudinal analysis of data from 2000 to 2012 among HIV+ and uninfected controls in the Veterans Aging Cohort Study (VACS). Patients were followed upon receipt of their first outpatient medication prescription dispensed from the Veterans Affairs Healthcare System (VA). Patients were excluded if during their first year of observation they 1) died; 2) had an opioid prescription >14 days supply to capture patients who had no or only minimal opioid receipt; or 3) had evidence of severe medical illness with a VACS index score (a validated measure of mortality risk) >100. Additionally, patients were excluded if: 1) they ever received chemotherapy or immunosuppressive medications; 2) had an initial opioid prescription with an average daily morphine equivalent dose exceeding 100 mg. Using outpatient VA pharmacy data, the exposure of interest, opioid receipt, was categorized as a time-varying 4-level variable based on receipt in the current and prior 30-day intervals as: 1) none, indicating no opioid receipt in the prior 60 day interval; 2) previous only, indicating opioid receipt only in the immediate prior 30 day interval; 3) current only, indicating opioid receipt in the current 30 day interval only, or 4) both, indicating opioid receipt in the prior and current 30 day interval. The outcome, CAP, was defined based on ICD-9 codes 480–487 and receipt of antimicrobials by the third day of hospitalization. Baseline covariates included demographics (age, gender, race/ethnicity), comorbidities (HIV, HCV), smoking status and VACS index score. We created time-varying Cox proportional hazards models to assess the association between opioid receipt and incident CAP.

RESULTS: Among our analytic sample ($n = 56,630$), patients were followed for a mean of 8.1 years. The mean age was 49 years, 98% were men, 39% white; 48% black; 9% Hispanic; 4% other and 34% were HIV+. Eleven percent of the sample had an incident CAP during the follow-up period. In adjusted analyses, compared to none, those with opioid receipt in the previous interval only [adjusted hazard ratio (aHR) [95% confidence interval] = 1.51 [1.31, 1.74]), current interval only (aHR [95% CI] = 4.35 [3.99, 4.73]), and both intervals (aHR [95% CI] = 1.82 [1.66, 2.01]) were more likely to have incident CAP.

CONCLUSIONS: Opioid receipt is independently associated with an increased risk of pneumonia, with greatest risk when initiating treatment. These data should inform discussions regarding benefit and harms associated with prescribed opioids. Among those for whom prescribed opioids are deemed necessary, efforts to address modifiable risk factors for pneumonia should be prioritized.

DO PRIMARY CARE PATIENTS PRESENTING WITH RECTAL BLEEDING RECEIVE RECOMMENDED COLONOSCOPIES? Sanja Percac-Lima[1, 2]; Lydia E. Pace[1, 3]; Kevin H. Nguyen[4]; Charis N. Crofton[5]; Katharine A. Normandin[5]; Sara Singer[1, 4]; Meredith Rosenthal[4]; Alyna T. Chien[1, 5]. [1]Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Division of Women's Health, Brigham and Women's Hospital, Boston, MA; [4]Department of Health Policy and Management, Harvard T. H. Chan School of Public Health, Boston, MA; [5]Division of General Pediatrics, Department of Medicine, Boston Children's Hospital, Boston, MA. (Control ID #2699120)

BACKGROUND: Missed and delayed cancer diagnoses are a major ongoing concern in primary care. Rectal bleeding can be the first symptom of colorectal cancer and clinical guidelines recommend colonoscopies for most patients with rectal bleeding. This study examined how often patients presenting to primary care with rectal bleeding receive recommended colonoscopies and how colonoscopy rates differ based on patient characteristics and utilization patterns.

METHODS: We conducted a cross-sectional study of 258 patients aged 40–80 who received primary care at 15 practices across 5 academic medical centers affiliated with Harvard Medical School between 2012 and 2016. In this period, practices were involved in learning collaboratives aimed at establishing team-based care and improving preventive cancer screening. We used ICD-9 codes indicative of rectal bleeding to randomly select 20 patients per practice across the 4 study years, oversampling for Medicaid-insured and non-Medicaid patients in a 1:1 manner. We followed CRICO (Controlled Risk Insurance Company) guidelines to determine if a colonoscopy was recommended. Three research assistants used a 2,620-item tool to abstract patient data across 4 electronic health record systems and dually abstracted 10% of charts (the Kappa = 0.95); primary care physicians adjudicated disagreements. We used multivariate logistic regression to examine the degree to which receiving recommended colonoscopies was associated with patient age, sex, non-White race/ethnicity, insurance type, number of chronic conditions, primary care no show rates, and number of primary care and subspecialist visits unrelated to rectal bleeding.

RESULTS: Of the 258 patients with rectal bleeding, 45% (115) were female, average age was 55 (SD 10) years, 60% (155) were non-White (e.g. Hispanic, Black, Other), and 49% (126) had Medicaid. CRICO guidelines indicated that 91% (234) of patients presenting with rectal bleeding should have received a colonoscopy; 55% (131 of 234) did within 1 year of presentation. The average time to colonoscopy was 76 (SD 81) days. Age, sex, insurance type, number of chronic conditions, primary care no show rates and number of subspecialist visits unrelated to rectal bleeding were not significantly associated with colonoscopy receipt. In multivariable analyses, non-White patients were more likely to receive a colonoscopy than White patients (OR = 2.05, CI [1.15,3.65] $p = 0.02$), and the number of primary care visits unrelated to rectal bleeding was negatively associated with the odds of receiving a colonoscopy (OR = 0.80, CI [0.66,0.97] $p = 0.03$).

CONCLUSIONS: Care for primary care patients presenting with rectal bleeding is sub-optimal. Prioritization of issues unrelated to rectal bleeding may explain some of these deficiencies. However, in contrast to previous studies in the same setting, non-White patients were more likely to receive recommended care.

DOES BEHAVIORAL HEALTH INTEGRATION IMPROVE PRIMARY CARE PROVIDERS' PERCEPTIONS OF HEALTHCARE SYSTEM FUNCTIONING AND THEIR OWN KNOWLEDGE?

Leah Zallman[2, 3]; Robert Joseph[2]; Emily Benedetto[2]; Ellie Grossman[1]; Lisa Arsenault[3]; Assaad Sayah[2]. [1]Cambridge Health Alliance, Somerville, MA; [2]Cambridge Health Alliance, Cambridge, MA; [3]Institute for Community Heatlh, Malden, MA. (Control ID #2704023)

BACKGROUND: Behavioral health integration (BHI) is an increasingly employed strategy for improving patient outcomes, reducing costs, and improving patient experience. The impact of these programs on primary care providers' (PCPs') experience caring patients with mental health and substance use disorders, in particular PCPs' perceptions of behavioral health (BH)-primary care (PC) system functioning and knowledge, are poorly understood. We aimed to examine the impact of BHI on PCPs' perceptions of behavioral health BH-PC system functioning and knowledge.

METHODS: We implemented BHI based on evidence-based models consisting of seven elements: (1) Screening for mental health and substance use disorders, (2) Training of PC teams, (3) Integration of BH providers into PC teams, (4) Roll-out of unlicensed mental health care managers and establishment of a BH registry, (5) Psychiatry consult service, (6) Site-based BHI meetings, and (7) Site self assessments. The intervention was rolled out in early integration sites during 2 years and late integration sites during the subsequent 2 years. In this observational pre-post study, we administered an anonymous online survey annually to PCPs; 381 PCPs at 11 primary care clinics participated. We examined changes in perceptions with chi-square tests and fisher's exact tests. We also conducted multivariable logistic regression analyses controlling for provider and site level characteristics.

RESULTS: The proportion of PCPs with high BH-PC systems functioning scores quadrupled from 14 to 55% (p <0.0001) and high knowledge scores increased from 63 to 85% ($p < 0.001$). Larger increases were demonstrated in early integration sites during the first 2 years and in late integration sites during the latter 2 years of the survey. Adjusting for participant and site level characteristics did not change these outcomes.

CONCLUSIONS: BHI improves PCP perceptions of BH-PC system functioning and knowledge. BHI is a strategy for improving PCP experience caring for patients with mental health and substance use disorders.

DOES BEIJING'S DIAGNOSIS-RELATED GROUP PAYMENT REFORM PILOT IMPROVE QUALITY OF ACUTE MYOCARDIAL INFARCTION CARE?

Adrienne N. Poon[1]; Kit Yee Chan[2]; WeiYan Jian[3]. [1]George Washington School of Medicine and Health Sciences, Clifton, NJ; [2]University of Edinburgh, Edinburgh, United Kingdom; [3]Peking University, Beijing, China. (Control ID #2706989)

BACKGROUND: In China, quality of acute myocardial infarction (AMI) management has previously been found to be poor with uneven guideline implementation. Previous studies have supported the use of DRG payment systems to help drive improvements in quality of care. In 2012, China's first pilot diagnosis-related group (DRG) payment system was implemented in Beijing. This study aims to explore whether this DRG payment pilot has improved quality of AMI management.

METHODS: Discharge and claims data from the Beijing Employee Basic Health Insurance Scheme were obtained from 14 tertiary care hospitals from January 2010 to September 2012. In October 2011, 108 DRGs for specific conditions/procedures were piloted in 6 hospitals while fee-for-service (FFS) payment was continued in controls. Four AMI DRGs included: percutaneous coronary intervention (PCI) procedure with stent that is complicated or uncomplicated and the higher risk coronary artery bypass grafting (CABG) surgery with and without cardiac catheterization. Regression was performed with a differences-in-differences design to assess whether DRG pilot implementation improved quality of care measures.

RESULTS: AMI DRG cases at pilot hospitals included 1,221 (88.9%) complicated PCI with stent, 69 (5.0%) uncomplicated PCI with stent, and 84 (6.1%) CABG surgeries. Of eligible DRG cases at pilot hospitals post-reform, 397 (28.9%) were ultimately paid through FFS including 69.1% of CABG surgeries. DRG payment led to a significant 72.2% reduction in in-hospital mortality though a 7.1% reduction in prescription of optimal AMI medications at arrival. DRG-eligible cases ultimately paid through FFS had a 24.1% increase in expenditures per admission, out-of-pocket (OOP) payment, and 15.4% increase in length of stay compared to cases paid through DRG. For higher quality uncomplicated PCI with stent cases, there were significant

reductions in expenditures (19.7%) and OOP payments (29.5%). For FFS medically managed and PCI only cases, there was an 8.9% reduction in OOP payments and a 5.4% increase in in-hospital mortality.

CONCLUSIONS: DRG payment for cardiac procedures stimulated significant reductions in in-hospital mortality while reducing costs for high quality uncomplicated PCI with stent cases showing potential for DRG payment to improve quality of AMI in Chinese hospitals. Outcomes in terms of in-hospital mortality, however, were worse likely due to access to expensive but potentially life-saving procedures only if payment was guaranteed. Furthermore, more expensive and medically risky cases were shifted towards FFS payment, which is a major gap. Given that the majority of PCI cases had procedural complications as well as poor-adherence to medication guidelines, there is an urgent overall need to improve overall quality of AMI care and create incentives to stimulate adherence to evidence-based practice.

DOES CARDIOVASCULAR DISEASE RISK IN POSTMENOPAUSAL SOUTH ASIAN WOMEN CATCH UP TO MEN Diana Thiara[2]; Feng Lin[3]; Namratha R. Kandula[1]; Alka M. Kanaya[3]. [1]Northwestern University, Chicago, IL; [2]University of California at San Francisco, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA. (Control ID #2703172)

BACKGROUND: South Asians (SA) bare a greater burden of cardiovascular disease (CVD) and have the highest rate of mortality from ischemic heart disease than other ethnic populations in the US. While studies have identified some modifiable risk factors associated with cardiovascular disease in SA populations, no study has examined whether there is sex difference in subclinical atherosclerosis among postmenopausal women and similarly aged men.

METHODS: We conducted a cross-sectional analysis including postmenopausal women and men age 50–84 years old without known cardiovascular disease from the Mediators of Atherosclerosis in South Asians Living in America (MASALA) study. Post-menopausal status was ascertained by self-report, and women with oophorectomy were excluded. High resolution ultrasonography was done to measure common carotid intima media thickness (CCA) and internal carotid intima thickness (ICA), and cardiac CT scan was performed to quantify coronary artery calcium (CAC). Regression models were used to examine the relationship between sex and ICA, CCA, and CAC, separately. Using multivariate analyses, we serially adjusted for traditional CVD risk factors (age, hypertension, diabetes, LDL, BMI, waist circumference, smoking, alcohol use, education, statin use, and family history of heart attack), behavioral factors (exercise and total caloric intake), psychosocial factors (depression, anxiety, burden and traditional cultural beliefs).

RESULTS: Of 576 SA (44% women), men had a mean age of 62 and women 59 years ($p < 0.001$). Men had significantly higher diabetes prevalence (34% vs 24%, $p = 0.005$), alcohol use (47% vs 16%, $p < 0.001$) and smoking (current or former: 31% vs 3%, $p < 0.001$), and were more likely to have higher levels of education than women (89% vs 82%, $p = 0.02$). Men also had higher rates of hypertension (55% vs 44%, $p = 0.01$) and larger waist circumferences (95.6 cm vs 90.0 cm, $p < 0.001$). Women had higher LDL than men (115 vs 104 mg/dl, $p < 0.001$) and higher depressive symptoms (CES-D score, 8.4 vs 7.2, $p = 0.05$). In unadjusted analyses, men had higher mean CCA (0.96 mm vs 0.88 mm, $p < 0.001$) and ICA (1.37 mm vs 1.21 mm, $p < 0.001$) and were more likely to have any prevalent CAC (70% vs. 33%) and higher extent of CAC compared to women. Multivariate adjustment for traditional CVD risk factors attenuated the association between sex and CCA and ICA completely, however the differences in CAC between sexes persisted. Men had a higher prevalence of any CAC (OR 4.67 (95% confidence interval, 2.63-8.28)) and extent of CAC (β 1.7, $p < 0.001$) in adjusted analyses.

CONCLUSIONS: While older postmenopausal women have similar prevalence of carotid intima media thickness compared to men, the prevalence and extent of CAC remains higher in men. These findings suggest that South Asian women, like women in other race/ethnic groups, may not benefit from aggressive statin therapy for primary prevention of coronary heart disease.

DOES DEPRESSION AFFECT GLYCEMIC CONTROL AND DELIVERY OF GUIDELINE-RECOMMENDED CARE IN PATIENTS WITH HEART FAILURE AND DIABETES Margaret Zupa; Kaleab Abebe; Yan Huang; Amy Anderson; Bea Herbeck Belnap; Bruce L. Rollman. University of Pittsburgh, Pittsburgh, PA. (Control ID #2703184)

BACKGROUND: Heart failure (HF) and type 2 diabetes mellitus (T2DM) are common, often comorbid chronic medical conditions which demand adherence with complex treatment regimens. While clinical practice guidelines can assist clinicians in providing evidence-based care, co-morbid depression may impair effective management of HF and T2DM and thereby increase afflicted individuals' risk of morbidity and mortality. However, little is known about the impact of depression in patients with both conditions. We therefore explored the effect of depression on glycemic and blood pressure control and delivery of guideline-recommended HF and T2DM care among patients enrolled in the NHLBI-funded Hopeful Heart Trial presently examining the impact of treating depression in HF patients.

METHODS: We screened patients hospitalized with systolic HF (ejection fraction (EF) $\leq 45\%$) and NYHA class II-IV symptoms for depression with the Patient Health Questionnaire (PHQ-2), and telephoned 2 weeks after discharge to administer the PHQ-9. We classified patients as depressed if they screened positive on PHQ-2 and scored ≥ 10 on the follow-up PHQ-9, and recruited a randomly sampled cohort of non-depressed subjects who screened negative on PHQ-2 and scored <5 on follow-up PHQ-9 as a control group. We collected sociodemographic information from patient self-report and abstracted the hospital discharge summary for medical diagnoses, medication use, cardiac ejection fraction, blood pressure, and HbA1c. We used student's t-test or chi-square test, when appropriate, to compare depressed and non-depressed HF patients with T2DM.

RESULTS: From 3/2014 to 11/2016, we enrolled 545 HF patients including 260 (48%) with T2DM. Depressed ($N = 211$) and non-depressed ($N = 49$) subjects were similar by mean age (65 years), gender (58% male), EF (28%), and marital status (45% married). Seventy-six percent of depressed patients were white compared with 55% of non-depressed; 23% of the depressed group was African American compared with 41% of non-depressed ($p = 0.01$ for racial distribution). Critically, baseline glycemic control as measured by mean HbA1c (8.2% vs 7.7% $p = 0.16$), systolic (126 vs 123 mmHg $p = 0.25$) and diastolic (71 vs 70 mmHg $p = 0.53$) blood pressure, and rates of HF and T2DM guideline-adherent prescription of ACE/ARB (63 and 69% $p = 0.40$) and statins (80 and 73% $p = 0.35$) were similar between depressed and non-depressed patients.

CONCLUSIONS: At baseline, comorbid depression was not related to glycemic or blood pressure control or delivery of guideline-adherent care to

patients with HF and T2DM. Further research is needed to identify practices that improve adherence with guideline-based care for medically complex patients with HF and T2DM and elucidate the long-term impact of depression on patients with these conditions.

DOES NURSE CARE MANAGEMENT OF PATIENTS AT HIGH RISK FOR ALCOHOL USE DISORDERS IMPROVE DRINKING OUTCOMES? RESULTS OF THE CHOOSING HEALTHIER DRINKING OPTIONS IN PRIMARY CARE (CHOICE) TRIAL

Katharine Bradley[1]; Jennifer F. Bobb[1]; Evette Ludman[1]; Laura Chavez[5]; Andrew J. Saxon[3]; Joe O. Merrill[6]; Emily Williams[4]; Eric Hawkins[3]; Ryan Caldeiro[1]; Gwen Lapham[1]; Julie E. Richards[1]; Amy K. Lee[1]; Daniel Kivlahan[2]. [1]Group Health Research Institute, Seattle, WA; [2]VA Puget Sound, Seattle, WA; [3]VA Puget Sound Health Care System, Seattle, WA; [4]Health Services Research and Development (HSR&D) Seattle Center of Innovation for Veteran-Centered and Value-Driven Care, Seattle, WA; [5]Ohio State University, Columbus, OH; [6]University of Washington, Seattle, WA. (Control ID #2706223)

BACKGROUND: Importance: Alcohol use disorders (AUD) are common and under-recognized, and most patients never receive treatment. Experts recommend that AUDs be managed as chronic conditions in primary care, but the effectiveness of AUD care management unknown. Objective: To test whether a year-long care management intervention by registered nurses (RNs), compared to usual care, improved drinking outcomes at 12 months among patients at high risk for AUDs.

METHODS: Design: Randomized, controlled, encouragement trial. Setting: Three primary care clinics in one Veterans Affairs (VA) Health Care System Participants: VA outpatients who reported heavy drinking twice weekly or once weekly if previous AUD treatment, and consented to participate in a trial in which they might be offered additional alcohol-related care. Intervention: Proactive outreach and engagement by an RN who offered 12 months of repeated brief counseling using motivational interviewing (with or without biomarker monitoring), shared decision-making about treatment options, and support accessing preferred care including AUD medications.

RESULTS: Main Outcomes and Measures: Percent heavy drinking days (%HDD) on a 28-day timeline follow-back (TLFB), and percent of patients with “good drinking outcomes” (GDOs), assessed by blinded telephone interviewers, at 12 months. GDO is defined as drinking below recommended limits (TLFB) without alcohol-related symptoms (past 3 months) on the Short Inventory of Problems. Results: Among 304 participants (91% male, mean age 51.4 years), 73% met criteria for DSM-IV AUDs. Most (91%) intervention patients engaged in care with study RNs: 6% 1 visit, 33% 2–5, 20% 6–9, and 32% $\geq$ 10 visits. Intervention patients were more likely to receive alcohol-related care (42% vs 26%; $p = 0.005$), reflecting increased use of AUD medications (32% vs 8.4%; $p < 0.0001$), but no differences in specialty alcohol treatment or mutual help. There were no significant differences main outcomes at 12 months. Among usual care and intervention patients, respectively, %HDD were 35 and 39% (p 0.44), and percent with GDOs were 20 and 15% ($p = 0.32$), respectively. Findings at 3 months were similar.

CONCLUSIONS: Conclusions and Relevance: The CHOICE intervention for AUDs engaged patients in alcohol-related care and increased use of AUD medications, but did not improve drinking outcomes at 12 months.

DOES PHYSICIAN GENDER EFFECT ORDERING PRACTICE

Nina Garza[2]; Fawaz Georgie[2]; Alexander Horbal[2]; David E. Willens[1]; Alexis C. Haftka-George[2]. [1]Henry Ford Health System, Detroit, MI; [2]Henry Ford Hospital, Detroit, MI. (Control ID #2701850)

BACKGROUND: Breast cancer cases represent 14.6% of all new cancer diagnosis in the United States. However, medical societies disagree when, and how often, we should be screening. The United States Preventative Service Task Force recommends starting at 50 years of age and screening biennially, while others recommend starting at 40 years of age, or screening annually. This has created an environment where physicians must decide which guideline is best for their patients. We sought to find out what factors influence this decision, specifically if the gender of the ordering physician was associated with different screening practices in women aged 40–49.

METHODS: We examined every office visit for female patients age 40–49 with an internal medicine (IM), family medicine (FM) or gynecology (Gyn) provider in our health system between July 1, 2015 to May 30, 2016. Patients with a history of breast cancer or other malignant neoplasm were excluded. The association between physician gender and mammogram ordering rates was assessed via chi-squared testing. Other factors, such as comparison between specialties, were assessed via multivariable binary logistic regression.

RESULTS: In female patients aged 40–49, female physicians are more likely to order mammograms than male physicians overall. This disparity between genders was largest in internal medicine. Gynecology physicians order mammograms at a higher rate than internal medicine or family medicine physicians. Women aged 45–49 were more likely to receive a mammogram order than women aged 40–44. Also, black patients were less likely to receive a mammogram order compared to white patients.

CONCLUSIONS: Physician ordering practices do appear to vary by gender, however, this pattern is also influenced by specialty. The decision also seems to be effected by the age and/or race of the patient. The results of this study support the need for more research in factors contributing to preventive healthcare disparities.

DOES STIGMATIZING LANGUAGE IN PATIENT CHARTS NEGATIVELY IMPACT PHYSICIAN ATTITUDES AND CLINICAL DECISION MAKING? AN EXPERIMENTAL STUDY

Anna P. Goddu[1]; Katie O’Conor[1]; Sophie Lanzkron[1]; Mustapha Saheed[1]; Somnath Saha[2]; Monica E. Peek[3]; Carlton Haywood[1]; Mary Catherine Beach[1]. [1]Johns Hopkins University, Baltimore, MD; [2]Portland VA Medical Center, Portland, OR; [3]The University of Chicago, Chicago, IL. (Control ID #2698556)

BACKGROUND: Clinician bias is a known contributor to health disparities. Research on implicit bias has primarily focused on individuals, rather than the transferability of such bias to others. Language used to describe patients may reflect physician bias, and also influence opinions of patients’ subsequent physicians. Few studies have evaluated written physician notes as a source of implicit bias. This study’s objective was to assess whether stigmatizing language written in a patient chart is associated with a subsequent clinician’s bias towards the patient and clinical management.

METHODS: Medical records from 82 inpatient and ED records were abstracted for stigmatizing language and used to create a single, hypothetical clinical case. Medical students and residents (internal medicine and emergency

medicine) were then asked to complete an online survey which randomized them to 1 of 2 physician chart notes, one with the stigmatizing language and one without. The notes presented medically-identical information about the same hypothetical patient, a 28 y/o man with sickle cell disease in a vaso-occlusive crisis. For example, the stigmatizing note described that Mr. R was hanging out with friends outside McDonald's and that Mr. R reported some "stressful situations" in his life. The neutral note stated that Mr. R spent yesterday afternoon with friends and reported recent stress. We assessed attitudes towards the hypothetical patient using the previously-validated Positive Attitudes towards Sickle Cell Patients Scale (range 5–35) and pain management decisions (residents only) using two multiple-choice questions (composite range 1–7 representing intensity of pain treatment). We used t-tests and Wilcoxon rank-sum tests to calculate differences in attitudes and treatment based on study arm assignment.

RESULTS: Respondents included 233 medical students and 180 residents (overall response rate 58%). About half (55%) identified as male. About half (54%) identified as white, 27% as Asian, 14% as Hispanic/Latino, and 10% as African-American. There were no differences between study arms in gender, race/ethnicity or year of training. Medical students and residents who reviewed the stigmatizing-language note had more negative attitudes towards the patient (20.6 stigmatizing vs. 25.6 neutral, $p < 0.001$). Further, residents exposed to the stigmatizing vs. neutral language note made less aggressive pain management decisions (5.56 stigmatizing vs. 6.22 neutral, $p = 0.003$).

CONCLUSIONS: Stigmatizing language written by one provider in a patient's medical record can negatively impact subsequent providers' attitudes towards the patient and influences clinical decision-making. Future work should explore which dimensions of stigmatizing language are most harmful. Attention to the language used in medical records may promote patient-centered care and reduce healthcare disparities for stigmatized populations.

DOES WISDOM PROTECT AGAINST DEPERSONALIZATON AMONG MEDICAL STUDENTS?

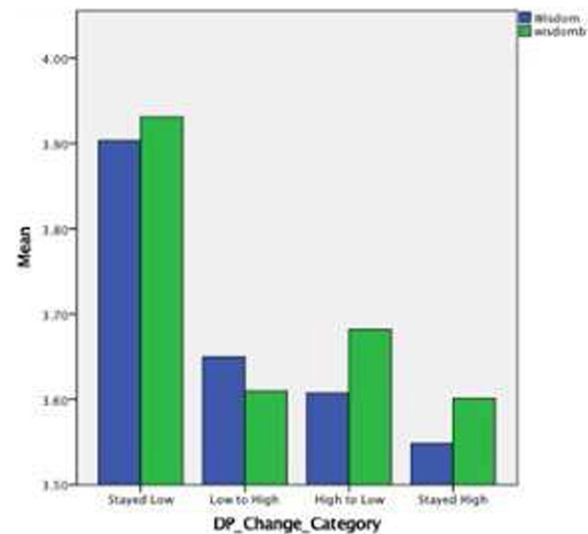
John Schorling; Margaret L. Plews-Ogan; Rachel Kon; Tabor Flickinger; Justine E. Owens. University of Virginia, Charlottesville, VA. (Control ID #2701545)

BACKGROUND: Burnout among medical students is an important issue, especially the development of depersonalization which has been associated with loss of empathy and unprofessional behavior. Wisdom has also received recent attention. Branch suggests "wisdom is what we should be striving for in our development as clinicians". Ardelt describes wisdom as: understanding deeper meanings, knowing limits of knowledge, tolerating ambiguity, engaging in reflection, having compassion and being other-centered. In cross-sectional analyses, we found that medical students high in wisdom had lower burnout scores. The purpose of this study was to evaluate whether students who score higher in wisdom are less likely to develop depersonalization over time.

METHODS: All students at one medical school were sent annual online surveys during the 2014–5 and 2015–6 years that included Ardelt's 3-Dimensional Wisdom Scale (3D-WS) and the Maslach Burnout Inventory. Scores of 10 or greater for depersonalization (DP) were considered high. ANOVA was used to compare mean scores on the 3D-WS by high and low DP status.

RESULTS: The survey was sent twice to 473 students. 143 (30%) had paired data from the 3D-WS and MBI for both years. The mean age was 25. 52% were female. Students were classified as those who never had high DP ($n = 76$), had low DP in the first year of the study but became high in the second ($n = 20$), had high DP in the first year but became low in the second ($n = 18$), or had high DP both years (n-29). Students who ever met criteria for high DP had similar mean wisdom scores (3.6), which did not vary significantly by year but which were significantly lower than those who never had high DP (3.9, $p < .001$).

CONCLUSIONS: Students who never met criteria for high depersonalization had significantly higher wisdom scores than the scores of those who ever had high depersonalization. This suggests that having high wisdom as measured by the 3D-WS might be protective with regard to developing depersonalization in medical school.



Association between wisdom scores and high and low DP. The first set of columns had low DP both years, the second went from low to high, the third from high to low, and the fourth were high both years.

DON'T CLICK IT, REDUCE THE STICK IT: A QUALITY IMPROVEMENT INITIATIVE TO REDUCE DAILY INPATIENT LABORATORY DRAWS

Clark A. Veet[1]; Orighomisan Pessu[2]; Gregory M. Bump[3]. [1]UPMC, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA. (Control ID #2695261)

BACKGROUND: It is accepted that diagnostic testing is over-used in stable hospitalized medicine patients, including the use of daily labs such as complete blood counts and electrolyte monitoring. The Society for Hospital Medicine recommends eliminating this process in stable patients without new symptoms. This project focused on assessing patient understanding and preferences regarding daily labs. It also desired to obtain baseline daily laboratory data and devise a model to reduce unnecessary phlebotomy to improve patient satisfaction and reduce unnecessary testing.

METHODS: This initiative had two parts. Part one identified patient understanding and preference regarding daily labs via a four question survey. Part two quantified the baseline lab ordering habits before and after educational intervention which included presentations to housestaff and attendings. The rates of lab draws were compared using a t-test.

RESULTS: Part one identified patient preferences and attitudes regarding daily inpatient lab draws. 79 inpatients completed a four question survey focusing on expected and desired frequency of daily lab draws. 21% of

respondants felt doctors ordered too many labs and only 45% of respondants expected daily labs. Part two measured the number of daily lab draws on an inpatient housestaff medicine service. A total of 2839 patient-days were analyzed on 7 medicine teams over the course of two months. At baseline, 75.7% of patients had CBCs, 78.9% had BMPs, and between 23 and 46% had Ca, Mg, and PO4. After intervention, 76.3% of patients had CBCs, 76.9% had BMPs, and between 23 and 49% had Ca, Mg, and PO4. There was no statistically significant difference between these groups.

CONCLUSIONS: This inpatient quality improvement initiative aimed to understand patient perspectives on daily labs and measure change associated with educational intervention on daily lab rates. Part one provided meaningful data regarding patient preferences and showed that patients do not necessarily expect “daily labs” as part of the hospital experience and do not equate it with optimal care. While other institutions have implemented similar projects with reductions in daily lab rates, we saw no significant difference after intervention due to many factors. On the individual level, junior housestaff are often responsible for order entry and may be uncomfortable without labs due to diagnostic uncertainty. Other factors include expectations from senior team members. Ineffective signout to covering team members may also create issue, as a patient without labs ordered may be perceived as an error. Interventions at other institutions have showed that a multi-disciplinary approach is needed to reduce daily labs. These include provider and nursing education as well as cultural shifts. Interventions to limit the number of days ordered on CPOE may be helpful, though it is met with pushback from generalists and specialists alike. At this institution, the project continues with additional interventions being implemented.

EARLY IMPACTS OF THE ACA ON OUT-OF-POCKET AND INSURANCE PREMIUM SPENDING Anna Goldman[2]; Stephanie Woolhandler[1]; David Himmelstein[1]; David Bor[2]; Danny McCormick[2]. [1]CUNY School of Public Health, New York, NY; [2]Harvard Medical School/ Cambridge Health Alliance, Cambridge, MA. (Control ID #2700865)

BACKGROUND: The Patient Protection and Affordable Care Act (ACA) has reduced the number of Americans who report being unable to afford care, but critics have cited exchange plans’ high premiums and deductibles. We examined changes in out-of-pocket (OOP) and household premium spending following implementation of the ACA’s coverage expansions on January 1, 2014.

METHODS: We analyzed data from the Medical Expenditure Panel Survey (MEPS) on non-elderly adults’ (age 18–64) OOP spending and premium contributions (for families that paid any private insurance premiums) prior to (2008–2013) and after the implementation of the ACA (2014), the most recent year of available data. We examined spending by persons in four groups based on family income: Poor (0–138% of the federal poverty level (FPL) - the eligibility threshold for Medicaid in most states); Lower income (139–250% of FPL - eligible for subsidized premiums and reduced cost-sharing on ACA exchanges); Middle income (251–400% of the FPL - eligible only for premium subsidies); and Higher income (>400% of FPL). We used linear regression models to estimate pre- to post-ACA changes in mean annual OOP spending and premium contributions, controlling for secular trends in the pre-ACA period. We used logistic regression to determine whether implementation of the ACA was associated with a reduction in the odds of health spending exceeding commonly used thresholds of affordability: Household OOP spending exceeding 10% of income (5% was also examined for the poor and near-poor); and family premium spending exceeding 9.5% of family income (the threshold defined by the ACA). Analyses employed weights to generate national estimates, and spending figures were adjusted to 2014 dollars using the consumer price index.

RESULTS: The 2008–2014 MEPS included 137,833 non-elderly adults. ACA implementation was associated with a significant $97.68 (SE, 38.75, $p = 0.01$) decrease in OOP spending for the lower income group, but not for others. We found no post-ACA change in the odds of household OOP spending exceeding >10% of family income for any income group; however, using the 5% threshold, the odds declined for lower income families (OR 0.81 [95% CI, 0.66–0.98]; $p = 0.03$). Mean premium contributions did not change post-ACA for any income group, although the odds of premium costs exceeding 9.5% of family income fell for the poor (OR 0.72 [95% CI 0.52–0.98]; $p = 0.04$). The rate of high-burden premium spending (>9.5% of family income) was 12 times higher in the poor income group compared to the wealthiest in the pre-ACA period (64.8% vs. 5.3%) and 11 times higher in the post-ACA period (58.7% vs. 5.2%).

CONCLUSIONS: In the first year after the law was implemented, the health spending burden on most families was unaffected by the ACA, and remained quite high. This has likely contributed to mixed political support for the law. Reforms that minimize OOP and premium spending among non-wealthy households might enjoy a more positive reception from the American public.

ECHOES OF BURNOUT IN INTERNAL MEDICINE RESIDENT NARRATIVE ESSAYS Emily Gordon. Rutgers New Jersey Medical School, Newark, NJ. (Control ID #2705234)

BACKGROUND: Burnout is a prevalent problem faced by general internists. It starts in medical school, continues through residency, and is a commonly cited cause for drop out among attending physicians. Narrative medicine is a practice that addresses the need to share experiences and challenges by way of telling stories. Introducing residents to narrative medicine could be a framework to identify and mitigate burnout, as well as cultivate resilience among trainees.

METHODS: From 2014–2015, all New Jersey Medical School Internal Medicine residents participated in a narrative medicine workshop. The workshop began with a sample reading of a narrative medicine piece by the course leader. The residents were then asked to submit a brief narrative essay on a memorable patient experience. Informed consent was requested from all participants to analyze their de-identified writing samples for common themes. Each sample was examined by the principal investigator for signs of burnout, as defined by the American Academy of Family Physicians Position Paper on Physician Burnout. We then calculated the frequency that such sentiments were expressed within and across writing samples.

RESULTS: Forty-three residents were asked to participate, and 39 consented to inclusion of their essays in this analysis. Of those, 13 (33%) contained statements concerning for burnout. Some examples were: “I realize from watching patients die that I have not enjoyed my life enough.” “I wake up crying. I’m exhausted and angry. A friend implores me to take the day off but I’m fearful of how I will be perceived at work.” “…hardened, impersonal, emotionless, well-oiled machines. This is the way a good doctor is supposed to be.”

CONCLUSIONS: Narrative medicine can be a powerful tool for identifying signs of burnout among Internal Medicine residents. In addition, sharing of

patient stories in groups can help trainees to reflect the commonality of challenging patient experiences, which might mitigate feelings of burnout. As one resident stated in her essay: “These reflections remind us of how often we do form strong, meaningful connections with our patients.”

EFFECT OF A SOCIAL INCENTIVE-BASED GAMIFICATION INTERVENTION USING WEARABLE DEVICES AND SMARTPHONES ON PHYSICAL ACTIVITY: THE BE FIT RANDOMIZED CLINICAL TRIAL

Mitesh Patel[1, 2]; Emelia J. Benjamin[3, 4]; Kevin G. Volpp[1, 2]; Caroline Fox[4]; Dylan Small[1]; Joseph Massaro[3, 4]; Jane Lee[4]; Victoria Hilbert[1]; Maureen Valentino[4]; Devon Taylor[1]; Emily Manders[3, 4]; Karen Mutalik[3, 4]; Jingsan Zhu[1]; Wenli Wang[1]; Joanne Murabito[3, 4]. [1]University of Pennsylvania, Philadelphia, PA; [2]Crescenz VA Medical Center, Philadelphia, PA; [3]Boston University, Boston, MA; [4]Framingham Heart Study, Boston, MA. (Control ID #2700003)

BACKGROUND: Social networks have been demonstrated to influence individual health behaviors, but interventions that leverage social incentives within these networks to change health behaviors have not been well examined. The objective of this study was to test the effectiveness of a gamification intervention that used insights from behavioral economics to enhance social incentives to increase physical activity in the community.

METHODS: The Behavioral Economics Framingham Incentive Trial (BE FIT) was a randomized clinical trial that recruited 206 adults comprising 97 groups of two or three family members in the Framingham Heart Study and occurred between December 2015 and August 2016. Participants used a wearable device or smartphone application to establish a baseline step count and selected a step goal increase for a 12-week primary intervention period and a 12-week follow-up period. Participants in both the control and intervention arms received daily feedback on their performance for 24 weeks. During the first 12 weeks, participants in the intervention arm played a game (including points, levels, and lifelines) with their family members that was designed using insights from behavioral economics to enhance social incentives such as peer support, accountability, and collaboration. The primary outcome was mean proportion of participant-days the step goal was achieved during the primary intervention period. Secondary outcomes included mean proportion of participant-days the step goal was achieved during the follow-up period and mean daily steps during the intervention and follow-up periods.

RESULTS: During the 12-week intervention period, participants in the intervention arm achieved physical activity goals on a significantly greater proportion of participant-days (Mean, 0.53 vs. 0.32; adjusted difference, 0.27 [95% CI, 0.20–0.33]; $P < .001$) and had signficantly greater increase in daily steps compared to baseline (Mean, 1661 vs. 636; adjusted difference, 953 [95% CI, 505–1401]; $P < .001$). During the 12-week follow-up period, participants in the intervention arm achieved physical activity goals on a significantly greater proportion of participant-days (Mean: 0.44 vs. 0.33, adjusted difference: 0.12 [95% CI, 0.05–0.19]; $P < .001$) and had a significantly greater increase in daily steps compared to baseline (Mean, 1385 vs. 798; adjusted difference, 494 [95% CI, 170–818]; $P < .01$).

CONCLUSIONS: Among groups of family members in the community, a social incentive-based gamification intervention was effective at increasing physical activity during the 12-week intervention. After the intervention completed, differences were smaller but sustained through the 12-week follow-up period. To our knowledge, this is one of the first clinical trials to demonstrate how gamification and social incentives can be used to change health behaviors in the community.

EFFECT OF DIRECT-TO-CONSUMER ADVERTISING (DTCA) ON STATIN USE IN THE UNITED STATES

Hsien-Yen Chang[1]; Irene Murimi[1]; Matthew Daubresse[1]; Dima Qato[2]; Sherry Emery[2]; G. Caleb Alexander[1]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]University of Illinois at Chicago, Chicago, IL. (Control ID #2705658)

BACKGROUND: The value of direct-to-consumer advertising (DTCA) of prescription drugs is widely debated, as is the effect of DTCA on prescription sales and health care utilization. We examined the association between DTCA intensity for statin medications and prescription sales and cholesterol-related health care utilization.

METHODS: We conducted an ecological study for 75 designated market areas (DMAs) from 2005 to 2009 in the United States using linked data regarding: (1) televised DTCA volume for rosuvastatin (Crestor™) and atorvastatin (Lipitor™) derived from Nielsen television ratings; (2) non-DTCA marketing and promotion derived from IMS Health Integrated Promotion Services; (3) retail, mail order and long-term care prescription drug sales derived from IMS Health Xponent; (4) prescription drug and ambulatory care health care utilization derived from Truven MarketScan; and (5) contextual factors such as health care density and socioeconomic status derived from the Area Resource File. We derived information for each month at each DMA and used multi-level negative binomial regression to account for nesting of individuals within DMAs.Main outcomes and measures were: (1) Volume of total, new and refilled prescription sales for the advertised statins; (2) number of statin prescriptions dispensed to commercially insured individuals; and (3) high cholesterol-related outpatient visits among the commercially insured.

RESULTS: The average intensity of rosuvastatin and atorvastatin ad exposures per household varied substantially across DMAs. After adjustment for socioeconomic, demographic and clinical characteristics, each 100-unit increase in advertisement viewership was associated with a 2.22% (95% confidence interval [CI] 0.30 to 4.19%) increase in rosuvastatin and atorvastatin sales. Similar patterns were observed between DTCA and statin dispensing among the commercially insured. DTCA was associated with increases in high cholesterol-related outpatient visits among adults 18–45 years of age (3.15% increase in visits per 100-unit increase in viewership, 95% CI: 0.98 to 5.37%) but not among those 46–65 years of age (0.51%, 95% CI: −1.49 to 2.55%).

CONCLUSIONS: DTCA for statins is associated with increases in statin utilization and hyperlipidemia-related outpatient visits, especially for young adults.

EFFECT OF HEALTH PLAN FINANCIAL INCENTIVE OFFERING ON EMPLOYEES WITH PREDIABETES

Anita D. Misra-Hebert; Bo Hu; Phuc H. Le; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Control ID #2705493)

BACKGROUND: Prediabetes, defined as a glycosylated hemoglobin(HbA1c) level between 5.7–6.4% or a fasting glucose level between 100–125 mg/dl, may be improved or reversed with lifestyle interventions including diet, exercise, and weight loss or may progress to diabetes.

Worksite wellness programs that offer financial incentives for participation in wellness activities or disease management may be effective in improving the health of employees with prediabetes at a population level. We studied the effect of offered employee health plan financial incentives on outcomes for employees with prediabetes.

METHODS: We conducted a retrospective cohort study using electronic medical record data. Exposures included fixed health plan financial incentives offered starting in 2009 through 2010, and then a premium discount starting in 2011 tied to program participation and achievement of goals. A total of 1115 employees identified with prediabetes from 2008–12 were matched per year, based upon when prediabetes was diagnosed, to 5705 non-employee patients with commercial insurance using propensity matching with baseline HbA1c, age, race(African American, White, Other), gender, and body mass index (<=25, 25.1–29.9, 30–35, and >35) included as covariates. We created longitudinal linear mixed models using the data for all employees and non-employees from the time that prediabetes was diagnosed to assess yearly changes in HbA1c, weight, and low density lipoprotein cholesterol (LDL).

RESULTS: Pooled analyses from 2010–12 beginning with the second year of the incentive program showed that the yearly change in HbA1c was greater for employees than for matched non-employees (−0.10% vs. −0.07%, respectively; p for difference in change = 0.002)). Pooled analyses for weight change and LDL cholesterol from 2010–12 showed that employees lost more weight than matched non-employees (−2.35 lbs vs. −0.02 lbs, respectively; p for difference in change = <0.001) and decreased LDL more than matched non-employees (−3.76 vs. −1.25, respectively; p for difference in change = 0.04).

CONCLUSIONS: A worksite wellness program offering employee health plan financial incentives for participation in wellness activities or disease management was associated with small improvements in HbA1c, weight, and LDL in employees with prediabetes at a population level. Longitudinal benefits may be greater than we observed over 3 years.

EFFECT OF NORMS ON LABORATORY AND IMAGING TESTING (ENLITEN): RANDOMIZED CONTROLLED TRIAL Kira L. Ryskina[1, 1]; Constance J. Dine[1, 1]; Yevgeniy Gitelman[1]; Damien Leri[1]; Mitesh Patel[2, 1]; Gregory Kurtzman[1]; Lisa Y. Lin[1]; Andrew Epstein[1, 1]. [1]University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania, New York, NY. (Control ID #2697527)

BACKGROUND: Normative feedback is an increasingly popular strategy to modify physician behavior that uses performance report cards. Little is known about the effect of normative feedback on the practice of cost-effective care by physicians-in-training (residents). Our objective was to test the effect of such feedback on the ordering of laboratory tests by internal medicine residents.

METHODS: This was a single-blinded randomized controlled trial (clinicaltrials.gov #NCT02330289). Between January and June 2016, 198 resident-blocks on six general medicine teams at the Hospital of the University of Pennsylvania were cluster randomized with equal allocation to two arms: (1) those emailed a summary of their routine lab ordering (e.g. complete blood count, metabolic panel, liver function, and common coagulation tests) vs. the service average, link to a continuously updated personalized dashboard containing patient-level details, and snapshot of the dashboard; and (2) those who did not receive the intervention. The email, timed to arrive in the middle of each resident's 2-week service to allow for baseline and follow-up periods, was followed by a reminder email. Our primary outcome was the count of routine lab orders placed by a resident per patient-day. Secondary outcomes included counts of imaging tests and non-routine lab orders. Outcomes were analyzed using an intent-to-treat approach. Weekend days were excluded. We modeled the count of orders per doctor-patient-day during the 2nd week of each resident's service-block (post-intervention) as a function of trial arm and the resident's order count in the 1st week (pre-intervention). The outcome was modeled using negative binomial models with adjustment for clustering within teams.

RESULTS: 114 unique residents participated (63 PGY1s and 51 higher-level residents), representing 833 resident-days. The mean count of labs per doctor-patient-day in the baseline period was 1.30 (SD 1.77) for the intervention group and 1.41 (SD 2.12) for controls ($p = 0.27$). We did not observe a statistically significant difference in routine lab ordering between residents who received normative feedback vs. those who did not; except for day 3 after the intervention, when orders were lower in the intervention arm by 0.44 labs per doctor-patient-day compared to controls (95% CI: 0.02, 0.85, $p = 0.04$). After stratifying the intervention cohort into residents who opened the summary email (74%) and those who did not (26%), we found that the change in ordering was concentrated among those residents who assessed the email. We did not observe a spillover effect to non-targeted orders.

CONCLUSIONS: A personalized dashboard reporting lab orders did not change targeted behavior among internal medicine residents, although there was a small decrease in orders among residents who accessed the information. Efforts to increase the physicians' uptake of normative feedback during training may improve the effectiveness of normative feedback interventions to optimize physician behaviors.

EFFECTIVENESS OF A PEER NAVIGATION INTERVENTION TO MAINTAIN VIRAL SUPPRESSION AMONG HIV+ MEN AND TRANSGENDER WOMEN RELEASED FROM A LARGE MUNICIPAL JAIL: RESULTS OF A RANDOMIZED CONTROLLED TRIAL William E. Cunningham[1, 1]; Terry Nakazono[1]; Mark Malek[1, 2]; Steve Shoptaw[1, 1]; Robert Weiss[1]; Susan Ettner[1, 1]; Nina Harawa[1, 1]. [1]University of California, Los Angeles, Los Angeles, CA; [2]Los Angeles County Sheriff's Department, Los Angeles, CA. (Control ID #2702734)

BACKGROUND: There are 1.2 million people living with HIV (PLH) in the US with 56,000 new infections annually. HIV diagnosis, linkage to and retention in care, and adherence to antiretroviral therapy (ART) are steps in the HIV care continuum (HCC) that enable consistent viral suppression (VS), extend longevity and prevent further transmission. Criminal justice-involved populations (CJI) are important to engage in the HCC as about one in seven PLH pass through correctional facilities each year. While incarcerated, PLH receive ART and achieve VS more consistently than after release, yet no published interventions have shown sustained VS post-release. To address this gap, we conducted a randomized controlled trial of a peer navigation (PN) intervention.

METHODS: From December 2012 through June 2016 we enrolled and followed PLH being released from Los Angeles County (LAC) jail. Eligible participants were: 1. Age 18+ years; 2. Men or transgender women with documented HIV diagnoses; 3. English- or bilingual Spanish-speaking; and 4. LAC residents. At baseline, we interviewed, measured viral load (VL), and randomized PLH 1:1 to the 12-session PN intervention or usual care (UC) control. We trained lay peer navigators (PNs) to act as role models who could

"walk PLH through" HCC steps. PNs assessed barriers, unmet basic needs and facilitators, and counseled on goal setting and problem solving during the first session held in jail. Post release, PNs continued counseling while they accompanied PLH to two HIV care visits, then facilitated communication with providers during the visits. The primary outcome was VS at 12 months. We used repeated measures logistic random intercept analysis to model VS outcomes over time.

RESULTS: Intervention ($n = 180$) and control ($n = 176$) arms were comparable; the sample was mostly black (42%) and Latino (31%), of low socioeconomic status, and uninsured (56%). Half (51%) had detectable VL at baseline. Study retention was high: 89% at 3 months, 80% at 6 months, and 70% at 12 months and did not differ by arm. Main findings are shown in Table 1: the adjusted probability of VS was 19% greater in the PN arm than the control arm ($p < 0.01$) at 12 months.

CONCLUSIONS: Although VS did not increase significantly from baseline to follow-up, the PN intervention was successful at preventing the declines in VS typically seen after release from incarceration. The intervention maintained VS over 12 months compared to the declines observed in the controls. While our PN intervention is likely to help PLH maintain VS after release from other large municipal jails, future research should examine ways to strengthen the intervention so that VS levels are increased above baseline levels.

Table 1. LINK LA: Adjusted probabilities (95%CI) of undetectable HIV viral load (VL)

Study Arm	Baseline	3 Months	12 Months
PN Intervention ($n = 180$)	0.49 (0.39, 0.59)	0.53 (0.42, 0.63)	0.49 (0.37, 0.61)
UC Controls ($n = 176$)	0.52 (0.42, 0.62)	0.37 (0.27, 0.47)*	0.30 (0.21, 0.42)**

*$p <= .05$; **$p <= 0.01$

EFFECTIVENESS OF INTERVENTIONS TO IMPROVE THE TRANSITION FROM PEDIATRIC TO ADULT-ORIENTED CARE: A SYSTEMATIC REVIEW OF SYSTEMATIC REVIEWS

Laura Hart; Sonya Patel-Nguyen; Daniel Jonas. University of North Carolina Chapel Hill, Chapel Hill, NC. (Control ID #2705475)

BACKGROUND: Because studies have shown worsening of outcomes during the transition from pediatric to adult-oriented care, increasing emphasis has been placed on improving this transition for adolescents and young adults with chronic illness. Steps in the transition process for internists include ensuring a smooth transfer to adult-care and maintaining access to care for young adults after transfer. Multiple interventions to improve transition have been studied, and systematic reviews evaluating those interventions have been conducted, though these often focused on a particular disease or a particular set of outcomes. Summarizing the available systematic reviews will serve as one means to understand the transition intervention literature more broadly. Thus, we sought to assess the effectiveness of interventions designed to improve the transition from pediatric to adult-oriented care by performing a systematic review to identify and describe published systematic reviews on the topic.

METHODS: We searched PubMed, Cochrane, PsycInfo, and CINAHL to identify relevant systematic reviews. Two authors reviewed all unique abstracts resulting from our searches, and using pre-specified inclusion and exclusion criteria, determined which articles did not meet study criteria. The remaining abstracts underwent full text review by two authors, resulting in the final set of articles for inclusion in the review. We summarized the included articles qualitatively and evaluated their quality using AMSTAR (A MeaSurement Tool to Assess systematic Reviews) criteria.

RESULTS: The searches resulted in 347 unique abstracts. Of those, 9 systematic reviews were found to meet all inclusion criteria. The included systematic reviews found 48 unique studies assessing interventions to improve transitional care. Only 2 of the 48 studies were RCTs. Most studies used a pre-post design or a historical control group for comparison. Studies used a variety of outcomes, including patient satisfaction with the process, clinic attendance, and disease-specific parameters, like HbA1C. None of the reviews found studies addressing transition in the primary care setting, and only 6 addressed interventions in adult-oriented settings, while the rest were set in pediatric clinics ($n = 12$) or combined pediatric and adult settings ($n = 30$). The included systematic reviews had scores of 4–8 using AMSTAR criteria, suggesting fair to good quality.

CONCLUSIONS: We found that very few RCTs have been conducted to address the effectiveness of interventions to improve transition from pediatric to adult-oriented care. Importantly, we found no studies to address transition in primary care settings and most studies in this area were conducted in pediatric or combined settings. RCTs or other comparative studies are needed to determine best practices for transition. More studies are needed assessing transition interventions in adult-oriented care settings. Studies addressing transition in primary care settings are also needed.

EFFECTIVENESS OF OPIOID THERAPY VERSUS NON-OPIOID MEDICATION THERAPY FOR CHRONIC BACK AND OSTEOARTHRITIS PAIN OVER 12 MONTHS: A PRAGMATIC RANDOMIZED TRIAL

Erin E. Krebs[3, 4]; Siamak Noorbaloochi[3, 4]; Matthew J. Bair[2, 1]; Amy Gravely[3]; Agnes C. Jensen[3]; Kurt Kroenke[1, 2]. [1]Indiana University, Indianapolis, IN; [2]Roudebush VA, Indianapolis, IN; [3]Minneapolis VA Health Care System, Minneapolis, MN; [4]University of Minnesota, Minneapolis, MN. (Control ID #2693271)

BACKGROUND: Chronic back pain and osteoarthritis (OA) pain are among the most prevalent and disabling conditions in primary care. Although these conditions are often treated with opioids, no randomized trials have evaluated effectiveness of long-term opioid therapy. The objective of the Strategies for Prescribing Analgesics Comparative Effectiveness (SPACE) trial was to compare benefits and harms of opioid therapy versus non-opioid medication therapy over 12 months.

METHODS: SPACE is a 12-month single-masked pragmatic randomized trial. Eligible patients were seen in VA primary care for moderate-severe chronic back pain or hip/knee OA pain despite analgesic use. Participants were randomized to 1 of 2 active treatment arms—opioid therapy or non-opioid medication therapy—using a computer to conceal allocation. Multiple FDA-approved drugs were included in each arm. Within each arm, medications were adjusted to target pain and functional goals. Masked assessors collected outcomes at 3, 6, 9, and 12 months. Primary and secondary pain outcomes were pain-related function (Brief Pain Inventory Interference; BPI-I) and pain intensity (BPI Severity; BPI-S), respectively. The primary harm outcome was an adverse symptom count. Individual pain response was 30% improvement from 0 to 12 months. Analysis was intent-to-treat. Primary comparisons of means used mixed models controlling for baseline values. Response rate comparisons used chi-squares.

RESULTS: Of 240 randomized participants, 97.5% ($n = 117$ in each arm) completed 12-month outcomes. Mean age was 57.8 years (range 21–80), 87.9% were male, 85.5% were white, and primary pain location was back in 65 and knee/hip in 35%. At baseline, mean BPI-I and BPI-S scores were 5.4 (SD 1.8) and 5.4 (1.5) in the opioid arm and 5.6 (2.0) and 5.4 (1.2) in the non-opioid arm. Over 12 months, pain-related function improved in both arms; mean 12-month BPI-I scores did not differ (3.4 opioids vs. 3.2 non-opioids; $p = 0.584$). The proportion with pain-related function response was 59.0% for opioids and 60.1% for non-opioids ($p = 0.789$). Pain intensity improved more in the non-opioid arm, with 0.47 points (95% CI: 0.909, 0.035) greater reduction in mean BPI-S score over 12 months; mean 12-month BPI-S was 4.0 opioids vs. 3.5 non-opioids ($p = 0.034$). The proportion with pain intensity response was 41.0% for opioids and 53.9% for non-opioids ($p = 0.049$). The adverse symptom count did not differ between arms at 12 months (mean 6.9 opioids vs. 6.7 non-opioids, $p = 0.682$).
CONCLUSIONS: In this pragmatic trial designed to be maximally applicable to primary care treatment decision-making, long-term pain outcome data showed no significant advantage of opioid therapy compared with non-opioid medication therapy. In the context of prior studies that have documented higher rates of serious harms among patients receiving opioid therapy, our findings support the recent CDC recommendation that non-opioid therapies are preferred over opioids for chronic pain.

EFFECTS OF DISCONTINUING LONG-TERM OPIOID THERAPY IN PATIENTS WITH CHRONIC PAIN Jawad M. Husain[1, 2]; Marc Larochelle[1, 2]; Julia Keosaian[1, 3]; Olivia Gamble[1, 3]; Ziming Xuan[1, 3]; Karen E. Lasser[1, 2]; Jane M. Liebschutz[1, 2]. [1]Boston Medical Center, Boston, MA; [2]Boston University School of Medicine, Boston, MA; [3]Boston University School of Public Health, Boston, MA. (Control ID #2700245)

BACKGROUND: Opioid prescribing guidelines for chronic pain recommend discontinuing opioid therapy if the risk-benefit ratio becomes unfavorable. However, reasons for discontinuing opioids and effects of discontinuation are largely unknown. Providers express concern for losing patients to follow-up, resulting in untreated pain or addiction and opioid-seeking from alternate sources.
METHODS: The Transforming Opioid Prescribing in Primary Care (TOPCARE) study is a cluster-randomized controlled trial to improve opioid prescribing among patients on chronic opioid therapy for non-cancer pain. We analyzed data from an urban safety-net hospital primary care practice participating in the trial. Primary care providers (PCPs) randomized to the intervention were supported by a nurse care manger, electronic registry, academic detailing, and electronic tools; control PCPs received electronic tools only. We conducted a retrospective chart review of patients in both study arms whose PCPs discontinued opioids by the final 60 days of the 12 month intervention period, as noted in the electronic health record (EHR). Key outcomes from the EHR audit include: reason for discontinuation; ≥1 PCP visit and ≥1 pain-related emergency department (ED) visit within 6 months after discontinuation. We dichotomized discontinuation reasons as misuse/aberrant monitoring or other, which included pain resolved, inadequate analgesia, and adverse effects. We used chi-square tests to compare the frequency and reason for discontinuation between intervention and control patients. We used unadjusted logistic regression to determine if study arm or reason for discontinuation was associated with PCP follow-up or pain-related ED visits.
RESULTS: Intervention patients discontinued opioids more frequently (60/331 [18%]) compared with control patients (28/233 [12%]; $p = 0.049$). Misuse/aberrant monitoring was the most common reason for discontinuation, and was more frequent among intervention (41/60 [68%]) vs. control patients (13/28 [46%]; $p = 0.049$). Similar proportions of patients discontinued due to other reasons in both trial arms. In the 6 months following opioid discontinuation, 70% of the patients returned for ≥1 PCP visit and 17% had a pain-related ED visit. Intervention patients were less likely to have PCP follow-up after discontinuation (odds ratio [OR] 0.3; 95% CI 0.1–0.9), and more likely to have pain-related ED visits (OR 8.2; 95% CI 1.0–66.0) than control patients. Discontinuation due to misuse/aberrant monitoring was not associated with PCP follow-up (OR 0.8; 95% CI 0.3–2.0) or pain-related ED visits (OR 1.9; 95% CI 0.6–6.6).
CONCLUSIONS: The TOPCARE intervention led to higher rates of opioid discontinuation attributable to misuse or aberrant monitoring. However, intervention patients discontinued from opioids were less likely to return for follow-up and more likely to seek care in the ED for pain. Future research should evaluate strategies to manage pain and keep patients engaged in care after opioid discontinuation.

EFFECTS OF HEALTH LITERACY, PATIENT ACTIVATION, AND COGNITION ON HEALTH OUTCOMES OF OLDER ADULTS Marina Arvanitis; Rachel O'Conor; Julia Yoshino Benavente; Laura M. Curtis; Michael S. Wolf. Northwestern University, Chicago, IL. (Control ID #2707612)

BACKGROUND: Limited health literacy (HL) has been repeatedly linked to poor health outcomes, yet interventions to address HL-associated disparities have been variable or ineffective. To address this, some have proposed expanding HL to include factors such as patient activation. We aimed to assess the degree to which patient activation and cognition may explain associations between HL and common intermediate health outcomes in older adults.
METHODS: We analyzed baseline data from Health Literacy and Cognition in Older Adults (LitCog): a prospective study of 900 adults, ages 55–74 from participating health centers in Chicago. During structured interviews, participants completed assessments of HL (Test of Functional HL in Adults (TOFHLA), Newest Vital Sign (NVS), Rapid Estimate of Adult Literacy (REALM)), patient activation (Patient Activation Measure (PAM)), and cognition (fluid cognitive abilities). We assessed participants' diabetes (DM) control by Hemoglobin A1c (HbA1c), blood pressure (BP) control by average systolic and diastolic pressures, and renal function by estimated glomerular filtration rate (eGFR) measurements from the medical record. We used bivariate statistics to describe participant characteristics, HL, activation, and cognition, and assess the relationships between these factors and health outcomes. We used a series of logistic regression models to examine the effects of patient activation and cognition, both individually and together, on the relationship between HL and each health outcome.
RESULTS: Nine hundred participants completed baseline interviews; their mean age was 63, 63% were female, and 71% were high school or college graduates. HL was limited in 32% by TOFHLA, 54% by NVS, and 28% by REALM. Most (84%) were highly activated per PAM, which did not vary by HL. Of participants with DM ($n = 166$), 35% had poor DM control (HbA1c >7%). Of all participants with available data, 6% had poor BP control (>140/>90), and 27% had renal dysfunction (eGFR <60). Limited HL by NVS and TOFHLA was significantly

associated with all poor health outcomes. Using the TOFHLA, we found that the associations between limited HL, poor DM control, poor BP control, and renal dysfunction were largely explained by cognition, which attenuated the odds of poor DM control by 54% (OR 2.8 (95% CI 1.4,5.5) to 1.3 (0.3,3.3)), poor BP control by 24%, and poor renal function by 19%. The inclusion of patient activation did not affect the associations between HL and health outcomes, nor the attenuation of these associations by cognition. We completed the same analyses for HL by NVS and REALM, with similar findings.
CONCLUSIONS: Despite its growing links to health outcomes, patient activation does not appear to influence the associations between limited HL and poor health outcomes in older adults, which are largely explained by cognition. Interventions aimed at reducing HL-associated disparities in the elderly should focus on reducing the cognitive burdens placed on patients by the health care system.

EFFECTS OF THE AFFORDABLE CARE ACT'S MEDICAID EXPANSION ON ACCESS TO CARE BY RACE AND ETHNICITY

John P. Shelley; Emily Levitan; Favel Mondesir; April Agne; Wilson Smith; Maria Pisu; Yufeng Li; Meredith Kilgore; Janet Bronstein; Andrea Cherrington. University of Alabama at Birmingham, Birmingham, AL. (Control ID #2697548)

BACKGROUND: Racial disparities in access to care have been well documented. The Affordable Care Act has the potential to mitigate these disparities with Medicaid expansion having the greatest prospect due to disproportionately high levels of poverty in minority populations. The expansion has been shown to increase access, but few have focused on disparities and none have focused on comparisons between changes by state expansion status. Our analysis tests the hypotheses that (1) access has improved for all groups regardless of race, ethnicity or expansion status and that (2) greater improvements occurred among minorities and in expansion states.
METHODS: We pooled cross-sectional data from the 2011–2015 Behavioral Risk Factor Surveillance System. Our sample includes adults ages 18–64 identifying as either white, black, or Hispanic of any race, further stratifying the Hispanic population by questionnaire language to capture heterogeneity. The expansion group ($n = 668{,}064$) included 24 states and the District of Columbia and the non-expansion group ($n = 615{,}863$) included 21 states; states expanding in 2014 or 2015 were excluded. Respondents interviewed in 2011–2013 and 2014–2015 were coded as pre- and post-implementation, respectively. Outcome variables were change in proportion of respondents having health insurance, a personal physician, not delaying care in the past year, and high-need respondents (reporting fair/poor health or a chronic condition) having a routine check-up in the past year. Difference-in-difference analyses were unadjusted to measure changes in observed disparities.
RESULTS: Access to care increased significantly for nearly all subgroups, regardless of race or expansion status, but were generally larger in minority groups. Expansion was associated with significantly greater increases in proportion of respondents insured in the white (+1.1%, $p < 0.001$), black (+0.9%, $p < 0.001$), and English-preferring Hispanic (+2.5%, $p < 0.001$) populations. Conversely, the change for insured Spanish-preferring Hispanics was significantly lower in expansion states (−2.1%, $p = 0.047$). Expansion was also associated with significantly greater increases in having a personal physician in the white (+0.7%, $p = 0.049$), black (+2.5%, $p = 0.005$), and English-preferring Hispanic populations (+3.3%, $p = 0.009$). Increases in respondents without cost-related care delays were only higher in expansion states for white respondents (+0.5%, $p < 0.001$). Increases in high need respondents with a check-up were also higher in expansion states but only significantly so for white respondents (+1.8%, $p < 0.001$). All other differences between states by status were not significant.
CONCLUSIONS: As a whole, the Affordable Care Act has improved access to care among all racial and ethnic groups with greater improvements in minority populations. Improvements in access associated with expansion were larger for some populations suggesting that expanding Medicaid can be an important step for improving access overall and moving towards equity.

EFFICACY AND SAFETY OF CANAGLIFLOZIN IN PATIENTS WITH TYPE 2 DIABETES BASED ON HISTORY OF CARDIOVASCULAR DISEASE OR CARDIOVASCULAR RISK FACTORS

Michael J. Davies[1]; Katherine Merton[1]; Ujjwala Vijapurkar[2]; Maurice Cuffee[1]; Jacqueline Yee[2]; Rong Qiu[2]. [1]Janssen Scientific Affairs, LLC, Titusville, NJ; [2]Janssen Research & Development, LLC, Raritan, NJ. (Control ID #2698864)

BACKGROUND: Treatment of patients with type 2 diabetes mellitus (T2DM) and a history of cardiovascular (CV) disease or CV risk factors may present clinical challenges due to the presence of comorbid conditions and use of concomitant medications. Canagliflozin (CANA), a sodium glucose co-transporter 2 (SGLT2) inhibitor, has been shown to improve glycemic control, body weight, and blood pressure (BP) with a favorable tolerability profile in a broad range of patients with T2DM. This post hoc analysis assessed the efficacy and safety of CANA in patients with T2DM based on CV disease history/risk factors.
METHODS: These analyses were based on pooled data from four 26-week, placebo (PBO)-controlled, Phase 3 studies of CANA 100 and 300 mg in patients with T2DM ($N = 2313$; mean A1C, 8.0%; body weight, 89 kg; systolic BP [SBP], 128 mmHg). Changes from baseline in A1C, body weight, and SBP at Week 26 were assessed in subgroups of patients based on history of CV disease (Y/N), history of hypertension (Y/N), baseline statin use (Y/N), and number of CV risk factors (0/1 vs ≥2). Safety was based on adverse event (AE) reports.
RESULTS: CANA 100 and 300 mg lowered A1C, body weight, and SBP versus PBO in patients across subgroups. At Week 26, A1C reductions with CANA 100 and 300 mg relative to PBO were generally similar in patients with history of CV disease (−0.95 and −1.07%) versus no CV disease (−0.71 and −0.90%), history of hypertension (−0.72 and −0.89%) versus no hypertension (−0.73 and −0.95%), baseline statin use (−0.77 and −0.99%) versus no statin use (−0.69 and −0.85%), and ≥2 CV risk factors (−0.74 and −1.02%) versus 0/1 CV risk factor (−0.72 and −0.87%). Similar body weight and SBP reductions were also seen with CANA versus PBO across subgroups. Incidence of AEs, AEs leading to discontinuation, and serious AEs was similar across subgroups.
CONCLUSIONS: CANA was efficacious and generally well tolerated in patients with T2DM regardless of CV disease history/risk factors.

EFFICACY OF MULTI-LINGUAL MOBILE APPLICATIONS TO PROMOTE PATIENT-PROVIDER COMMUNICATION AMONG ASIAN AMERICANS

Judith M. Walsh[1]; Janice Y. Tsoh[1]; L. E. Goldman[2]; mandana khalili[2]; Ginny gildengorin[1]; Tung T. Nguyen[1]. [1]UCSF, San Francisco, CA; [2]Zuckerberg San Francisco General Hospital, San Francisco, CA. (Control ID #2699407)

BACKGROUND: Asian Americans (AA) are the fastest growing racial group in the U.S. and are high users of technology; few studies have evaluated the impact of mobile technology on health outcomes.

METHODS: Using patient-centered methods, we developed 2 mobile applications (app) for the iPad in English, Cantonese, Mandarin, and Vietnamese. One app addressed hepatitis B and C (HEP), the other addressed healthy Nutrition, Physical Activity and weight (NPA). Primary care providers (PCP) and their patients were randomized to either HEP or NPA. Eligible patients were AA age 18 and older who spoke one of the 4 languages, had not had HEP B screening as per USPSTF recommendations, and who received primary care at UCSF or ZSFG. Patients used the app prior to a PCP visit. The app included questions leading to audio-visual messages delivered by doctors to address the patient's response. A printout summarizing the patient's concerns and recommendations was generated for the provider. Data were collected via survey prior to the use of the app and immediately after the visit. General linear models adjusted for provider clusters were used to compare the 2 arms on participants' perceived helpfulness of the intervention, self-report of patient-provider discussions of health topics during the visit, and provider's recommendations of HEP screening tests.

RESULTS: The sample included 362 AA (41% ZSFG and 59% UCSF) with a mean age of 58.4 years (range: 18–93), 63% females, 59% married, 33% with high school or less education, and 39% currently employed. The majority (81%) were born outside of the U.S. including 33% from China, 24% from the Philippines and 7% from Vietnam; 39% were limited English proficient. A majority (76%) had heard of HEP B; 53% had heard of HEP C. 220 participants (of 60 PCPs) were assigned to HEP and 142 (of 48 PCPs), to NPA. A majority (85%) completed the entire video and 55% reported giving the printout to their provider at the visit. Participants in both groups liked the app they used (81%), perceived it as "somewhat" or "very" helpful (80.5%), and thought it helped them to talk with their PCP about their health (85.5%). Compared to NPA, higher proportions of participants in the HEP group reported having had a discussion with their PCP about HEP B (73% vs. 21%, $p < 0.001$) or HEP C (66% vs. 17%, $p < 0.001$). Compared to HEP, NPA participants were more likely to report a PCP discussion on nutrition (56% vs. 34%, $p < 0.001$), physical activity (60% vs. 42%, $p < 0.01$), and weight (56% vs. 31%, $p < 0.002$). HEP participants were more likely than the NPA participants to report that their provider recommended testing for HEP B (57% vs 17%, $p < 0.001$) or HEP C (42% vs. 13%, $p < 0.001$).

CONCLUSIONS: Patient-centered multi-lingual mobile applications for health promotion were well received by AA in two healthcare settings and led to more patient-provider discussion. Further research is needed to assess the impact of the mobile applications on behavior and health outcomes.

EFFICACY VERSUS EFFECTIVENESS OF DIABETIC MEDICATIONS Anish Vani; Keith Goldfeld; Michael Cantor. NYU School of Medicine, New York, NY. (Control ID #2672008)

BACKGROUND: Diabetic medications are approved by the Food and Drug Administration (FDA) based on efficacy in controlled clinical settings. Real world effectiveness may often vary from the results of clinical trials. We attempted to quantify the "efficacy versus effectiveness" gap at our institution.

METHODS: We performed a retrospective analysis of all patients prescribed oral diabetic medications at New York University Langone Medical Center, a large urban tertiary care center, using data extracted from our electronic health record from October 2009 to September 2014. We limited the dataset to include newly diagnosed diabetic patients who were started on monotherapy or a combination pill. We excluded patients who were prescribed insulin or multiple diabetic agents. We used two-tailed Welch's t-tests to compare the initial Hemoglobin A1c (HbA1c), final HbA1c, and total HbA1c reduction to clinical trial data used for FDA approval, with statistical significance defined as $p < 0.05$.

RESULTS: Among the 566 of the 2452 patients who met our inclusion criteria, the mean age was 62.9 +/− 12.2 years, the majority of whom were male (51.1%), white (61.1%), non-Hispanic (80.4%), and prescribed metformin monotherapy (70.3%). The mean treatment time for each drug class ranged from 32–39 weeks. The mean initial HbA1c for all groups was 8.95%, the mean final HbA1c was 7.44%, and the mean HbA1c reduction was 0.51%. For almost all drug classes, the initial HbA1c was lower than the initial HbA1c from efficacy trials. For most drug classes, effectiveness was about half of the expected value from efficacy trials. Most patients achieved their goal HbA1c levels [Table].

CONCLUSIONS: In our study population, real world effectiveness did not reflect measures of efficacy from controlled clinical settings. The results highlight the need for clinicians to realize that a medication may not perform as well as it does in a controlled setting and they may need to increase the intensity of treatment more quickly than expected. Also, replicating the results of clinical trials in an actual clinical setting is challenging, both from the perspective of data availability and clinical practice patterns.

Medication	Population	Initial HbA1c (%) 95% CI	p	Final HbA1c (%) 95% CI	p	Change HbA1c (%) 95% CI	p

NYU versus FDA Clinical Trial HbA1c Levels

EHR-BASED MEDICATION SUPPORT AND NURSE-LED MEDICATION THERAPY MANAGEMENT: THE NORTHWESTERN AND ACCESS COMMUNITY HEALTH NETWORK MEDICATION EDUCATION STUDY (NAMES) RANDOMIZED CONTROLLED TRIAL Stephen Persell[2]; Danielle Lazar[3]; Elisha Friesema[4]; Kunal N. Karmali[2]; Ji Young Lee[1, 2]; Alfred Rademaker[1]; Michael S. Wolf[1, 2]. [1]Northwestern University, Chicago, IL; [2]Northwestern University, Evanston, IL; [3]Access Community Health Network, Chicago, IL; [4]University of Minnesota, Minneapolis, MN. (Control ID #2701908)

BACKGROUND: Nurse-led medication management in primary care may improve medication use. Electronic health record (EHR) tools may offer low-cost approaches to support medication management.

METHODS: We performed a three-arm 12-clinic-level cluster-randomized trail in a Chicago area network of federally qualified community health centers that compared: usual care, EHR-based medication management tools alone (printed medication lists to prompt review at each visit and automated plain-language information after the visit), and EHR tools plus nurse-led medication management support (one-on-one counseling about medication regimens to clarify discrepancies and identify medication-taking concerns plus follow-up telephone calls after new prescriptions to perform medication review). We recruited patients from randomized clinics who were ≥18 years of age with ≥3 prescribed medications and suboptimal blood pressure (≥130/80 mm Hg if diabetes or ≥135/85 mm Hg diastolic if not). Outcomes at 1 year included systolic blood pressure (primary outcome, using a standard protocol), blood pressure control (<140/90 mm Hg), basic understanding of medication indications, reconciliation between patient-report and the medical record, and self-reported 4-day adherence. Analyses of study arm effects used generalized linear models accounting for subjects' baseline outcome values (which sometimes differed by study arm) and clinic-level random effects.

RESULTS: 920 participants enrolled; 796 completed 1-year follow up. Of subjects completing follow up, mean age was 53 years, 69% were women, 87% were African American, 67% had high school education or less and 47% had limited health literacy. Subjects used a mean of 5.4 medications and 25% used 7 or more. At 1 year, systolic blood pressure was higher with EHR-tools only (+3.3 mm Hg [95% CI 0.2 to 6.5]) vs usual care and lowest in the EHR + nurse arm (−5.5 mm Hg [−3.1 to −7.8]) vs EHR-only, (−2.1 mm Hg [−5.4 to +1.1]) vs usual care. Compared to usual care, blood pressure control at 1 year was better in the EHR + nurse arm (odds ratio [OR] 1.21 [1.01-1.45]) but worse in the EHR-only arm (0.68 [0.58-0.78]). Understanding of indications was not changed with either intervention compared to usual care. Medication reconciliation substantially improved with both interventions, OR (95% CI) compared to usual care for antihypertensives, chronic disease medications, and all medications with EHR-tools only: 1.7 (1.2-2.4), 2.3 (1.3-4.2), and 4.6 (1.7-13), respectively and for EHR tools + nurse: 1.9 (1.4-2.7), 2.1 (1.2-3.5), 4.9 (1.6-15), but did not significantly differ between active intervention groups. Medication adherence was worse than usual care in the EHR-tools only arm for all chronic disease medications, OR 0.83 (0.71-0.98).

CONCLUSIONS: Both interventions improved medication reconciliation. Only nurse-led medication management plus EHR tools improved hypertension control. EHR tools only may have had unintended effects on blood pressure control.

ELECTRONIC LEARNING IN GRADUATE MEDICAL EDUCATION: A NATIONAL SURVEY OF RESIDENCY PROGRAM DIRECTORS Christopher M. Wittich[2]; Anoop Agrawal[1]; David A. Cook[2]; Andrew J. Halvorsen[2]; Jayawant N. Mandrekar[4]; Saima Chaudhry[3]; Denise Dupras[2]; Amy Oxentenko[2]; Thomas J. Beckman[2]. [1]Baylor College of Medicine, Houston, TX; [2]Mayo Clinic College of Medicine, Rochester, MN; [3]Memorial Healthcare System, Hollywood, FL; [4]Mayo Clinic, Rochester, MN. (Control ID #2706097)

BACKGROUND: E-learning - the use of computers, mobile devices, and internet to learn - is a prevalent instructional approach. However, little is known about the role of e-learning in residency education. Our goal was to determine utilization of e-learning by United States (U.S.) internal medicine residency programs, program director (PD) perceptions of e-learning, and associations between residency program characteristics and e-learning utilization.

METHODS: This was a national survey performed in collaboration with the Association of Program Directors in Internal Medicine of 368 internal medicine residency programs (92.9% of the 396 U.S. programs) in 2016. Program directors were asked about utilization, resources for implementation, and perceptions of e-learning. To assess representativeness of the programs sampled, characteristics of survey responders were compared with survey non-responders for 5 publicly-available variables using the Fisher exact test or Welch t-test, as appropriate. Associations between PD characteristics and PD perceptions of e-learning scores were assessed using a multiple analysis of variance (ANOVA) model. Multiple logistic regression was used to generate odds ratios (ORs) and test associations between program characteristics and the regular use of synchronous and asynchronous e-learning. For the continuous predictors of ACGME-approved positions, ABIM 3-year rolling pass rate, percentage of positions filled by international medical graduates, number of hospital beds, and mean PD perception of e-learning score, the adequacy of bivariate models assuming linearity of the log odds was checked using Hosmer-Lemeshow goodness-of-fit tests.

RESULTS: A total of 214 (58.2%) PDs completed the e-learning survey and 85 (39.7%) reported that they utilize synchronous e-learning at least sometimes, somewhat often, or very often. More programs (153, 71.5%) reported that they utilize asynchronous e-learning at least sometimes, somewhat often, or very often. Most programs ($N = 168$, 79%) did not have a budget to integrate e-learning into their educational curricula. Mean (SD) scores for the PD perceptions of e-learning ranged from 3.01 (0.94) to 3.86 (0.72) on a 5-point scale; the overall mean (SD) score was 3.45 (0.54). There was a higher odds of synchronous e-learning in programs that had a budget for implementation (OR, 3.0 [95% CI, 1.04–8.7]; $p = 0.04$).

CONCLUSIONS: U.S. residency programs could be better resourced to integrate e-learning technologies. Asynchronous e-learning was used more than synchronous, which may be a result of busy resident schedules and duty hour restrictions. Programs use locally and externally-developed e-learning resources with roughly similar frequency. PD perceptions of e-learning, while above the scale median, are only modest. Future work should determine why PDs are hesitant to integrate e-learning despite evidence of its effectiveness.

ELECTRONIC MEDICAL RECORD DOCUMENTATION HAS POOR AGREEMENT WITH PATIENT SURVEYS FOR RECEIPT OF INPATIENT TOBACCO CESSATION CARE. Ethan Kuperman[2, 3]; Jennifer Chapin[4]; David A. Katz[1]. [1]University of Iowa, Iowa City, IA; [2]University of Iowa Carver College of Medicine, Iowa City, IA; [3]Iowa City VA Medical Center, Iowa City, IA; [4]Iowa VA Medical Center, Iowa City, IA. (Control ID #2702062)

BACKGROUND: Joint Commission (TJC) created a set of ORYX quality measures to assess inpatient tobacco treatment, as care provided during and after admission may increase long term cessation. The objective of this study was to quantify the agreement between documented tobacco treatment in the electronic medical record (EMR) and patient-reported receipt of ORYX-concordant care in Veterans Administration (VA) inpatients.

METHODS: We retrospectively reviewed the EMR of daily smokers admitted to a general medical inpatient unit at 2 VA medical centers and were previously enrolled in a guideline implementation trial. Patients hospitalized for <

72 hours, significant cognitive impairment, or with terminal illness were excluded. Three measures were evaluated using TJC audit criteria: 1) TOB-1: Screened for tobacco use within 24 hours of admission. 2) TOB-2: Offered intensive cessation counseling AND pharmacotherapy during admission. 3) TOB-3: Offered cessation counseling AND pharmacotherapy at discharge. We compared the EMR audit data with the corresponding patient responses from a survey administered within 72 hours of discharge during the trial. Chart reviewers were blinded to survey data. Agreement between EMR audits and patient surveys was calculated using Cohen's κ.

RESULTS: Results: The analysis sample included 138 patients (mean age = 59, 97% male). Overall 7-day point-prevalence abstinence at 6-month follow-up was 26%. Over 90% of patients met TOB-1 for both EMR audit and patient survey, but κ was <0.01. No patient met TOB-2 on EMR review and only 25% passed by patient survey. For TOB-3, 14.6% passed on EMR audit and 13.0% passed on patient survey (κ = 0.25).

CONCLUSIONS: Conclusions: Performance on TJC tobacco cessation measures from the EMR did not correlate with patient-reported tobacco treatment. Changes in documentation templates and increasing staff awareness may improve correlation between metric performance and care delivery.

ELEVATED HBA1C IN UNITED STATES VETERANS AND RISK OF INCIDENT DIABETES AND ALL-CAUSE MORTALITY

Jordan Davis[5]; Mengling Liu[5, 1]; Farrokh Alemi[3]; Scott Sherman[1, 4]; Sundar Natarajan[1, 4]; Ashley Jensen[2]; Sanja Avramovic[3]; Esther Levy[5]; Richard B. Hayes[5, 1]; Mark D. Schwartz[1, 4]. [1]NYU School of Medicine, New York, NY; [2]University of Calgary, Calgary, AB, Canada; [3]George Mason University, Fairfax, VA; [4]Department of Veterans Affairs New York Harbor, New York, NY; [5]New York University, New York, NY. (Control ID #2704151)

BACKGROUND: United States Veterans are at excess risk for Type 2 diabetes and early mortality. Our objective is to determine the impact of prediabetes and related risk factors on the occurrence of diabetes and mortality in this at-risk population.

METHODS: At the primary care practices of the VA New York Harbor (VA NYHHS) during 2004–2014, we identified 15,173 diabetes-free Veterans, among those who received 2 or more hemoglobin A1c tests (HbA1c). Among these participants, we identified 14,361 veterans with HbA1c values below the diabetic range (i.e., <6.5% HbA1c) and characterized these individuals with respect to selected risk factors. We followed these individuals through 2014 for incident diabetes and all-cause mortality. Cox proportional hazard regression was used to relate HbA1c levels, age, sex, race/ethnicity, anthropometric measures, and comorbid cardiovascular conditions (ischemic heart disease, cerebral vascular accident, congestive heart failure and peripheral vascular disease) to incident diabetes and all-cause mortality (Hazard Ratio [HR] and 95% confidence intervals).

RESULTS: Among 8,145 Veterans with prediabetes (HbA1c 5.7–6.4%), 1,170 (14.4%) developed diabetes and 1,139 (14%) died during the course of follow-up. Compared to 5,292 normoglycemic Veterans (HbA1c: 5.0–5.6%), 4,207 prediabetics in the moderate risk group (HbA1c 5.7–5.9%) had a greater than 2-fold increased risk of incident diabetes (HR 2.46 [2.08–2.92]), and those 3,938 in the prediabetic high risk group (HbA1c 6.0–6.4%) had a greater than 5-fold risk (HR 5.70 [4.88–6.65]). Furthermore, all-cause mortality was increased in 924 participants with low glycemia (HbA1c <5.0%: HR 1.40 [1.17–1.68]) and among those 812 in the diabetes risk range (HbA1c ≥6.5%: HR 1.44 [1.22–1.71]) compared with the normoglycemic group. Excess all-cause mortality was not observed among the prediabetic group, compared to the normoglycemic group.

CONCLUSIONS: Among Veterans, prospective risk of transition to Type 2 diabetes ranged from 2.5-fold to 5.7-fold among prediabetics, depending on HbA1c level. Patients with HbA1c < 5.0 and those in the diabetic range had increased risks of all-cause mortality, while prediabetics showed no excess mortality. The higher risk population (HbA1c 6.0–6.4%) is an important group to target with diabetes prevention efforts.

ELUCIDATING MEDICAL TRAINEES' BARRIERS TO INCIDENT REPORTING

Jose R. Valery[2]; Fernando Stancampiano[1]. [1]Mayo Clinic, Jacksonville, FL; [2]Mayo Clinic Florida, Ponte Vedra, FL. (Control ID #2703654)

BACKGROUND: Incident reporting is an important tool used by hospitals to improve patient care by systemically eliminating errors. Although medical trainees are at the forefront of healthcare delivery their incident reporting is very low. The Department of Health and Human Services released a report noting that 86% of events are unreported [1]. As low as 6.2% of medical trainees complete an incident report [2]. The ACGME has recognized the importance of including patient safety in medical education and launched the Clinical Learning Environment Review (CLER) Program in 2012 to stimulate such initiatives. Elucidating reasons for medical trainees' reporting habits is essential in developing a successful educational intervention. In this study, we aim to refine existing knowledge on resident attitudes and behaviors pertaining to incident reporting. We hypothesize that non-technical aspects of incident reporting, such as concern about negative consequences or lack of faith in the effectiveness of the system, are significant in addition to technical barriers such as knowing how to report and having enough time to do so.

METHODS: Medical trainees' attitudes and behaviors regarding incident reporting were evaluated through an anonymous and voluntary REDCap survey distributed via email to 207 medical and surgical trainees at the Mayo Clinic in Jacksonville, FL, in June of 2016. The trainees had between 11 and 83 months of clinical experience.

RESULTS: 24.6% (51/207) of trainees responded to the survey after 3 distributions. 17.6% (9/51) of respondents were interns and 68.9% (35/51) were male. 25.4% (13/51) had previously filed a report and 49% (25/51) reported not knowing how to file a report. Fear of personal and colleague repercussions from filing a report were significant with 35.2% (18/51) and 39.2% (20/51) respectively. Only 7.8% (4/51) thought filing a report would not contribute to patient safety. 37% (19/51) indicated that time was a significant barrier to reporting.

CONCLUSIONS: Our study suggests that technical aspects of incident reporting are significant and seem to be consistent with recently published data. However, the significance of non-technical aspects as barriers was found to be higher in our trainee population than previously reported [3]. Further research is needed to confirm the relative significance of barriers to incident reporting among medical trainees. When compared with published studies, our results suggest a significant heterogeneity in known barriers across institutions. As the generalizability of results may be limited, each institution may benefit from a similar survey to elucidate specific barriers prior to developing an educational intervention.

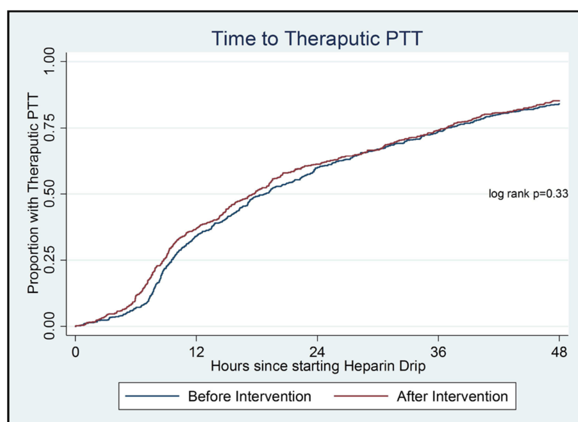
EMBEDDED DECISION SUPPORT DOES NOT LEAD TO RECOMMENDED HEPARIN DOSING Sarah W. Baron; William Southern. Montefiore, Bronx, NY. (Control ID #2704934)

BACKGROUND: Anticoagulation with heparin decreases recurrent thromboembolic events, but delays to therapeutic levels are associated with worse outcomes. In previous research using paper charting, a weight-based Heparin Nomogram improved time to therapeutic anticoagulation among hospitalized patients. However, it is unclear if the Heparin Nomogram remains effective in computerized patient order entry (CPOE) systems. We examined the effect of incorporating the Heparin Nomogram in a CPOE system on anticoagulation-related process measures among adult inpatients.

METHODS: We conducted a retrospective pre/post analysis of a validated decision-support tool, the Heparin Nomogram, by embedding it into the CPOE system of a large, academic, multi-hospital system in the Bronx, NY. Following implementation, all access to intravenous heparin orders displayed titration guidelines, weight and partial thromboplastin time (PTT) measurements. The primary outcome was time to therapeutic anticoagulation, defined as hours until PTT measurement between 46 and 70 s. Secondary outcomes were appropriateness of initial drip and initial bolus doses. All orders of intravenous heparin were examined for timing and dosing of drips and boluses, as well as PTT measurements. Time to therapeutic PTT was plotted using the Kaplan-Meier method. Differences between pre and post groups were tested using a log rank test. Percentages of each group receiving appropriate dosing were examined. Differences between groups were tested with chi-squared tests. Orders were analyzed three months prior to and three months following implementation.

RESULTS: A total of 1728 unique initial heparin orders were examined. Time to therapeutic PTT did not differ significantly between groups (Figure, $p = 0.33$). There were no significant differences in percent of patients receiving the appropriate initial drip dose (27% vs. 29%, $p = 0.50$), or bolus dose (7% vs. 8%, $p = 0.50$).

CONCLUSIONS: Embedding a Heparin Nomogram into the Computerized Patient Order Entry system did not significantly change time to therapeutic anticoagulation or initial heparin dosing. It remains unclear how best to use CPOE systems to support providers in dosing intravenous heparin for optimal anticoagulation among inpatients.



EMERGENCY PHYSICIAN OPIOID PRESCRIBING PATTERNS AND RISK OF LONG-TERM USE Michael L. Barnett[2]; Andrew Olenski[1]; Anupam B. Jena[1]. [1]Harvard Medical School, Boston, MA; [2]Harvard T.H. Chan School of Public Health, Boston, MA. (Control ID #2705830)

BACKGROUND: Rising rates of opioid prescribing and opioid-related overdose deaths have increasingly affected the elderly Medicare population, among whom hospitalization rates for opioid overdoses grew five-fold from 1993–2012. Growing opioid overuse may be partly driven by physician prescribing. However, the extent to which individual physicians vary in opioid prescribing and the implications of that variation for patients' long-term opioid use and adverse outcomes are unknown.

METHODS: We performed a retrospective analysis of Medicare beneficiaries with an index emergency department (ED) visit during 2008–2011 without opioid prescriptions in the 6 months prior. To address selection bias, we relied on the fact that patients are unlikely to choose their ED physician once they have chosen a facility. Assigning patients to emergency physicians within a hospital, we categorized physicians as high- or low-intensity opioid prescribers based on their relative quartiles of prescribing rates within the same hospital. We compared rates of long-term opioid use, defined as 6 months of days supplied, in the 12 months subsequent to an ED visit among patients treated by high- vs. low-intensity prescribers, adjusting for patient characteristics. We also assessed rates of hospital encounters (ED visits or admissions) for opioid-related complications in older adults such as falls/fractures.

RESULTS: Our sample contained 215,678 and 161,951 patients treated by low- and high-intensity prescribers, respectively. Patient characteristics, including ED diagnoses, were similar across both groups. Opioid prescribing rates varied widely within hospital between high and low-intensity prescribers (24.1% vs. 7.3%). Overall, long-term opioid use at 12 months was significantly higher among patients treated by high vs. low-intensity prescribers, 1.51% vs. 1.16% (unadjusted OR 1.31, 95% CI 1.24–1.39). After adjustment, this difference changed minimally (adjusted OR 1.30, 95% CI 1.23–1.37). Rates of hospital encounters for falls/fracture were significantly higher in the 12 months subsequent to an index ED visit for patients treated by high- vs. low-intensity opioid prescribers (4.56% vs. 4.28%; adjusted OR 1.07, 95% CI 1.03–1.11).

CONCLUSIONS: We found over three-fold variation in emergency physician opioid prescribing rates within the same hospital associated with increased rates of long-term opioid use and hospitalizations for falls/fractures among patients treated by high-intensity opioid prescribers. We reduced selection bias by taking advantage of quasi-randomization of patients to ED physicians within the same facility, supported by the minimal change in our results with adjustment. These results suggest that an increased likelihood of receiving an opioid for even one encounter could drive significant future long-term opioid use and potentially increased adverse outcomes among the elderly.

END-OF-VISIT PRACTICES TO ENSURE OUTPATIENT SAFETY: RESIDENT PHYSICIANS' PERFORMANCE IN USP CASES WITH OUTPATIENT SAFETY CHALLENGES Colleen Gillespie[1]; Lisa Altshuler[1]; Kathleen Hanley[1, 2]; Adina Kalet[1, 1]; Amanda Watsula-Morley[1, 1]; Heather Dumorne[1, 1]; Sondra Zabar[1, 1]. [1]NYU School of Medicine, New York, NY; [2]Gouverneur Healthcare Services, New York, NY. (Control ID #2705472)

BACKGROUND: Safe, high quality outpatient care often depends on the degree to which patients understand their situation and how to follow through

on physician recommendations. However, we do not know enough about how often physicians focus on ensuring that their patients have achieved these understandings by the end of the visit and whether such end-of-visit practices are associated with physicians' communication, patient education and activating skills.

METHODS: Two Unannounced Standardized Patient cases (highly trained actors who present as real patients) were delivered to 71 internal medicine residents in two clinics: one required the physician to identify a patient's depression and engage him in follow-up care, and the other required the physician to recognize a patient's failure to use her asthma medicine correctly and educate her in using it properly. End-of-visit practices were: reviewing the plan; asking if further questions; giving information about follow-up care and further contact; and helping the patient navigate the system in order to follow through on next steps. Each was assessed by the SP as not done, partly done, or well done. SPs also rated physicians' communication skills, patient activating skills, and case-specific education skills. Summary scores were calculated as % of items well done.

RESULTS: Close to three-quarters of the physicians reviewed the plan with the patient and invited further questions in the depression case and slightly more than half did so in the asthma case (56 and 60%). Patients were given complete information about follow-up care and how to navigate the system in just under half of depression visits (49 and 47%) and just over half of asthma visits (58 and 58%). On average, residents were rated as performing 61% of these 8 items well (SD 28%) across both cases. Primary care residents performed significantly better than categorical internal medicine residents (67% vs 47%, $p = .004$). There were no differences by physician gender. End of visit scores were significantly positively correlated with both general and case-specific clinical skills, and after controlling for the variance contributed by the program ($R^2 = 12\%$, $p = .004$), case-specific education scores explained 10% of the variance in end of visit score ($p = .005$), patient activating skills 10% of the variance ($p = .002$) and communication skills 13% of the variance ($p = .001$). With all variables in the model, only the general communication domain of patient education and counseling was independently associated with end of visit scores (Std Beta = .35, $p = .015$).

CONCLUSIONS: Had these patients been real patients, in one-quarter to one-half of the visits, the patient would have left not fully understanding the plan or how to follow-through on care. Resident physicians with more effective communication and patient activating skills tended to provide safer end-of-visit care, suggesting that these may reflect an outpatient safety orientation or skillset.

ENGAGEMENT IN AN INTERNET SUPPORT GROUP FOR MOOD AND ANXIETY DISORDERS IS ASSOCIATED WITH IMPROVED PSYCHIATRIC OUTCOMES Emily M. Rosenberger; Bea Herbeck Belnap; Kaleab Abebe; Scott D. Rothenberger; Bruce L. Rollman. University of Pittsburgh, Pittsburgh, PA. (Control ID #2687850)

BACKGROUND: Internet support groups (ISGs) are emerging as popular forums in which individuals with similar health conditions exchange resources and offer support by posting on online discussion boards, yet little is known about the role of engagement with an ISG on health outcomes. The Online Treatment for Mood and Anxiety Disorders Trial (OT Trial) evaluated the effect of computerized cognitive behavioral therapy (CCBT) plus access to a moderated ISG on clinical outcomes in primary care patients with mood and anxiety disorders delivered via a collaborative care model. Here, we examine whether differing levels of engagement in the OT Trial's ISG impacted mental health related quality of life (HRQoL) and psychiatric outcomes.

METHODS: The OT Trial randomized 704 patients referred by their PCPs from 26 primary care practices in southwestern Pennsylvania with PHQ-9 and/or GAD-7 scores ≥10 to receive either: CCBT + ISG access, CCBT, or usual care in a 3:3:1 randomization ratio. We classified engagement among the 302 CCBT + ISG arm patients according to the 1% Rule (van Mierlo, 2014), a model that describes participation in online forums. We then assigned patients to engagement groups based on number of posts made on the ISG during the 6-month intervention phase of the study. We used descriptive statistics to compare outcomes across engagement groups on the MOS SF-12 and PROMIS Anxiety and Mood short forms at 12 months after randomization.

RESULTS: CCBT + ISG patients had a mean age of 43 years, and 71% had both depression and anxiety as measured by the PRIME-MD. 75% logged in to the ISG at least once; of these, 63% made at least one post. Among patients who posted, the mean number of posts per patient was 10.5. Our sample had a broader distribution of posts than predicted by the 1% Rule: Superusers (top 1%; $n = 3$) made 40% of posts (mean ± SD, 210 ± 118), Top Contributors ($n = 30$) made 38% of posts (mean,17 ± 13), Sparse Contributors ($n = 110$) made 22% of posts (mean, 3 ± 2), and Observers ($n = 85$) logged in but never posted. At 12 months, all engagement groups showed improvements in HRQoL and depression and anxiety symptoms relative to baseline assessments. Top Contributors reported the largest improvements in HRQoL (mean $\Delta \pm$ SD, 16 ± 10) and anxiety symptoms (mean Δ, −12 ± 11), whereas Superusers reported the smallest improvement in HRQoL (mean Δ, 6 ± 8).

CONCLUSIONS: Differential engagement in a moderated ISG for mood and anxiety disorders is associated with varying levels of improvement in HRQoL and depression and anxiety symptoms. At 12 months of follow-up, Superusers, who were the most engaged with our ISG, reported the lowest levels of benefit, while Top Contributors, who engaged often but less than Superusers, reported the greatest benefit. While the motivations for very high levels of ISG engagement are still unclear, more work is needed to understand the minimum level and type of engagement necessary to yield benefits from participating in an ISG for mental health disorders. ENGAGING AFRICAN AMERICAN VETERANS WITH HEALTHCARE ACCESS CHALLENGES IN A COMMUNITY-PARTNERED CARE COORDINATION INITIATIVE: A QUALITATIVE NEEDS ASSESSMENT Adriana Izquierdo[5, 6]; Michael Ong[4, 6]; Felica U. Jones[7]; Loretta Jones[2]; David Ganz[3, 6]; Lisa V. Rubenstein[1]. [1]GLA VA, North Hills, CA; [2]Healthy African American Families, Los Angeles, CA; [3]RAND Corporation, Santa Monica, CA; [4]UCLA, Los Angeles, CA; [5]University of California Los Angeles, Los Angeles, CA; [6]VA Greater Los Angeles Healthcare System, Los Angeles, CA; [7]Healthy African American Families II, Los Angeles, CA. (Control ID #2683713)

BACKGROUND: Little has been written about engaging potentially eligible members of a health care system who are not accessing the care to which they are entitled. Knowing more about the experiences of African American Veterans who regularly experience healthcare access challenges may be an important step towards equitable, coordinated Veterans Health Administration (VA) care.

METHODS: We partnered with a community organization to recruit and engage Veterans from South Los Angeles in three exploratory engagement

workshops to understand better the experiences of African American Veterans at risk of experiencing poor care coordination. Veterans were asked to describe their VA and community care experiences. Field notes taken during the workshops were analyzed by community and academic partners using grounded theory methodology to identify emergent themes.

RESULTS: 23 Veterans participated in one or more engagement workshops. Their trust in VA was generally low. Negative themes included: functional barriers to accessing VA healthcare services; insensitive VA healthcare environment; lack of trust in the VA healthcare system; and Veteran status as disadvantageous for accessing non-VA community services. Positive themes included: Veterans have knowledge to share and want to help other Veterans; and connecting to VA services can result in positive experiences.

CONCLUSIONS: Veterans living in underserved areas who have had difficulty accessing VA care have unique perspectives on VA services. Partnering with trusted local community organizations to engage Veterans in their home communities is a promising strategy to inform efforts to improve care access and coordination for vulnerable Veterans.

EVALUATING GLYCEMIC CONTROL IN LOW-INCOME PATIENTS WITH TYPE 2 DIABETES Rosette J. Chakkalakal[3]; Richard O. White[1]; Jonathan Schildcrout[3]; Brooklyn Stanley[3]; Ken Wallston[4]; Russell L. Rothman[2]. [1]Mayo Clinic, Jacksonville, FL; [2]Vanderbilt, Nashville, TN; [3]Vanderbilt University, Nashville, TN; [4]Vanderbilt University, Pisgah Forest, NC. (Control ID #2707610)

BACKGROUND: Long-term maintenance of glycemic control is difficult to achieve for patients with type 2 diabetes (T2DM). Few studies have described predictors of deterioration in glycemic control among low-income patients with T2DM. Here we (1) assess change in hemoglobin A1C (HbA1C) after a period of sustained glycemic control among low-income patients with T2DM and (2) identify predictors of deterioration in glycemic control in this population.

METHODS: We conducted an exploratory subgroup analysis of data from the Partnering to Improve Diabetes Education (PRIDE) study, a cluster randomized controlled trial testing a program designed to address limited health literacy and numeracy and promote effective health communication in caring for patients with T2DM at state Department of Health clinics in middle Tennessee. English and Spanish-speaking patients with T2DM were eligible for the study if their most recent hemoglobin A1C (HbA1C) was greater than 7.5%. Participants were scheduled for routine T2DM follow-up visits every 3 months for 2 years. This subgroup analysis was restricted to PRIDE participants who, at any point during the study, were found to (1) improve their HbA1C by at least 0.7% between 2 consecutive study visits, (2) sustain this improvement for at least 2 consecutive study visits (defined as the monitoring period), and (3) attend at least 2 of their next 3 scheduled study visits (defined as the follow-up period). We fit a linear regression model (base model) to assess the a priori association of change in HbA1C during the follow-up period with (1) change in HbA1C from baseline to the monitoring period and (2) mean HbA1C during the monitoring period. We then tested the association of change in HbA1C during the follow-up period with the following characteristics by including them, in turn, as independent variables in the base model: gender, body mass index, income, race, ethnicity, English proficiency, health literacy, numeracy, medications, years diagnosed with T2DM, depressive symptoms, food security, perceived diabetes self-management, and receipt of care at a control or intervention site.

RESULTS: One hundred PRIDE participants met the inclusion criteria. The base model indicated that HbA1C of low-income patients with T2DM increases after a period of sustained glycemic control ($b_0 = 0.38$, SE = 0.14) but there was a significant inverse association between mean HbA1C during the monitoring period and change in HbA1C during the follow-up period (b = −0.32, SE 0.10, $p = 0.002$). The only other variables significantly associated with change in HbA1C during the follow-up period were English proficiency (b = 0.72, 95% CI 0.06-1.37, for patients who did not speak English very well) and treatment group (b = −0.74, 95% CI −1.29- -0.19, for patients receiving care at intervention sites).

CONCLUSIONS: Efforts to promote effective communication could play a key role in preventing deterioration in glycemic control among low-income patients with T2DM.

EVALUATING QUALITY OF DIABETIC CARE IN PATIENTS WITH SEVERE MENTAL ILLNESS (SMI) IN AN ACADEMIC PRIMARY CARE CLINIC Smita Y. Bakhai[1]; Rujuta Katkar[1]; Neal Shah[1]; Gregory D. Gudleski[2]. [1]SUNY at BUffalo, Williamsville, NY; [2]SUNY at Buffalo, Buffalo, NY. (Control ID #2690472)

BACKGROUND: Higher prevalence of type 2 Diabetes Mellitus and cardiovascular risk factors has been reported in patients with serious mental illness. SMI patients get suboptimal diabetes care when compared to non-SMI patients, resulting into higher morbidity and mortality. The primary objective of this study was to test the hypothesis that SMI patients get suboptimal diabetes care as compare to non- SMI patients in an academic Primary Care Clinic.

METHODS: Utilizing electronic medical records, we conducted a retrospective cohort study of 183 SMI and 185 non -SMI patients between June 1, 2013 and May 31, 2015 in a hospital based primary care clinic, consisted of 40 residents. SMI was defined as schizophrenia or bipolar disorder diagnosed by psychiatrist. Inclusion criteria included patients between age 18–75 years and diabetes patients who were managed by a primary care provider at the ECMC Primary Care Clinic for a minimum one year with at least two visits and two HbA1c levels drawn during the study period. Diabetes patients managed by endocrinologist were excluded. Variables of interest included; 1) National Committee for Quality Assurance (NCQA) diabetes recognition program (DRP) 2015 based outcome measures included HbA1c, Blood pressure, LDL, eye and foot exam, nephrology assessment and smoking status 2) Pharmacological therapy; ACE/ARB, oral anti-hyperglycemic agents and insulin 3) Health care utilization measures ;clinic visits attended and continuity of care with the same primary care provider 4) vaccinations included pneumonia, influenza and hepatitis B.

RESULTS: Results were analyzed using univariate (chi-square) and multivariate (logistic regression) models. Patients who were on insulin therapy were less likely to achieve HbA1c < 7 without any significant difference between SMI and non-SMI groups (12.5% vs 11.8%). However SMI patients who were not on insulin were more likely than non-SMI patients to achieve HbA1C < 7 (75.3% vs 63.2%, OR = 3.26, 95% CI: 2.05–5.19, $p < .001$). No significant between group difference was observed in remaining NCQA parameters of Nephropathy assessment ($p = .519$), Blood pressure ($p = .934$), Foot Exam ($p = .079$), Smoking Cessation treatment offered ($p = .107$) except for eye Exam (OR = 1.90, 95% CI: 1.08–3.34; $p = .027$). Pneumovax administration was significantly higher in SMI group (OR = 3.02, 95% CI: 1.58–5.56; $p = .001$) There was no significant difference in above parameters after adjusting for Antipsychotics use. There was no significant difference between the groups for number of clinic visits or continuity of primary care provided.

CONCLUSIONS: Improved control of diabetes and cardiovascular risk factors in SMI patients was found in our primary care clinic when compared with non SMI patients. Further studies assessing patients by living in a supervised group home facility status and measuring individualized HbA1c target as dynamic variable are needed for understanding these outcomes.

EVALUATING RISK OF MAJOR BLEEDING AND THROMBOEMBOLIC EVENTS FOR RIVAROXABAN VERSUS WARFARIN IN A REAL WORLD SETTING Giavanna Russo-Alvarez[2]; Kathryn A. Martinez[2]; Megan Valente[2]; James Bena[2]; Bo Hu[2]; Jennifer Luxenburg[2]; Andrei Brateanu[1]; Michael B. Rothberg[2]. [1]CCF, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH. (Control ID #2701591)

BACKGROUND: Randomized trials demonstrate the non-inferiority of rivaroxaban compared to warfarin for the prevention of stroke and venous thromboembolism (VTE) in atrial fibrillation (AF) and for the treatment of VTE and pulmonary embolism (PE). Yet doubts regarding validity of some original trial findings have surfaced. Studies examining the effectiveness and safety of these drugs in clinical practice are therefore critical. The objective of this study was to assess the relative effectiveness and safety of rivaroxaban versus warfarin in a large integrated health system.
METHODS: We conducted a retrospective cohort study in the Cleveland Clinic Health System (CCHS). Eligible individuals, identified via the electronic health record (EHR), included patients 18 years or older who initiated warfarin or rivaroxaban for treatment of VTE or non-valvular AF between January 2012 and March 2014. The primary measure of effectiveness was thromboembolic events, defined as DVT, PE, atrial thrombus, or ischemic stroke. The primary measure of safety was incidence of major bleeding events, defined as any clinically overt sign of hemorrhage that required an intervention to stop or treat bleeding and that led to hospitalization or increased level of care. Outcomes were first ascertained via the EHR and then confirmed through medical record review by two clinical pharmacists. Appropriateness of anticoagulant dosing was evaluated for each event that occurred while on therapy. Rivaroxaban and warfarin patients were propensity matched 1:1 based on demographic and health history measures from the EHR. Drug groups were then compared using Cox proportional hazards models. To evaluate whether the effectiveness and safety of the drugs varied by time in therapeutic range (TTR), the aforementioned analysis was then stratified at the median TTR of the warfarin patients.
RESULTS: The cohort consisted of 531 propensity-matched pairs. Mean age was 68.9 years (SD: 14.4), and 42% had private insurance. Eighty-two percent of patients were treated for AF and the mean $CHADS_2$ score was 1.94. Median TTR for warfarin patients was 51%. There were no significant differences in patient characteristics or indication for anticoagulation between the rivaroxaban and warfarin groups. Compared to warfarin, rivaroxaban was associated with significantly greater risk of thromboembolic events (HR:4.16, $p = 0.034$), but there was no significant difference in bleeding risk. Compared to warfarin patients with >51% TTR, rivaroxaban was associated with more major bleeding events ($p = 0.017$).
CONCLUSIONS: In clinical practice, warfarin was associated with fewer thromboembolic events and did not increase bleeding risk compared to rivaroxaban. While the risk of thromboembolic events was similar, rivaroxaban was associated with more major bleeding than warfarin among patients with a high TTR. For patients who are able to maintain a high TTR, warfarin appears safer than rivaroxaban and no less effective.

EVALUATING THE AGREEMENT BETWEEN SELF-REPORTED AND DOCUMENTED ANALGESIC USE IN OLDER VETERANS WITH OSTEOARTHRITIS Alexander Domanski[2, 3]; Matthew J. Bair[1, 5]; Ruth Balk[4]; Cynthia Brandt[6]; Abraham A. Brody[3]; Rachel Dismore[5]; Vera Gaetano[6]; Melissa Garrido[3]; Dorian Gittleman[3]; Robert Kerns[6]; Erin E. Krebs[4]; Erin Linden[4]; R. S. Morrison[3]; Diana Natividad[5]; Joan Penrod[3]; Anthony Rinaldi[6]; Lee Stefanis[3]; Daniel Sun[3]; Ula Hwang[3, 2]. [1]Center for Health Information and Communication, Indianapolis, IN; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]James J. Peters VAMC, New York, NY; [4]Minneapolis VAMC, Minneapolis, MN; [5]Richard L. Roudebush VAMC, Indianapolis, IN; [6]VA Connecticut Health System, West Haven, CT. (Control ID #2673143)

BACKGROUND: Studies using prescription claims data demonstrate higher rates of adverse events with opioids compared to NSAIDs for treating pain in older adults. The validity of these results, however, relies on reimbursement data as an indicator of analgesic exposure, despite evidence of the contrary. We compared health record documented prescriptions versus self-reported analgesic use in older veterans to evaluate administrative data as a proxy for analgesic exposure.
METHODS: This was a cross-sectional study of the first 14 months of data (3/2015-5/2016) collected in an ongoing prospective telephone survey of veterans from 4 VA hospitals ≥50 years of age with ≥2 inpatient or outpatient diagnoses of knee or hip arthritis. Subjects were analgesic-free (based on prescription records) for ≥180 days prior to starting a new analgesic (opioid, NSAID, other [e.g. acetaminophen]) or control (filling a non-analgesic prescription) and surveyed ≤30 days of prescription filling. Comparisons were calculated between self-reported analgesic lists (ref.) and health record analgesic prescriptions filled using k coefficients, sensitivity, and specificity for analgesic classes. This study received CIRB approval.
RESULTS: 595 subjects were recruited. Mean age was 66y (±8.9y), 93% were male. Agreement between self-reported analgesics versus health record analgesic prescriptions over 30 days was fair (k = 0.26). This varied by drug class: opioids (k = 0.56), NSAIDs (k = 0.41), other (k = 0.37). Sensitivity was higher for opioids (0.71) than NSAIDs (0.57) or other (0.39), while specificity across drug classes was similar (0.89, 0.84, 0.93 respectively).
CONCLUSIONS: Discordance exists between health record versus self-reported analgesic use in older veterans. Caution should be exercised when interpreting pharmacoepidemiological safety studies that use administrative health record data to measure analgesic exposure.

EVALUATING THE EFFECTIVENESS OF A HEALTHY FOOD SHOPPING TOUR IN LOW-INCOME AFRICAN-AMERICAN NEIGHBORHOODS IN CHICAGO Ashley K. Haddad; Adam H. Lewis; Nyahne Q. Bergeron; Daniel J. Rowell; Kathryn E. Gunter; Yolanda O'Neal; Sandra Ham; Marshall Chin; Monica E. Peek. University of Chicago, Chicago, IL. (Control ID #2705597)

BACKGROUND: Diet-related chronic diseases cause significant morbidity and mortality, and are disproportionately prevalent amongst African-Americans. Disparities in diet-related chronic diseases are complex, with multiple contributors including individual preferences, social relationships, and the built environment. Nutrition education has the potential to address these disparities if tailored to an individual's specific behavioral, social, and environmental context.

METHODS: We evaluated the effectiveness of a 1-hour, in-store, group nutrition education tour (led by dieticians and diabetes educators) in 4 low-income, predominantly African-American neighborhoods in Chicago. We used a mixed-method approach to evaluation. We qualitatively analyzed 2 focus groups ($n = 25$) using a framework approach. Sessions were transcribed verbatim and analyzed using ATLAS.ti software. We also quantitatively analyzed pre/post food knowledge surveys ($n = 104$) using chi-squared, t-tests, and longitudinal regression modeling, and analyzed food purchase receipts ($n = 99$) using Wilcoxon ranked sign tests. We are obtaining grocery store control data to compare food purchases made by non-tour participants.
RESULTS: A majority of surveyed participants were female (80%) and African-American (95%).The mean age was 58.4 years, and 36% of participants ($n = 37$) attended more than one tour. Focus group participants noted barriers to healthy eating including the influence of family ("It's difficult for me when I go to my sister's house…she's an old-fashioned cook") and an unhealthy food environment ("sugar is in everything!"). Motivators for tour participation included knowledge gained ("It's not about $10… it's about the information that we get and how we can use it to better ourselves"), support from other participants ("The important thing about this tour is that all of us are in the same boat"), and the interactive learning environment ("Me, I'm a literal person so…being in the store and actually seeing the product you understand more"). Participants demonstrated improved knowledge after a single tour (6.1 vs 5.8 of 10 questions correct, $p = 0.18$); for those who participated in multiple tours, knowledge improvements were statistically significant (6.5 vs 5.5 correct questions, $p < 0.001$). Additionally, the number of tours that a participant attended was a significant predictor of knowledge gained ($\beta = 0.03$, $p < 0.001$). After the tour, 34% of participant food purchases were fruits or vegetables (vs. 19% nationally) with no difference between one-time and repeat participants (36% vs 28%, $p = 0.24$).
CONCLUSIONS: Our findings suggest that in-store group nutrition education tours in low-income, minority neighborhoods can improve participant knowledge regarding healthy eating and potentially increase the consumption of fruits and vegetables, compared to national averages. Additionally, it is important to consider behavioral, social, and environmental context when designing interventions to overcome barriers to healthy eating.

EVALUATING THE EFFECTIVENESS OF LUNG CANCER SCREENING IN PATIENTS WITH COPD Minal Kale; Bart Ferket; Juan Wisnivesky. Mount Sinai School of Medicine, New York, NY. (Control ID #2707373)

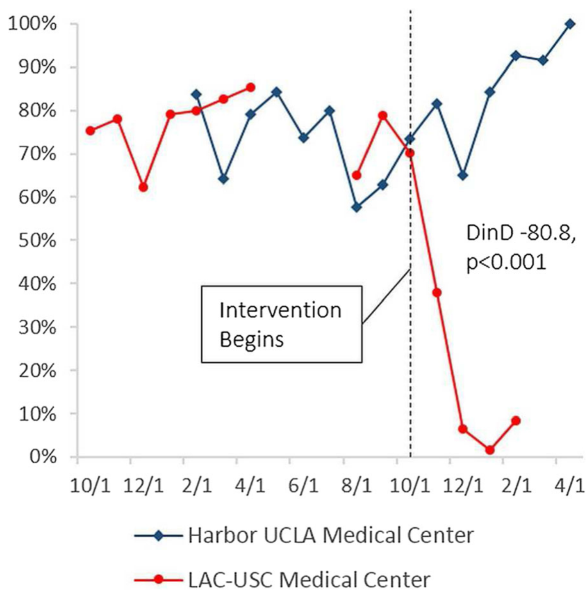
BACKGROUND: Chronic obstructive pulmonary disease (COPD) is a highly prevalent disease that shares a common risk factor, tobacco exposure, with lung cancer. Moreover, studies show that COPD is an independent risk factor for lung cancer and that lung cancer is a major cause of death in COPD patients. Thus, patients with COPD are important candidates for lung cancer screening. However, results from the National Lung Screening Trial (NLST) are difficult to generalize to this population due to differences in lung cancer risk, increased likelihood of complications from diagnostic work-up, and potential ineligibility of receiving full resection due to limited lung function. Thus, there is a need to assess the benefits and harms of lung cancer screening in this population.
METHODS: We created an individual level state transition model using decision analysis software that simulated the experience of individuals with all stages of COPD, undergoing lung cancer screening either with annual chest radiograph (CXR) or low dose computed tomography (LDCT) for 3 cycles with a 10-year time horizon. We estimated model parameters using a combination of published data and analysis of NLST data. The screening cohort was composed of data from the NLST cohort and consisted of individuals with spirometry findings consistent with COPD based on the American Thoracic Society and European Respiratory Society Task Force. Parameters regarding prevalence of cancer, screening performance (sensitivity and specificity) and diagnostic work-up derived from the NLST. Overall survival for individuals with lung cancer was estimated based on Surveillance, Epidemiology, and End Results data. Background mortality was based on United States 2011 life tables accounting for sex and stage of COPD. Model outcomes included difference in life expectancy with CXR vs. LDCT screening, overall survival, and complication rate.
RESULTS: We found that that lung cancer screening with LDCT in individuals with COPD leads to a mean increase in life expectancy within a 10-year time horizon of 0.65 months. We found a reduction in overall mortality at 10 years by 1% (29% vs 28%). We also found a lower rate of non-fatal complications; 172 in 4655 individuals screened with LDCT compared to 178 in those screened with CXR.
CONCLUSIONS: Our microsimulation model suggests that LDCT screening leads to a lengthening of life expectancy and reduction in overall mortality in individuals with COPD. We also found that LDCT screening was associated with non-fatal complications in individuals with COPD. Future simulation modeling is needed to characterize the effect of screening on lung cancer mortality, the benefit of screening across different stages of COPD, and the optimal screening criteria.

EVALUATION OF A CHOOSING WISELY™ INTERVENTION TO REDUCE LOW VALUE PREOPERATIVE CARE FOR PATIENTS UNDERGOING CATARACT SURGERY AT A SAFETY NET HEALTH SYSTEM John N. Mafi[1, 2]; Patricia Godoy-Travieso[3]; Eric Wei[3]; Jesse Berry[3]; Rudy Amaya[3]; Brandon Wong[4]; Carmen A. Carillo[5]; Laura Sarff[3]; Lauren P. Daskivich[6]; Sitaram Vangala[7]; Emmett Keeler[2]; Cheryl Damberg[2]; Catherine Sarkisian[5, 7]. [1]David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]RAND Corporation, Santa Monica, CA; [3]LAC + USC Medical Center, Los Angeles, CA; [4]LAC + USC, Los Angeles, CA; [5]University of California, Los Angeles, Los Angeles, CA; [6]Harbor-UCLA Medical Center, Los Angeles, CA; [7]UCLA and Greater Los Angeles VA, Los Angeles, CA. (Control ID #2699282)

BACKGROUND: Because pre-op testing for cataract surgery provides virtually no patient benefit, we evaluated an initiative to eliminate it.
METHODS: *Design*: pre-post quasi-experiment comparing pre-op cataract surgery care at LAC + USC Medical Center (intervention site) vs. Harbor-UCLA (control site). *Data*: administrative data to identify pts undergoing cataract surgery between 10/15/14-4/15/16. *Intervention*: a quality officer at LAC + USC 1) reviewed cataract surgery pts' charts, 2) presented data on overuse to anesthesia/ophthalmology chairs—gaining their support for the initiative, 3) recruited a resident champion and 4) empowered nurses to stop scheduling pre-op visits. On 9/30/15, the team emailed pre-op guidelines to physicians/trainees/staff, calling to eliminate routine pre-op testing for cataract surgery by 10/13/15. *Outcomes*: pre-op visits, labs, EKGs, and wait-time between cataract diagnosis and surgery. *Analysis*: difference-in-differences (DinD) comparing utilization between sites using logistic regression adjusting for pt characteristics.
RESULTS: We identified 1,009 intervention and 959 control pts undergoing cataract surgery during the study period. Baseline mean age/sex (61 yrs/53%

female) was similar between both groups. The proportion of pre-op visits, labs, and EKGs declined more for intervention than control pts; *intervention pts*: 77, 91, and 74% before the intervention vs. 20, 39 and 27% after the intervention respectively; *control pts*: 62, 40, and 66% before vs. 86, 72, and 86% after the intervention respectively (DinD −81%, $p < 0.001$, −83%, $p < 0.001$, −67%, $p < 0.001$ respectively). Median surgical wait-time declined more for intervention pts (245 days before vs. 64 days after the intervention) than for control pts (27 days before vs. 22 days after the intervention), DinD −176, $p < 0.001$.

CONCLUSIONS: This intervention substantially reduced low value pre-op care and surgical wait-times among pts undergoing cataract surgery.



Pre-Op Visits at LAC + USC (intervention) vs. Harbor-UCLA (control), 10/15/14-4/15/16

EVALUATION OF A COACHING BY TELEPHONE INTERVENTION FOR VETERANS AND CARE TEAM ENGAGEMENT (ACTIVATE)

Eugene Oddone[2, 3]; Laura Damschroder[1]; Jennifer Gierisch[2]; Maren Olsen[2]; Linda L. Sanders[2]; Angie Fagerlin[4]; Carrie L. May[2]; Jordan Sparks[1]; Felicia A. McCant[2]. [1]Ann Arbor VA Center for Clinical Management Research, Ann Arbor, MI; [2]Durham VA Medical Center, Durham, NC; [3]Duke Medicine, Durham, NC; [4]Salt Lake City VA Medical Center, Salt Lake City, UT. (Control ID #2702001)

BACKGROUND: A large proportion of deaths and many illnesses can be attributed to three modifiable risk factors: tobacco use, overweight/obesity, and physical inactivity. Health risk assessments (HRAs) help individuals define their risk. HRA's are widely available online, but have not been consistently employed in healthcare systems to as a tool to activate patients' participation in behaviorally-focused prevention programs. Health coaching is an emerging method for promoting behavior change that relies on theories of human development, social psychology, and adult learning. There is growing evidence that coaching can improve health outcomes by aligning patient preferences, values, and patient-determined goals with behavior change strategies. This study was designed to determine if a brief telephone coaching intervention, when coupled with results from an HRA, could activate patients to address their modifiable risk by enrolling in a prevention program.

METHODS: We conducted a 3 site randomized controlled trial among veterans ($n = 417$) enrolled in primary care. To be eligible, veterans must have had at least one modifiable risk factor: BMI >30, less than 150 min of physical activity per week, and/or current smoker. All veterans completed the Veteran Affairs Health System's web-based HRA. Controls ($n = 209$) were encouraged to share HRA results with their primary care provider. Intervention participants ($n = 208$) received two telephone calls from a trained health coach: one week, and four weeks after completing the HRA. Coaches worked with veterans to collaboratively set a specific and actionable goal about enrolling in, and attending a structured prevention program designed to reduce their modifiable risk. The co-primary outcomes were enrollment in a prevention program by 6 months, and change in behavioral activation as measured by Patient Activation Measure (PAM). Logistic regression was used to estimate the treatment difference in enrollment. General Linear Models with unstructured covariance and parameters of time and group × time interaction were used to estimate the treatment group difference in the PAM.

RESULTS: Most veterans were male (85%), white (50%), or African American (40%) with a mean age of 56. Veterans were eligible because their BMI was > 30 (80%), were physically inactive (50%), or current smokers (39%). 58% had more than one eligibility criteria. From baseline to 6 months, intervention participants reported higher rates of enrollment in a prevention program (51% vs 29%, $P < 0.0001$) and greater mean increase in PAM (4.8 vs 2.4, $p = 0.03$) compared to controls.

CONCLUSIONS: Brief health coaching, informed by HRA results, improves patient activation and can help facilitate veterans' enrollment in effective prevention programs to address health behaviors and health risk.

EVALUATION OF A COMMUNITY-BASED SAFE FIREARM AND AMMUNITION STORAGE INTERVENTION

Joseph A. Simonetti[2, 4]; Ali Rowhani-Rahbar[3, 5]; Cassie King[1]; Elizabeth Bennett[1]; Frederick P. Rivara[5, 3]. [1]Seattle Children's Hospital, Seattle, WA; [2]University of Colorado School of Medicine, Denver, CO; [3]University of Washington School of Public Health, Seattle, WA; [4]Denver VA Medical Center, Denver, CO; [5]University of Washington, Seattle, WA. (Control ID #2702749)

BACKGROUND: Firearms injured nearly 115,000 Americans in 2014. Safe firearm storage practices, such as storing them locked and unloaded, are associated with a lower risk of unintentional and self-inflicted firearm injury and death among household members. However, few community interventions have been developed to promote such practices and a large proportion of U.S. firearms remain unsafely stored. The aim of this study was to assess the effectiveness of a community-based firearm safety intervention.

METHODS: We performed a before-after evaluation of two firearm safety events in Washington State in 2015. Events were held at sporting goods' stores that included firearm retail and were promoted through social and traditional media. Participants received a brief safety message, their choice of a free firearm safety device (firearm trigger lock or lockbox), demonstration on using both devices, and demonstrated their ability to lock and unlock a mock firearm using each device. We included all participants 18 years or older who spoke English or Spanish, completed baseline and follow-up telephone surveys, and signed legal release forms to participate. We used McNemar's test for matched pairs to assess whether changes in four study outcomes from baseline to

follow-up were statistically significant, including whether all household firearms were stored locked, all were unloaded, all ammunition was locked, and a composite measure assessing whether all firearms were locked and unloaded and all ammunition was stored locked. We performed a subgroup analysis of households with children less than 18 years of age.

RESULTS: Of 415 participants, 404 completed baseline surveys, 313 consented to the follow-up, and 206 (65.8%) completed follow-up surveys and were included. Sixty-one percent were male, 23.3% were Veterans or active military, and 53.4% had children less than 18 years in their household. Eighty-seven percent preferred the firearm lockbox rather than the trigger lock. At baseline, 63.7% stored all household firearms locked, 62.7% stored all firearms unloaded, 54.6% stored all ammunition locked, and 32.9% reported storing all firearms locked and unloaded and all ammunition locked. At follow-up, a significantly greater proportion reported storing all firearms locked (+13.7% [95%CI: 5.6-21.9]) and unloaded (+8.5% [95%CI: 2.3-14.7]) and a non-significantly greater proportion reported storing all ammunition locked (+6.3 [95%CI: −1.2-13.7]). A significantly greater proportion reported practicing all three safe firearm and ammunition storage practices (+12.6% [95%CI: 4.5-20.6]). Findings were unchanged among households in which children were present.

CONCLUSIONS: This community-based intervention that included distribution of a free, participant-selected locking device was effective in increasing safe firearm storage practices. Differences in participant preferences for devices suggest that a "one size fits all" approach may be inadequate in affecting population-level storage practices.

EVALUATION OF AN ALGORITHM TO CLASSIFY EMERGENCY DEPARTMENT UTILIZATION IN THE CONTEXT OF PATIENTS WITH ESTABLISHED PRIMARY CARE

Sharon Rikin; Emilia Hermann; Jessica R. Singer. New York Presbyterian Hospital - Columbia University Medical Center, New York, NY. (Control ID #2704841)

BACKGROUND: Identifying factors associated with emergency department (ED) utilization for patients with established primary care may reveal problems within the primary care system or patient barriers to accessing timely care. The NYU ED Algorithm has been used by health service researchers to distinguish between four categories of ED visits: non-emergent, emergent but primary care treatable (PCT), emergent requiring ED care but primary care preventable, and emergent requiring ED care that are not primary care preventable. This study sought to validate the NYU ED algorithm from the perspective of primary care physicians in order to improve health care utilization of patients with established primary care.

METHODS: This nested, case–control study took place at an academic medical center in Manhattan, NY. We identified ED visits made by primary care patients during two 7-day study windows. Two reviewers independently classified each visit as PCT or non-PCT following an adapted NYU ED Algorithm. Visits were categorized based on the patient's initial complaint, vital signs, medical history, treatment/tests provided, and final diagnosis. Frequency of ED and primary care visits and chronic health conditions including psychiatric illness were also collected. Cohen's kappa was used to evaluate inter-rater agreement. Multivariable logistic regression was used to evaluate associations between characteristics and odds of PCT visit.

RESULTS: Among the 92 ED visits identified, 48.91% were PCT. Inter-rater agreement for acuity of complaint was high (Cohen's kappa 0.68, 95% CI (0.45, 0.90)), moderate for PCT vs. non-PCT determination (Cohen's kappa 0.52, 95% CI (0.36, 0.68)), and fair for determination if medical complaint was potentially preventable (Cohen's kappa 0.35, 95% CI (0.06, 0.64)). The average number of primary care and ED visits in the previous 12 months was 4.27 (SD 2.98) and 4.21 (SD 4.57), respectively. There was no difference in the number of primary care or ED visits between those with PCT vs. non-PCT visits (OR 0.92, 95% CI (0.79, 1.09) and OR 1.02, 95% CI (0.90, 1.17)). Patients with PCT visits were more likely to have <2 vs. ≥ 2 chronic conditions (OR 5.19, 95% CI (0.89, 30.39).

CONCLUSIONS: There was only a moderate level of inter-rater agreement in determination of PCT vs. non-PCT visits, likely because our adaptation of the algorithm relies on provider evaluation of the clinical scenario as compared to the original algorithm which utilizes ICD coding to determine appropriate level of care. Frequency of healthcare utilization did not differ between patients with PCT vs. non-PCT visits. Those with fewer chronic conditions were more likely to have PCT visits while those with more chronic conditions were more likely to have non-PCT visits. This study highlights the need for primary care physician and patient perspectives in future programs designed to evaluate health care utilization in order to adequately address barriers to obtaining prompt, non-emergent medical care.

EVALUATION OF AN INTERDISCIPLINARY COMMUNICATION TOOL CALLED TEMPO (TEAM ENGAGEMENT TO MONITOR PATIENT OUTCOME).

Alok Arora[1]; Idrees Mohiuddin[2]; Larissa Verda[3]. [1]Weiss Memorial Hospital, CHI, IL; [2]Weiss Memorial Hospital, Park Ridge, IL; [3]Weiss Memorial Hospital, Chicago, IL. (Control ID #2705058)

BACKGROUND: Weiss Memorial Hospital is in a healthcare provider shortage area and 40% of our patients are from long term acute care hospital (LTACH) and skilled nursing facility (SNF) with multiple co-morbidities and high readmission rates, such background demands synchronized medical care to ensure safe and timely discharges. TEMPO board rounds were introduced in our hospital in November 2015 as an enhanced visual tool to coordinate and promote interdisciplinary communication. TEMPO involves a large white board on medical floors which is manually populated with data retrieved from various medical information systems and includes patient's 'geometric mean length of stay' (GMLOS), discharge disposition and an anticipated discharge date which drives the TEMPO discussion. Morning TEMPO rounds includes a medical resident, named nurse, social worker and a case manager. Patient status relative to discharge date is indicated by '*red*, *yellow and green*' triangles and act as a cue to identify 'barriers to discharge' and address key patient specific needs. Early recommendations from physical and occupational therapy help with rehabilitation and placement planning for 'fall risk/stroke' patients.

METHODS: We performed an anonymous survey for the efficacy of the TEMPO rounds process. Random cohort of t participants were selected which included 10 case managers/social workers, 14 RNs and 28 medical residents ($N = 52$). Respondent commented on time management (*consumption*/*saving*), communication (*improved*/*worsened*), patients care (*improved*/*worsened*) and discharge planning (*facilitates*/*complicates*).

RESULTS: The visibility of the information during TEMPO rounds was widely appreciated as compared to the old style 'sit around the table' collaborative case rounds. Most respondents reported a high level of satisfaction with TEMPO rounds. 76% ($N = 40$) reported improvement in *delivery* of optimal patient care due to TEMPO rounds. 75% ($n = 39$) of respondents expressed satisfaction with *time savings* associated due to improved interdisciplinary communication and early

identification of discharge barriers. A better formulated *discharge strategy* following TEMPO was reported by 70% ($N=36$) respondents; but 40% ($N=21$) also thought that the TEMPO process did not lead to an actual reduction in the GMLOS. We think the large LTACH/SNF demographics we cater to can explain this variance.

CONCLUSIONS: TEMPO delivers an effective discharge strategy by promoting communication and participation between various stake holders. An interdisciplinary TEMPO board has empowered our staff to bring in changes and has improved health care delivery at our hospital by addressing barriers to a safe discharge.

Impact of TEMPO on patient safety and outcomes

Specific attention to readmissions	Early identification of frail and deconditioned for early placement
Improved compliance of CAUTI and CLABSI toolkits	Increased adherence with care bundles.
Switching IV to PO antibiotics and stopping IV fluids early	Higher flu and pneumococcal vaccination rates
Keeping track of Medicare days	Contact precautions compliance
Improving 'core measure' compliance	Identifying 'falls risk' patients

EVALUATION OF BURNOUT AMONG RESIDENTS IN AN ACADEMIC PRIMARY CARE CLINIC SETTING Caroline Falker[3, 1]; Frank D. Buono[3]; Faith Harrington[1]; Rebecca Kosowicz[2, 1]; Sumit Kumar[2, 1]; Rachel Laff[1]; Yungah Lee[2, 1]; Kenneth Morford[4, 1]; Destiny M. Printz[3]; Jonathan Stock[2, 1]; Rebecca Brienza[1, 2]. [1]VA Connecticut Healthcare System, West Haven, CT; [2]Yale New Haven Hospital, Newington, CT; [3]Yale School of Medicine, New Haven, CT; [4]Yale University School of Medicine, New Haven, CT. (Control ID #2706022)

BACKGROUND: Physician burnout is a work-related syndrome involving emotional exhaustion, depersonalization, and a sense of reduced personal accomplishment. Burnout is prevalent among healthcare providers, especially in primary care settings. Studies show that the prevalence of burnout is near or exceeding 50% in physicians. Medical residents are especially vulnerable to burnout. However, there are few studies focusing on the evolution of burnout among residents over time. Additionally, most studies of resident burnout focus on inpatient settings rather than outpatient primary care settings. Identifying the presence of burnout and designing residency curriculum to minimize those factors would benefit overall health and wellbeing of resident trainees, and potentially improve quality of patient care.

METHODS: We utilized the Tedium Measure-21, which is a validated questionnaire to assess burnout. TM-21 comprises of total 21 questions that assess three domains: physical, emotional and mental exhaustion. Each question is weighted with a scale from 1 (never) to 7 (always). The Tedium mean score is calculated for each survey to measure critical stress (mean score between 3 and 4) or burnout (mean score greater than 5). TM-21 was administered to Internal Medicine residents (PGY1-PGY3) and Nurse Practitioner residents over the course of the academic year 2016–2017 at the end of each ambulatory block. Each group of residents completed the TM-21 once every three months for a total of four survey submissions throughout one academic year.

RESULTS: We collected a total of 63 TM-21 surveys from Internal Medicine and Nurse Practitioner (NP) residents over the first two (out of four) data collection periods. Surveys were completed by 24 (38%) PGY-1 residents, 21 (33%) PGY-2 residents, 13 (21%) PGY-3 residents, and 5 (8%) NP residents. Of the total surveyed, 52 residents (82.5%) met criteria for critical stress, 10 residents (15.9%) met criteria for burnout and 1 resident (1.6%) met criteria for neither. Higher rates of burnout were observed in PGY-2 residents as compared to other training levels although preliminary results have not reached significance. Higher rates of critical stress were noted in PGY1 residents.

CONCLUSIONS: We found that a significant proportion of Internal Medicine and Nurse Practitioner residents meet criteria for burnout according to the validated TM-21 survey. Critical stress and burnout varied across different training levels and this may reflect a need for more targeted interventions. Furthermore, studying rates of critical stress and burnout overtime can provide valuable information regarding burnout prevention. Further characterizing burnout into the three subdomains (physical, mental, emotional) may help provide clues to identify factors associated with burnout. We acknowledge that the Maslach Burnout Inventory is accepted as a gold standard for burnout, but we used TM-21 because it has been shown to better assess burnout in healthcare providers with test-retest reliability

EVALUATION OF HOUSE STAFF BURNOUT AND WORK ENVIRONMENT: HOW CAN WE HELP? Mitchell A. Izower; Johanna Martinez; Andrew Yacht. Northwell Health, Manhasset, NY. (Control ID #2702835)

BACKGROUND: Burnout is a long term stress reaction that adversely affects house staff psychological health, patient care and satisfaction, and increases self-perceived errors. The ACGME has increasingly focused on burnout management and mitigation, but specific methods to decrease burnout are needed. We sought to evaluate and delineate sources of, and means to improve, house staff burnout.

METHODS: A cross-sectional study of Northwell Health house staff was performed. 1652 house staff received a ten-item Mini-Z survey regarding stress, burnout, and work conditions, as well as 2 open-ended questions on work life and wellbeing. A formal content analysis was performed for open-ended question responses.

RESULTS: Among 1652 house staff surveyed, 611 responses were received (37%). High stress was present in 52%, with 24% reporting burnout. 47% reported a very busy or chaotic workplace. 32% felt they did not have satisfactory control of their work. 33% felt they did not have sufficient time for documentation. 11% described too much home EMR time. Responses to "What suggestions do you have that would improve your well-being?" were classified by suggestion type. Requested activities included more physical activity (59%) and social events (21%). Services included improved nutrition (29%) and an on-campus gym (25%). Support/work-life changes included decreased work hours (46%). Work flow/dynamic suggestions included EMR improvements (28%), more clinical support staff (23%), and better team dynamics (17%). Training/education suggestions included more educational time (35%). Responses to "If you could change one thing to improve your work life, what would it be?" were classified by suggestion type. Requested work flow/dynamic changes included EMR improvements (44%) and more efficient workflow (19%). Program changes included reduced work hours (34%) and schedule improvements (20%). Services included improved nutrition (27%). Personal wellness suggestions included more exercise (34%) and sleep (19%).

CONCLUSIONS: Given the deleterious effects of burnout on house staff and patient care, programs should seek to reduce house staff burnout. The Mini-Z survey is an efficient method to determine burnout and burnout sources, and house staff feedback should be solicited to address burnout. In our sample,

nearly one-quarter of house staff were experiencing burnout, and over half felt highly stressed. Almost half reported a very busy or chaotic workplace, while one-third felt they did not have satisfactory control of their work or sufficient time for documentation. House staff felt their wellbeing and work life would improve with changes to their amount of physical activity and exercise, nutrition, social activities, educational time, scheduling and work hours, clinical support staff availability, team dynamics, workflow, and EMR functionality. Programs should optimize these factors to decrease house staff burnout.

EXPERIENCES OF LESBIAN, GAY, BISEXUAL, TRANSGENDER AND QUEER (LGBTQ) PEOPLE OF COLOR IN SHARED DECISION-MAKING WITH HEALTHCARE PROVIDERS ABOUT INTIMATE PARTNER VIOLENCE Fanny Y. Lopez[1]; Kathryn E. Gunter[1]; Scott Cook[1]; Justin Jia[1]; Arshiya A. Baig[2, 1]. [1]The University of Chicago, Chicago, IL; [2]University of Chicago, Chicago, IL. (Control ID #2704939)

BACKGROUND: High-quality Shared Decision-Making (SDM) has been positively associated with patient satisfaction, quality of care, and health outcomes. However, SDM has been infrequently studied among minority populations, especially LGBTQ people of color (POC). Successful SDM is especially important for survivors of intimate partner violence (IPV) where sharing information, deliberating options and making decisions collaboratively between patients and providers can result in outcomes ranging from life-saving to catastrophic. However, no research studies have investigated how IPV survivors who are LGBTQ POC engage in SDM with providers. We aim to describe LGBTQ POC's SDM experiences with providers (i.e. physicians, nurses, counselors) to address IPV and provide recommendations to improve SDM with this patient population.

METHODS: From December 2015 to December 2016, we conducted one-on-one, semi-structured interviews with LGBTQ POC, 18 years of age or older, who reported past history of IPV with same-sex, transgender or genderqueer partners. We explored participants' definitions of IPV, experiences discussing IPV and decision-making with providers, and their preferences regarding tools to improve communication and SDM about IPV. Data extracted from audio recordings were transcribed verbatim. To ensure internal consistency, multiple reviewers developed a codebook through an iterative process. We used a modified template approach for data analysis to identify barriers and facilitators that LGBTQ POC experience when discussing IPV and making decisions with providers.

RESULTS: We conducted 36 interviews and coded 24 transcripts. From preliminary analysis, we found that 12 of the 24 participants discussed IPV with healthcare providers. Those who did not discuss IPV cited barriers, including lack of time and trust, as well as concerns about provider's assumptions about IPV based on the patient's race/ethnicity, sexual orientation and/or gender identity. Those who discussed IPV cited facilitators, such as providers' LGBTQ identity, as well as sensitivity and understanding of LGBTQ POC's life stories and experiences of IPV within same-sex, transgender and genderqueer relationships. Participants recommended that providers become culturally competent in LGBTQ and racial/ethnic minority health, ask about IPV in a sensitive way, and address the unique needs of LGBTQ POC to improve IPV SDM.

CONCLUSIONS: The majority of study participants are open to providers asking about IPV and providing culturally tailored resources. Participants recommended that providers use tools, such as face-to-face conversation, written materials, phone and web-based communication, and support groups to facilitate SDM about IPV. Future research should design and evaluate tools that improve SDM with LGBTQ POC experiencing IPV.

EXPERIENCES OF NEIGHBORHOOD CRIME, ADVERSE PSYCHOLOGICAL RESPONSES, AND CHRONIC DISEASE STATUS IN A HIGH-RISK, URBAN POPULATION Elizabeth L. Tung; Monica E. Peek. University of Chicago, Chicago, IL. (Control ID #2705101)

BACKGROUND: Neighborhood crime can have deleterious health effects that lead to or worsen chronic conditions, such as obesity and hypertension. Prior studies have predominantly attributed these health effects to adverse psychological responses to crime, such as negative perceptions about neighborhood safety and chronic stress. However, few studies have examined both the direct experience of crime and adverse psychological responses, in order to corroborate theoretical pathways to downstream health consequences. The purpose of this study is to examine the relationships between experiences of neighborhood crime, adverse psychological responses, and obesity and hypertension status in a high-risk, urban population.

METHODS: An address-based probability sample of 267 participants (ages ≥ 35 years) was conducted to query residents on the South Side of Chicago about neighborhood crime. During hour-long, in-person interviews, participants were asked about their prior experience of neighborhood crime (theft or property damage), psychological responses to crime (perceived neighborhood safety and stress due to crime), demographics, and health status. Objective biological measures (height, weight, and blood pressure) were obtained at the time of interview. Multivariable logistic regression models were used to assess obesity and hypertension status as a function of neighborhood crime and psychological response measures, adjusting for demographic characteristics, self-reported health status, and interaction effects for perceived safety and stress.

RESULTS: Overall, 431 eligible residents were invited to participate and 267 (62%) completed the survey. People were primarily non-Hispanic black (68.9%) or Hispanic (19.3%), female (62.9%), and between the ages of 35–70 (86.5%). More than half (54.9%) were obese and almost half (49%) had hypertension. Prior experience of neighborhood crime was associated with higher adjusted odds of perceived neighborhood safety concerns (Adjusted odds ratio [AOR] = 2.3; 95% CI, 1.3–4.0; $P = 0.003$) and stress due to crime (AOR = 2.9; 95% CI, 1.6–5.2; $P = 0.001$). However, perceived neighborhood safety and stress due to crime were not associated with obesity or hypertension status. Any prior experience of neighborhood crime was independently associated with 87% higher adjusted odds of obesity (95% CI, 1.07–3.26; $P < 0.05$) and 74% higher adjusted odds of hypertension (95% CI, 0.96–3.17; $P = 0.07$).

CONCLUSIONS: Psychological measures, such as perceived neighborhood safety or stress due to crime, may be insufficient to fully examine the relationship between neighborhood crime and chronic conditions in a high-risk, urban population. Alternative pathways, such as community-level processes (e.g., breakdown of social ties may lead to inadequate social support for self-management activities) should be explicitly examined for a more robust understanding of the intersection between neighborhood crime and chronic disease.

FACILITATING HIGH VALUE CARE THROUGH THE ACCURATE DIAGNOSIS OF SKIN DISEASE: A SYSTEMATIC REVIEW Syril Keena T. Que[5]; Sara-Megumi L. Naylor[1, 2]; Robert Dellavalle[3, 4]. [1]Division of Primary Care at the VA Greater Los Angeles Healthcare System, Los Angeles, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Denver VA Medical Center, Denver, CO; [4]University of Colorado, Denver, Denver, CO; [5]Brigham and Women's Hospital, Boston, MA. (Control ID #2705634)

BACKGROUND: Primary care physicians (PCPs) are frequently the frontline providers of care for skin disease. Dermatologic complaints make up 6-22% of PCP visits, with only a third of these patients referred to dermatologists for further work-up or management. Accurate diagnosis and optimized care coordination between PCPs and dermatologists is a high priority as it influences subsequent management decisions, including prescriptions, biopsies, referrals, and patient outcomes. It is unclear if current education on dermatologic conditions is sufficient for PCPs to accurately diagnose common skin conditions. In this systematic review, we assess the diagnostic accuracy of PCPs and dermatologists for adult skin conditions encountered in the outpatient setting. To our knowledge, this is the first systematic review that examines diagnostic accuracy for a broad spectrum of dermatologic conditions, including neoplastic, infectious, and inflammatory skin conditions.

METHODS: A systematic review of observational studies and randomized controlled trials was conducted using PubMed and EMBASE from database inception to August 2016. Bibliographies of retrieved studies were further analyzed. Two independent reviewers identified studies and abstracted data. Studies were assessed using *a priori* inclusion and exclusion criteria. Our aim is to compare the diagnostic accuracy of PCPs and dermatologists. Primary outcome measures are sensitivity and specificity.

RESULTS: A total of 25 studies were included, with data from more than 1,953 PCPs, 866 dermatologists, and 12,446 lesions. Only three (12%) studies reported both sensitivity and specificity. Dermatologists showed higher accuracy when compared to PCPs in diagnosing all skin conditions, which reached statistical significance for basal cell carcinoma, seborrheic keratosis and psoriasis. Pooled weighted sensitivity for basal cell carcinoma was 0.46 (95% CI 0.36, 0.55) for PCPs and 0.92 (95% CI 0.84, 1.00) for dermatologists. For seborrheic keratosis it was 0.23 (95% CI 0, 0.48) and 0.79 (95% CI 0.60, 0.98), respectively. For psoriasis it was 0.56 (95% CI 0.43, 0.68) and 0.97 (95% CI 0.94, 1.00), respectively. PCPs exhibited high sensitivity for certain inflammatory and infectious skin conditions including acne— 0.88 (95% CI 0.7, 0.99) and verruca vulgaris— 0.79 (95% CI 0.67, 0.91).

CONCLUSIONS: Dermatologists showed higher diagnostic accuracy when compared to PCPs. Educational initiatives for current and future PCPs should focus on common diagnoses with gaps in diagnostic accuracy, which are highlighted in this systematic review. Meanwhile, increased involvement of PCPs in the management of conditions like acne and verruca allows for improved access to care and reduced health care utilization. Increased collaboration between providers and improvements in diagnostic accuracy can ultimately decrease the number of unnecessary or inappropriate prescriptions, biopsies, referrals, and other indicators of low value care.

FACILITATORS AND BARRIERS OF INTERDISCIPLINARY TEAM FUNCTION IN PRIMARY CARE: SIX YEAR POST-PCMH IMPLEMENTATION Linda Kim[1]; Karleen Giannitrapani[2]; Alexis K. Huynh[1]; Danielle Rose[1]; Alison B. Hamilton[1]; Susan E. Stockdale[1]; Lisa V. Rubenstein[1]. [1]VA Greater Los Angeles Healthcare System, Los Angeles, CA; [2]VA Palo Alto Healthcare System, Palo Alto, CA. (Control ID #2706118)

BACKGROUND: Findings from earlier implementation studies provide some understanding on how elements of the Patient Centered Medical Home (PCMH) model of care delivery affect primary care providers (PCPs), nurses, and administrative staff; however, more work is needed to understand what factors promote or hinder PCP and staff performance and team function. In this study we aim to describe provider mentioned facilitators and barriers to team function, six years post-PCMH implementation, as the initial step in a longitudinal study evaluating changes in team function over time.

METHODS: Data were collected through semi-structured interviews of 36 frontline staff (PCPs, RNs, LVNs, and administrative staff) in 6 VA primary care practices, as part of a larger PCMH implementation study. To ensure we captured a range of perspectives we employed a quota sampling approach to randomly select key informants from each teamlet member role. All sites had implemented Patient Aligned Care Teams (PACT), the VA's version of PCMH, four to six years prior to the interviews. Data were analyzed using a content analysis method of constant comparison to capture provider identified facilitators and barriers to team function.

RESULTS: Factors that facilitated team function include: 1) increased familiarity with team members' roles: "*we still come across some kinks here and there, but…We know what's expected of each of us to make the teamlet*;" 2) participatory decision making: "*And if there's something, we all kind of brainstorm together what should we do. It's a team effort*;" 3) effective communication: "*We have just talked amongst ourselves… if something comes up that we need to talk about… there's never a problem really with our teamlet*;" and 4) having various communication methods available within teams to facilitate coordination of care and between teams to share strategies regarding change processes. Barriers include: 1) staffing shortages/coverage: "*So I think that's one of the issues with PACT that we have here. It may have to do with staffing or just the way coverages need to be coordinate*;" and 2) poor conflict resolution skills: "*… the only time that she would talk to me is if there's a problem and then she will tell me how to fix the problem*;" and 3) systems/processes that hinder workflow: "*You have to cut and paste the note… and then… to an addendum… It seems like a lot of extra work.*"

CONCLUSIONS: Six years after PCMH implementation, there were several elements that helped to promote team function and enhance communication within and between teams; however we also provide insight into areas that need further improvement. Findings from this study can help inform future efforts evaluating changes in team function over time, which can then be used to guide development of evidence-based improvement strategies aimed at optimizing team function.

FACTORS ASSOCIATED WITH BASELINE HYPERTENSION CONTROL IN HEART HEALTH NOW Samuel Cykert[1]; Kamal Henderson[2]; Jacqueline Halladay[2]. [1]University of North Carolina, Chapel Hill, NC; [2]University of North Carolina School of Medicine, Chapel Hill, NC. (Control ID #2706870)

BACKGROUND: Heart Health Now (HHN) is the North Carolina Cooperative for Evidence NOW (EN). EN is an AHRQ funded initiative designed to measure the impact of practice facilitation on the implementation of patient centered evidence in small primary care practices. The current focus of HHN and EN is cardiovascular risk reduction for the adult population cared for by participating practices. This report addresses baseline hypertension control in the first 96 practices reporting and factors associated with higher percentages of control.

METHODS: Practice sites qualified for HHN if the provider staff did not exceed 10 full time equivalents and used an electronic health record (EHR). Note that 90% of primary care practices in NC utilize EHRs. Independent practices and practices that are distant from their affiliated organization were

prioritized for enrollment. Data for HHN measures were extracted from electronic health records (EHRs). Given that these practices used 18 different EHR vendors, once data were extracted, they needed to be normalized using continuity care documents from the various vendors then processed into uniform data sets and dashboards. At baseline, clinicians in each practice completed a practice member survey that included a series of questions on the practice's adaptive reserve (ARS). The primary outcome for this analysis is the proportion of patients with controlled hypertension defined as systolic blood pressure (BP) < 140 mmHg and diastolic BP < 90 mmHg. To identify factors that were associated with practices with higher percentages of patients with BP control, we performed linear regression. Independent variables incorporated in the model included practice ownership/affiliation, daily patient visits per provider, number of clinicians per site, payer mix, PCMH recognition status, the use of practice data discussions, and ARS scores.

RESULTS: EHR baseline data from 96 practices of an eventual 246 have been obtained (practice start dates were randomized). An average of 5.3 providers practiced per site. 65% of practices were clinician owned, 4% hospital owned, and 31% were federally qualified or rural health centers. The average payer mix was Medicare 25%, Medicaid 16%, dual 9%, uninsured 12%, commercial insurance 31%, "other" 6%. 65% of practices were PCMH recognized. The average proportion of patients diagnosed with hypertension who met the definition of control per practice site was 59.5% (SD +/− .17). Regression analysis yielded an adjusted R-squared of 0.36. Factors that were significantly associated with higher percentages of BP control were PCMH recognition ($p = 0.04$) and higher ARS scores ($p = 0.04$).

CONCLUSIONS: Given the correlation between adaptive reserve scores and baseline BP control, a close examination of the effect of practice facilitation on adaptive reserve will likely add to the theoretical understanding of how practice facilitation can influence practice performance. Neither payer mix nor practice affiliation was associated with BP control.

FACTORS ASSOCIATED WITH BOWEL RESECTION IN ACUTE MESENTERIC ISCHEMIA David Mossad[2]; Drew Triplett[1]; Ronald J. Markert[1]; Sangeeta Agrawal[1]. [1]Wright State University, Dayton, OH; [2]Wright State University Boonshoft School of Medicine, Dayton, OH. (Control ID #2705755)

BACKGROUND: Acute mesenteric ischemia (AMI) is a serious and urgent condition. Morbidity and mortality in these presenting patients are significant, with intestinal resection at times being a major necessary intervention. The purpose of this study was to evaluate patient demographics, comorbidity burden, and hospital characteristics in patients with AMI undergoing bowel resection.

METHODS: We used ICD-9 diagnosis codes from the 2001–2010 National Hospital Discharge Survey to identify cases of AMI. ICD-9 procedure codes were then used to identify patients who underwent bowel resection. Comparisons on demographics, comorbidities, hospital length of stay (LOS), and selected health system characteristics were made between those who underwent bowel resection and those who did not. SPSS was used for chi-square and t test analysis at alpha = 0.05.

RESULTS: Among 3,441 cases of AMI, 1,393 underwent bowel resection and 2,048 did not. The resection group was similar in age (64.4 vs 65.7 years, $p = 0.11$) but had a longer LOS (18.0 vs 7.9 days, $p < 0.001$). Males were more likely to undergo resection (43.1% of males vs 38.9% of females, $p = 0.015$). No differences were seen in resection rate based on race ($p = 0.55$). Patients with hypertension (25.5% vs 44.8%, $p < 0.001$), coronary artery disease (CAD) (28.5% vs 41.6%, $p < 0.001$), and diabetes (30.3% vs 41.5%, $p < 0.001$) had lower resection rates. Patients who suffered acute kidney injury (AKI) (51.4% vs 38.6%, $p < 0.001$), and sepsis (61.3% vs 38.9%, $p < 0.001$) during their hospitalization were more likely to undergo resection. Those undergoing surgery were more often being discharged to a short term (37.9%) or long term (58.6%) care facility compared to going directly home (32.4%) ($p < 0.001$). Patients needing resection had a higher mortality rate (23.0% vs 20.4%) but this did not reach statistical significance ($p = 0.067$). Patients in the Northeast (35.5%) were less likely to undergo resection compared to the Midwest (42.9%), South (41.7%), and West (41.6%) ($p = 0.007$). Neither hospital size ($p = 0.36$) nor ownership ($p = 0.29$) were associated with resection. Principal source of payment was not associated with resection ($p = 0.21$). Emergent admissions (42.2%) were more likely to undergo resection compared to urgent (35.8%) and elective (37.4%) admissions ($p = 0.013$).

CONCLUSIONS: Bowel resection is often a necessary step in the management of AMI. This study shows that factors such as gender, LOS, regional distribution, and type of admission were associated with undergoing resection. Comorbidities potentially prohibiting safe intervention such as CAD, diabetes, and hypertension were linked to lower resection rates. Indicators of disease severity, including sepsis and AKI, pointed to a greater likelihood of resection. Those undergoing resection also appeared to have worse functional outcomes as they were less likely to be discharged home.

FACTORS ASSOCIATED WITH WELL PERSON EXAMINATIONS AMONG ADOLESCENTS AND ADULTS WITH DOWN SYNDROME

Kristin M. Jensen[1, 2]; Elizabeth J. Campagna[2]; Elizabeth Juarez-Colunga[2, 2]; Desmond K. Runyan[2]; Allan V. Prochazka[1]. [1]University of Colorado School of Medicine, Aurora, CO; [2]University of Colorado, Aurora, CO. (Control ID #2705371)

BACKGROUND: Persons with Down syndrome (DS) now live well into adulthood and are at risk for comorbidities both congenital and acquired that necessitate regular follow-up across their lifespan. Yet, little is known about their preventive healthcare patterns as they age. In this retrospective study, we evaluate factors that are associated with routine well-person care in adolescents and adults with DS.

METHODS: Using Medicaid claims data (2006–2010) in California (CA), Colorado (CO), Michigan (MI), and Pennsylvania (PA), we defined our cohort as DS patients ≥12yo, enrolled in Medicaid for ≥45/60mo without concurrent Medicare ($n = 629$) for a total of 3951 patients. DS cases were identified by ICD-9 = 758.0 for non-obstetric claims. Well-person examinations were identified by billing codes. The odds of receiving a well examination were modeled using logistic regression controlling for patient demographics, comorbidities, and health care utilization. The model retained all covariates regardless of significance.

RESULTS: Our cohort was 53% male, with 20% adolescent (12–17yo), 31% transition age (18–25yo), and 49% adult (≥26yo). Only 37% of the cohort received at least one well examination during this 5 year study (18% had 1 well examination, 19% had ≥2). Factors predictive of well examination included younger age (Odds Ratio [95% Confidence Limits]: 12–17yo vs ≥26yo = 1.6[1.3–2.0]; 18–25yo vs ≥26yo = 1.5[1.2–1.7]), female gender (1.7[1.4–1.9]), rural residence (1.5[1.2–1.8]), involvement in neurologic (1.5[1.2–1.8]), genitourinary (1.3[1.1–1.5]), or dermatologic organ systems (1.3[1.1–1.5]), mental health diagnoses (1.3[1.1–1.5]), the lack of respiratory (1.2[1.0–

1.4]) or hematologic disorders (1.2[1.0–1.5]), and residence outside of CA (MI 4.0[2.5–6.6]; CO 3.2[2.5–4.2]; PA 4.2[3.1–5.7]). Subgroup analysis excluding CA data showed increased rates of well person examination to 64% (19% had 1 well examination, 44% had ≥2). Predictors of well examinations in the non-CA subgroup included age <26 years, female gender, at least one sick encounter, involvement in neurologic or dermatologic organ systems, and lack of hematologic disorders. Neither emergency department nor inpatient encounters were predictive of receiving well examinations, nor were the presence of comorbidities commonly-associated with DS: congenital heart disease, hypothyroidism, or obstructive sleep apnea.

CONCLUSIONS: The majority of adolescents and adults with DS do not receive well examinations routinely. Although the factors of age and gender correspond to national trends in preventive healthcare, the DS population is inherently more medically complex with risks of acquired comorbidities throughout their lives and thus requires regular follow-up. Our findings represent a significant opportunity to improve delivery of primary care to persons with DS to actively screen for and identify comorbidities with known associations in DS.

FACTORS INFLUENCING PATIENT DECISIONS TO SELF-TITRATE MEDICATIONS FOR DIABETIC PERIPHERAL NEUROPATHY TREATMENT

Somalee Banerjee[2, 3]; Lin Ma[1]; Alyce S. Adams[1]. [1]Kaiser Permanente, Oakland, CA; [2]Kaiser Permanente Oakland, San Francisco, CA; [3]University of California, Berkeley, Berkeley, CA. (Control ID #2705361)

BACKGROUND: Treating diabetic peripheral neuropathy (DPN), one of the most common complications of diabetes, has been challenging due to limited effectiveness of medications, and the need to titrate to balance symptom relief and side effects to prevent medication non-compliance. This study assesses patient self-titration of DPN medications within a larger randomized trial, the Diabetes Telephone Study (DTS), to improve treatment outcomes through automated monitoring of symptoms and treatment side effects.

METHODS: Self-reported data were collected from patients in the intervention arm of DTS between September 2014 and July 2016 and integrated with demographic and clinical data from the electronic health record. The primary outcome was patient initiated titration, as reported via 3 interactive voice response calls over 8 months. Chi square tests were used to examine associations between each of the titration outcomes and patient demographics, drug coverage benefits and clinical characteristics. We used multiple logistic regression models to identify independent predictors of patient titration.

RESULTS: Of the 605 patients studied, 195 or 32% of these patients reporting self-titration during the 8 months following treatment start. Self-titration was associated with gabapentin or nortriptyline use, higher baseline pain interference and being an English speaker, but age, sex, race, chronic pain diagnoses, diabetes severity and other related complications were not. After controlling for baseline demographic and clinical features, factors associated with higher odds for self-titration included: higher baseline pain interference scores (OR: 1.02; 95% CI: 1.00, 1.04); age between 65 and 74 as compared to those older than 75 (OR: 1.62; 95%CI: 1.02, 2.58), speaking English (vs. Spanish) (OR: 5.08; 95%CI: 1.41, 18.30) and more months of full drug coverage benefits (OR: 1.79; 95%CI: 1.01, 3.18). Compared to those taking gabapentin, patients taking nortriptyline (OR: 0.58; 95%CI: 0.38, 0.89) had lower odds of self-titration.

CONCLUSIONS: In summary, self-titration of DPN pain medications in this population was associated with the type of medication prescribed and higher baseline pain levels. Importantly, patients with more continuous drug coverage had nearly twice the odds of self-titration, underscoring the importance of medication cost to patient decision-making. Also, while being an English (vs. Spanish) speaker dramatically increased one's odds of self-titration, the estimates lacked precision due to the small number of Spanish speaking patients in this sample. Further exploration using data from clinical settings is needed to confirm these findings and explore potential barriers to optimal pharmacologic treatment for Spanish-speaking patients.

FACTORS PROMOTING RECOVERY FROM BURNOUT AMONG INTERNAL MEDICINE RESIDENTS: A QUALITATIVE STUDY

Nauzley C. Abedini; Shobha W. Stack; Jessie L. Goodman; Kenneth P. Steinberg. University of Washington, Seattle, WA. (Control ID #2673813)

BACKGROUND: Burnout has been well documented among physicians at all career stages, yet little is known about how physicians recover from and avoid recurrent burnout. Residents are particularly vulnerable, and burnout rates for internal medicine residents are among the highest for all specialties. Using qualitative methods, we sought to identify factors promoting recovery from and avoidance of recurrent burnout among residents in the University of Washington Internal Medicine Residency Program.

METHODS: Between June and August 2016, 25 in-depth semi-structured, 60-min interviews were conducted with a convenience sampling of PGY2, PGY3, and recent graduates of the University of Washington Internal Medicine Residency Program who both experienced and recovered from burnout during residency. Residents were deemed ineligible for participation if they were currently experiencing burnout, as determined by a validated single-item burnout measure. Interviews were audio-recorded and transcribed verbatim. Three investigators independently performed coding in an iterative fashion consistent with Grounded Theory. Investigators compared open and axial codes and reached a consensus regarding major themes.

RESULTS: Participating residents identified factors that put them at risk for burnout, including: uncertainty in their professional role and expectations; lack of connection with patients and co-workers; lack of awareness of burnout syndrome; personal challenges outside of work; workplace challenges; and physical exhaustion. Participants cited multiple factors that contributed to their recovery and avoidance of recurrent burnout, namely (1) professional identity formation through guided reflection, role models, future career planning, setting boundaries, and/or improving medical knowledge; (2) connection with patients, co-workers, family and friends; (3) awareness of burnout and feeling validation of their experience from others; (4) time away from clinical responsibilities; and (5) resolution of personal challenges. The majority of participants reported deriving meaning in medicine from relationships with patients and co-workers, and that burnout was often linked to a loss of that meaning.

CONCLUSIONS: Residents utilize a number of different strategies to recover from burnout. Thus, interventions to alleviate burnout might reflect these strategies. We hypothesize that efforts should be made to (1) raise awareness of burnout and create opportunities for dialogue to validate resident experiences; (2) improve systems and circumstances that lead to fatigue and work compression, and promote self-care; (3) facilitate professional identity formation through reflection and mentorship; and (4) foster connection and relationships with patients and colleagues. In particular, helping residents identify where they derive meaning in medicine and supporting them in building that meaning into their work may be protective against burnout.

FAILURES IN REPEAT DIABETES SCREENING IN PATIENTS WITH PREDIABETES IN AN URBAN SAFETY-NET HEALTH CARE SYSTEM Brooks Brodrick; Hua Lin; Ethan Halm; Michael E. Bowen. Univ of TX Southwestern Med Ctr, Dallas, TX. (Control ID #2706186)

BACKGROUND: National diabetes screening guidelines recommend repeat screening every 12 months for those with prediabetes and every 36 months for those with normal screening results. However, little is known about frequency and timing of repeat diabetes screening in real world clinical practice.

METHODS: We conducted a retrospective cohort study in a large, integrated safety-net healthcare system using electronic medical record (EMR) data from 2010 to 2014. Eligible patients were age 18–65, non-pregnant, and had an index, outpatient visit and a resulted gold standard diabetes screening test (fasting glucose or hemoglobin A1C) between January 2010 and June 2013. Eligible patients had ≥1 additional office visit before December 2014. Patients with diabetes were excluded using ICD-9 codes and test results consistent with diabetes. We describe the frequency of rescreening and examine characteristics associated with rescreening in patients with initial test results in the normal and prediabetes range. We used Cox proportional hazards regression to describe the time to repeat diabetes testing in normal vs. prediabetes patients. Multivariate models adjusted for age, sex, race, BMI, hypertension, hyperlipidemia, and family history.

RESULTS: A total of 18,323 patients met inclusion criteria. On average, patients were 48 years old and had a BMI of 31.7. Overall, 62% were female, 83% were non-white, 53% had a family history of diabetes, and 57% had hypertension. Only 37% of patients completed repeat screening (mean time to follow-up time was 398 days). Rescreening was more common among those that were older, female, had a higher BMI, prediabetes, hypertension, and hyperlipidemia ($p < 0.01$). Those with prediabetes on their initial screening ($N = 6585$) were more likely to be rescreened compared with those with normoglycemia (HR = 1.33) in multivariate analysis. However, at 12 months, only 25% of those with prediabetes had been rescreened, and by 18 and 36 months, repeat screening improved to only 34 and 41% respectively. Those with high-risk prediabetes (A1C ≥ 6% or FBG ≥ 110 mg/dL) were more likely be rescreened than those with low risk prediabetes at 12 months (34% vs 18%), 18 months (42% vs. 28%), and 36 months (49% vs. 36%) ($p < 0.01$ for all). Among those who were rescreened, 17% transitioned from normal to prediabetes, 3% transitioned from normal to diabetes, and 9% transitioned from prediabetes to diabetes.

CONCLUSIONS: Although patients with prediabetes are more likely to be rescreened than those with normoglycemia, only slightly more than one third of patients with prediabetes completed repeat diabetes screening at 18 months. Even among those with high risk pre-diabetes, no more than half were rescreened within 3 years. Better, more systematic, population health approaches to promote timely rescreening in patients with prediabetes are needed.

FEASIBILITY AND ACCEPTABILITY OF A GROUP MEDICAL VISIT INTERVENTION TO IMPROVE HCV TREATMENT UPTAKE AMONG PERSONS WHO INJECT DRUGS (PWID) IN A PRIMARY CARE SETTING Brianna L. Norton[4]; Mary Gover[4]; Cara McMurry[3]; Joseph Deluca[4]; Chinazo Cunningham[2]; Alain H. Litwin[1]. [1]Albert Einstein College of Medicine, Bronx, NY; [2]Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY; [3]Montefiore, Brooklyn, NY; [4]Montefiore Medical Center, Bronx, NY. (Control ID #2707549)

BACKGROUND: Throughout the US, the majority of people infected with HCV (hepatitis C virus) are persons who inject drugs (PWID), yet very few have ever initiated treatment. We set out to investigate the feasibility and acceptability of implementing a primary care based HCV Group Evaluation and Treatment Uptake (HCV GET-UP) intervention to improve HCV treatment uptake among PWID.

METHODS: Patients were recruited from a primary care clinic in the Bronx, NY. Participants were considered potentially eligible if they had a positive HCV antibody in the electronic health record. Patients were then called for study screening, and if eligible, asked to attend a baseline visit where patients signed written consent, were asked baseline demographic information, and provided urine for drug toxicology screening. The study intervention consisted of 4-weekly group medical visits with a physician where HCV-related medical evaluation/work-up, education, support, and skill building were provided. All visits were billed to insurance as a 1-hour group medical visit. At the end of the intervention, patients were offered an expedited appointment within 2 weeks for onsite HCV treatment at the primary care clinic. We assessed feasibility via recruitment and retention rates, and acceptability via brief post-group visit surveys with 5-point Likert scale (not helpful-very helpful).

RESULTS: Among 40 patients determined to be preliminarily eligible (HCV Ab+) for the study, phone contact was made with 27 (67.5%). Of the 27 patients reached, 13 (48.1%) persons agreed to be screened, and 7 were ultimately enrolled. Among the seven participants, 71.4% were male, all were either African American or Latino/Hispanic, with a median age of 54.5 (41.0-63.0). The majority were on public insurance (85.8%), over half received food stamps (57.1%), and one person was homeless (14.3%). Nearly all were on opioid agonist treatment (85.7%), and three (42.9%) were actively using drugs at baseline. Six participants made it to at least one group visit (participant range 4–6 at each group). Acceptability was high among participants; all components were found to be very helpful (median Likert scores for medical evaluation: 5, education: 4.8 (4–5), skill building: 5, group activity (support): 5. Of the 6 participants who attended at least one visit, 5 attended their follow-up appointment for HCV treatment and 4 have initiated treatment.

CONCLUSIONS: These findings indicate that a primary care based HCV Group Evaluation and Treatment Uptake (HCV GET-UP) intervention for PWID is both feasible and acceptable. We will now commence a randomized control trial to test this intervention for improving HCV treatment uptake and cure among PWID in primary care. This intervention has potential to improve individual health outcomes, while reducing the prevalence of HCV in a community with continued transmission.

FEMALES IN ACADEMIA WITH THE FEMALE MENTORS HAVE A DECREASED LIKELIHOOD OF PROMOTION: RESULTS FROM A NETWORK ANALYSIS OF ACADEMIC GENERALISTS Krisda H. Chaiyachati[1]; Joshua M. Liao[1]; Gary E. Weissman[1]; Rebecca Hubbard[2]; Anna U. Morgan[1]; Anna Buehler[3]; Judy A. Shea[1]; Katrina Armstrong[4]. [1]The Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]UC San Diego Medical School, San Diego, CA; [4]Massachussetts General Hospital, Boston, MA. (Control ID #2706314)

BACKGROUND: While mentorship is critical for academic careers, the association between academic promotion and mentorship attributes is poorly

understood. Moreover, we hypothesized that mentor attributes may affect the known gender disparities in promotion. We used network analysis methods to explore the relationship between mentorship and promotion among academic generalists trained in internal medicine, pediatrics, and family medicine.

METHODS: Through online searches and contacting programs, we identified graduates of generalist-oriented fellowships (e.g., general medicine, RWJ Clinical Scholars Program) between 2002–2007. We manually extracted PubMed publication data and electronically surveyed graduates to obtain information about grants, academic rank, and their top 10 most influential career mentors at the 5-year mark post-fellowship. With respondent mentees and nominated mentors represented as vertices, and mentor relationships as edges, we constructed a generalist community graph and generated 2 network measures: percent of common gender dyads (i.e., gender concordant mentee-mentor pairs) and mentor centrality (i.e., how connected a mentor is to other network mentees). Using multivariable logistic regression adjusted for respondent and training institution characteristics, we evaluated the impact of common gender dyads, mentor centrality, and the interaction between the two on promotion to associate professor or higher, 5 years post-fellowship. We also calculated "gender assortativity" for the community graph, a composite measure of mentee preference for the same gender mentors [range: −1 (pref. for opposite-gender) to 1 (pref. for same-gender)].

RESULTS: In total, 162 graduates representing 19 institutions completed our survey (51% response rate). Among the 136 who remained in academia 5 years post-fellowship, the majority were female (65%) and white (67%). At the 5-year mark, respondents reported a median of 3 mentors (IQR 3–5) and 10 peer reviewed publications (IQR 4–18). Thirty-nine percent reported < $500 K in grants and 13% achieved associate professor or higher. In multivariable analysis, neither gender nor percent of common gender dyads independently predicted promotion. However, the association between common gender dyad and promotion differed for men and women respondents with an odds ratio (OR) of 8.61 for men and 0.06 for women (interaction term p-value = 0.03). Other significant associations with promotion included mentor centrality, publications, and grant dollars. The assortativity of the mentorship graph was 0.11 ($p < 0.001$).

CONCLUSIONS: We identified facets of mentorship that may affect early career promotion. While more work is needed, we found the relationship between promotion and common gender dyads varied by gender—female mentees are less likely to be promoted with more female mentorship compared to males mentees with more male mentorship. Educators should consider mentorship disparities to help generalists, irrespective of gender, achieve academic promotion.

FINANCIAL IMPLICATIONS OF NON-VISIT-BASED PRIMARY CARE UNDER CAPITATED PAYMENT: A MODELING STUDY

Sanjay Basu[3]; Russell Phillips[1]; Zirui Song[2]; Asaf Bitton[1]; Bruce E. Landon[1]. [1]Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Stanford University, Stanford, CA. (Control ID #2701995)

BACKGROUND: Capitated payments may provide incentives for primary care practices to shift towards new care models. Our objective was to simulate whether shifting toward team- and non-visit-based care is financially sustainable for internal medicine primary care practices under traditional fee-for-service (FFS), capitated payment, or a mix of the two.

METHODS: We utilized a microsimulation model of utilization, cost and revenue under different care models at U.S. primary care practices, which sampled from data in the Medical Group Management Association national Cost and Revenue survey ($N = 969$ primary care practices, 2014). We externally validated the model by ensuring it was within 5% absolute error from utilization, revenue, and cost estimates (by age, sex, race/ethnicity, primary ICD-9 diagnostic code, and insurance type) among participants in the National Ambulatory Medical Care Survey (NAMCS, 2014, $N = 31{,}229$ patients) and an independent national survey of $N = 2{,}518$ practices. In the model, simulated practice revenues and costs were computed across a range of FFS and capitated payments, with the capitated proportion of payment varied from 0% (traditional FFS) to 100% (fully capitated). Revenues and costs were compared before and after substitution of low-complexity physician visits (those for low-risk diagnoses without any laboratory testing, medication prescriptions, or imaging) with team- and non-visit-based services (nurse visits, nurse/physician telephone/email visits, and care coordination with a medical assistant).

RESULTS: Substitution of low-complexity visits with team- and non-visit-based services produced financial losses for simulated practices under FFS payment, reducing net revenues from $78,288 per full-time physician per year (95% CI: $12,517, $98,552) to $35,890 (95% CI: −$42,846, $91,283). Substitution produced financial gains for simulated practices under capitated payment if >68% of annual payment was capitated. At 100% capitation, net revenues increased to $205,418 (95% CI: $140,206, $222,780) per full-time physician, due to growth in panel size. When practices received a bonus of 0.6% of total expenditures, substitution of low-complexity produced financial gains for simulated practices if >58% of annual payments were capitated.

CONCLUSIONS: A shift to capitated payment may create an incentive for practices to increase non-visit-based primary care delivery, but a high share of capitation may be required to make such a shift financially attractive.

FINANCIAL INCENTIVES FOR SMOKING ABSTINENCE IN HOMELESS SMOKERS: A RANDOMIZED CONTROLLED TRIAL

Travis P. Baggett[4, 3]; Yuchiao Chang[4, 1]; Awesta Yaqubi[2]; Claire McGlave[2]; Stephen Higgins[5]; Nancy A. Rigotti[2, 1]. [1]Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Boston Health Care for the Homeless Program, Boston, MA; [4]Division of General Internal Medicine, Massachusetts General Hospital, Boston, MA; [5]Vermont Center on Behavior and Health, University of Vermont, Burlington, VT. (Control ID #2707557)

BACKGROUND: Three-quarters of homeless adults smoke cigarettes, contributing to 3- to 5-fold higher rates of tobacco-attributable mortality compared with the general population. Homeless smokers want to quit smoking, but the proportion who are able to do so is one-fifth the national average and studies of conventional treatment approaches have yielded modest results. Financial incentives for smoking abstinence have shown promise in non-experimental studies of homeless smokers, but randomized trial data are lacking in this population. We conducted a pilot randomized controlled trial of financial incentives for smoking abstinence among homeless smokers in Boston, MA.

METHODS: All study procedures occurred between October 2015 and June 2016 at Boston Health Care for the Homeless Program. Eligibility criteria included age ≥18 years, current smoking (≥5 cigarettes/day, ≥100 cigarettes lifetime), current homelessness, and desire to quit smoking in the next month. Individuals were not excluded for current drug or alcohol use. Participants randomized to the financial incentives arm ($N = 25$) could earn escalating monetary rewards ($15-$35) for carbon monoxide (CO)-defined smoking abstinence (<8 parts per million [ppm]), assessed 14 times over 8 weeks.

Control arm participants ($N = 25$) were given $10 at each assessment visit, regardless of their exhaled CO levels. All study payments were made onto reloadable debit cards issued to each participant at enrollment. Participants in both arms were offered nicotine patches and weekly behavioral counseling. The primary outcome was a repeated measure of point-in-time smoking abstinence (CO <8 ppm) across the 14 study visits. The secondary outcome was point-in-time abstinence at 8 weeks. Exploratory smoking outcomes were self-reported past 1-day and 7-day abstinence from 1) any cigarette and 2) any puff of a cigarette. Other outcomes included quit attempts, nicotine patch use, counseling attendance, and changes in alcohol and drug use severity scores.

RESULTS: Compared with control arm participants, financial incentive arm participants had greater point-in-time abstinence overall (OR 7.28, 95% CI 2.89, 18.3) and at the end of treatment (48.0% vs. 8%, $p = 0.004$). Similar effects were seen for past 1-day abstinence, but the rates of past 7-day puff abstinence were negligible (0-4%) in both arms. Incentive arm participants made significantly more past-month quit attempts at 4 weeks ($p = 0.03$). Nicotine patch use ($p = 0.80$) and counseling attendance ($p = 0.43$) did not differ significantly between groups. There were no significant changes in alcohol or drug use severity scores in either group.

CONCLUSIONS: Among homeless smokers, financial incentives increased brief smoking abstinence and quit attempts without worsening substance use. This approach is promising but requires modification to achieve more sustained smoking abstinence in this vulnerable population.

FINANCIAL INCENTIVES OF HIGH-DEDUCTIBLE PLAN MEMBERS AND CLINICIAN-BASED PREDICTORS OF LOW-VALUE BACK IMAGING

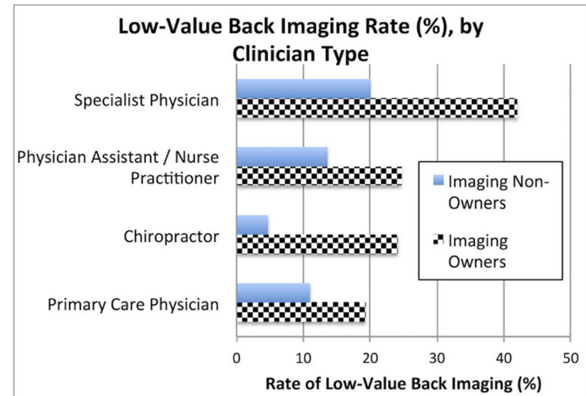
Arthur Hong; Dennis Ross-Degnan; Fang Zhang; James F. Wharam. Harvard Medical School and Harvard Pilgrim Healthcare, Boston, MA. (Control ID #2701134)

BACKGROUND: Physicians and policy-makers often cite patient demand as a driver of unnecessary medical care, while other analysts point to unexplained variations in clinician practice. Consumer-driven health plans (CDHPs) are touted to reduce patient demand, are increasingly prevalent, and are prominent among proposals to replace the Affordable Care Act. We examined whether patient financial incentives outweigh clinician characteristics as predictors of one of the most common low-value services: low-value back pain imaging.

METHODS: Using commercial insurance claims from 2010–2014, we used multivariate logistic regression to model the likelihood of imaging for acute uncomplicated back pain, in adults aged 18–64. We used claims algorithms from the literature to define imaging (X-ray, CT scan, or MRI) after a back pain visit, excluding patients with red flag symptoms such as cancer or neurologic deficit. Patient predictors were patient demographics, CDHP enrollment (high-deductible plan with health savings account), and whether a patient had zero out-of-pocket cost for the defining clinician visit and thus likely faced no cost sharing for potential imaging. Clinician predictors were clinician type (primary care, specialist, chiropractor, physician assistant/nurse practitioner), imaging equipment ownership, and if a clinician's prior patient received imaging. Ownership was established from claims details using validated methods. We used marginal effects to estimate adjusted imaging rates by clinician type and ownership.

RESULTS: Our sample had 1,017,440 visits seen by 103,041 clinicians. CDHP members had 0.91 [95% CI: 0.89, 0.92] lower odds of low-value image, and patients with no cost sharing for a potential image had 1.26 [95% CI: 1.23, 1.29] higher odds. If a clinician owned imaging equipment, low-value image odds were 1.97 higher [95% CI: 1.94, 2.00], and marginally adjusted rates of image were higher for all types of clinician owners (figure). If a clinician's prior patient received imaging, odds of image were 2.57 higher [95% CI: 2.54, 2.60].

CONCLUSIONS: Clinician factors appeared to be stronger predictors of low-value back imaging than patient financial incentives. Policymakers should be aware of the limitations of increasing patient cost sharing to reduce unnecessary care.



FIREARM STORAGE PRACTICES, RISK PERCEPTIONS, AND PLANNED SUICIDE PREVENTION ACTIONS AMONG U.S. VETERANS WITH AND WITHOUT SELF-HARM RISK FACTORS

Joseph A. Simonetti[1, 2]; Deborah Azrael[3]; Matthew Miller[4]. [1]Denver VA Medical Center, Denver, CO; [2]University of Colorado School of Medicine, Denver, CO; [3]Harvard TH Chan School of Public Health, Boston, MA; [4]Northeastern University, Boston, MA. (Control ID #2704086)

BACKGROUND: Veterans accounted for 18% of all U.S. adult suicides in 2014, two-thirds of which involved firearms. Despite the disproportionate use of firearms in veteran suicides and the well-established link between firearm access and suicide risk, little is known about Veterans' firearm storage practices or their beliefs about the relationship between firearm access and suicide risk.

METHODS: Data come from a nationally representative, Web-based survey designed by the investigators and conducted in April 2015 by the survey firm Growth for Knowledge. Respondents were drawn from a group of approximately 55000 U.S. adults selected (on an ongoing basis) with an equal probability of selection. Primary outcomes were the proportion of veteran firearm owners who: 1) stored any household firearm loaded and unlocked, 2) *agreed* or *strongly agreed* that a household firearm increases suicide risk, and 3) reported they would limit firearm access were a household member to become suicidal. We categorized respondents based on the presence of any self-harm risk factor (yes/no), including chronic pain, mood or anxiety disorder, schizoaffective disorder or schizophrenia, and alcohol intake in excess of recommended gender-specific limits. We examined how outcomes varied based on risk for self-harm. We applied weights to account for oversampling and nonresponse and describe findings using weighted proportions and 95% confidence intervals (CI).

RESULTS: Of 7318 panel members invited to participate, 3949 (54.6%) completed the survey and 580 met inclusion criteria. The mean age of Veteran firearm owners was 62.8 years; 94.6% (CI 92.0,96.4) were male and

33.4% (CI 28.8,38.4) had at least one self-harm risk factor. Thirty-four percent (CI 28.8,38.7) of Veteran firearm owners reported storing at least one firearm loaded/unlocked and 6.2% (CI 4.5,8.6) *agreed* or *strongly agreed* that firearms increase household suicide risk. Findings did not differ substantially by self-harm risk factor status. A greater proportion of firearm owners with (than without) self-harm risk factors indicated they would limit firearm access if a household member were suicidal [89.3% (CI 82.2,93.8) vs. 78.6% (CI 72.3,83.8)]. Of those who would take steps to limit firearm access, 24.6% (CI 20.2,29.6) would store firearms away from home and 21.5% (CI 17.6,26.0) would lock all household firearms. Of the 36.4% (CI 31.5,41.6) of firearm owners who indicated they would not need to take action with regard to their firearms because all guns were already inaccessible, 22.1% (CI 16.0,29.7) reported at least one firearm was stored loaded/unlocked.

CONCLUSIONS: One in three U.S. Veteran firearm owners store a firearm in their home loaded and unlocked, only one in twenty believe that a household firearm increases suicide risk, and one in four consider a loaded and unlocked firearm to be inaccessible to suicidal household members. Affecting risk perceptions may be a critical aspect of interventions addressing lethal means safety among U.S. Veterans.

FOOD INSECURITY IN VETERANS RECRUITED FOR A PILOT WEIGHT MANAGEMENT STUDY FOR VETERANS IN PRIMARY CARE: AN EXPLORATORY ANALYSIS Clare M. Viglione[4, 1]; Nadera Rahman[4, 1]; Omar Sanon[4, 1]; Amzad Chowdhury[4, 1]; Yixin Fang[3]; Scott Sherman[4, 2]; Adina Kalet[1]; Joanna Dognin[4]; Melanie Jay[4, 1]. [1]NYU Langone Medical Center, New York, NY; [2]NYU School of Medicine, New York, NY; [3]New Jersey Institute of Technology, Newark, NJ; [4]VA New York Harbor Healthcare System, New York, NY. (Control ID #2704919)

BACKGROUND: Food insecurity (FI) occurs when individuals or households have limited or uncertain access to adequate food. People with FI may find it particularly difficult to eat a balanced diet and manage weight. Individuals who report FI are 1.4 times more likely to have obesity. U.S. Veterans have a greater prevalence of FI compared with the general population (24% vs. 19%). As part of a pilot randomized controlled trial to test the impact of an obesity intervention for Veterans, we explored the prevalence of FI in our sample and assessed the impact of FI on weight outcomes.

METHODS: Veterans with a Body Mass Index of greater than or equal to 30 or between 25 and 29.99 with at least one comorbidity were recruited by phone for a pilot study. Participants randomized to the intervention received a technology-assisted health coaching session and follow-up coaching calls; control participants received a VA "healthy living messages" pamphlet. At baseline and 3 months, participants had weight measurements and completed surveys. To measure FI, we used a 6-item Household Food Security Scale (FI = 2 or more affirmative responses). We assessed the impact of FI on variables independent of arm assignment in participants who returned for a 3-month measurement visit (Wilcoxon rank sum tests and Fisher's Exact Test). We also analyzed the role of FI as a moderator between arm and study variables using ANOVA.

RESULTS: Out of 31 Veterans who enrolled in the study (Mean age = 53.48, 63% male, mean BMI = 31.72), 10 demonstrated FI at baseline and 25 participants completed 3 month measurements. Independent of the intervention, those with FI ($n = 10$) lost .01 kg of weight and those without FI ($n = 15$) lost 1.69 kg at 3-months but the difference was not significant ($p = 0.2$). Similarly, 0/10 Veterans with FI achieved 2.5% weight loss, compared to 4/15 of those without FI ($p = 0.12$). Those with FI in the control group gained weight when compared to those without FI (1.04 kg, SD = 1.41 vs. −1.75, SD = 3.96) and those with FI in the intervention lost the same amount of weight as those without FI (−1.59 kg, SD = 0.83, vs. -1.59, SD = 2.27; $p = 0.24$ for the interaction (not significant)).

CONCLUSIONS: FI in Veterans enrolled in a weight management study is high. Participants with FI in the control arm may have gained weight when compared to non-FI participants, while intervention arm participants with FI lost similar amounts of weight to those without FI. This suggests that the intervention may reduce the negative impact of FI. While this pilot study was not powered to show a significant difference, we have amended health coaching protocols to better address FI in our intervention (e.g. screening for FI and linking participants with Supplemental Nutrition Assistance Program (SNAP) benefits and similar resources) hoping to maximize its effectiveness.

FORECASTING CHANGE IN HEMOGLOBIN A1C LEVELS OVER 60 WEEKS IN TYPE 2 DIABETICS Douglas Gunzler[1]; Shari Bolen[3]; Neal V. Dawson[2]. [1]Case Western Reserve University, Cleveland, OH; [2]MetroHealth Medical Center, Cleveland, OH; [3]MetroHealth/Case Western Reserve University, Cleveland, OH. (Control ID #2702117)

BACKGROUND: One size fits all treatment strategies targeting individuals with Type 2 Diabetes (DM2) may fail to show objective population results in management of DM2 symptoms. Methods were developed to help clinicians classify a DM2 patient population into risk level subgroups based on EHR-available clinical and economic risk factors used to forecast expected change in Hemoglobin A1c (HbA1c) levels over the short term. Understanding risk factor levels of change in HbA1c over time may help clinicians tailor treatment strategies for individual DM2 patients.

METHODS: We analyzed retrospective cohort data over 60 weeks in 2011 from an EHR data base of DM2 patients from a large safety net hospital. We included all subjects with at least three clinic appointments ($N = 3758$). A linear mixed effects modeling approach was used to evaluate the relationship between changes in HbA1c level at follow-up appointments and risk factors at baseline including HbA1c, sex, age, comorbidities (via Charlson), body mass index, education (in years), insulin usage, socioeconomic position (SEP), health insurance type, depression diagnosis and DM2 complications. A predicted slope was calculated for each individual to measure expected trajectory change in HbA1c level. Individuals were classified into quintiles based on these slopes to examine risk level spectral effects that might explain HbA1c level trajectory change over time for different subgroups.

RESULTS: Before accounting for risk factors, on average, over the 60 weeks there was no significant change in HbA1c over time ($p = 0.770$). However, after accounting for risk factors, and classifying subjects into quintiles, different subgroups of individuals were forecasted for positive (>0) and negative (<0) trajectory slope change in HbA1c level (see Figure). The five quintiles significantly differed from each other ($p < 0.05$) in baseline HbA1c, age, comorbidities, SEP, sex, depression diagnosis, insulin usage, and health insurance type. The first quintile was characterized by the highest average baseline HbA1c (mean = 9.67, SD = 2.30), a low SEP (mean = −0.14, SD = 1.87), and the highest number of insulin users (Yes = 555, No = 116), while the fifth

quintile had the lowest average baseline HbA1c (mean = 6.75, SD = 1.32), a high SEP (mean = 0.08, SD = 1.72), and the lowest number of insulin users (Yes = 94, No = 577).

CONCLUSIONS: Treatment of DM2 patients should include specifically tailoring care based on individual clinical risk factor levels. On average, this DM2 population, did not show any significant change in HbA1c level over 60 weeks. However, particular subgroups of patients were forecasted to positive or negative changes in HbA1c levels over this time period. Recognizing the risk factor levels of patients in these different quintiles and tailoring care accordingly may help patients better stabilize their HbA1c levels over the short term.

FRAILTY AND THE IMPACT OF PRIMARY CARE ON OUTCOMES AMONG PATIENTS WITH CHRONIC RENAL INSUFFICIENCY Jodi B. Segal[1, 2]; Hsien-Yen Chang[2]; Ravi Varadhan[1]; Raquel Greer[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD. (Control ID #2704924)

BACKGROUND: Fried and colleagues described a frailty phenotype. This phenotype is manifest with 3 or more of the following: low grip strength, low energy, slowed waking speed, low physical activity, or unintentional weight loss. Frailty has been associated with disability and hospitalization among older individuals. In these analyses, we aimed to assess whether frailty impacts death and ESRD development among individuals with CKD and whether it alters the impact of primary care on these outcomes.

METHODS: We quantified the association between primary care utilization and ESRD incidence or death among older US adults with chronic kidney disease (CKD) in 2005–2006 using Medicare claims. We previously developed the Claims Based Frailty Index (CFI) which allows frailty to be detected with claims data alone. We generated the CFI for each individual using diagnosis codes from their claims data from the preceding 6 months. We used Cox proportional hazard models and competing risk models to estimate hazard ratios (HRs) for ESRD and mortality including our measure of frailty in the models and in stratified analyses, and tested the impact of a PCP visit on these outcomes.

RESULTS: Among 106,765 individuals, 4,264 patients developed ESRD and 45,059 died over four years. Most (79%) had at least one primary care visit in 2006. The presence of frailty was an independent predictor of the outcomes of death [HR 1.14 (95% CI 1.15–1.25)] and ESRD [HR 1.50 (95% CI 1.48–1.58)], after extensive adjustment for comorbid conditions. Compared to patients with no PCP visits, patients with at least one visit had a lower risk of death [HR 0.73 (95%CI 0.72–0.75)] overall and in age stratified models. The benefits of a PCP visit on averting mortality were equivalent among frail and non-frail individuals, HR 0.74 (95% CI. 0.71–0.78) and HR 0.74 (95% CI 0.72–0.77), respectively. In the competing risk model, a PCP visit did not significantly reduce ESRD incidence [HR 0.93(95% CI 0.87–1.0)]; PCP involvement benefited neither frail nor non-frail individuals.

CONCLUSIONS: Frailty is an independent predictor of death and ESRD among older individuals with CKD. PCP involvement in the care of frail and non-frail individuals with CKD lessens the risk of death, non-differentially, but not the risk of ESRD. The impact of primary care is likely through modification of comorbid conditions associated with death. We found that frailty status did not alter the impact of primary care on outcomes among patients with chronic renal insufficiency.

FROM ACUTE TO CHRONIC: OPIOID RECEIPT FOLLOWING INCIDENT USE COMPARED ACROSS SURGICAL, MEDICAL AND OUTPATIENT SETTINGS Hilary Mosher[2, 3]; Brooke Hofmeyer[3]; Brian C. Lund[1]. [1]Center for Comprehensive Access & Delivery Research and Evaluation, Iowa City, IA; [2]University of Iowa Hospitals and Clinics, Iowa City, IA; [3]Iowa City VA Medical Center, Iowa City, IA. (Control ID #2689998)

BACKGROUND: Opioid analgesics may be initiated following surgical and medical hospitalization or in ambulatory settings. Rates of subsequent long-term opioid therapy (LTOT) have not been directly compared. We present rates of LTOT following incident opioid exposure at surgical discharge, medical discharge and outpatient visits, and identify factors associated with LTOT following surgical and medical discharge.

METHODS: This observational study using Veterans Administration (VA) Corporate Data Warehouse (CDW) data included all patients receiving an outpatient opioid prescription from a VHA provider in FY2011, preceded by 365 days with no outpatient opioids. The first 30 days of exposure after incident opioid prescription were considered independently of the outcome, LTOT, which is a period of continuous opioid supply beginning within 90 days of initial prescription and lasting 90 days. If a continuous opioid episode began within the first 30 days, the episode start date was re-set to day 31 (i.e., opioid supply must extend through days 31–121 to be considered long-term). We repeated the analysis excluding all patients with an initial 30-day supply, which may signal planned (intentional) LTOT. We performed bivariate and multivariate analyses to identify factors associated with LTOT following surgical and medical discharges.

RESULTS: Following incident prescription, 2.9% of discharged surgical patients, 10.2% of discharged medical patients, and 14.9% of outpatients received LTOT. Where only initial <30 days prescription were considered (N = 278,771), rates were 2.3%, 7.1%, and 5.1%, respectively. The adjusted odds ratio for LTOT was 0.32 (95% CI 0.29–0.36) for surgical vs medical patients, and 0.33 (95% CI 0.30–0.36) for surgical vs ambulatory patients. In surgical and medical patients, substance abuse, age 50–64 years, ≥90 days of prior non-opioid analgesic use, and concurrent antidepressant or muscle relaxant use were associated with LTOT. In surgical patients, initial dose of ≥12.5 mg/day of morphine equivalents, and initial days' supply of >14 were significant; in medical patients, initial dose ≥25 mg/day of morphine equivalents and initial days' supply of >7 were associated with LTOT. Number of opioid prescription fills within the initial 30 day exposure period was strongly associated with the outcome in both groups; 22.6% of discharged medical patients who received 2 fills, 33.6% who received 3 fills and 44.2% of patients with ≥ 4 fills had subsequent LTOT.

CONCLUSIONS: Rates of long-term opioid receipt following new opioid prescription are lower following surgical discharge than medical discharge or outpatient visit. Characteristics of opioid prescribing within the initial 30 days, including initial dose, days prescribed, and most prominently repeat prescriptions, are strongly associated with LTOT and may offer opportunities for early recognition or intervention if long-term opioid therapy is unintended or undesirable.

FROM PRACTICE EMPLOYEE TO (CO-)OWNER: YOUNG PRIMARY CARE PHYSICIANS PREDICT THEIR FUTURE CAREERS. A CROSS-SECTIONAL SURVEY

Luzia B. Gisler[1]; Marius Bachofner[2]; Cora N. Moser-Bucher[3]; Nathalie Scherz[4, 5]; Sven Streit[1]. [1]University of Bern, Bern, Switzerland; [2]Family Practice, Nottwil, Switzerland; [3]Center for Primary Care Medicine, Basel,

Switzerland; [4]Institute of Primary Care, Zürich, Switzerland; [5]Arud Centres for Addiction Medicine, Zürich, Switzerland. (Control ID #2698599)

BACKGROUND: In Switzerland, the mean age of Primary Care Physicians (PHP) is 55, and PHPs over 65 make up 15% of the workforce of the about 6000 PHPs. Switzerland already is short about 2000 PHPs. As many will retire over the next years, the shortage will increase to 4000, and the country will need young doctors to fill their positions. In a previous study, we found that 41% of future PHPs wanted to be employees rather than practice owners. As a result, some journalists declared that young PHPs were not brave enough to venture out on their own. We set out to determine what kind of employment young PHP wanted, if their preferences would differ depending on ownership of practices, and to determine the working conditions and factors most important in their choice of practice.
METHODS: This is a cross-sectional study using an online survey. As Switzerland has no national register of PHP residents, we administered the survey to members of the Swiss Young PHP Association. All 456 members were medical students (3rd year on), residents, or PHP within five years after residency. We excluded 13 (2.9%) members with no valid email address. Participants' characteristics, their preferred type of practice and working conditions were collected using closed and open-questions. We asked participants to rate the attractiveness of fictional job ads that differed in ownership (PHP-owned/not-PHP-owned). To compared the attractiveness of job adds we calculated means and 95% confidence intervals (CI) for their ratings. To identify factors most important with their choice, we used logistic regression models adjusting for age, sex, language, civil status, desired workload and other covariates after a hierarchical stepwise elimination and calculated odds ratios (OR) and 95% CI.
RESULTS: We received 270 (61%) replies. Most respondents were female (71%) and aged in mean 32.9 (SD 4.7) years. Most wanted to work in the suburbs or countryside and intended to work part-time: mean desired workload was 78% for men and 66% for women. Positive working climate was a major factor in choosing a practice. A large majority rated job ads higher when they were from PHP-owned practice (89%, 95%CI 84–92%). Those wishing to work full-time and to be employed long-term were less in favour of a PHP-owned practice (OR 0.13, 95%CI 0.02–0.95 and OR 0.20, 95%CI 0.04–0.95, respectively). Most participants projected a career arc from employment to (co-)ownership of a practice within five years; only 7–9% preferred to remain employees.
CONCLUSIONS: Future PHPs in Switzerland want to work part-time in small, PHP-owned group practices. Stakeholders who claim that young doctors prefer employment to owning a practice are telling only part of the truth. Young PHPs intend to spend a relatively short time as employees and most of their career as owners or co-owners. This initial desire for employment must be acknowledged and met, but it should also be understood as a career stage, rather than a permanent condition.

FRONT-END VS. BACK-END CLINICAL DOCUMENT DICTATION PREFERENCES AMONG PHYSICIANS AT A LARGE, INTEGRATED HEALTHCARE SYSTEM Leigh Kowalski[2]; Foster Goss[3]; Adam B. Landman[2, 4]; Shiri Assis-Hassid[4, 2]; Marie Meteer[6]; Suzanne Blackley[5]; David W. Bates[1, 4]; Li Zhou[2, 4]. [1]Brigham and Women, Boston, MA; [2]Brigham and Women's Hospital, Wellesley, MA; [3]University of Colorado, Aurora, CO; [4]Harvard Medical School, Boston, MA; [5]Partners HealthCare System, Boston, MA; [6]Brandeis University, Waltham, MA. (Control ID #2703821)

BACKGROUND: Speech recognition (SR), the automated transcription of spoken language, has the potential to improve productivity (e.g., turnaround time) and reduce costs associated with clinical documentation. SR can assist physicians with dictation through two modes: 1) *Front-end*: Physicians dictate directly into the electronic health record (EHR) using SR software (e.g., Dragon®); and 2) *Back-end*: Physicians dictate via phone or recording device and their voice is transcribed by SR software, followed by professional transcriptionist review. However, documentation quality, productivity and physician satisfaction with SR systems have not been widely studied; we therefore conducted a physician survey to gather their feedback and understand their needs.
METHODS: A questionnaire with 71 questions was created using REDCap and given to 810 physicians in the Brigham and Women's Physician Organization who were registered to use a dictation system (front-end or back-end). Multiple choice questions assessed native language, percentage of time spent editing clinical documentation, and satisfaction with the system. Free-text questions asked about common errors observed with dictation systems. This study was approved by Partners IRB.
RESULTS: 153 (19%) physicians completed our survey, of which, 89 (58.2%) currently use front-end dictation systems, 27 (17.6%) use back-end, 23 (15.0%) use both, and 14 (9.1%) use other methods or none. Front-end users tend to be younger (<45 year old; 45.6% vs. 28.0% for back-end). Both front-end and back-end users are mostly White (79.0 and 74.0%, respectively) and native English speakers (92.1 and 94.0%). Results showed significant differences in perceived percent of documentation time spent editing between the two groups. For front-end users, half spent 10–25% of documentation time editing and 9% spent >50% of time. For back-end users, the major (60%) spent only 0-10% of time editing. Back-end users also reported fewer errors created by the dictation system than front-end users (85.2% vs. 69.7% reported fewer than 10 errors per document). A variety of errors were reported, including "word recognition", "medication dosages", and "misspelled names." Users expressed concerns about accuracy and efficiency of the dictation systems. In general, compared to front-end users, back-end users are more satisfied with the systems they have been using.
CONCLUSIONS: Overall, the results suggest that physicians prioritize convenience and efficiency of dictation system, and the quality of note produced. Thus, documentation method and dictation system choice may depend on physician specialty and workflow. SR systems have the potential to prevent physician burnout by easing the burden of clinical documentation. Future assessment is needed to further investigate the best way to incorporate SR with clinical documentation in the EHR to ensure both accuracy and efficiency of documentation, as well as satisfaction of physicians.

FUTURE PLANNING AND LONG-TERM CARE FOR PEOPLE WITH INTELLECTUAL DISABILITIES Sophia Jan[3, 4]; Natalie Stollon[1]; Angela Liang[2]; Sujatha Changolkar[3]; Symme W. Trachtenberg[4]. [1]University of Washington, Seattle, WA; [2]Princeton University, Princeton, NJ; [3]University of Pennsylvania, Philadelphia, PA; [4]Children's Hospital of Philadelphia, Philadelphia, PA. (Control ID #2707524)

BACKGROUND: The number of adults with intellectual disabilities (ID) is growing, with most living with aging parental caregivers in family homes. Yet publicly-funded long-term care (LTC) supports, which enable adults with ID to continue living in family homes or other community settings, are limited. Few families complete future plans for when aging parental caregivers are no longer able to provide care, leading to crisis, emotional trauma, dilemmas for other family members, and/or costly and unwanted institutional placement. Drivers of LTC planning behavior and emergent placements are largely unknown.

METHODS: We conducted semi-structured qualitative interviews with parents and adult siblings of adults with ID, who also completed demographic and other surveys on adaptive functioning and problem behavior of the adult with ID, caregiving burden and caregiver general health. Parents and adult siblings were recruited from community listservs, a free-standing children's hospital, a large academic medical center, the social services agency of a large city. Interviews were recorded, transcribed, and analyzed using modifed grounded theory.

RESULTS: Participants included 16 parents and 10 adult siblings. Of these, 5 were parent-sibling dyads. Caregivers were primarily female, Caucasian race, with a mean age of 60 years for parents and 29 years for siblings. Most caregivers were of high income and education. Dependent adults with ID had a mean age of 28.5 (range 18 to 41) years, with some enrolled in Medicaid LTC waivers. All scored low on proxy measures of adaptive functioning and many had problematic behaviors. Future planning domains identified include housing arrangements and housing maintenance, legal and financial management, transportation, medical management, oversight of direct caregiving staff to manage instrumental and basic activities of daily living. Many caregivers lacked concrete plans in one or more domains. Drivers of future planning were caregiver access to information, "systems literacy", trust and acceptance of external supports, perceived urgency of future planning, and capacity to let go/accept caregiving responsibilities. Mediators were caregiving needs of dependent ID adult, family structure and supports, and non-family/paid supports. These changed with time and experiences with prior crisis. Few caregivers discussed their plans with other family caregivers, and none discussed with the dependent adult. Contrasts between parents and sibling caregivers included perceived urgency towards future planning, ideal vision for caregiving arrangements, and expectations for future caregivers.

CONCLUSIONS: This study identifies primary drivers of future planning or non-planning behavior, and intervention targets to improve family caregiving planning of dependent adults with ID, and potentially prevent institutional placement. Our findings can be used to help medical and educational professionals, and supports coordinators to better understand and assist caregivers with future planning.

GATEKEEPING AND PATTERNS OF OUTPATIENT SPECIALTY CARE IN THE POST-HEALTH REFORM ERA Michael L. Barnett[3, 1]; Bruce E. Landon[2]. [1]Brigham and Women, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Harvard T. H. Chan School of Public Health, Boston, MA. (Control ID #2705764)

BACKGROUND: As US health care spending increases, insurers are focusing attention on decreasing unnecessary specialist care using one of two approaches. Patient-facing strategies rely upon high deductibles and narrow networks to limit specialist use whereas provider-facing strategies use primary care physicians (PCP) as 'gatekeepers' to approve and coordinate referrals. Little recent research has assessed whether the provider-facing strategy of gatekeeping used in contemporary health maintenance organizations (HMO) is associated with lower utilization of specialty care.

METHODS: We used the Massachusetts all-payer claims database to identify all individuals aged 21–64 with any HMO or preferred provider organization (PPO) insurance coverage with the same private insurance carrier continuously from 2010–2013. The key exposure of interest was whether a patient had HMO vs. PPO insurance. We assessed rates of primary care visits, new specialists visits and spending, and also whether new specialist referrals were within the same health system as patients' PCPs. We assigned patients' PCPs annually through the plurality of claims billed and defined new specialist visits using 'new visit' billing codes. We estimated multivariable regression models for each outcome (linear, Poisson or logistic), adjusting for all available patient characteristics and insurance carrier fixed effects. Sensitivity analyses included repeating all analyses using propensity score weighting for each individuals' likelihood of having HMO coverage.

RESULTS: In 2010–2013, 533,112 and 316,930 individuals had continuous coverage with HMO or PPO insurance, respectively. Compared to PPO patients, HMO patients were slightly younger and had lower comorbidity scores ($p < 0.001$), but had similar rates of PCP visits (adjusted difference 0.03 annual visits, $p < 0.001$). HMO patients had 12% fewer annual new specialist visits per member vs. PPO (0.36 vs. 0.43, adjusted difference 0.05, 95% CI 0.046-0.051), and these visits were more likely to be with a specialist in the same health system as the patient's PCP (44.9% vs. 40.7%, adjusted difference 2.5%, $p < 0.001$). HMO patients were also less likely to have specialists in ≥2 health systems (21.7% vs. 24.3%, adjusted difference 2.2%, $p < 0.001$). Mean annual spending on new specialist visits per member was lower in HMO vs. PPO patients (unadjusted $59.02 vs. $73.40), translating to 12% lower spending after adjustment (adjusted difference $8.86, $p < 0.001$).Adjusted analyses were unchanged using propensity score weighting.

CONCLUSIONS: Having HMO insurance was associated with lower use of new specialist visits vs. PPO insurance. In addition, specialist use within HMOs was more likely to be in the PCP's health system and less likely to be spread across multiple health systems. Our analyses suggest that HMO gatekeeping may meaningfully reduce specialist utilization, though the impact of this change on overall spending and clinical outcomes is unknown.

GENDER DIFFERENCES IN CLINICIAN SATISFACTION, STRESS AND BURNOUT. RESULTS FROM THE HEALTHY WORK PLACE STUDY. Elizabeth Goelz[5, 4]; Sara Poplau[2, 3]; Roger Brown[1]; Jule Muegge[3]; Mark Linzer[2, 3]. [1]University of Wisconsin, Madison, WI; [2]Hennepin County Medical Center, Minneapolis, MN; [3]Minneapolis Medical Research Foundation, Minneapolis, MN; [4]University of Minnesota, Minneapolis, MN; [5]Hennepin County Medical Center, MInneapolis, MN. (Control ID #2705540)

BACKGROUND: Gender differences in clinician work-life have been previously described with increased burnout, time pressure and work pace seen in women physicians. The current study sought to assess whether these differences have persisted and determine current predictors of stress and satisfaction among women and men primary care clinicians.

METHODS: The Healthy Workplace Study (HWP), a randomized trial of 34 clinics and 165 primary care clinicians (143 physicians and 22 Nurse Practitioners (NPs) and Physician Assistants (PAs)) assessed the impact of work-life interventions. Multiple linear regressions modeled satisfaction, stress and burnout by time pressure, work control, work pace, and organizational culture including trust, values alignment, ability to go part-time, and emphasis on work-life balance. Burnout rates in HWP were compared with rates in the 422 of physicians in the MEMO (Minimizing Error Maximizing Outcome) study of primary care work conditions and clinician outcomes (Linzer M, et al. *Ann Intern Med*. 2009; 151:28–36).

RESULTS: There were 90 female and 75 male HWP clinicians with complete data available for analysis. Although no significant differences were seen in burnout between HWP females and males (41.5% in females vs 32.3% in males,

$p = 0.24$), both males and females reported burnout at levels greater than in MEMO. Males showed a greater increase in burnout rates (35.8% → 41.5% (increase 5.7%, $p = 0.42$) for females, versus 19.1% → 32.3% for males (increase 13.2%, $p = 0.01$)). Female HWP clinicians were more likely to work part-time (38.5% vs 9% for males, $p < .01$). Females in HWP reported more psychosocially complex patients (47% vs 32% in males, $p < 0.01$), more time pressure for new patient visits (52% more time needed vs 24%, $p < 0.01$), less control over workload (2.19 on 1–4 scale vs 2.51, $p < 0.01$), and less values alignment with leaders (2.15 on 1–4 scale vs 2.52, $p < 0.01$). While stress and satisfaction of HWP clinicians did not differ by gender, predictors of these antecedents of burnout showed gender differences. (See table of beta coefficients: for one point rise in predictors, betas represent change in stress or satisfaction.)

CONCLUSIONS: Burnout in primary care is increasing in both female and male clinicians but at a greater pace in males. Part-time practice may be slowing the rate of rise in females. Addressing gender-associated stressors may be effective in combating burnout and improving job satisfaction.

Stress and satisfaction predictors for male and female clinicians in HWP

GENDER MATTERS: INTERNAL MEDICINE RESIDENT PERCEPTIONS OF GENDER IN MEDICAL TRAINING Evan K. Moser-Bleil; Mumtaz Mustapha; Briar Duffy; Sophia Gladding; Qi Wang; Elizabeth A. Rogers. University of Minnesota, Minneapolis, MN. (Control ID #2704843)

BACKGROUND: Gender differences are documented throughout academic medicine, including in compensation, promotion, and leadership. Less is known about whether gender influences medical training.

METHODS: Residents in an academic internal medicine program (categorical medicine, medicine-pediatrics (med-peds), and medicine-dermatology (med-derm)) were electronically surveyed regarding perceptions of gender differences in medical training. The survey was informed by a literature review and an informal focus group with face validity and interpretability tested among three physicians. It utilized Likert scale and open-ended questions. Data was analyzed using Excel and SAS. Quantitative data was analyzed using descriptive statistics, the Mann–Whitney-Wilcoxon test, and the Wilcoxon signed rank sum test for comparisons. Formal content analysis was used for qualitative data.

RESULTS: Seventy residents completed the survey (50% response rate). Forty-seven percent were female; 60% medicine, 3% med-derm, and 37% med-peds; and 39% PGY1, 24% PGY2, 24% PGY3, and 13% PGY4. Overall, respondents felt that male residents were treated more positively than female residents in their communication with ancillary staff, consultants, supervising physicians, and supervisees; in their opportunities for leadership; and in how teams responded to their leadership style (all ps < 0.001). Consistent with this, females reported being treated more negatively than their male colleagues in communication with ancillary staff ($p < 0.0001$), supervising physicians ($p = 0.001$), consultants ($p = 0.002$), and supervisees ($p = 0.01$). Females also reported fewer leadership opportunities ($p = 0.01$) and a more negative response toward their leadership style ($p = 0.002$). Males were significantly more likely to report their gender positively affected their work experiences ($p = 0.0001$). Open-ended responses illustrated these differences. Common themes included more difficult communication for females with ancillary staff ("when I say something to the nurses, things get done, but…my female counterparts have to almost convince them" (male)), differences in leadership style ("men who are firm, direct, kind, and empathetic…are viewed more favorably than women exhibiting the same behaviors" (female)), and inequity in leadership opportunities ("in order to get the same leadership opportunities as my male colleagues I…have to show that I can already do the said skill while they just have to show…the confidence to try it out" (female)).

CONCLUSIONS: Resident physicians in an internal medicine program perceived gender differences in communication, leadership styles, and leadership opportunities. While results may be subject to social desirability bias, themes from open-ended questions reinforce quantitative results. Curriculum designed to recognize and mitigate gender bias in medical education may begin to address gender differences early in physicians' careers.

GERIATRIC TRAUMA CONSULTATION: TARGETING THE RIGHT POPULATION Meera Sheffrin[1]; Astrid Block[2]; Ankur Bharija[1]. [1]Stanford University School of Medicine, Palo Alto, CA; [2]Stanford Healthcare, Stanford, CA. (Control ID #2704037)

BACKGROUND: Geriatric consultation has been shown to improve outcomes for elderly trauma patients. However, geriatric consults are resource intensive, and it is unknown which patients would benefit most from this intervention. We examined the acceptability and feasibility of targeting geriatric consults to older adults admitted to the trauma service who were 1) admitted after a fall from standing, or 2) deemed to be high risk from a geriatric screen focusing on geriatric syndromes.

METHODS: Partnering with the Trauma service, we identified two populations of older trauma patients to target for routine geriatric consultation. In our institution, older adults with fall from standing who sustain injuries are admitted to the Trauma service. We selected this fall population as the Trauma service deemed them to be vulnerable. Additionally, we developed a 10 question geriatric screen for older adults to be done at the time of the tertiary survey that included questions on geriatric syndromes (ie baseline cognitive and functional impairment, polypharmacy, delirium). We implemented routine geriatric consults for all patients age 65+ with fall from standing and those who screened positive on the geriatric screen (1+ positive answers). We assessed the acceptability and feasibility of routine geriatric consults on these two populations through tracking the frequency of consults, extent of recommendations that were followed (all or some vs. none), and Trauma service satisfaction with geriatric consultation.

RESULTS: From Nov 1 to Dec 31 2016, geriatrics consults were requested on a total of 40 elderly trauma patients. Mean age was 83 years (range 65–101), and 60% (24/40) were female. Overall, 39 patients were seen after a fall from standing. Only 3% (1/39) of fall patients were found not to have any geriatric

syndromes. Only 1 patient was assessed using the geriatric screen due to difficulty using the screen in the electronic health record. Trauma service reported satisfaction with geriatric consults for older patients with falls, clear criteria for consultation, and patient satisfaction. Trauma service reported willingness but had difficulty using the geriatric screen. Some or all of the geriatrics recommendations were followed in all (100%) of patients.

CONCLUSIONS: Routine geriatric consults for trauma patients age 65+ admitted with fall from standing were well received, and identified a population that had geriatric syndromes. A geriatric screen for older trauma patients may target additional patients, but details in implementation impeded its use. Using the criteria of older adults with "fall from standing" may help to target geriatric consultation to high risk elderly trauma patients who could benefit most from this intervention.

GETTING BY WITH A LITTLE HELP FROM MY FRIENDS: THE IMPACT OF SOCIAL SUPPORT ON DEPRESSION, QUALITY OF LIFE, AND GUIDELINE-RECOMMENDED MEDICATION USE IN PATIENTS WITH HEART FAILURE. Emily Guhl; Anam A. Waheed; Kaleab Abebe; Yan Huang; Amy Anderson; Bea Herbeck Belnap; Bruce L. Rollman. University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #2703768)

BACKGROUND: Higher levels of social support are associated with better health outcomes. Yet, it is unclear whether this relationship is confounded by disease burden, adherence with guideline-recommended care, or other factors. We examined this question among patients enrolled in the NIH-funded Hopeful Heart Trial presently examining the impact of treating depression in patients with systolic heart failure (HF).

METHODS: We screened patients with systolic HF and NYHA class II-IV symptoms for depression with the Patient Health Questionnaire (PHQ-2) at 8 Pittsburgh-area hospitals, prior to discharge home, and telephoned them two weeks later to administer the PHQ-9. Protocol-eligible patients had both: (1) a positive PHQ-2 depression screen and scored ≥ 10 on the PHQ-9 ("depressed"); or (2) a negative PHQ-2 depression screen and scored <5 on the follow-up PHQ-9 ("non-depressed"). We administered the ENRICHD Social Support Instrument (ESSI) to assess perceived social support, and classified participants who scored in the top quartile as having a "top levels" of social support, and used student's t-test or chi-square test, when appropriate, to compare this group to the combined other quartiles on a variety of sociodemographic and clinical characteristics we collected at baseline by patient self-report (age, race, gender, NYHA classification) and chart review (medical diagnoses, medication use, cardiac ejection fraction), or during the two-week call (mental and physical health-related quality of life (HRQoL): SF-12 MCS and PCS, respectively; mood: PHQ-9).

RESULTS: From 3/14-11/16 we enrolled 545 patients with systolic HF, including 178 assigned to our top level of social support (ESSI ≥32). Compared with patients at lower levels of social support, those who scored at the top level were more likely to be white (79% vs. 69%, $p = 0.02$), married (60% vs. 34%, $p < 0.001$), reporting fewer mood symptoms (PHQ-9, mean score: 9.7 vs. 12.6, $p < 0.001$), reporting higher levels of mental HRQoL (SF-12 MCS, mean score: 48.3 vs. 41.8, $p < 0.001$), and using a statin (73% vs. 63%, $p = 0.02$); however, the two groups were similar by age (mean: 63.6 years), gender (44% female), physical HRQOL (SF-12 PCS, mean: 31.3), medical comorbidity (50% DM, 83% HTN), EF (27.6%), NYHA class (II 40%, III 51%, IV 9%), use of ACE/ARB (59%), and beta-blockers (86%).

CONCLUSIONS: Despite similar HF disease severity and medical burden, high perceived levels of social support are associated with fewer mood symptoms and higher levels of mental HRQoL that may, in turn, translate to differences in clinical outcomes. Upon opening our Trial's study blind in 2018, future analyses will evaluate the impact of social support on clinical outcomes and use of guideline-recommended therapy.

GETTING TO PATIENT CENTERED PRIMARY CARE: THE ROLE OF CLINIC ENVIRONMENT, PROVIDER BURNOUT, AND PATIENT-PROVIDER COMMUNICATION Susan E. Stockdale[2]; Danielle Rose[4]; Jill E. Darling[4]; Lisa S. Meredith[3]; Christian D. Helfrich[6]; Timothy Dresselhaus[4]; Philip Roos[5]; Lisa V. Rubenstein[1]. [1]GLA VA, North Hills, CA; [2]Greater Los Angeles VA Healthcare System, Sepulveda, CA; [3]RAND Corporation, Santa Monica, CA; [4]VA GLA Healthcare System, Sepulveda, CA; [5]VA Loma Linda Healthcare System, Loma Linda, CA; [6]VA Puget Sound Healthcare System, Seattle, WA. (Control ID #2694414)

BACKGROUND: Patient Centered Medical Home (PCMH) models of primary care aim to improve patient experience, but may not achieve desired results due to dynamic relationships among factors at the clinic, provider, and patient levels. No studies have assessed the roles of factors at multiple levels on patient experience. We examined the roles of provider-evaluated clinic environment, provider burnout, and patient-rated provider communication on patients' self-reported satisfaction with their primary care providers (PCPs) in the early phase of the Veterans Health Administration (VHA)'s PCMH model.

METHODS: We matched cross-sectional self-administered surveys of a) VHA PCPs ($n = 129$) and b) patients of these providers ($n = 3298$). Surveys were conducted in 21 clinics in one administrative region in 2011–12. We assessed the clinic environment based on provider survey scales assessing leadership openness to new ideas (Organizational Readiness to Change Assessment); the ability of teams in the clinic to handle conflict and work together (Organizational Readiness to Change Assessment); and the clinic's implementation of PCMH principles (adapted from a previous instrument). We measured provider burnout using a provider survey scale for emotional exhaustion (Maslach burnout inventory). We assessed patient-provider communication and patient satisfaction with their provider based on VHA's routinely administered Survey of Healthcare Experiences of Patients. We analyzed matched patient-provider pairs using hierarchical linear regression to account for nested data structure and controlled for PCP and patient characteristics.

RESULTS: In multivariable models, poor clinic environment (low readiness to change and poor team communication) was associated with higher PCP burnout, but burnout did not explain the relationship between clinic environmental factors and patient satisfaction. Poor team communication was associated with lower patient satisfaction, and patient-rated communication explained 56% of this effect. Environments with poor team communication and low patient ratings of provider communication predicted very low patient satisfaction levels (22%).

CONCLUSIONS: PCPs are likely to suffer burnout in a leadership environment unsupportive of change and a primary care team environment characterized by conflict and poor communication. A poor provider-perceived team communication environment appears to contribute to patients' perceptions of poor communication with their providers, and the combination of these two factors may produce lower patient satisfaction. For improved patient satisfaction in the PCMH, clinic-level interventions to support good team and patient-provider communication may be necessary.

GOALS OF CARE DISCUSSIONS: DO ADVANCED CANCER PATIENTS HAVE THEM AND WHAT DIFFERENCE DO THEY MAKE? Nina A. Bickell[2]; Kerin Adelson[4]; Jason Gonsky[5]; Sofya Pintova[1]; Benjamin Levy[3]; Jenny J. Lin[1]; Rebeca Franco[2]; Natalia Egorova[1]; Cardinale B. Smith[1]. [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Mount Sinai School of Medicine, New York, NY; [3]Mount Sinai Beth Israel, New York, NY; [4]Yale Smillow Cancer Center, New Haven, CT; [5]Kings County Hospital Center, Brooklyn, NY. (Control ID #2700215)

BACKGROUND: Advanced cancer patients often have a poor understanding of the incurability of their cancers and this is associated with higher rates of aggressive treatment near end of life. Goals of Care (GoC) discussions typically include information about the cancer, its treatment, side effects, prognosis and elicit patients' values in the setting of their cancer diagnosis. Little is known about the best ways to enhance patient understanding, clarify values and move GoC discussions earlier in the disease process when patients would have time to act on their values. We report the effect of communication skills coaching on GoC discussions and the impact on patients' knowledge of what to expect & clarity of values during the disease trajectory. Utilization data to follow.
METHODS: At academic, community, municipal and rural hospitals, we recruited & randomized solid tumor oncologists & their newly diagnosed advanced cancer patients with <2 year prognosis to participate in a RCT testing communication skills training using a coaching model. Patients consent after advanced cancer diagnosis and are surveyed after their 3 month post-imaging visit. We define GoC discussions as patients reporting their doctor talked about the likely outcome of their illness and clarified things most important to them given their illness. Outcome variables assess the impact of the discussion on patients' knowledge, and getting clearer about their values.
RESULTS: We enrolled 22/25 (88%) oncologists and 175/256 (70%) patients. To date, 96 patients completed their post-imaging visit survey. On average, doctors are 44 yrs old (32–66) and in practice 14.5 yrs (5–40). Patients' mean age is 62 (20–95), 40% females, 58% white, 24% Latino & 22% black. Overall, 66% of patients reported their treatment's goal was to cure their cancer; 14% reported cure to be unlikely. Patients felt more knowledgeable about what to expect (79% vs 21%; $p = 0.02$) when their doctors discussed treatments, side effects & quality of life. When patients were asked about important things in life given their cancer diagnosis, they report being a bit clearer about their values (65% vs 35%; $p = 0.16$). Compared to controls, intervention patients felt more knowledgeable about what to expect (78% v 63%; $p = 0.17$) but did not feel clearer about their values (60% v 54%; $p = 0.59$). Multivariate modeling found that poor health literacy (OR = 0.2; 95%CI: 0.07–0.82), having a GoC discussion (OR = 10.2; 1.7–63.1) and being in the intervention group (OR = 8.8; 1.4–55.2) significantly affected knowledge about what to expect (model c = 0.88; $p < 0.01$). However, discussing what's important to patients did not help patients feel clearer about their values (OR = 2.7; 0.6–12.2; model c = 0.82; $p < 0.05$).
CONCLUSIONS: Using a coaching model to teach oncologists communication skills may improve patients' understanding of what to expect with their cancer but does not appear to impact their clarity of values.

GRIT AS PREDICTOR OF BURNOUT IN INTERNAL MEDICINE RESIDENTS Andrei Brateanu[1]; Susan Combs[1]; Jennifer Ramsey[1]; James Thomascik[2]; Amy S. Nowacki[2]; Colleen Colbert[2]. [1]CCF, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH. (Control ID #2704540)

BACKGROUND: Residency is a highly competitive environment requiring trainees to have both physical and emotional resilience. Residents' career dedication and determination might influence the incidence of professional burnout. The association between grit, defined as the perseverance and passion for long-term goals and professional burnout is not known. The objective of this study was to evaluate grit as an independent predictor of burnout.
METHODS: *Design* A total of 168 postgraduate year (PGY) 1–3 residents from the Internal Medicine residency program at the Cleveland Clinic were surveyed during weekly academic noon conferences from April to June 2016, to measure grit and burnout. The following residents' characteristics were collected: age, gender, marital and family status, medical school attended (United States versus international medical graduate (IMG), Post Graduate Year (PGY) level, last In-Training Examination (ITE) score, and interest in pursuing a sub-specialty. *Participants* All residents were invited to participate in the study, and a total of 139 residents completed the questionnaires. *Measurement tools* A 10-item questionnaire, with 8 items related to grit and 2 items related to burnout were used to measure the constructs of interest. Grit was measured using the Short Grit Scale, with scores ranging from 1 (not at all gritty) to 5 (very gritty). Burnout was measured using the modified Maslach Burnout Inventory (one question for emotional exhaustion, and another for depersonalization). *Statistical Analysis* Descriptive statistics were used to characterize the study cohort, using chi-square or Fisher's exact tests and t -test for categorical and continuous variables, respectively. The relationship between burnout and GRIT scores were investigated with two-sample independent t tests and multivariable logistic regression models.
RESULTS: Emotional exhaustion and depersonalization were identified in 64%, and 43% of the residents, respectively. Emotional exhaustion was higher for residents with family members living with them (81% vs. 58%, $p = 0.01$), PGY1 and PGY2 compared to PGY3 residents (68 and 73% vs. 48%, $p = 0.04$), and residents scoring above the 50th percentile in the last ITE ($Q_3 = 71$ and $Q_4 = 65\%$ vs. $Q_2 = 40\%$, $p = 0.01$). Grit scores were higher for residents not reporting emotional exhaustion (mean score 3.86 vs. 3.59, $p = 0.004$). With every 1 unit increase in grit score, residents were 36% less likely (OR 0.36; 95% CI 0.15–0.84) to experience emotional exhaustion, after adjustments for demographics, ITE scores, type of medical school, PGY level, and interest to pursue a sub-specialty.
CONCLUSIONS: In a single academic center, residents' professional grit was an independent predictor of burnout with higher level of grit being associated with less burnout. Measuring grit can identify residents at risk for burnout, and emotional exhaustion in particular. These findings need to be replicated in other residency programs.

GUIDELINE ADHERENCE OF VA PRIMARY CARE FOR ABNORMAL UTERINE BLEEDING Kristina M. Cordasco[1, 2]; LaShawnta S. Jackson[1]; Melissa Farmer[1]; Ellen F. Yee[3]; Donna L. Washington[1, 2]. [1]VA Greater Los Angeles Healthcare System, Los Angeles, CA; [2]UCLA, Los Angeles, CA; [3]New Mexico VA Healthcare System, Albuquerque, NM. (Control ID #2703314)

BACKGROUND: Abnormal Uterine Bleeding (AUB) is common among female primary care (PC) patients. Several evidence-based guidelines for AUB care apply to the PC setting. We assessed the extent to which VA PC patients with AUB are receiving guideline-adherent care.
METHODS: We identified women who presented to PCPs with AUB across 4 VA healthcare systems from 6/01/13 to 9/30/15. We first identified all women

who had one or more encounters in this timeframe with an ICD-9 code indicating AUB or CPT code for endometrial biopsy (EMB). We then reviewed all PC notes for these women to identify distinct episodes of AUB initiated during the timeframe. An episode was distinct if there was no mention of active AUB in the prior 6 months. We excluded episodes in which the patient did not present in-person to a VA PC setting, was previously identified as being pregnant, or had a recent gynecologic procedure. For each episode, we performed a structured chart abstraction for data relevant to 14 previously-developed indicators of guideline-adherent AUB care by PCPs, and then determined if the documented care was guideline-adherent for applicable indicators.

RESULTS: Our sample included 304 women with 316 episodes of AUB, across 83 PCPs, 49 (59%) of whom were VA Designated Women's Healthcare Provider (DWHPs). DWHPs provided care for 262 (83%) of the 316 episodes. Episodes had a mean of 5.4 (range 3–8) applicable indicators. Across indicators, 58% of the documented care was guideline-adherent. Adherence was 100% for two indicators regarding the PCP assessing the patient's hemodynamic stability and, when needed, transferring care to the emergency department. There was very high adherence with indicators for documenting menopausal status (98%); obtaining a trans-vaginal ultrasound or referring to gynecology for bleeding in post-menopausal women (89%); and documenting the bleeding pattern (87%). Providers had lower adherence with guidelines regarding performing an EMB or making a timely gynecology referral after ultrasound visualized a thickened endometrium in a pre-menopausal woman (67%); or, on the day of presentation, performing a pelvic examination (66%) or documenting assessment of whether there was active bleeding (55%). Less than half the time, providers obtained thyroid testing in premenopausal women (47%); performed an EMB or made a timely referral to a gynecologist in women aged <40 years with elevated endometrial cancer risk (40%); assessed for pregnancy (32%); assessed for cervical motion, uterine or adnexal tenderness in patients with intrauterine devices (30%); or assessed for elevated endometrial cancer risk in premenopausal women (6%).

CONCLUSIONS: VA PCPs have high guideline-adherence with triaging potential emergent episodes of AUB, and caring for post-menopausal women with AUB. However, their documentation of care for pre-menopausal women reveals less guideline-adherence. Quality improvement and educational initiatives need to continue targeting improved PCP care for younger women Veterans.

HEALTH INSURANCE DESIGN FEATURES AND DECISION-MAKING IN VULNERABLE POPULATIONS Melissa Gosdin; Susan Perez; Jessie Pintor; Patrick S. Romano. UC Davis, Sacramento, CA. (Control ID #2709067)

BACKGROUND: Health insurance marketplaces were created under the Affordable Care Act to offer subsidized, high-quality options to households below 400% of the Federal poverty level (FPL). Our objective was to explore how those insured through Covered California, California's marketplace, apply concepts of value in insurance design when making healthcare purchasing decisions, compared with economically similar persons with employer-sponsored insurance (ESI).

METHODS: We conducted 12 two-hour focus groups of 6–12 consumers ($N = 117$) in three geographically distinct regions in Northern California. The structured moderator guide was developed to elicit perceptions of healthcare value and reactions to three different plan design features (e.g., narrow networks, reference pricing, value based design). Focus groups were audiorecorded, transcribed verbatim and hand-coded by multiple researchers. Transcripts were analyzed using a grounded theory approach identifying codes, categories and themes emerging from the data. Participants were eligible for participation if they spoke English or Spanish (two groups were held in Spanish), were 30–60 years of age, were insured through an employer or Covered California, and were low- or middle-income. Groups were stratified based on type of health care coverage (ESI vs Covered California) and income level (138–250% versus 250–400% of FPL).

RESULTS: When selecting a health plan or providers, these vulnerable individuals desire choice even when some of the options are undesirable. Regarding cost-sharing and benefit design factors such as narrow networks, reference pricing and value based design, their primary concern is to have access to high quality care. Knowledge of options contextualizes tradeoffs for the consumer, such as keeping a highly trusted provider and paying significantly more. For participants with limited income, choice is described as empowering even if some options are economically unrealistic. There were disparities between ESI and Covered California participants in how they make sense of their plan options. While participants in both groups expressed distrust in their health plans, those with ESI have a network of work colleagues and human resource professionals to turn to for assistance in the decision making process. However, those enrolled in the marketplace reported not having trusted resources.

CONCLUSIONS: While both ESI and exchange participants expressed distrust in their health plans, those with ESI turn to their social networks to assist in the decision making process. However, those enrolled in covered California report not having trusted resources to help them negotiate the process of selecting a plan and using their benefits. Trust appears to play a significant role in healthcare related decisions for these vulnerable individuals. Health insurance exchanges may choose to take a grass roots approach to supporting consumers with their healthcare decisions as insurance benefit design becomes more complex and out-of-pocket costs rise.

HEALTH INSURANCE REFORM DIFFERENTIALLY AFFECTED BLOOD PRESSURE OUTCOMES AND DISPARITIES Nancy R. Kressin[2]; Norma Terrin[3]; Alejandro Moreno-Koehler[3]; Amresh D. Hanchate[1]; Amy LeClair[3]; Jillian Suzukida[3]; Karen M. Freund[4]. [1]Boston University School of Medicine, Boston, MA; [2]Dept of Veterans Affairs and Boston University, West Roxbury, MA; [3]Tufts Medical Center, Boston, MA; [4]Tufts University School of Medicine, Boston, MA. (Control ID #2705422)

BACKGROUND: Racial/ethnic disparities in chronic disease outcomes are well documented and linked to health insurance coverage. Insurance instability (switches or gaps in insurance coverage) may contribute to disparities. Focusing on the outcome of uncontrolled blood pressure (UBP), we examined whether insurance reform was associated with 1) overall race differences in UBP, 2) diminished racial disparities in UBP, and 3) whether insurance instability was associated with better outcomes or fewer disparities.

METHODS: Using clinical outcomes data from 2 urban hospitals with diverse patients (N patients = 47,594; 34% Non-Hispanic white (NHW), 4% Hispanic, 56% African American (AA), 58% female, mean age: 49), spanning the period of Massachusetts health insurance reform (2005–2013), we identified patients aged 21–64 diagnosed with hypertension and examined patterns of UBP over time, by group. We categorized insurance stability at the *person-6-month-interval* level as always privately insured, having insurance switches but always insured, losing

insurance coverage, always publicly insured, or always uninsured. We plotted trajectories of BP control over time by race/ethnicity and tested for race × time interaction. We estimated the relation between insurance stability and BP control, and variations by race. We examined the subset of patients whose pre-reform insurance was characterized, with always privately insured as the reference (least affected by reform), compared with any switches or losses, and assessed whether reform differentially affected them. Logistic regression models adjusted for age, race/ethnicity, time, sex, comorbidities, area-level education and income, location of care and insurance status, with UBP as the outcome.

RESULTS: Absolute values for UBP were consistently different by race/ethnicity over time ($p < 0.0001$), with more UBP for AAs, followed by Hispanics, NHWs and Asians. However, slopes did not significantly differ by race/ethnicity over time (p-value for interaction between race and time = 0.251). Insurance stability was significantly associated with better BP outcomes ($p < 0.001$). For every switch in insurance, there was a 4% increased odds of having UBP. Those always publically insured had the best BP control. There was no significant interaction between pre-reform insurance group and time (p-value = 0.322).

CONCLUSIONS: Racial disparities in BP outcomes existed before, during and after insurance reform. Insurance instability was differentially associated with outcomes and varied by race. Patients with consistent public insurance had the best outcomes for all racial groups. The most vulnerable pre-reform insurance groups were not differentially affected by insurance reform. We conclude that consistency in insurance coverage is associated with better BP control, but BP outcomes are affected by more factors than insurance coverage.

HEALTH SYSTEMS THAT PUBLISH PHYSICIAN-LEVEL PATIENT EXPERIENCE DATA Tara Lagu[2]; Caroline Norton[3]; Lindsey Russo[3]; Aruna Priya[2]; Peter K. Lindenauer[1]. [1]Baystate Medical Center, Springfield, MA; [2]Baystate Medical Center, Florence, MA; [3]University of Massachusetts, Amherst, MA. (Control ID #2702220)

BACKGROUND: A majority of patients have stated that online reviews are an important tool for choosing a physician. However, commercial physician-rating websites have few reviews. Recently, some hospitals and health systems have begun to report, on clinician biographical webpages, data drawn from systematically-collected patient experience surveys. We aimed to identify health systems reporting clinician-level patient survey data and to describe the characteristics of these reports.

METHODS: We examined the websites of all hospitals listed on the Center for Medicare and Medicaid Services' *Hospital Compare*. We included websites active between June 1, 2016 and June 30, 2016 that had at least one clinician with star ratings or narrative comments on his or her biographical webpage. We identified websites characteristics (e.g., search criteria; presence of patient narratives). In a subset of 14 included health systems for which we had lists of clinicians, we randomly selected 10 clinicians. We then extracted the number of star ratings and narrative comments for each clinician.

RESULTS: From 4800 hospitals on Hospital Compare, we identified 162 hospitals (3.4%) representing a total of 42 health systems from 26 states. Of these, all published star ratings ($n = 42$, 100%) and most published narrative reviews ($n = 33$, 79%). The majority ($n = 27$, 64%) stated on their main page that they removed narratives deemed inappropriate or offensive. Most allowed users to search for physicians by name ($n = 39$, 93%), specialty ($n = 41$, 98%), and location ($n = 31$, 74%). Of 140 clinicians from 14 health systems, a majority had reviews (star ratings, $n = 122$, 87%; narrative reviews, $n = 114$, 81%), with a median of 110 star ratings and 25 narratives. The median (IQR) rating was 4.8 (4.7 - 4.9) out of 5 stars. Of the 140 physicians, none had a score below 4.2.

CONCLUSIONS: In the first study to examine the phenomenon of health systems posting systematic survey results on physician biographical webpages, we found that clinicians had a large number of median reviews and most had star ratings that were near perfect. The narrow range of scores may make it difficult for patients to use star ratings to differentiate between physicians. Still, systematic collection of experience data from known patients addresses some of the limitations of unsolicited online physician reviews (response bias, unrepresentative sample), and patients could use the large number of narratives on these sites to glean information about the experience of care with individual physicians. There is a move by policy makers to include patient narratives on public-reporting websites, such as *Physician Compare*. Until that occurs, the lack of online narrative reviews in other places may mean that health system websites, such as those described here, will emerge as the main location in which patients read narratives about physicians.

HEALTH, INTIMACY, HIV-RELATED ANXIETY AND STIGMA: PERSPECTIVES OF WOMEN PRESCRIBED HIV PRE-EXPOSURE PROPHYLAXIS AT AN URBAN, COMMUNITY-BASED SEXUAL HEALTH CLINIC Connie Park; Minia N. Rios Gutierrez; Oni J. Blackstock. Montefiore Medical Center/AECOM, New York, NY. (Control ID #2703235)

BACKGROUND: Pre-exposure prophylaxis (PrEP) is an innovative HIV prevention strategy that involves taking a pill a day to stay HIV-negative. Despite being the only HIV prevention method that can be both used *and* controlled by women, PrEP remains vastly underutilized among women. As such, among women prescribed PrEP, little is known about their experiences with and perspectives on this new HIV prevention tool.

METHODS: The study took place at a community-based comprehensive sexual health clinic that offers PrEP care. The clinic is a part of the largest health care system in the Bronx, NY, a region with a high HIV prevalence. We recruited cisgender women who have sex with men and who had received at least one prescription for daily oral PrEP. We conducted individual semi-structured interviews that asked women about their reasons for wanting to initiate PrEP as well as what benefits and challenges they had encountered taking PrEP. Interviews were audiotaped and professionally transcribed. We used grounded theory and the constant comparative method to identify emergent themes.

RESULTS: Among our sample ($n = 10$), median age was 40 years (range: 35–49); most women were either Latina or non-Latina Black. Women learned about PrEP from a friend or partner or were referred by the health care system's HIV testing and counseling program. Most women were in a known sero-discordant partnership (i.e., had a known HIV-positive partner), while few reported having multiple partners with unknown HIV status. In general, women felt that PrEP allowed them to protect themselves and to "stay healthy", both for themselves and for their loved ones (usually their children). Specifically, for women in a known sero-discordant partnership, PrEP enabled women to maintain these relationships while remaining HIV-negative. With regards to their sex lives, PrEP allowed some women to feel more connected to their partners ("closer" "more intimacy") because the women felt that with PrEP they could forgo condoms. In contrast, for others, PrEP provided "an extra layer of protection" when used with condoms and helped to decrease anxiety related to contracting HIV. Despite these benefits, many women

perceived and/or experienced stigma related to taking PrEP. As a result, most did not disclose their PrEP use to others (besides their partners) for fear that they would be assumed to be HIV-positive or promiscuous, or be judged for being in a relationship with an HIV-positive partner.

CONCLUSIONS: While reasons for wanting to initiate PrEP and perspectives on PrEP centered on maintaining health, improved intimacy, and lessening HIV-related anxiety, PrEP-related stigma figured prominently into women's experiences. Future research should ascertain what role, if any, stigma may play in PrEP uptake among women including potential effects on adherence or continued use of PrEP. Such understanding may help to inform the development of interventions to promote PrEP use among women.

HEALTHCARE FRAGMENTATION AND VARIATION BY PAYER

Lisa M. Kern[1, 1]; Joanna K. Seirup[1]; Rachel Jawahar[1]; Yesenia Miranda[1]; Susan S. Stuard[2]. [1]Weill Cornell Medical College, New York, NY; [2]Lake Fleet Consulting, Irvington, NY. (Control ID #2705394)

BACKGROUND: American healthcare is often described as "fragmented," yet the extent of fragmentation is rarely quantified. Most previous studies have measured fragmentation in the Medicare population, but this may not be generalizable to Medicaid or commercially insured populations. Our objective was to compare the extent of fragmented ambulatory care across commercially insured, Medicare, and Medicaid populations.

METHODS: We conducted a cross-sectional study in the Hudson Valley, a 7-county region in New York State, using claims data from 2010 from 5 commercial payers, Medicare, and Medicaid. We included adult patients ($N = 252{,}879$) who were continuously insured through the participating payers, were attributed to a primary care physician in the region, and had ≥4 ambulatory visits in the study year. We defined ambulatory visits using a modified definition from the National Committee for Quality Assurance, which excludes emergency department visits. For each patient, we calculated a fragmentation score from the patient's pattern of ambulatory visits using the Bice-Boxerman Index, which captures both the dispersion of care across multiple providers and the relative share of visits by each provider. We reversed the direction of the Index, so that higher scores reflected more fragmented care. We separately calculated for each patient the proportion of visits with the most frequently seen provider. We conducted comparisons across payer groups using t-tests and chi-squared tests. To explore the potential roles of other variables, we conducted sensitivity analyses stratified by the number of chronic conditions and the number of ambulatory visits.

RESULTS: Patients with Medicaid insurance had significantly more fragmented ambulatory care (mean fragmentation score 0.84) than patients with either commercial insurance (0.73) or Medicare (0.74) ($p < 0.0001$). This finding was due, in part, to the fact that Medicaid patients had the lowest mean proportion of ambulatory visits with the most frequently seen provider (36% of visits), compared to commercially insured patients (48% of visits) and Medicare patients (45% of visits) ($p < 0.0001$). Differences in fragmentation scores by payer persisted when we stratified by the number of chronic conditions and when we stratified by both the number of chronic conditions and the number of ambulatory visits.

CONCLUSIONS: Patients with Medicaid have more fragmented ambulatory care than patients with either commercial insurance or Medicare. Because we included only those with continuous insurance coverage, this finding is distinct from the separate problem of churning (temporary losses of insurance coverage). High rates of fragmentation across all payers suggest that patterns of ambulatory care may not be optimized. This finding is important, because all payers are currently seeking new strategies for improving value in healthcare, and fragmentation may represent a novel target for improvement.

HEALTHCARE SERVICES AND AMBULATORY RESOURCES UTILIZED BY VETERANS WITH CHRONIC NONCANCER PAIN

Joanne Bernstein[3]; Erica M. Wozniak[2]; Cynthia Kay[1, 3]. [1]Zablocki VA Medical Center, Milwaukee, WI; [2]Medical College of Wisconsin, Milwaukee, WI; [3]Medical College of Wisconsin, Whitefish Bay, WI. (Control ID #2689982)

BACKGROUND: Chronic pain is prevalent in the Veterans population with the estimated rate twice that of the civilian population. Prior studies have shown an association between chronic pain and increased healthcare utilization. However, many of these studies focused on traditional services, such as emergency room (ER) visits, hospitalization, and prescriptions. Little is known about resources not billed, such as telephone calls and nurse visits. These resources are integral parts of ambulatory medicine, especially primary care. The objectives of this study are to describe Veterans Affairs (VA) healthcare utilization by patients based on chronic pain, pain agreement status, and type and amount of opioids prescribed. We also examine potential independent predictors of healthcare utilization in a multiple regression context.

METHODS: Retrospective chart review of primary care patients of a Midwest VA medical center on long-term opioids for chronic noncancer pain with or without a pain agreement between April 1, 2014 and April 1, 2015 ($N = 617$). Age-matched patients without pain served as controls ($N = 565$). Healthcare utilization was compared by univariate statistics based on the presence of chronic pain, pain agreement status, opioid dose and schedule. Logistic regression was used to assess predictors of healthcare utilization, with hospitalizations and nurse triage calls as binary outcomes and emergency room (ER) visits, office visits, and nurse visits/telephone calls/secure messages as ordinal outcomes.

RESULTS: Patients with chronic pain utilized more healthcare services compared to patients without pain (all $p < 0.001$, except for hospitalization $p = 0.003$). Patients on schedule II controlled medications were likely to have more messages and nurse visits compared to those on schedule III or IV ($p < 0.001$). There were not significant differences in any utilization measure based on morphine equivalent dose or pain agreement status. Model-based results show that, controlling for relevant demographic and clinical characteristics, chronic pain patients were more likely to have an ER visit than non-pain control patients (adjusted common OR, 1.9; 95% CI 1.4–2.4). Patients with chronic pain also had more nurse triage encounters (adjusted common OR 1.4; 95% CI 1.0–1.9), and telephone calls, messages or nurse visits (adjusted common OR, 1.6; 95% CI 1.2–2.0) compared to patients without chronic noncancer pain.

CONCLUSIONS: Past studies have shown that the VA's Patient Aligned Care Team (PACT), which is equivalent to the Patient Centered Medical Home, decreases utilization of ER visits and hospitalizations. However, those studies did not take chronic pain into account. Our results show that patients with chronic noncancer pain still utilized more healthcare services compared to those without chronic pain, even with a PACT. Future research is needed to find ways to effectively reduce healthcare utilization among patients with chronic pain, without sacrificing the quality of care.

HEATH PRIORITIES FOLLOWING MYOCARDIAL INFARCTION: RESULTS FROM A NATIONAL SURVEY Megan Obi[1]; Nathalie Moise[2]; Carmela Alcantara[2]; Anusorn Thanataveerat[2]; Ian M. Kronish[2]. [1]Case Western Reserve University, Cleveland, OH; [2]Columbia University Medical Center, New York, NY. (Control ID #2706492)

BACKGROUND: Recurrent myocardial infarctions (MIs) are prevalent in the U.S. and are associated with increased morbidity and mortality. Prior research has failed to incorporate the individual perspectives and concerns of MI survivors. A better understanding of symptom and health priorities may inform the development of interventions to offset the risk of poor outcomes in this population.

METHODS: YouGov, a nonpartisan research firm, administered an online nationally representative opt- in survey in English and Spanish to 1500 US adults who indicated they had previously been given an MI diagnosis by a health professional. Sampling targets and sampling weights were set based on gender, age, and race distribution of MI according to the 2010 National Health Interview Survey. Participants were asked to identify their single-most bothersome symptom and health concern related to their attack from a list generated from formative focus groups. Sampling weights were used to calculate weighted percentages for categorical variables.

RESULTS: Of 1500 participants, 18.2% reported at least 2 prior MIs. The average age was 64.7 years; 61.0% were male, 9.6% non-Hispanic black (NHB), 4.3% Hispanic and 612 (40.8%) had a self-reported history of depression and/or current elevated depressive symptoms (Patient Health Questionnaire-8 ≥ 10). Participants predominantly identified comorbid medical conditions (e.g., cholesterol, diabetes) (73.0%) and behavioral risk factors (e.g., smoking) (67.5%), as their single most important health concern as opposed to quality of life (QOL) (25.6%) or heart-related concerns (35.8%). In adjusted analysis, ever/current depressed (vs. non-depressed) participants were less likely to identify comorbid medical conditions (67.2% vs. 76.4%, $p < 0.0001$) and behavioral risk factors (61.5% vs 71.6%, $p < 0.0001$) as health concerns, and were more likely to identify quality of life (QOL) (34.3% vs 19.7%, $p < 0.001$) and heart concerns (44.0% vs 30.3%, $p < 0.001$) as their single most important health concern. Overall, 64% of participants endorsed a non-cardiac symptom as their single most bothersome symptom as compared to 35.9% who endorsed a cardiac-related symptom. Reduced energy (55.3%) and shortness of breath (42.3%) were the two most common symptoms reported while reduced energy and trouble sleeping (23.8%) were the two most common non-cardiac symptoms.

CONCLUSIONS: We found that MI survivors tended to report greater non-cardiac symptoms, and were more likely to be concerned about behavioral and medical risk factors. Certain sub-populations, such as those with depressive symptoms may have different health priorities and concerns, namely related to QoL and recurrent cardiac events, suggesting a need for patient-centered interventions that address not just cardiac, but also non-cardiac symptoms and health concerns. Tailoring treatment strategies to address chronic disease management may subsequently help promote better adherence and patient satisfaction.

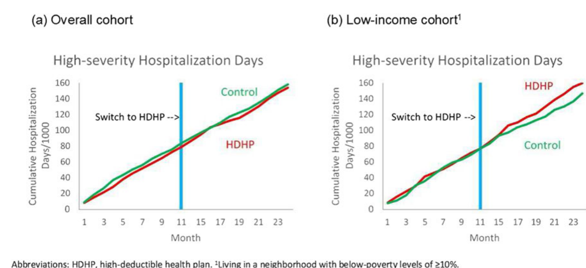
HIGH DEDUCTIBLE INSURANCE AND HIGH-ACUITY OUTCOMES IN DIABETES James F. Wharam[3]; Fang Zhang[4]; Emma Eggleston[5]; Christine Lu[6]; Stephen B. Soumerai[1]; Dennis Ross-Degnan[2]. [1]Harvard Medical School, Boston, MA; [2]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; [3]Harvard Medical School and Harvard Pilgrim Healthcare, Boston, MA; [4]Harvard Pilgrim Health care Institute, Boston, MA; [5]West Virginia University, Morgantown, WV; [6]Harvard Medical School and HPHCI, Boston, MA. (Control ID #2702896)

BACKGROUND: High deductible health plans (HDHP) have recently become the predominant private health insurance arrangement in the US and the centerpiece of proposals to replace the Affordable Care Act. However, effects on high-acuity outcomes among chronically ill patients and vulnerable subgroups are unknown.

METHODS: We studied Optum data derived from a large US health insurer. We used a controlled interrupted time series design to examine employer-mandated HDHP transitions, minimizing selection bias. The intervention group comprised 26,674 HDHP members with diabetes age 12–64 included between 2003–2012. HDHP members were enrolled for 1 year in a low deductible (≤$500) plan followed by 1 year in a HDHP (≥$1000) and propensity score matched 1:1 to diabetes patients with low deductibles. Low income HDHP members ($n = 9641$) were a subgroup of interest. Measures included emergency department (ED) visits, hospitalizations, and total healthcare expenditures. Measure of adverse outcomes were high severity ED visit expenditures and high severity hospitalization days. We estimated pre-to-post changes among HDHP members versus controls using adjusted segmented regression on monthly cumulative measures.

RESULTS: HDHP members experienced small pre-to-post reductions in ED visits (−3.1% [−3.9,-2.3]), hospitalizations (−4.2% [−5.5,-2.8]), and total healthcare expenditures (−3.6% [−4.3,-3.0]) relative to controls, and no changes in measures of adverse outcomes. However, low income HDHP members experienced relative increases in high severity ED visit expenditures (8.1% [3.0,13.2]) and high severity hospitalization days (26.1% [19.7,32.5]) at follow-up compared to baseline.

CONCLUSIONS: Low income diabetes patients who were switched to HDHPs experienced substantial increases in adverse high-acuity outcomes. Results could inform tailored health insurance designs that improve health outcomes among vulnerable HDHP members with diabetes.



HIGH UTILIZERS OF CONDITION HELP: DEMOGRAPHIC AND MEDICAL CHARACTERISTICS OF PATIENTS WHO REPEATEDLY ACTIVATE RAPID RESPONSE TEAMS Elizabeth Eden[1]; Allison DeKosky[2]; Ling-Wan Chen[3]; Laurie Rack[1]; Gregory M. Bump[2]. [1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]University of Pittsburgh, Pittsburgh, PA. (Control ID #2705951)

BACKGROUND: Patient activated rapid response teams have been increasingly implemented to improve patient safety and enhance patient engagement. The University of Pittsburgh Medical Center (UPMC) implemented a patient

and family initiated rapid response system called Condition Help. Condition Help triggers a patient care liaison or administrator on duty along with a charge nurse to convene at the patient's bedside to address concerns. A previously conducted analysis of 3.5 years of UPMC data revealed that nearly half of Condition Help events were activated by a small subgroup of patients, yet fewer than 6% of these events were categorized as safety concerns by the authors. Most of these calls were attributed to unsatisfactory pain control or other medical management issues. We sought to further describe demographic and medical characteristics of those patients who frequently activate Condition Help, given the high utilization of resources required to address their concerns. It is critical to understand more about these patients, for potentially earlier identification and alternative interventions to better meet their needs.

METHODS: Of the 240 patients who activated Condition Help at UPMC Presbyterian from January 2012 through July 2015, 43 patients called more than once, accounting for 46% of events (170 of 367). Charts were reviewed for these 43 patients to collect basic demographic information including age, gender, race, marital status, employment status, and category of insurance. Documentation of substance use, comorbid psychiatric disease and primary medical diagnosis leading to inpatient admission were recorded.

RESULTS: Most patients were female (72%), Caucasian (70%) and single (72%) with a mean age of 39 years (SD 12.8). On average members of this group were admitted 5.67 times per year (SD 5.4). 79% were unemployed or on disability and 21% were employed or retired. 58% had Medicaid or Medical Assistance, 32% had Medicare, and 10% had commercial insurance. One patient was homeless. Most patients used chronic opiates (77%), 16% used marijuana, and 12% used other illicit substances including heroin or cocaine. Primary medical reason for admission was related to gastrointestinal complaints in 51%; of these 18% had inflammatory bowel disease and 18% had acute or chronic pancreatitis. 5% had sickle cell disease. Comorbid psychiatric illness was identified for 82% of patients. 88% were discharged to home and the remainder were placed at either skilled nursing facilities or transferred to inpatient psychiatry.

CONCLUSIONS: Patients who repeatedly activate Condition Help demonstrate high medical resource utilization. Prevalence of unemployment and qualification for Medicaid and Medical Assistance indicate that they have limited income and resources. We also show that most of these patients have chronic pain and comorbid psychiatric conditions. These data suggest that this group may benefit from early interventions targeting pain management and psychiatric care.

HIGH-DEDUCTIBLE INSURANCE AND MACROVASCULAR DISEASE IN DIABETES James F. Wharam[1]; Christine Lu[1]; Fang Zhang[1]; Matthew Callahan[1]; Stephen B. Soumerai[1]; Dennis Ross-Degnan[1]; Joseph Newhouse[2]. [1]Harvard Medical School and HPHCI, Boston, MA; [2]Harvard Medical School, Boston, MA. (Control ID #2702885)

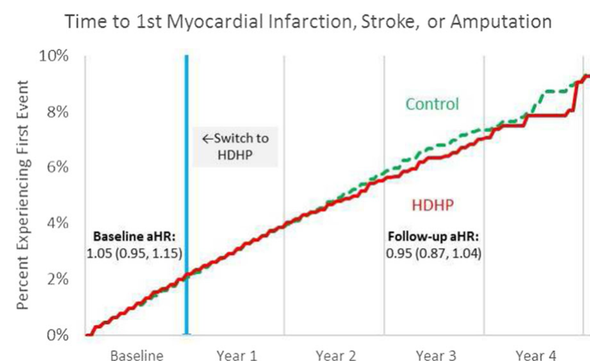
BACKGROUND: High deductible health plans (HDHP) are the centerpiece of proposals to replace the Affordable Care Act, but longer-term impacts on chronically ill populations are unknown. We sought to determine effects of HDHPs on macrovascular disease diagnostic testing, treatment, and adverse events among diabetes patients.

METHODS: We studied Optum data derived from a large US health insurer. We used a controlled segmented survival design to examine employer mandated HDHP transitions, minimizing selection effects. The intervention group comprised 50,749 HDHP members with diabetes age 12–64 included between 2003–2012. HDHP members were enrolled for 1 year in a low deductible (≤$500) plan then up to 4 years in a HDHP (≥$1000) and propensity score matched 1:1 to diabetes patients with low deductibles. Measures were assessed within and aggregated across coronary heart disease, cerebrovascular disease, and peripheral artery disease states and included macrovascular disease major diagnostic testing; major procedure-based treatment; and major adverse events (MI, stroke, and lower extremity amputation). To calculate baseline and follow up period adjusted hazard ratios (aHRs), we used Cox proportional hazards segmented survival adjusted for baseline population differences and changing demographics over time.

RESULTS: HDHP members experienced follow up delays in receiving major diagnostic tests (aHR: 0.92 [0.89, 0.95]) but time to major treatment was not statistically different (0.92 [0.84, 1.02]). We detected no change in timing of MI (0.94 [0.76, 1.16]), stroke (0.95 [0.81, 1.10]), or lower extremity amputation (0.89 [0.68, 1.17]). The aggregated aHR for these 3 outcomes was 0.95 [0.87, 1.04]).

CONCLUSIONS: Among diabetes patients, HDHP enrollment was associated with a delay in diagnostic testing but no acceleration in major macrovascular complications. Subsequent research should assess similar outcomes among vulnerable HDHP populations with diabetes such as low-income members.

Time to first myocardial infarction, stroke, or lower extremity amputation among diabetes patients transitioning to HDHPs and matched control diabetes patients remaining in low-deductible plans.



HIGH-RISK PATIENTS IN VHA: WHERE DO THEY GET THEIR PRIMARY CARE? Evelyn T. Chang[4]; Rebecca I. Piegari[5]; Donna M. Zulman[4]; Karin M. Nelson[5, 2]; Ann-Marie Rosland[3]; Stephan D. Fihn[5, 2]; Lisa V. Rubenstein[1, 4]. [1]GLA VA, North Hills, CA; [2]University of Washington, Seattle, WA; [3]VA Ann Arbor, Ann Arbor, MI; [4]VA- Greater Los Angeles, Los Angeles, CA; [5]Department of Veterans Affairs, Seattle, WA. (Control ID #2699677)

BACKGROUND: Healthcare systems are increasingly accountable for the populations that they manage, spurring interest in identifying and developing programs for patients who are at high risk for hospitalization. Veterans Health Administration (VHA) has implemented patient-centered medical homes throughout general primary care and has supported similar models, often with smaller panel sizes and additional resources, tailored to specific special populations, such as women, homeless, HIV, and home-bound. Potential strategies to improve outcomes for high-risk patients are to either provide greater support for intensive management within primary care or to create more or larger special population primary care programs. Our objectives are to provide a foundation for planning by describing where the top 5% sickest patients in VHA, in terms of their risk for hospitalization, receive their primary care.

METHODS: Cross-sectional study of patients enrolled in VHA general or special population primary care nationally ($n = 4,309,192$) using the VHA Corporate Data Warehouse. We defined high-risk patients as those with a Care Assessment Need score (VHA-specific risk prediction model for 90-day hospitalization) ≥ 95th percentile during April 1, 2015 - September 30, 1015 ($n = 351,012$).
RESULTS: Most (88%) high-risk patients were managed in general primary care (GPC), even when they had a characteristic that, in combination with their high risk, might make them eligible for specialized primary care (SPC). Proportions of target groups of high-risk patients receiving SPC varied between geriatrics SPC (6% of high-risk patients >70 years old) and homelessness SPC (5% of high-risk homeless) compared to HIV SPC (51% of high-risk patients with HIV) and SPC for women (68% of high-risk women). Only 3% of high-risk patients overall were managed in home-based SPC. SPC programs, however, had higher proportions of high-risk patients; 41% of home-based SPCs, 8% of geriatrics SPC, 28% of infectious disease SPC, and 28% of homelessness SPC were high-risk, compared to 8% high-risk in GPC. Overall, few high-risk patients utilized disease management telehealth services (8% over previous two months), housing services (4%), intensive mental health care management (1%) or palliative/hospice care (1%).
CONCLUSIONS: The vast majority of high-risk Veterans are managed in general primary care without a special population focus or additional intensive primary care resources. Patients in special population primary care are more likely, however, than those in general primary care to be at high risk for hospitalizations. Effective system-level planning for improving outcomes among high-risk Veterans will likely need to focus on supporting intensive management within general primary care, as well as on maximizing the impact of care delivered within special population primary care programs.

HIGH-RISK PRESCRIPTION OPIOID USE AMONG PEOPLE LIVING WITH HIV Chelsea Canan[1]; Geetanjali Chander[2]; G. Caleb Alexander[1]; Anne Monroe[2]; Kelly Gebo[2]; Richard D. Moore[2]; Allison Agwu[2]; Bryan Lau[1]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD. (Control ID #2702360)

BACKGROUND: Despite an epidemic of opioid-related injuries and deaths in the United States, relatively little is known regarding how prevalent high-risk prescription opioid use is among people living with HIV (PLWH).
METHODS: We analyzed clinical and demographic data from the HIV Research Network (HIVRN), a longitudinal multi-site cohort, and opioid prescription claims from Medicaid for non-cancer patients seeking HIV treatment at four urban sites between 2006–2010. We examined 4 measures of high-risk opioid use: 1) high daily dosage (≥100 morphine mg equivalents for 30 consecutive days), 2) early refills (refilling ≥3 days early), 3) overlapping prescriptions (≥2 distinct drugs from the same Drug Enforcement Agency classification on the same day), 4) multiple opioid prescribers (≥3 prescribers in 90 days).
RESULTS: Of 4,553 eligible PLWH, 3,122 (68.6%) received at least one opioid prescription and were included in the analysis. The sample was 63% male and 60% African American. Forty percent were 35–44 years of age and 40% were 45–65. Thirty-four percent of patients' HIV risk factor was injection drug use (IDU). Forty-six percent of patients had a depression diagnosis and 38% received a diagnosis for chronic pain. High-risk opioid use occurred among 45% of patients (high dosage: 317 (10%); early refills: 1,121 (36%); overlapping prescriptions: 772 (25%); multiple providers: 938 (30%)). 199 (6%) patients met criteria for all four outcomes while 440 (14%), 359 (12%) and 398 (13%) met criteria for one, two and three outcomes, respectively. The most commonly co-occurring outcomes were early refills and multiple providers. Among patients with multiple outcomes, early refills most often occurred first. In multivariable Cox regression models, patients with IDU as an HIV risk factor and patients with a diagnosis of chronic pain demonstrated a significantly increased hazard for each of the four outcomes. Males were more likely than females to refill prescriptions early. Older age was associated with early refills. See Table for further details.
CONCLUSIONS: High-risk opioid use is common among PLWH, and is significantly associated with IDU and chronic pain diagnoses. The incidence rate is highest with early refills, which may serve as a metric to identify patients at risk for opioid use disorders.

Summary of high-risk opioid utilization

	High daily dosage	Early refills	Overlapping prescriptions	Multiple providers
N (%) with outcome	317 (10.2)	1,121 (35.9)	772 (24.7)	938 (30.0)
Incidence rate per 100 PY	5.9	31.4	10.1	23.3
Median years to first occurrence	Undefined	2.57	Undefined	3.38
Multivariable Cox regression model, Hazard Ratio (95% CI)				
Age 18-34	Ref	Ref	Ref	Ref
Age 35-44	**1.89 (1.20-2.98)**	**1.68 (1.35-2.09)**	**1.36 (1.06-1.74)**	**1.25 (1.00-1.56)**
Age 45-65	**1.86 (1.17-2.95)**	**1.73 (1.39-2.17)**	**1.42 (1.10-1.83)**	1.14 (0.91-1.43)
Male sex	0.92 (0.72-1.18)	**1.24 (1.08-1.42)**	0.87 (0.74-1.01)	1.12 (0.97-1.30)
IDU as HIV risk factor	**1.45 (1.13-1.86)**	**1.37 (1.20-1.57)**	**1.45 (1.23-1.71)**	**1.31 (1.13-1.52)**
Depression diagnosis	1.02 (0.80-1.31)	1.05 (0.92-1.20)	1.01 (0.86-1.18)	0.98 (0.85-1.13)
Chronic pain diagnosis	**1.71 (1.34-2.18)**	**1.34 (1.18-1.54)**	**1.72 (1.47-2.02)**	**1.35 (1.17-1.56)**

HIGH-VALUE CARE CULTURE AND RESIDENT TRAINING IN SAFETY-NET MEDICAL CENTERS Reshma Gupta[2]; Neil Steers[3]; Christopher Moriates[1]; Soma Wali[4]; Clarence H. Braddock[3]; Michael Ong[3]. [1]UT Southwestern Medical Center, San Francisco, CA; [2]University of California, Los Angeles, Los Angeles, CA; [3]University of California Los Angeles, Los Angeles, CA; [4]Olive View-UCLA Medical Center, Los Angeles, CA. (Control ID #2706188)

BACKGROUND: The goal of residency training is to prepare future physicians to meet society's healthcare needs, including striving for the triple aim. Differences in how health systems function and their available resources to promote high-value care could affect trainees' exposure to a high-value care culture and environment. We assessed the relationship between high-value care culture reported by internal medicine residents and the type of medical center in which they train (i.e. university, community, or safety-net). We also assessed

whether high-value care culture correlates with institutional value-based care delivery across diverse delivery systems.

METHODS: Five-hundred seventeen internal medicine residents at 12 university, community, and safety-net based GME programs across California completed a previously validated cross-sectional survey assessing their perceptions of high-value care culture (HVCCS™) within their training program. We used multi-level linear regression to assess the relation between type of medical center and HVCCS scores, adjusting for age, gender, track in training, number of months training in safety-net centers, and medical center bed size. We also calculated the correlation between mean institutional HVCCS and Centers of Medicare and Medicaid Service's Value-based Purchasing (VBP) scores using Spearman rank coefficients.

RESULTS: Of the 517 residents, 306 (59.2%), 83 (16.1%), and 128 (24.8%) trained in university, community, and safety-net based GME programs respectively. Across the 12 sites, the mean HVCCS score was 51.2 (SD 11.8) on a 0–100 scale, with a significantly lower mean among safety-net based training programs 47.9 (SD 10.9). Residents reported lower mean HVCCS scores if they were from safety-net based training programs (β –4.4, 95% Confidence Interval (CI) −8.2– −0.6) or were male (β −2., 95% CI −4.7− −0.60). Mean institutional HVCCS scores among the university and community sites positively correlated with VBP scores (Spearman r = 0.71, $p < 0.05$); safety net sites had a negative correlation between HVCCS and VBP scores (Spearman r = −1.00).

CONCLUSIONS: Safety-net medical centers have a vital role in GME training and serving community needs. However, trainees based in these environments report less exposure to aspects of a high-value care culture. This finding and the different correlation between HVCCS and VBP scores among safety-net sites may be due to different definitions of value, the closed financial structure of safety-net centers, and needed improvements in the training environment for high-value care. Tactics for fostering a high-value care culture include faculty and resident training, increasing access to data, and improving open communication about value.

HIV PREVENTION IN PRIMARY CARE SETTINGS: FACILITATORS AND BARRIERS ASSOCIATED WITH PRESCRIBING HIV PRE-EXPOSURE PROPHYLAXIS (PREP) IN THE UNITED STATES

Viraj V. Patel[3]; Saudat Fadeyi[5]; Paul Meissner[1]; Oni J. Blackstock[3]; Sarit A. Golub[4]; Briana Cousins[3]; Marcus Bachhuber[2]; Kim S. Kimminau[6]; Jonathan Tobin[5]; Julia H. Arnsten[3]. [1]Montefiore Medical Center, Bronx, NY; [2]Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY; [3]Montefiore Health System/Albert Einstein College of Medicine, Bronx, NY; [4]Hunter College, City University of New York, New York, NY; [5]Clinical Directors Network, New York, NY; [6]University of Kansas Medical Center, Kansas City, KS. (Control ID #2706124)

BACKGROUND: PrEP with antiretrovirals is a highly effective novel HIV prevention tool that primary care providers (PCPs) can implement, but little is known about factors associated with PrEP prescribing by PCPs. We assessed attitudes and other characteristics associated with PrEP prescribing by PCPs to inform primary care interventions to prevent HIV.

METHODS: We conducted an online survey of providers (MD, DO, NP, or PA) affiliated with a primary care practice-based research network from 8/2015 to 2/2016. We assessed provider and practice characteristics, attitudes about PrEP, and PrEP prescribing history. We categorized respondents into 3 mutually exclusive prescribing groups: 1) have already prescribed PrEP ("prescribers"); 2) likely to prescribe PrEP in the next 6 months ("likely prescribers"), and 3) have not prescribed PrEP and not likely to ("non-prescribers"). We used multivariable multinomial logistic regression to identify attitudinal and other factors associated with prescribing category. We used multiple imputation to account for missing data, and constructed final models with all factors significant ($p < 0.05$) in bivariate analysis.

RESULTS: Respondents ($N = 448$) came from 41 states and Puerto Rico, 67% were female, 13% identified as non-heterosexual, and 46% practiced for <10 years. They practiced in diverse settings: 73% urban, 50% in community health centers, 31% in academic settings, 37% in practices with no onsite HIV care, and 39% in practices with onsite HIV care. Most (87%) had heard of PrEP, but only 27% were identified as prescribers, while 31% were identified as likely prescribers, and 42% as non-prescribers. Prescribers (compared to likely prescribers) recognized facilitators to prescribing PrEP more often and were less deterred by barriers (Table). Prescribers also tended to have greater PrEP knowledge, prescribe antiretrovirals, identify as non-heterosexual, have been in practice fewer years, practice in urban areas, and have more MSM patients. Compared to non-prescribers, likely prescribers endorsed fewer negative PrEP attitudes (Table), tended to prescribe antiretrovirals, and had more MSM patients.

CONCLUSIONS: PrEP prescribing in primary care settings is not common, despite PCPs reporting intentions to prescribe. Our findings highlight the importance of provider education about PrEP, HIV, and LGBTQ health, and suggest that addressing barriers to prescribing may increase PrEP adoption in primary care.

Table. Factors Associated with PrEP Prescribing

	Prescribers vs. Likely Prescribers (ref)		Likely Prescribers vs. Non-Prescribers (ref)	
	RRR (95% CI)	P	RRR (95% CI)	P
Facilitator				
It's my job to screen patients and prescribe PrEP	2.47 (1.58-3.85)	<0.001	ns	
Barriers				
PrEP is not effective enough	0.54 (0.35-0.84)	0.007	ns	
I do not have time to engage in the prevention counseling that would be required	ns		0.63 (0.47-0.85)	0.002
Patients on PrEP may engage in riskier behaviors	ns		0.66 (0.49-0.90)	0.007
My patients will not be able to adhere to a PrEP regime	0.48 (0.30-76)	0.002	0.56 (0.38-0.82)	0.003
Other methods to prevent HIV are better than PrEP	0.63 (0.40-0.99)	0.043	0.59 (0.40-0.88)	0.009
Provider and Practice Characteristics				
Self-rated PrEP knowledge	2.95 (2.16-4.04)	<0.001	ns	
Currently prescribe antiretrovirals	6.55 (3.13-13.73)	<0.001	4.23 (2.22-8.05)	<0.001
Practice in urban area	23.67 (8.79-63.78)	<0.001	ns	
Non-heterosexual identity	14.64 (5.91-36.27)	<0.001	ns	
<10 years in practice	4.19 (2.21-7.94)	<0.001	ns	
Have >5% MSM patients	7.73 (3.95-15.11)	<0.001	3.24 (1.15-3.60)	<0.001

HOME BASED PRIMARY CARE IMPROVES PATIENT OUTCOMES IN FRAIL, MEDICALLY COMPLEX ELDERS

Christine Patterson[3]; Bruce Kinosian[2]; Peter Boling[3]; Daniel M. Gilden[5]; George Taler[1]; IAH Learning Collaborative[4]. [1]Georgetown University School of Medicine, Washington, DC; [2]University of Pennsylvania, Philadelphia, PA; [3]Virginia Commonwealth University, Richmond, VA; [4]American Academy of Home Care Medicine, Chicago, IL; [5]JEN Associates, Cambridge, MA. (Control ID #2698375)

BACKGROUND: The Independence at Home (IAH) demonstration has shown that home-based primary care (hbpc) practices improve care and reduce overall costs for patients with multiple chronic conditions. While cost savings and summary quality measures have been reported for the demonstration, hospitalization and readmission rates have not. This study compared hospitalization and readmissions collected by one IAH demonstration site (Mid Atlantic Consortium [MAC]), to rates for an IAH-qualified (IAH-Q) population in the MAC counties (Philadelphia, Richmond, and the District of Columbia) and then generalized the findings to the full IAH demonstration

using the NPI-linked 5% Medicare files. We expected that MAC and IAH demo enrollees' utilization would decline at a greater rate than local IAH-Q patients who did not receive hbpc, consistent with the reported cost savings.

METHODS: Data were collected by MAC practices from 2012–2016, from internal tracking and reporting, among all IAH-eligible practice patients. We used NPI- linked 2011–14 5% Medicare files to identify IAH-Q enrollees in the 15 IAH demo practices (through their NPIs), and for comparison the local IAH-Q non-hbpc beneficiaries. IAH-Q patients were determined by hosp. and post-acute care in the 12 months prior to eligibility, 2+ chronic conditions, and 2+ ADL dependencies operationalized by a JEN frailty index >6. IAH-Q controls matched the age, disease, and utilization trajectory profiles of IAH-Q enrollees in the demonstration practices. Benchmark rates were created for each practice county, and aggregated to produce MAC and national benchmarks. Benchmarks were compared to the hospital, 30d readmit, and ACSC hosp pooled rates for the IAH-Q enrollees. Long term institutionalization (LTI) was recorded for the MAC practices, but were unable to be measured with precision for the 5% demo sample. Rates are per 100 beneficiary months (or hosp. for readmissions). Benchmark rates were pooled over the 3 years.

RESULTS: There were 617 IAH-Q enrollees in demo practices (4.9% of the 12,500 demo participants), and 8,712 IAH-Q non-hbpc beneficiaries in the demo practice counties. IAH-Q enrollee rate ratios were 0.77 (95% CI .74–.81) for hosp,0.73 (CI .69–.79) for 30d readmits and. 0.56 (CI .52–.60) for ACSC hosp from control rates of 12.4 (hosp.), 21.4 (30d) and 9.2 (ACSC). Rate ratios for MAC were 0.71 (CI .62–.80; hosp.), 0.80 (CI .72–.88; 30d readmit), and 0.56 (CI .48–.64; ACSC). By Year 3 MAC rate ratios had declined to 0.54 (CI .44–.63; hosp.), 0.64 (CI .55–.73; 30d), 0.42 (CI .38–.46; ACSC), and 0.47 (CI .32–.62; LTI) against pooled benchmarks of 13.25 [hosp.]. 23.5 [30d readmits], 9.7 [ACSC] and 17.1 [LTI].

CONCLUSIONS: Hbpc, operating through IAH's aligned incentives reduces hospitalizations and readmissions, while producing cost savings. Detailed analysis of one site confirmed the sample analysis of all demonstration sites, with additional reductions in later demonstration years.

HOSPITAL MORTALITY TRENDS DURING THE ACADEMIC YEAR ON MEDICINE SERVICES IN A COMMUNITY HOSPITAL: A RETROSPECTIVE ANALYSIS

Maidah Yaqoob[2]; Wasseem Skef[2]; Claudia Nader[1]; Bertrand Jaber[2]. [1]Saint Elizabeth's Medical Center, Brighton, MA; [2]Saint Elizabeth Medical Center, Boston, MA. (Control ID #2684844)

BACKGROUND: In the first 3 months of the Internal Medicine Residency Program's academic year, newly recruited first-year residents and newly matriculated second-year residents have the potential to negatively impact hospital-based patient care, due in part to lack of experience. We hypothesized an association between resident experience and hospital mortality rates.

METHODS: A single-center retrospective cohort study spanning two academic years (July 2013-June 2015) was conducted at St. Elizabeth Medical Center. Hospitalized adults who expired on medicine services (excluding cardiology) were identified in the departmental Death Review database. Using monthly hospital discharge volume by service, monthly mortality rates were calculated and grouped by quarters in accordance with the start and conclusion of the academic year. After excluding decedents with comfort-care-only (CMO) status on admission, mortality rates in the first 24 hours were also computed, as proxy for preventable deaths. The study was approved by the IRB.

RESULTS: Over 24 months, there were 265 deaths. 51.3% were men and mean (± SEM) age was 73 ± 1 years. 55.8% died in the ICU and 43.4% on medical floors.Leading causes of death were sepsis (23.8%) and cancer (18.1%). 69.8% were full code, 26.4% DNR, and 3.4% CMO on admission. 70.9% were CMO, 18.8% DNR and 9.8% full code at time of death. 20.4% died in the first 24 hours. There was a significant increase in hospital mortality during the 3rd quarter of the academic year ($P = 0.01$), representing the winter season, which persisted after excluding decedents with CMO status on admission. While mortality in the first 24 hours appeared higher in 2nd quarter, this did not reach statistical significance. ($P = 0.19$). Most common causes of death were sepsis (33.9%, 30.5%) in the 1st and 2nd quarter, cancer (23.3%) in the 3rd quarter, and pneumonia (20.4%) in the 4th quarter.

CONCLUSIONS: In this retrospective analysis, we did not identify an association between resident experience and mortality rates on medicine services. However, we observed a trend of increased mortality during the 3rd quarter of the academic year corresponding with the winter season, which is consistent with a national phenomenon.

HOSPITAL-LEVEL CARE AT HOME FOR ACUTELY ILL ADULTS: A PILOT RANDOMIZED CONTROLLED TRIAL

David M. Levine[1]; Kei Ouchi[2]; Bonnie Blanchfield[1]; Keren Diamond[3]; Charles T. Pu[4]; Jeffrey L. Schnipper[1]. [1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Partners HealthCare at Home, Boston, MA; [4]Partners Healthcare System Center for Population Health, Boston, MA. (Control ID #2706921)

BACKGROUND: Hospitals are the standard of care for management of acute illness, but hospital care can be unsafe, uncomfortable, and expensive. Providing substitutive hospital-level care in a patient's home potentially reduces cost while improving quality and safety, although evidence from randomized controlled trials is lacking.

METHODS: We piloted a randomized controlled trial of acute hospital-level care at home versus usual care at an academic medical center. Patients who presented to the emergency department with any infection, heart failure exacerbation, or COPD/asthma exacerbation were eligible to enroll and be randomized only after an admission decision was made. Patients were excluded if they lived over 5 miles away or were medically unstable by several disease-specific risk scores. Patients randomized to home received at least 1 daily physician visit, 2 daily nurse visits, 24/7 video and text contact with clinicians, continuous vital signs monitoring, medications by any route, and portable diagnostics. Additional services were tailored to each patient as needed, such as physical therapy, social work, and food delivery. Our primary outcome was direct cost of the acute care episode. We calculated cost by totaling non-physician labor, supplies, medications, labs, radiology, and transport. We secondarily studied utilization (eg, labs, consultations) during the care episode, 30-day post-discharge cost and utilization, and quality and safety (eg, adverse events, sleep, physical activity [objective data via vital signs monitor]). We compared groups with Mann–Whitney and Fisher exact tests. We present cost data as percent change from control.

RESULTS: Nine patients (2 female, 4 white) randomized to home had a median age of 65 (IQR, 28) years; 11 patients (8 female, 5 white) randomized to control had a median age of 60 (IQR, 29) years. Median direct cost of the acute care episode for home patients was 52% (IQR, 28%; $p = 0.05$) lower than for control patients. Median length of stay was 3.0 days in both groups ($p = 0.8$). During the care episode, home patients had fewer lab orders (median per admission: 6 vs 19;

$p < 0.01$) and less often received consultations (0% vs 27%; $p = 0.04$). At 30-days post-discharge, median direct cost for home patients was 67% (IQR, 77%; $p < 0.01$) lower, with trends toward less use of home care services (22% vs 55%; $p = 0.20$) and fewer readmissions (11% vs 36%; $p = 0.32$). No safety events occurred in home patients; 1 control patient had hypokalemia. Home patients were more active (median min of activity per day, 209 vs 78; $p < 0.01$), with a trend toward more sleep (median hours per day, 5.4 vs 4.1; $p = 0.3$).

CONCLUSIONS: In this randomized controlled pilot of patients admitted with acute illness, the use of substitutive home hospitalization compared to usual care in the hospital reduced cost and utilization and improved patient activity. Preliminary results suggest quality and safety were maintained or improved, with more definitive results awaiting a larger trial.

HOW DO PROVIDERS RESPOND TO PATIENT DISCLOSURES OF MEDICATION NON-ADHERENCE? A MIXED METHODS ANALYSIS OF PATIENT-PROVIDER DIALOGUE IN HIV CARE

Wynne Callon[1]; Somnath Saha[3]; Mary Catherine Beach[2]. [1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Portland VA Medical Center, Portland, OR. (Control ID #2706113)

BACKGROUND: Antiretroviral therapy (ART) adherence among people with HIV/AIDS is critical to ensure viral suppression and to prevent further viral transmission. Effective behavior change counseling techniques such as motivational interviewing have been suggested as useful for conversations about non-adherence, but little is known about which communication strategies are associated with future behavior change. This study aimed to characterize HIV provider responses to disclosures of ART non-adherence and evaluate whether response-type was associated with future adherence.

METHODS: We analyzed audio-recorded, transcribed encounters from 4 US cities between 31 providers and 43 patients who disclosed in the encounter that they had been non-adherent. We conducted a content analysis to characterize types of provider responses to these disclosures, grouping them into three broader categories (positive, neutral, and negative) according to their emotional valence. We evaluated whether provider response types were associated with subsequent viral load, which we obtained from medical records 6 months after the initial encounter, using logistic regression models controlling for baseline viral load.

RESULTS: Most ($n = 34$) patients identified as black, 5 white and 3 Hispanic/Latino. The mean patient age was 44 years; 23 were male. Most providers identified as white ($n = 21$) and just over half ($n = 17$) were male. The average dialogue about adherence was 654 words (range 0–3228). Positive responses by physicians included encouragement ($n = 10$ dialogues), praise ($n = 12$), partnering/support ($n = 9$), and empathy ($n = 5$). Negative responses included admonishment ($n = 14$ dialogues), disengagement ($n = 15$), threats ($n = 8$), and confrontation ($n = 5$). Neutral responses included information-gathering ($n = 35$ dialogues), education ($n = 26$), convincing with reward-focused ($n = 11$) or consequence-focused ($n = 16$) reasoning, emphasis on importance of adherence ($n = 14$), and expressions of concern or hope ($n = 17$). Responses that we categorized as negative were associated with an *increased* odds of having an undetectable viral load at follow-up (OR 3.98, 95% CI 1.20–13.23) whereas positive and neutral responses had no association with subsequent viral load (OR 0.80, 95% CI 0.32–1.98 positive; OR 0.55, 95% CI 0.27–1.14 neutral). There was no association between subsequent viral load and whether the provider used a reward or consequence-focused orientation to convince the patient, or the amount of dialogue about adherence.

CONCLUSIONS: Despite studies suggesting that confrontational and threatening dialogue is counterproductive, our study suggests that in this context, the opposite might be true. If these results are reproducible, this raises serious moral and communication challenges about how providers should respond to patient non-adherence.

HPV VACCINATION IN CORRECTIONAL CARE: KNOWLEDGE, ATTITUDES, BARRIERS, AND RATES OF VACCINATION AMONG FEMALE INMATES

Alia Moore[1]; Matthew Cox-Martin[3]; Katie Berenbaum[2]; Ingrid A. Binswanger[1]. [1]University of Colorado Denver, Denver, CO; [2]University of Colorado School of Medicine, Denver, CO; [3]University of Colorado, Denver, CO. (Control ID #2702898)

BACKGROUND: Women in prison are nearly 5 times more likely to develop cervical cancer than women in the general population. The Human Papillomavirus (HPV) has been implicated as an important risk factor for cervical cancer, and incarcerated women have high rates of HPV infection due to risky sexual behaviors and lack of healthcare access in the community. Few studies have examined HPV vaccine knowledge and attitudes among female inmates. This study aimed to assess attitudes toward, knowledge of, and barriers to HPV vaccination among incarcerated women, in addition to assessing self-reported HPV vaccination rates and willingness to receive the vaccine while in prison.

METHODS: English-speaking female inmates aged 18–26 at a Colorado prison were randomly selected to meet individually with an investigator, who then administered the structured survey in person. The 10-min survey was developed using a Health Belief Model framework and existing studies about HPV vaccine attitudes and acceptability which were adapted for the prison environment. Verbal consent was obtained from all participants. We conducted descriptive analyses.

RESULTS: Of 142 eligible women in prison, 38 (27%) completed the survey. The average participant age was 24 (CI 23.3-24.4). Seventy-nine percent ($n = 30$) of women had heard of HPV, and 58% (22) had heard of the HPV vaccine. Thirty-seven percent (14) reported receiving at least one HPV dose prior to incarceration. Regarding knowledge, 11% (4), 34% (13), and 50% (19) believed that HPV can cause oral cancer, genital warts, and cervical cancer, respectively. The majority of women (63%, 24) believed that they have the same cervical cancer risk as women who have never been incarcerated. Most participants (71%, 27) were willing to receive the vaccine while in prison, but cited concerns about lack of care in the event of an adverse reaction (29%, 11) and uncertainty about how to obtain more information about the vaccine (58%, 22).

CONCLUSIONS: Incarcerated women were aware of both HPV and the vaccine, but had knowledge gaps regarding both. Additionally, most participants were unaware of their potentially increased cervical cancer risk compared to the general population. Many women did not receive the vaccine prior to incarceration, but the majority reported a willingness to get it while in prison. This is important because women may age out of the vaccine by the time they are released. Also, while many female inmates have likely been exposed to HPV prior to arrest, the vaccine may still prevent future infection by strains that they have not been exposed to. Colorado women's prisons do not currently offer HPV vaccination, and though a larger sample size is needed to confirm the findings of this study, age-appropriate female inmates should be offered HPV education and vaccination. Such initiatives may reduce the cervical cancer burden in the correctional population and protect women even after they leave prison.

IDEAS FOR PROMOTING PATIENT-CENTERED CARE IN INPATIENT SETTINGS

Barbara G. Bokhour[2, 3]; Rendelle Bolton[2]; Gemmae Fix[1, 3]; Carol Van Deusen Lukas[3]. [1]Center for Healthcare Organization and Implementation Research/Boston University School of Public Health, Bedford, MA; [2]ENRM Veterans Affairs Medical Center, Bedford, MA; [3]Boston University School of Public Health, Boston, MA. (Control ID #2705750)

BACKGROUND: While patient-centered care (PCC) has been well described in outpatient settings, inpatient PCC has had less focus. Inpatient providers may focus more on the diagnosis than the person in the face of acute biomedical concerns. Nonetheless, in the inpatient setting a patient-centered approach is important for taking into account individuals' needs, illness experience, hospital care, and discharge planning. The objective of this study was to identify key inpatient PCC practices.

METHODS: We conducted two, day long ethnographic observations and qualitative interviews with patients ($n = 19$) and inpatient providers ($n = 26$) on medical/surgical units at two US Department of Veterans Affairs medical centers. Three investigators coded fieldnotes of observations and interviews to identify and categorize practices in relation to the a priori categories of PCC based on Hudon's conceptual framework. We then categorized practices according to congruence with these PCC principles.

RESULTS: We identified practices 4 practices aligned with PCC principles: 1) Attending to patients' disease and illness experience - providers communicated with patients about their current experience, before attending to routine clinical tasks. 2) Establishing a common ground - providers helped patients understand their care, orienting them to clinical tasks. 3) Bringing biopsychosocial perspectives - providers learned about patients as individuals and incorporated personal histories into care. 4) Establishing a therapeutic alliance - providers treated patients with respect, establishing relationships even with those with limited communication capacity. We identified 3 practices that contrasted with PCC principles: 1) Failure to share power and responsibility - providers elevated rules and procedure over patients' preferences, needs or concerns. 2) Failure to establish a common ground for practices - providers did not communicate about procedures thus delaying attention to patients' immediate needs and 3) Whole person - providers failed to ascertain patient's life context to understand the origins of illness and plan for appropriate discharge. We developed a rubric for providing inpatient PCC: IDEAS - Inquire about patients' well-being and daily life; Describe purpose of procedures; Engage in small talk to humanize interactions; Ask permission for all interactions; and Stay flexible about processes where possible.

CONCLUSIONS: As healthcare systems move towards providing more PCC it is critical to understand how these principles apply to inpatient care. Our study provides exemplars of provider care practices that are aligned with PCC principles, in contrast to those that focus on the disease or institutional procedures. IDEAS can be used to teach PCC principles or as the basis for an observational tool to evaluate PCC in inpatient settings.

IDENTIFYING A SHARED MENTAL MODEL FOR "NEW" FACULTY COMPETENCIES TO BETTER ALIGN EDUCATION WITH HEALTH CARE TRANSFORMATION

Jed Gonzalo[1]; Amarpreet Ahluwalia[1]; Maria Hamilton[1]; Heidi Wolf[1]; Daniel R. Wolpaw[1]; Britta M. Thompson[2]. [1]Penn State College of Medicine, Hershey, PA; [2]Penn State Hershey COM, Hershey, PA. (Control ID #2702422)

BACKGROUND: Health care transformation in US Academic Health Centers (AHC) involves new models of care delivery aimed at achieving the Quadruple Aim, which requires engagement of faculty who are prepared to practice, educate, and lead in these emerging areas. Despite a growing mandate and potential benefits to the mission of AHCs, corresponding professional development efforts have been slow to emerge, in part due to lack of a comprehensive competency framework that moves beyond patient safety and quality improvement. We interviewed 23 health system leaders to develop a potential competency framework for faculty development programs in Health Systems Science with the ultimate goal of improving health outcomes.

METHODS: In 2016, we interviewed health systems leaders who were actively involved in health care delivery, either at the clinical or administrative levels, and in leadership positions within the health system. We performed digitally-recorded, one-on-one interviews with each participant to explore perceptions regarding necessary competencies in evolving health systems and current challenges in health care. Interview transcripts were analyzed using constant comparative and thematic analysis. Competencies and curricular concepts were coded into subcategories and subtopics. Lead investigators reviewed drafts of the categorization scheme and themes related to gaps in faculty knowledge and skills, collapsed and combined domains and subcategories, and resolved disagreements via discussion.

RESULTS: Analysis identified four themes related to needs in faculty development: (1) Foundational competencies, which included systems thinking, change agency/management, teaming, and leadership. (2) Core functional competencies and curricular domains for conceptual learning, including patient-centered care (e.g. patient experience), health care processes (e.g. collaboration), policy and payment (e.g. reform), clinical informatics (e.g. decision support), population and public health (e.g. community-based resources), value-based care (e.g. cost), and health system improvement (e.g. measurement). (3) Paradigm shifts in how academic faculty approach and conceptualize health care, categorized into four areas: delivery, transformation, provider characteristics and skills, and education. (4) Faculty awareness of challenges to providing quality care and innovating in AHCs.

CONCLUSIONS: This broad competency framework for faculty development programs expands existing curricula by including a comprehensive scope of Health Systems Science content and skills. The need for faculty to know and be skilled in foundational competencies has significant implications for education and supports the premise that knowledge acquisition alone is insufficient. AHCs can use these results to better align faculty education with the real-time needs of their health systems. Future work will need to investigate optimal prioritization and methods for teaching.

IDENTIFYING BEHAVIORAL HEALTH COMPETENCIES FOR INTERNAL MEDICINE RESIDENTS: QUALITATIVE INTERVIEWS WITH RESIDENTS, FACULTY AND BEHAVIORAL HEALTH CLINICIANS AT A CLINIC WITH INTEGRATED BEHAVIORAL HEALTH

Patrick Hemming[1]; Lawrence Greenblatt[2]; Jessica Revels[2]. [1]Duke University School of Medicine, Durham, NC; [2]Duke University, Durham, NC. (Control ID #2704693)

BACKGROUND: Primary care providers frequently provide behavioral health (BH) services as part of patients' comprehensive care; these BH services include care for mental health and substance abuse, as well as assistance with behavioral risk factor reduction. Compared with other specialties involved with

primary care, internal medicine residencies lack formal expectations regarding what components of BH care should be incorporated in the course of residents' training. To determine appropriate BH competencies for internal medicine residents, we conducted focus groups with residents, faculty and behavioral health clinicians (BHCs) at our academic primary care clinic.

METHODS: Between June and August 2016, residents with continuity practice at the clinic were invited to participate in focus groups. Additional separate focus groups were conducted with attending physicians and BHCs who are integrated into the clinic's care. In all, 25 residents, 2 advanced practice providers, 6 attendings and 4 BHCs participated. The focus group leader asked open-ended questions regarding the following: residents' successes and challenges managing BH issues; specific learning competencies that participants see as necessary to manage these BH conditions; and what methods would facilitate learning BH competencies. Focus groups were recorded and transcribed. Two researchers coded, using editing analysis to develop a list of common categories and sub-categories.

RESULTS: Proposed competencies were grouped into three main categories. The first category Interpersonal Skills Training had three sub-categories: Visit Management, Counseling Skills, and Shared Decision-making. For Interpersonal Skills Training, residents repeatedly requested experiential learning with a skilled preceptor in the setting of patient care. The second two categories were Social Determinants of Health (SDH), and Mental Health Management (MHM); for each of these categories, residents repeatedly expressed a desire to learn specific resources for patients with problems related to SDH and/or MHM. Many residents wished that there were a better resource guide available to help them address these needs.

CONCLUSIONS: Many internal medicine residents can identify important gaps in their knowledge of BH. Curricula to address these gaps should focus on interpersonal skills relating to BH. Residencies may enhance residents' BH learning about social determinants of health and mental health management by facilitating co-management with IBHCs in residents' clinical care.

IDENTIFYING BURNOUT AND RELATED DEMOGRAPHIC, PROGRAM, AND TEAM FACTORS: A HOSPITALIST SURVEY ACROSS 4 HOSPITALS

Henry J. Michtalik[1, 4]; Peter J. Pronovost[4, 5]; Jill A. Marsteller[2, 4]; Joanne E. Spetz[3]; Daniel E. Ford[5, 2]; Eric Howell[5, 4]; Daniel Brotman[1]. [1]Johns Hopkins Hospital, Baltimore, MD; [2]Johns Hopkins School of Public Health, Baltimore, MD; [3]University of California, Los Angeles, San Francisco, CA; [4]Armstrong Institute for Patient Safety and Quality of Care, Baltimore, MD; [5]School of Medicine, Johns Hopkins University, Baltimore, MD. (Control ID #2701746)

BACKGROUND: Reducing physician burnout remains an important goal in preserving an engaged and satisfied workforce for a resilient healthcare system. The objective of this study was to characterize hospitalist burnout, its prevalence, factors associated with burnout, and potentially modifiable targets for further study and intervention.

METHODS: As part of a statewide hospitalist survey on workload, safety and quality of patient care, physician burnout, and the impact of healthcare reform, we surveyed 4 hospitalist programs within a large academic hospital system. This survey obtained demographic information (race, gender, marital status, age, years in practice), workload measurements (patient encounters, workhours per day/shift, frequency of self-reported "unsafe workload"), program structure (scheduling, program type, percent clinical time), and team structure (geographical localization of patients, housestaff/advanced practitioner assistance, and systems for workload fluctuation). Using norms for healthcare workers, burnout was defined using the Maslach Burnout Inventory as a dichotomous variable (burnout present/absent). The depersonalization, emotional exhaustion, and personal achievement categories of burnout were individually assessed. Controlling for site, we used logistic regression to determine the association between each of these factors to burnout.

RESULTS: Of the 128 hospitalists across 4 sites, 96 responded (75% response rate; range: 63–90%). The majority of hospitalists were male (54.2%), Asian (46.9%) or Caucasian (35.5%), married/in a domestic partnership (78.1%), with a mean age of 40 years old (SD 5.9) and median 6 years in practice [IQR: 4, 10]. Providers saw a median of 13 patients per day/shift [10, 17.5], worked a median of 11 hrs per day/shift [10, 12], and 21 (23%) reported workload exceeded a safe level at least once a month. Most hospitalists were on a variable scheduling pattern (56.3%), worked primarily in an academic teaching hospital (53.1%), and had median 80% clinical time [55, 99]. Patients were primarily seen in multiple, different sections of a hospital (57%) with no housestaff or advanced practitioner assistance (51%), with a system in place to manage increased patient volumes (58.6%). On the Maslach Burnout Inventory, 31 (36.5%) experienced emotional exhaustion, 36 (42.4%) experienced depersonalization, and 45 (52.9%) had low personal achievement, with only 17 (20%) experiencing all three. Comparing individuals meeting all 3 criteria to those who did not meet any, only being in a community hospital ($p = 0.049$) and reporting an unsafe workload at least once a month ($p = 0.002$) were significantly associated with burnout.

CONCLUSIONS: Rather than traditional factors such as scheduling and clinician experience, our study suggests that organizational structure and culture may be an important driver for burnout. Further research is needed in assessing and determining specific mitigation strategies for these organizational factors.

IDENTIFYING MESSAGES TO PROMOTE VALUE AND EDUCATION (IMPROVE) OF GENERIC ORAL CONTRACEPTIVE PRESCRIBING

Samantha Ngooi[5]; Mark Chee[6]; Christopher Moriates[4]; September Wallingford[2]; Tracy Cardin[5]; Arlene Weissman[1]; Jeanne M. Farnan[5]; Anita Samarth[8]; Neel Shah[3, 3]; Shalini Lynch[9]; James X. Zhang[5]; Marilyn Stebbins[9]; David Meltzer[5]; Michelle L. Cook[7]; Diane Padden[7]; Vineet M. Arora[5]. [1]American College of Physicians, Philadelphia, PA; [2]Costs of Care, Quincy, MA; [3]Harvard Medical School, Boston, MA; [4]UT Southwestern Medical Center, San Francisco, CA; [5]University of Chicago, Chicago, IL; [6]Pritzker SOM, Chicago, IL; [7]American Association of Nurse Practitioners, Austin, TX; [8]Clinovations Government and Health, Washington D.C., DC; [9]University of California San Francisco, San Francisco, CA. (Control ID #2699753)

BACKGROUND: In the United States, oral contraceptive pills (OCPs) are the most frequently used contraceptive method in women of reproductive age. Prescribing generic OCPs over brand-name OCPs is an important strategy to improve the value of care and reduce healthcare expenditures. In 2013, 22% of OCP prescribed were brand-name, of which 98% had an available generic alternative. The study aims were to understand the barriers to and facilitators of generic OCP prescribing and identify potential solutions to increase generic

OCP prescribing among key prescribers: primary care physicians and nurse practitioners.

METHODS: To elicit provider perceptions of generic OCP prescribing, focus group scripts based on the 4D model of appreciative inquiry (Discovery, Dream, Design, Destiny was developed, pilot-tested, and revised. Discovery and Dream questions inquired about providers' understanding of FDA bioequivalence standards and their experience prescribing OCPs compared to other drug classes. The Design and Destiny sections explored how to improve and promote generic prescribing. Two 60-min focus groups occurred, one at the American College of Physicians Internal Medicine meeting and one at the American Association of Nurse Practitioners National Conference. Transcripts were analyzed qualitatively via ATLAS.ti software using a constant comparative method with no a priori hypothesis to generate emerging and reoccurring themes.

RESULTS: A total of 12 PCPs and 12 NPs participated (76% female, 62% non-Hispanic White, 14% Black or African-American). Participants identified 25 subthemes affecting generic prescribing under four major themes- health system, workflow, provider, and patient factors (Table 1). Overall, providers' knowledge of FDA bioequivalence standards was low. Moreover, negative attitudes and accessibility of information about generic options were frequently cited as barriers, commenting that "generics are not going to be efficacious." Participants also identified 13 solutions to increase generic prescribing that aligned with the four identified themes, including IT system defaults and simpler naming schema, noting "There are so many different names…there's no current compendium of what the names are, what's in them, or what the dosage is."

CONCLUSIONS: This study suggests that generic OCPs are underutilized due to barriers related to health system, workflow, provider, and patient factors. Interventions addressing these factors could be used to promote generic OCP prescribing.

Table 1: Barriers and Facilitators of Generic OCP Prescribing

Health System Factors						
State substitution laws	Availability of samples	Insurance companies	Availability of generics	Performance metrics		
Workflow Factors						
Practice disruption	Default to generic	Pharmacy	Insurance	Formulary	Generic nomenclature	Point of care IT tools
Provider Factors						
Attitude towards generics	Lack of trusted sources	Reluctance to switch patient medication	Level of knowledge about generics	Accessibility of information about generics	Multiple generic brands	Specialists
Patient Factors						
Cost	Preference	Prior experience	Side effects	DTC advertising	Pill and package	

IDENTIFYING VETERANS AT HIGH-RISK FOR PROGRESSION TO END-STAGE RENAL DISEASE AND OPPORTUNITIES FOR NEPHROLOGY REFERRAL Joel C. Boggan; Richard M. Atkins; David Simel; Blake Cameron. Durham VAMC and Duke University, Durham, NC. (Control ID #2707788)

BACKGROUND: Patients with chronic kidney disease (CKD) are at increased risk for progression to end-stage renal disease (ESRD) and cardiovascular mortality. Appropriate nephrology referral and management of patients with CKD can slow progression to ESRD and mitigate cardiovascular risk. In this study, we sought to identify patients at high risk for progression to ESRD using predictive algorithms within Durham VA Medical Center (DVAMC) to determine appropriate nephrology referral patterns.

METHODS: We incorporated data on primary care and nephrology utilization within DVAMC over a two-year period from December 2014-December 2016 and nephrology referrals from December 2013 onward. We measured creatinine levels and degree of proteinuria for affiliated patients, when available. Five-year risks of progression to ESRD were estimated using the 3-variable Kidney Failure Risk Equation (KFRE) for all patients with a creatinine value, and the 4-variable KFRE for all patients with urine albumin values. We stratified the population according to the cutoffs from the KFRE (<5%, 5–15%, and >15%) as low, intermediate, and high-risk for progression to ESRD. We identified the number of patients who would benefit from nephrology referral at the threshold of 15% risk of progression over 5 years. Additionally, we estimated the number of patients currently followed within our Nephrology clinics with risks below the 15% threshold.

RESULTS: Overall, 59,449 unique patients were seen in primary care clinics during the study period and 2015 (3.4%) were referred to or seen within Nephrology. In the population, 10,192 patients had no creatinine values and could not have any risk assessment, while 16,481 patients had a urinary albumin value allowing for 4-variable estimation. During the study period, 2313 patients had a risk of progression to ESRD > 15% using the 3-variable formula, while 406 had risk > 15% using the 4-variable equation. Within these high-risk categories, 46% (1071 of 2313) and 48% (193 of 406) had had either a nephrology referral or clinic visit over the previous two years, although up to approximately 330 patients receiving hemodialysis followed in the community outside the nephrology clinic were not captured. Across the whole population, 47% of patients referred to or seen in Nephrology clinics had a risk of progression to ESRD < 15%.

CONCLUSIONS: Within a single Veterans Affairs medical center, approximately half of patients with a significant risk of progression to end-stage renal disease had not had either a nephrology referral nor a nephrology clinic visit. Many of these patients would likely benefit from nephrology referral for management of renal disease progression, while many patients are being referred to nephrologists who have lower risks for progression. Next steps include design and implementation of e-consult outreach and testing and referral protocols to optimize use of nephrology clinics within our veteran population.

ILLICIT DRUG AND TOBACCO USE DELAY TIME-TO-PRESENTATION IN PATIENTS WITH ASCENDING AORTIC DISSECTION Tanya Doctorian. Kaiser Permanente Fontana Medical Center, Fontana, CA. (Control ID #2704497)

BACKGROUND: Ascending aortic dissection (AoD) is the most lethal condition involving the aorta. Despite increasing awareness of AoD among clinicians and improvements in diagnostic imaging, the mortality and morbidity rates of this condition remain high. In an effort to further optimize outcomes, symptom onset and its impact on presentation is needed. The onset of symptoms to hospital presentation, or pre-hospital delay, is a known cause for increased morbidity and mortality. Despite illicit drug use, smoking, and alcohol abuse being a major public health issue in the United States, there are no studies providing insight into their impact on pre-hospital delays in ascending AoD. The objective of this study was to determine whether tobacco use, alcohol use, and illicit drug use were associated with delays in presentation of patients with ascending AoD.
METHODS: 235 patients presenting with ascending AoD from 2007 to 2016 to a tertiary hospital with a diverse patient population were retrospectively studied. 145 patients with complete data were included in this analysis. Patients without complete data were excluded. Symptom-onset-to-hospital-arrival time was analyzed for the following factors: smoking history, alcohol use, methamphetamine, cocaine, or marijuana abuse. Symptom onset time was identified by review of medical records and emergency services data. Non-parametric univariate and multivariate analyses were carried out to compare differences in time to presentation between groups.
RESULTS: See table
CONCLUSIONS: As expected, in this study there were pre-hospital delays in patients with current tobacco, methamphetamine, cocaine, or marijuana use/abuse. Contrary to expectation, alcohol use (current or past use) was not associated with pre-hospital delays. Of interest, symptom-onset-to-hospital-presentation remains long even in patients without tobacco, alcohol, or illicit drug use. Continued and enhanced population education and awareness, especially in smokers and illicit drug users, is necessary to see further decreases in pre-hospital delays and to further optimize outcomes in ascending AoD patients. Further research is needed to investigate other causes for increased symptom-onset-to-presentation time and barriers to healthcare access.

	Percentage of population	Symptom onset-to-presentation time {median (min-max)} in hours	P-value
Smokers			
Never	49.50%	2 (0.5 – 48)	Reference
Current	22.50%	8 (2 – 336)	<0.001
Past	27.90%	2 (0.5 – 144)	0.001

IMPACT OF A PILOT COMMUNITY-BASED CLINICAL PHARMACIST HYPERTENSION PROGRAM ON PATIENT ACTIVATION AMONG CHINESE AMERICAN SENIORS
Emiley Chang[1]; Sae Byul Ma[2]; Andrew Tseng[3]; Lily Lu[4]; Rong Guo[1]; Michael Ong[1]; Catherine Sarkisian[1, 5]. [1]University of California, Los Angeles, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA; [3]Community member, San Gabriel, CA; [4]The Johns Hopkins Hospital, Baltimore, MD; [5]Veterans Affairs - Greater Los Angeles, Los Angeles, CA. (Control ID #2706795)

BACKGROUND: Older Chinese Americans have a disproportionately higher rate of undertreated hypertension (HTN) compared to non-Latino Whites, and Asian Americans report weaker patient-provider engagement than desired. As patient activation can be a powerful driver of improved HTN control, we assessed the efficacy of a culturally tailored clinical pharmacist intervention on patient activation among immigrant Chinese American seniors with uncontrolled HTN.
METHODS: We conducted a pre-post, prospective intervention with repeated measures in Los Angeles County. We screened and recruited patients from 8 community health centers and private practice clinics between 2015–2016. Eligible patients (age 60+, medically insured, past year visit at study clinic, at least 2 of 3 systolic blood pressure [BP] readings above JNC-8 goal in past year) were invited to a study information session through mailings and telephone calls in either Mandarin or Cantonese. Enrolled participants had 3 visits within 3 months with bilingual study pharmacists, who were trained to elicit HTN explanatory models when providing HTN education and use motivational interviewing (MI) and shared decision-making (SDM) when counseling patients on lifestyle changes and BP medications. Study participants' physicians received a brief summary of each visit and signed pharmacist recommendations for medications or lab orders if in agreement. Participants completed baseline and final surveys before their first and after their last pharmacist visit, including demographic information and the Patient Activation Measure (PAM). We also conducted chart reviews to obtain clinical information. We estimated a sample size of 50 patients would detect a clinically significant 3 to 5-point difference in our primary outcome, PAM scores, with 80% power. We tested for statistical significance ($\alpha = 0.05$) using the Wilcoxon signed rank test.
RESULTS: We screened 415 potential participants to enroll 50 immigrant Chinese American seniors who received the intervention. The average age was 71 years, and 23 (47%) were female. Participants had resided in the U.S. for an average of 30 years, but only 10 (20%) were comfortable speaking English. Median baseline level of trust in pharmacists was "somewhat" to "strongly trust". The mean baseline PAM score was 58.8 signifying "beginning to take action," with a mean change of −2.04 +/− 13.9 ($p = 0.48$) at follow-up.
CONCLUSIONS: While clinical pharmacist HTN interventions have shown success in some settings, our intervention utilizing MI and SDM strategies was not associated with increases in PAM scores for immigrant Chinese American seniors with uncontrolled HTN. Despite strong project involvement of community partners in these predominantly Asian neighborhoods, eligible seniors frequently declined to enroll. We will continue to work closely with our community partners to identify other team-based care approaches which may be more appealing and successful at increasing patient activation for HTN control in this population.

IMPACT OF A POPULATION HEALTH MANAGEMENT INTERVENTION ON DISPARITIES IN CARDIOVASCULAR DISEASE CONTROL
Aisha James[3]; Seth A. Berkowitz[2]; Jeffrey M. Ashburner[3]; Yuchiao Chang[1]; Daniel M. Horn[3]; Sandra OKeefe[3]; Steven J. Atlas[3]. [1]Harvard Medical School, Boston, MA; [2]MGH, Boston, MA; [3]Massachusetts General Hospital, Boston, MA. (Control ID #2690284)

BACKGROUND: Healthcare systems are using population health management (PHM) programs to improve the quality of cardiovascular disease care. Whether these programs also improve racial/ethnic disparities in care is unclear.
METHODS: Eighteen primary care practices were studied from 7/1/14-12/31/14. All used the same PHM information technology system (TopCare, SRG

Technology) to identify and track patients with cardiovascular disease or hypertension. To help patients meet quality metrics, 8 intervention practices were assigned a dedicated central population health coordinator and 10 control practices used office-based staff. Outcomes included clinically relevant low-density lipoprotein (LDL) cholesterol and/or blood pressure (BP) measures. The LDL goal was LDL < 100 mg/dL, or prescription of a high dose "statin". The BP goal was < 140/90 mm Hg for patients < 60 years, < 150/90 mm Hg for patients ≥ 60 years, or prescription of ≥3 BP lowering medications. We examined changes in meeting LDL and BP goals in intervention and non-intervention practices by self-reported race/ethnicity (non-Hispanic white, non-Hispanic Black, or Hispanic). Analyses used logistic regression with generalized estimating equations for repeated measures, adjusted for age, gender, health insurance, primary language, patient-provider attribution, and whether care was received in a health center.

RESULTS: There were 12,555 participants in the LDL analyses (85.5% non-Hispanic white, 4.8% non-Hispanic black, 4.7% Hispanic), and 41,183 participants in the BP analyses (79.7% non-Hispanic white, 7.5% non-Hispanic black, 6.6% Hispanic). Across all practices at baseline, there were racial/ethnic disparities (LDL: non-Hispanic white 70.3% at goal, non-Hispanic black 64.2%, Hispanic 68.5%, $p = .007$; BP: non-Hispanic white 76.4% at goal, non-Hispanic black 73.4%, Hispanic 74.8%, $p = .0003$). Comparing intervention and non-intervention practices before and after the study period, non-Hispanic white patients in intervention practices had significantly increased odds of LDL control (OR 1.20 95% CI 1.09–1.32), while Non-Hispanic black (OR 1.15 95%CI 0.80–1.65) and Hispanic (OR 1.29 95%CI 0.66–2.53) patients saw similar, but not statistically significant, changes. For odds of BP control, non-Hispanic white patients in intervention practices saw improvement (OR 1.13 95% CI 1.05–1.22), which was similar, though not significant, for non-Hispanic black patients (OR 1.17 95% CI 0.94–1.45), but Hispanic (OR 0.90 95% CI 0.59–1.36) patients did not. Interaction testing confirmed that pre-existing disparities did not improve ($p = 0.73$ for LDL and $p = 0.69$ for BP).

CONCLUSIONS: The intervention improved the odds of cardiovascular risk factor control in most analyses, though with wide confidence intervals in racial/ethnic minority patients, likely related to smaller sample sizes. However, there were no large changes in disparities. Future population health management interventions should explicitly target both healthcare equity and quality.

IMPACT OF A PRIMARY CARE TEAM REDESIGN IN A PATIENT CENTERED MEDICAL HOME ON ACCESS AND EMERGENCY/URGENT CARE UTILIZATION Alison R. Landrey[1]; Valerie S. Harder[2]; Marie Sandoval[1]; John King[3]; MacLean Charles[1]. [1]University of Vermont/Fletcher Allen Medical Center, Morristown, VT; [2]University of Vermont, Burlington, VT; [3]University of Vermont Medical Center, Burlington, VT. (Control ID #2706232)

BACKGROUND: Poor access to primary care is associated with decreased healthcare quality and increased cost. The development of the Patient Centered Medical Home (PCMH) model within the last decade has been inconsistent in its ability to fully address these issues. Further primary care redesign that incorporates a) team-based care with expanded roles for non-physicians and b) increased use of non-face-to-face visits may improve care access and value while providing a potentially more satisfying and efficient primary care work environment. More research is needed to evaluate such care team models. We assessed the impact of a team redesign on access to primary care and use of emergency department (ED) and urgent care services, a measure of care value, in a PCMH.

METHODS: A redesigned team was developed within a larger internal medicine PCMH from May 2015 to April 2016 and consisted of two co-located teamlets each comprised of one physician, one nurse practitioner, one registered nurse, and two licensed practical nurses. The redesign team utilized a) physician-NP co-management b) expanded roles for RNs and LPNs and c) dedicated provider time for telephone and email medicine. We compared changes in office, ED and urgent care visits during the implementation year compared with a baseline year for patients on the redesigned team compared to patients receiving the standard of care in the same clinic using a differences-in-differences method. Time to 3rd next available appointment for providers was used to assess access.

RESULTS: There were no differences between the redesign group ($n = 1807$ patients) and control group ($n = 4715$ patients) in per-patient mean change in office visits (Δ -0.04 visits vs. Δ -0.07; $p = 0.98$), ED visits (Δ 0.00 vs. Δ 0.01; $p = 0.25$) or urgent care visits (Δ 0.00 vs. Δ0.05; $p = 0.08$). Mean time to 3rd next available appointment improved for both the redesign and control groups during the implementation year (Δ-5.2 days vs. Δ -6.4 days).

CONCLUSIONS: The redesign did not significantly impact ED, urgent care or primary care utilization within 1 year of follow up. Time to 3rd next available appointment improved for both the redesign and control groups during the redesign implementation. This parallel improvement in primary care access may have limited the ability to demonstrate improvement in ED/urgent care utilization in the redesign group compared to control. Additionally, the 1 year duration may not have been long enough to observe significant differences in utilization, and ED/urgent care use may not have been the best measure of care value in this setting. Further studies of similar primary care redesign efforts could explore longer follow up, additional care value outcome measures, and patient and provider satisfaction.

IMPACT OF A PROGRAM TO SUPPORT ACADEMIC SCHOLARSHIP DURING INTERNAL MEDICINE RESIDENCY TRAINING ON RESEARCH PRODUCTIVITY Timothy Anderson[4]; Andrea Carter[2]; Shanta M. Zimmer[1]; Carla Spagnoletti[2]; Alison Morris[2]; Wishwa N. Kapoor[2]; Michael J. Fine[3, 2]. [1]University of Colorado, Denver, CO; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]VA Pittsburgh Healthcare System, Pittsburgh, PA; [4]University of California, San Francisco, San Francisco, CA. (Control ID #2704212)

BACKGROUND: Scholarship is an essential component of residency training that is required by the Accreditation Council for Graduate Medical Education and identified by residents as influencing career choices and satisfaction. Leadership and Discovery (LEAD) is a program developed in 2012 as a component of the University of Pittsburgh Medical Center Internal Medicine (IM) Residency Program that requires all categorical residents to engage in mentored scholarship, generally carried out as a research project. To assess its impact on resident scholarship, we compared the research productivity of residents before and after initiation of the LEAD Program.

METHODS: We compared the research productivity of categorical residents graduating in 2015 or 2016 who were exposed to LEAD (post-LEAD[FMJ1]) to those graduating in 2013 or 2014 who were not exposed to LEAD (pre-LEAD). As a control group, we also assessed research productivity during the same time frames for research track residents who had a research infrastructure independent of LEAD. For all IM residents who completed the 3-year training program between 2013 and 2016, we measured scholarly productivity by counting original, peer reviewed research publications and scientific

presentations at national and international meetings from the start of residency to 6-months following graduation. We excluded clinical case vignettes, reviews, and editorials. We identified data through Medline searches and self-reported annual surveys administered by the residency training program. We used chi-square tests to compare proportions, and Student's t-tests for means, using 2-tailed *P*-values < .05 to define statistical significance.

RESULTS: Our evaluation comprised 114 categorical residents (62 pre- and 52 post-LEAD); controls comprised 34 research-track residents (6 pre- and 18 post-LEAD). As shown in the Table, significantly larger proportions of post-LEAD than pre-LEAD categorical residents presented at a scientific conference (48% vs 29%, $p = .03$) and presented at a conference and published a peer review paper (23% vs 10%, $p = 0.05$). Post-LEAD residents also had a larger mean number of presentations and/or publications than pre-LEAD residents (1.3 vs 0.7, $p = .02$). Although significantly larger proportions of research track than categorical residents completed presentations and/or publications, these scholarship outcomes for research track residents did not change before and after LEAD.

CONCLUSIONS: Introduction of a longitudinal and experiential research program at the University of Pittsburgh was associated with increased research productivity among categorical IM residents, with no secular changes in research productivity among non-participating research track residents.

Scholarship Outcomes	Categorical Residents	Research-Track Residents						
	Pre-LEAD (*N* = 62)	Post-LEAD (*N* = 52)	Total (*N* = 114)	*P*-value pre- vs. post-LEAD	Pre-LEAD (*N* = 16)	Post-LEAD (*N* = 18)	Total (*N* = 34)	*P*-value pre- vs. post-LEAD
≥1 presentation	29%	48%	37%*	0.03	73%	56%	64%*	0.29
≥1 publication	21%	27%	23%*	0.43	67%	56%	61%*	0.52

IMPACT OF A STUDENT-FACULTY COLLABORATIVE PRIMARY CARE CLINIC ON EMERGENCY DEPARTMENT UTILIZATION: SHIFTING THE DISCUSSION TOWARDS VALUE-BASED HEALTHCARE Anjali Thakkar[2]; Bonnie B. Blanchfield[1]. [1]Brigham & Womens Hospital, Weston, MA; [2]Harvard Medical School, Cambridge, MA. (Control ID #2706905)

BACKGROUND: Many student-run clinics (SRCs) provide primary care to underserved patients who otherwise would pursue more expensive avenues of care such as through visits to emergency departments (ED). Decreasing ED use offers a major opportunity to create value and would be a welcomed justification for funding SRCs. However, few SRCs have rigorously studied this. Many patients in Crimson Care Collaborative (CCC), a network of student-faculty primary care clinics at 6 locations in Massachusetts, do not have primary care access, and are thought to be higher utilizers of the ED. This study estimates the value that CCC creates by identifying the change in ED utilization before and after patients enrolled at the CCC clinic at Massachusetts General Hospital-Internal Medicine Associates (MGH-IMA), and calculating the cost savings to the provider and payer. The effect other covariates may have on ED utilization will also be assessed.

METHODS: A retrospective analysis of 767 adult patients who enrolled at CCC-IMA between 9/1/10 and 9/30/16 is being conducted to determine if ED utilization changed after patients enrolled in CCC and had access to primary care. Descriptive analysis will clinically and demographically characterize the annual patient cohorts using Research Patient Data Registry (RPDR) and CCC RedCap survey data. RPDR will also provide ED visits for each patient; the 30 months pre and post enrollment in CCC will be used to estimate the average change. Outpatient clinic visits will be calculated for all patients post-enrollment. Financial data from MGH's internal cost accounting system for FY 2014 & 2015 will be used to calculate the cost and net revenue per ED visit, stratified and weighted by payer, to quantify financial impact to payers and the provider. A regression analysis will evaluate the effect of covariates on the changes in ED use.

RESULTS: Preliminary analysis of ED utilization shows that in the first 2 years of CCC operation, average ED utilization per patient increased by 14.5% ($p = 0.23$) and 52% ($p = 0.03$) despite CCC access; however, the subsequent three annual cohorts, 2013–2015, each show an average per patient decrease in ED utilization of 28% ($p < 0.001$), 40% ($p < 0.001$) and 35% ($p < 0.001$). The estimated avoided ED visit cost to the provider (MGH) is estimated at $28.5 K, $72.4 K, $81.2 K for 2013, 2014 & 2015 respectively. The estimated savings to payers for avoided ED visits is estimated at $31.3 K, $78.1 K, $90.04 K for 2013, 2014 & 2015 respectively.

CONCLUSIONS: It appears that CCC created value to both payers and the provider from 2013–2015 by providing an alternative source of care. As the CCC SRC program matured, effectiveness of decreasing ED utilization improved. Scheduling lead-times in early years, and other factors may have reduced outpatient access and contributed to early cohort results. Further analysis is ongoing and includes examining outpatient visit volume, in-depth financial analysis, and regression analysis to further our understanding of the value created by CCC.

IMPACT OF ADMISSION URINE CULTURE ON ANTIBIOTIC USE AND HOSPITAL LENGTH OF STAY Molly J. Horstman[2, 3]; Andrew Spiegelman[4]; Aanand D. Naik[3]; Barbara Trautner[1]. [1]BCM/VA Hospital, Houston, TX; [2]Baylor College of Medicine, Houston, TX; [3]Michael E. DeBakey VAMC, Houston, TX; [4]The Adivsory Board Company, Washington, DC. (Control ID #2705674)

BACKGROUND: Overuse of urine testing may result in downstream events that impact antibiotic use and hospital length of stay (LOS). The aims of this study were to examine the impact of inpatient urine culture testing on the first day of hospital admission on inpatient antibiotic use and hospital length of stay using a national administrative dataset.

METHODS: We performed a retrospective cohort study using a national dataset of adult hospitalizations from The Advisory Board Company from 2009 to 2014. We excluded hospitalizations that were pregnancy-related, had a urologic procedure, or had LOS greater than 30 days. The exposure was a urine culture on day 1 of hospitalization. Hospitalizations were matched with coarsened exact

matching by facility, patient age, gender, Medicare Severity-Diagnosis Related Group (MS-DRG), DRG severity level, DRG mortality level, Elixhauser co-morbidity score, and ICD-9 codes for infection on admission. A multi-level linear Poisson model and a multi-level linear regression model were used to determine the impact of urine culture on inpatient antibiotic use and LOS.

RESULTS: Matching produced a cohort of 88,481 ($n = 41,070$ with a urine culture on day 1, $n = 47,411$ without a urine culture). A urine culture on day 1 of admission was associated with an increase in days of inpatient antibiotic use (incidence rate ratio 1.26; p-value <0.001). The difference in antibiotic use between admissions with and without a urine culture on day 1 resulted in an additional 36,607 days of inpatient antibiotic use. Urine culture on day 1 of the admission resulted in a 2.1% (SE 0.7%) increase in LOS. The predicted difference in bed days of care between hospital admissions with and without a urine culture on the first day of admission resulted in 6,071 excess bed days of care overall. The impact of urine culture testing varied by MS-DRG. For example, urine culture testing on day 1 of the hospitalization resulted in a 4.5% increase in LOS (875 excess days) for patients admitted for major joint replacement of the lower extremity and 1,006 excess days of antibiotic use.

CONCLUSIONS: Collecting a urine specimen for culture is a simple procedure that has major downstream impacts. Overall, patients with a urine culture sent on the first day of the hospital admission receive more days of antibiotics and have a longer hospital stay than patients who do not receive a urine culture. These findings varied by diagnosis group. Targeted interventions for specific diagnoses may achieve the best balance between reducing the potential harm associated with low-yield urine cultures and supporting clinician autonomy to order a culture in the appropriate clinical setting.

IMPACT OF BISPHOSPHONATE USE ON INCIDENT CARDIOVASCULAR EVENTS AMONG ELDERLY BREAST CANCER SURVIVORS Nana Gegechkori[2]; Natalia Egorova[1]; Grace Mhango[1, 2]; Juan Wisnivesky[3, 2]; Jenny J. Lin[1, 2]. [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Icahn School of Medicine at Mount Sinai New York, Brooklyn, NY; [3]Mount Sinai School of Medicine, New York, NY. (Control ID #2700556)

BACKGROUND: Cardiovascular disease (CVD) is one of the major causes of competing mortality in women with early-stage breast cancer. Recent studies suggest that bisphosphonates may decrease cardiovascular disease risk in elderly patients. Adjuvant bisphosphonates have shown to reduce the rate of breast cancer recurrence in the bone and improve breast cancer survival, among postmenopausal women. Because elderly breast cancer patients may also be at higher risk for developing CVD due to cancer treatment, we sought to evaluate whether bisphosphonate use was associated with decreased risk of developing new cardiovascular events after cancer diagnoses among women with primary breast cancer.

METHODS: We identified women >65 years with stage 0-III primary breast cancer diagnosed between 2007 and 2010 from the SEER-Medicare registry. We excluded women who had any history of CVD prior to cancer diagnosis. Study participants were followed from 6 months prior to until 36 months after the date of cancer diagnosis. Our primary outcome was a composite of incident heart failure, myocardial infarction, stroke, angina pectoris, and atrial fibrillation/flutter. Bisphosphonate use was defined as presence of at least one pharmacy claim from 6 months prior to cancer diagnosis to incident CVD event. We used propensity score matching by age, race/ethnicity, Charlson comorbidity score, and history of osteoporosis cancer stage, receipt of chemotherapy, surgery, use of angiotensin converting enzyme inhibitors (ACE-i), aldosterone antagonists, angiotensin receptor blockers (ARB), beta-blockers and statins to select a matched group of breast cancer survivors without bisphosphonate use. A competing risk Cox regression model was used to assess the association between time-to-new cardiovascular events and bisphosphonate use.

RESULTS: A total of 2180 breast cancer survivors had had at least one bisphosphonate prescription during the study period; the average length of bisphosphonate use of 15 months. Survival analyses showed that 87.0% of bisphosphonate users and 76.6% of non-bisphosphonate users were free of any cardiovascular disease after a median follow-up of 36 months ($p < .0001$). After propensity score adjustment, bisphosphonate use remained significantly associated with fewer incident cardiovascular events (hazard ratio 0.51, 95% confidence interval: 0.44 to 0.59).

CONCLUSIONS: Bisphosphonate use is associated with lower incidence of cardiovascular events among women >65 years old with primary early-stage breast cancer. Further work should evaluate the mechanisms underlying this association.

IMPACT OF COMORBIDITIES ON SURVIVAL AFTER INCIDENT HEART FAILURE: FINDINGS FROM THE NHANES I EPIDEMIOLOGIC FOLLOW-UP STUDY (NHEFS) Adithya Kumar[1, 2]; Binhuan Wang[2]; Robert Donnino[1]; Sundar Natarajan[1, 2]. [1]New York University School of Medicine, New York, NY; [2]The Department of Veterans Affairs New York Harbor Healthcare System, New York, NY. (Control ID #2706419)

BACKGROUND: Heart failure (HF) is the leading cause of hospitalization among US adults, significant increasing mortality and reducing quality of life. Most importantly, prognosis following HF is dismal, being worse than that for most cancers. This population-based observational study evaluates the mortality outcomes for individuals hospitalized for incident heart failure and elucidates the impact of co-existing clinical conditions on mortality.

METHODS: We identified participants admitted for heart failure from the NHEFS cohort of 14,407 adults. They were followed from their initial interview (1971–1975) until their last interview in 1992. Information regarding cardiovascular disease risk factors was collected at each interview. Health care facility stay data was used to identify hospitalizations and diagnosis of incident HF. Mortality before last interview was determined using information from the National Death Index-linked mortality file. The relationship between comorbidities and mortality was evaluated using: a) median survival time (with 95% confidence intervals [CI])) from life table analyses for the unadjusted analyses, and b) hazard ratios (with 95% CI) from Cox proportional-hazards models that adjusted for age, sex, race, and education. All analyses incorporated the complex sampling design (strata, cluster, and weight variables) to provide population estimates.

RESULTS: Our analysis focused on the sample of 1080 participants who survived their incident CHF-related event. Their median age was 72.2 years (interquartile range 64.6–78.1), 506 (46.8%) participants were male, 89.3% were white, and 37.2% did not complete high school. Median follow-up time was 14.96 years. Diabetes mellitus (DM) was present in 23.5%, hypertension (HTN) in 14.4%, hyperlipidemia in 45.0%, and prior myocardial infarction (MI) in 23.6%. Median survival time (with 95% CI) was lower for individuals with DM [0.73 (0.48–1.07) years with DM vs. 2.04 (1.46–2.58) years without DM, $p = 0.002$] and prior MI [1.42 (0.79–2.16) with prior MI vs. 1.64 (1.25–2.30) without MI, $p = 0.004$]. There was no significant difference in median survival time for hypertension [0.96 (0.69–1.60) with HTN vs. 1.67 (1.39–

2.19) without HTN, $p = 0.833$] or hyperlipidemia [1.37 (1.00–2.03) with hyperlipidemia vs. 1.62 (1.30–2.41) without hyperlipidemia, $p = 0.321$]. Participants with DM (HR = 1.82 (1.39–2.37), $p < .0001$), hypertension (HR = 1.45 (1.05–2.15), $p = 0.028$) and hyperlipidemia (HR = 1.37 (1.06–1.77), $p = 0.015$) were at very high risk for mortality using multivariable Cox models adjusting for age, sex, race, and education.

CONCLUSIONS: Participants with diabetes had the highest mortality after incident HF. In both adjusted and unadjusted analyses, patients with diabetes had significantly worse outcomes than those with other conditions. Patients with diabetes should be targeted for HF prevention and if HF develops, they should be the focus of intense monitoring and treatment.

IMPACT OF PATIENT SOCIO-ECONOMIC DISADVANTAGE AND BEHAVIORAL HEALTH ON READMISSIONS IN MASSACHUSETTS' TWO LARGEST SAFETY NET HOSPITALS

Leah Zallman[2, 3]; Srinivasa Rao[4]; Nancy R. Kressin[1]; Danny McCormick[2]. [1]Dept of Veterans Affairs and Boston University, West Roxbury, MA; [2]Harvard Medical School/Cambridge Health Alliance, Cambridge, MA; [3]Institute for Community Health, Malden, MA; [4]Datycs, Inc, Methuen, MA. (Control ID #2704202)

BACKGROUND: Hospital readmission rates are increasingly used as indicators of quality of care and as bases for hospital reimbursements. Among elderly adults, socio-economic disadvantage and behavioral health conditions (SDBH) are associated with higher 30 day readmission rates (30DRE). The impact of SDBH on 30DRE in safety net hospitals (SNH), those caring for large shares of patients with SDBH, or among non-elderly adults is unclear. We sought to determine whether SDBH are associated with 30DRE in Massachusetts' (MA) two largest SNH.

METHODS: We conducted standardized interviews with 479 inpatients aged 18–64 on the medicine services regarding SDBH (insurance status, education, income, language, self-reported English, employment, marital status, living with others, social support, and concern about cost/safety of housing, affording food, paying for utilities, getting basic needs met) and, using open-ended questions, the events leading to admission. Physicians determined whether alcohol, substance use and psychiatric illness led to admission. We examined the impact of SDBH, using multivariable logistic regression models controlling for age, gender, clinical factors during admission (All Payer Refined Diagnosis Related Groups weight, intensive care unit stay) and clinical factors prior to admission (whether the admission was a 30DRE; had a primary care provider (PCP); number of emergency department, inpatient and outpatient visits in prior year).

RESULTS: Overall, 14% of patients had a 30DRE. Participants were most likely to be male (58%), aged 51–65 years (49%), and be unemployed (69%). Substantial minorities were unstably (33%) or publicly (9%) housed, had ≤1 person they count on for support (26%), and were concerned all the time about having enough money for basic expenses (25%). Most SDBH variables including education, employment and marital status, level of social support, language, and housing were not associated with 30DRE. However, being insured by Medicaid vs commercial insurance (OR 2.49, $p = 0.031$) and having a psychiatric illness that led to admission (OR 3.25, $p = 0.028$) were associated with increased odds of readmission. Being concerned about ability to pay utilities all the time (OR 3.1, $p = 0.057$) was of borderline significance. Compared with having an income of ≥ \$30 K, there was no difference for those earning \$5-20 K but patients with incomes of < \$5 k were less likely to be readmitted (OR 0.27, $p = 0.04$).

CONCLUSIONS: These SNH with robust readmission reduction programs achieved 30DRE that were similar across multiple dimensions of SDBH. Nonetheless, in order to avoid unfairly penalizing SNH in MA, hospital quality assessments should account for the greater 30DRE among patients with Medicaid insurance, economic concerns and psychiatric illness. Reimbursement methodologies using 30DRE should account for the greater likelihood of readmission among patients with economic concerns and psychiatric illness. A potential limitation was limited statistical power.

IMPACT OF RIFAXIMIN ON HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH DIARRHEA-PREDOMINANT IRRITABLE BOWEL SYNDROME

Brooks D. Cash[1]; Zeev Heimanson[3]; Lin Chang[2]. [1]University of South Alabama, Fairhope, AL; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Salix Pharmaceuticals, Calabasas, CA. (Control ID #2699154)

BACKGROUND: Irritable bowel syndrome (IBS) is associated with an impaired health-related quality of life (QOL). The adult IBS prevalence in North America is approximately 10 to 15 and females are generally 1.5 times more likely to have IBS vs males. Substantial quantitative and qualitative differences (eg, composition and diversity) in the gut microbiota have been observed in patients with IBS vs healthy individuals. Rifaximin is an oral nonsystemic antibiotic approved for the treatment of diarrhea-predominant IBS (IBS-D) in adults. The aim of this analysis was to examine the effect of repeat rifaximin treatments on IBS-related QOL.

METHODS: Adults with IBS-D who responded to a 2-week course of open-label (OL) rifaximin and subsequently experienced symptom relapse during an 18-week treatment-free observation phase were randomly assigned to receive two 14-day double-blind (DB) repeat treatments with rifaximin 550 mg or placebo, each three times daily. Each repeat treatment was separated by 10 weeks. A validated 34-item IBS-QOL questionnaire was completed either in person or by phone during the OL and DB phases of the study. Scoring of each subdomain on the IBS-QOL instrument utilized a 5-point Likert scale (range, 1 = "not at all" to 5 = "extremely" or "a great deal"). Overall and subdomain scores were summed to generate a score ranging from 0 to 100 with a higher score indicative of better QOL. The minimal clinically important difference was defined as improvement from baseline of ≥14 points in IBS-QOL score at a given time point.

RESULTS: Of the 2579 patients receiving OL rifaximin (mean age, 46.4 years; 68.2% female; mean ± standard deviation baseline IBS-QOL score = 48.3 ± 21.2), patients with response to OL rifaximin ($n = 1074$) had significantly greater improvement from baseline in IBS-QOL overall and subdomain scores compared with nonresponders ($n = 1364$) at 4 weeks posttreatment ($P < 0.001$ for all comparisons). A significantly greater percentage of responders achieved the minimal clinically important difference in IBS-QOL overall score from OL baseline to 4 weeks posttreatment vs nonresponders (52.2% vs 21.0%, respectively; $P < 0.0001$). The mean change from baseline in IBS-QOL overall and individual subdomain scores for interference with activity, body image, and food avoidance was significantly greater in OL responders to rifaximin remaining relapse-free during the OL observation phase (up to 22 weeks posttreatment; $n = 370$), compared with responders who relapsed during the OL observation phase ($n = 636$; $P < 0.05$). In the DB phase of the study, the minimal clinically important difference for the IBS-QOL overall score from baseline to 4 weeks posttreatment was achieved by a significantly greater percentage of patients receiving rifaximin ($n = 328$) vs placebo ($n = 308$; 38.6% vs 29.6%; $P = 0.009$).

CONCLUSIONS: Initial and repeat treatment with rifaximin resulted in clinically meaningful improvement of QOL in patients with IBS-D.

IMPACT OF THE AFFORDABLE CARE ACT ON OUT-OF-POCKET COSTS AND UTILIZATION OF PRESCRIPTION CONTRACEPTIVES Nora V. Becker. University of Pennsylvania, Philadelphia, PA. (Control ID #2691518)

BACKGROUND: The Affordable Care Act (ACA) mandates that preventive services, including FDA-approved prescription contraceptives, be covered by private health insurance plans with no consumer cost-sharing. Economic theory and empirical evidence suggest that decreasing the out-of-pocket (OOP) costs of contraception to consumers will result in increased utilization, however, the actual impact of the ACA mandate on OOP costs and use of prescription contraceptives has not yet been determined.
METHODS: Using a 10% sample of an administrative medical and prescription claims dataset from a large national insurer, I estimate individual OOP costs and utilization of eight types of prescription contraceptive methods for 679,864 individual women insured by 21,519 employers between 2008 and 2013. The impact of the ACA mandate is identified by using variation in the magnitude of the change in the OOP price at the employer level. If there is any response to the change in OOP price, we would expect a larger change in claim rates among women insured by employers where the OOP price dropped by a larger amount. This analysis is performed for the two most commonly claimed methods in the data, the pill and the IUD.
RESULTS: OOP costs of contraceptive have decreased sharply since the implementation of the ACA mandate. The mean and median costs for most methods fall sharply following August 2012. For both contraceptive methods, I find a statistically significant relationship between the drop in OOP price and the probability that a woman will use that method following the mandate. In other words, women working for firms where the OOP price dropped by larger amounts post-mandate demonstrate increased use of both the pill and the IUD compared with women in firms where the change in mean OOP price was smaller or zero. Claim rates for the pill increased by 3.62%, while claim rates for the IUD increased by 5.67%. Back-of-the-envelope estimates of the arc elasticity of demand for the pill (−0.04–−0.12) and IUDs (−0.03–−0.09) suggest inelastic demand for these methods.
CONCLUSIONS: My results suggest that the ACA mandate has produced large drops in OOP expenditures on prescription contraceptives, and that these price drops have increased utilization of the two most commonly used methods of birth control, the pill and the IUD. There is a larger impact on utilization of the IUD, a long-term method that is more effective than the pill, but prior to the mandate was also more expensive for privately-insured women. The magnitude of the impacts thus far suggest that privately-insured women are relatively unresponsive to changes in out-of-pocket price for prescription contraceptives. This fact may limit the ultimate impact of these price changes on overall rates of use of prescription contraceptives among privately insured women in the U.S.

IMPACT OF THE NEW YORK STATE PRESCRIPTION MONITORING PROGRAM (ISTOP) ON CHRONIC PAIN MANAGEMENT BY PRIMARY CARE PROVIDERS Josiah Strawser[2]; Lauren Block[1]. [1]Northwell Health, Lake Success, NY; [2]Hofstra Northwell School of Medicine, Hempstead, NY. (Control ID #2702863)

BACKGROUND: Prescription drug monitoring programs have been established in many states to minimize the abuse of controlled drug substances. Provider-initiated efforts to limit overprescription include the use of pain contracts, urine tests, monthly visits and pain management co-management. The purpose of this study is to investigate whether use of these management strategies by primary care providers has changed following implementation of the New York State Prescription Monitoring Program (IStop).
METHODS: An anonymous, cross-sectional survey was developed and distributed to primary care providers from four academic medical centers in New York. The survey investigated provider perspectives regarding their experience with IStop. Data was analyzed via STATA v.12 using descriptive statistics for the demographic data and Pearson's correlation coefficients for correlations between measures. A total of 135 providers responded from four institutions, including 48 attending physicians, 80 residents, and 4 NPs. Semi-structured interviews were also conducted with primary care providers, including residents, attending physicians and pharmacists. Interviews investigated provider perspectives regarding IStop usage and management of patients with chronic pain. Interview audio was transcribed and analyzed via an open-coding approach to identify interview themes and patterns.
RESULTS: Survey results indicated the following changes in primary care provider management of patients with chronic pain: 25% (32/128) of providers increased usage of monthly visits, 28% (36/128) of providers increased usage of pain management co-management with other health care providers, 46% (60/129) of providers increased usage of at least one of four management strategies - contracts, urine tests, monthly visits, pain management co-management. Residents indicated much higher rates of change in management strategies due to IStop usage; increase in the use of monthly visits ($p = 0.02$) and co-management ($p = 0.01$) occurred at a much higher rate in residents than attending physicians. Interview themes which were identified in 75% or more of interviews included emphasis on finding opioid alternatives when possible, emphasis on communication between the patient and provider to protect the relationship in chronic pain management, and the need for frequent patient visits in effective pain management.
CONCLUSIONS: Increased utilization of management strategies and the provider emphasis on communication and increased patient visits could indicate the effectiveness of IStop in reinforcing the importance of thoughtful management of chronic pain in primary care.

IMPACT OF WOMEN'S HEALTH RESIDENCY TRACKS ON CLINICAL PRACTICE Amy H. Farkas[2]; Melissa McNeil[4]; Erin C. Contratto[3]; Brigid M. Dolan[1]; Sarah A. Tilstra[5]. [1]Northwestern University, Chicago, IL; [2]UPMC, Pittsburgh, PA; [3]University of Alabama Birmingham, Birmingham, AL; [4]University of Pittsburgh Medical Center, Pittsburgh, PA; [5]University of Pittsburgh School of Medicine/Medical Center, Pittsburgh, PA. (Control ID #2705293)

BACKGROUND: To address the need for women's health training, internal medicine residencies have established women's health tracks (WHT) as a model of enhanced training for those interested in developing a gender focus to their careers. There has been little assessment of the impact of these tracks on the career outcomes of these graduates. The objective of this study was to determine if the graduates of WHT have continued their focus on gender specific care for women in their clinical practice.
METHODS: We conducted a multi-institutional survey of internal medicine WHT graduates starting in 2000 of the University of Pittsburgh, University of

Alabama, and Northwestern University. As a control for the impact of gender on clinical practice, we paired each WHT graduate with a non-women's health track (NWHT) female graduate from the same residency program. The survey was conducted online in the fall of 2016 and designed to assess their current clinical practice and incorporation of gender specific care. Descriptive statistics and statistical comparisons between WHT and NWHT graduates were performed using Fisher's exact test and Wilcoxon rank-sum test.

RESULTS: Out of the 216 graduates surveyed, 133 responded for a response rate of 61.6% (62.4% were WHT graduates and 37.5% were NWHT graduates). While our data did not meet statistical significance, there were differences between WHT and NWHT graduates. Among those who had completed training, WHT graduates were more likely to report being in primary care (40.9% vs 32.3%) and among those in primary care, 48.2% of WHT graduates reported a focus on women's health within their practice compared to 30.0% of NWHT graduates. WHT graduates were more likely to report treating menopause (85.2% vs 70%) and eating disorders (63% vs 40%) and to address contraception (88.9% vs 80%) and preconception counseling (85.2% vs 70%). Additionally, 22.2% of WHT graduates reported inserting sub-dermal contraceptives and 14.8% reported placing intrauterine devices as part of their practice where none of the NWHT graduates reported performing these procedures. Among those in subspecialty practices, 20.5% of WHT graduates reported that their practice was focused on women's health compared to 9.5% of NWHT graduates. Additionally, WHT graduates, in the subspecialties, were much more likely to report treating a women's health specific condition (73.7% vs 57.1%). Examples of women's health specific conditions treated included fertility concerns, pregnancy issues, and counseling regarding contraception and teratogenic medications.

CONCLUSIONS: Despite a non-significant difference in reporting of providing women's health care in primary care practice, the domain of the primary care providers from the WHTs is substantially broader than that of the NWHT. In addition, subspecialty graduates of WHT are more likely than NWHT graduates to incorporate women's health in their care of women patients.

IMPACT ON PATIENTS COMPLIANCE WITH MEDICATION USING PRE-PACKED BLISTERS FOR LONG TERM MEDICAL THERAPY (I-COMPLY STUDY) Andrei Brateanu[1]; Gautam Shah[3]; Jennifer Luxenburg[2]; Michele Reali-Sorrell[1]; Rita Lovelace[1]; Elizabeth Pfoh[1]; Nana Kobaivanova[1]. [1]CCF, Cleveland, OH; [2]Cleveland Clinic, Mayfield Heights, OH; [3]Mount Sinai Beth Israel, New York, NY. (Control ID #2706610)

BACKGROUND: In United States, billions of dollars are spent annually as a result of poorly controlled chronic medical conditions due to medication non-compliance. The aim of this study was to assess the effect of home delivered pill packs on medication compliance in a low income African American population.

METHODS: We conducted an open labeled randomized control trial of adult patients followed by primary care physicians at the Cleveland Clinic Stephanie Tubbs Jones Health Center and taking four or more different medications daily. Of the 353 patients who met the inclusion criteria, 114 consented to participate in the study and were randomized either to a study group or a control group. Patients in the study group had home delivered pill packs with medications packed according to the daily administration time and frequency. Patients in the control group continued to receive medications from pharmacies, as they did prior to being enrolled in the study. The primary outcome was medication compliance at least 4 months after enrollment, measured as the percentage of pills and number of daily medication doses missed per patient in the two groups. The mean percentage of missed pills between the two groups was compared using t-test and followed the intention-to-treat principle.

RESULTS: Of the 114 patients enrolled, 80 completed the study. Patients in the study (39) compared to the control group (41) had 6.3 ± 2.3 vs. 6.1 ± 2.8 chronic medical conditions ($p = 0.72$) and at the time of enrollment were receiving an average of 8.0 ± 2.2 vs. 7.4 ± 2.5 medications ($p = 0.34$). The percentage of missed pills per patient in the study group was lower than in the control group ($3.7\% \pm 6.0\%$ vs. $17.4\% \pm 16.6\%$, $p < 0.001$, respectively). The number of daily medication doses missed per patient was lower in the study group than in the control group (0.3 ± 0.5 vs. 0.7 ± 0.6, $p = 0.002$, respectively).

CONCLUSIONS: In a population of low income African American patients, home delivered packed medications improves compliance. The effect of such intervention on clinical outcomes needs to be studied in a larger cohort.

IMPLEMENTATION AND OUTCOMES OF A NATIONWIDE PATIENT-CENTERED MEDICAL HOME DEMONSTRATION IN FEDERALLY QUALIFIED HEALTH CENTERS Justin W. Timbie[2]; Claude Setodji[4]; Amii Kress[2]; Tara Lavelle[5]; Mark W. Friedberg[3]; Peter Mendel[6]; Emily K. Chen[2]; Beverly Weidmer[6]; Christine Buttorff[2]; Rosalie J. Malsberger[3]; Mallika Kommareddi[6]; Afshin Rastegar[6]; Aaron Kofner[2]; Liisa Hiatt[6]; Ammarah Mahmud[2]; Katherine Giuriceo[7]; Katherine L. Kahn[1, 6]. [1]David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]RAND Washington, Arlington, VA; [3]RAND Boston, Boston, MA; [4]RAND Pittsburgh, Pittsburgh, PA; [5]Tufts University Medical Center, Boston, MA; [6]RAND Santa Monica, Santa Monica, CA; [7]Centers for Medicare & Medicaid Services, Baltimore, MD. (Control ID #2705241)

BACKGROUND: The Federally Qualified Health Center (FQHC) Advanced Primary Care Practice Demonstration was a nationwide patient-centered medical home (PCMH) demonstration involving health centers. We assessed the impact of financial and technical assistance to facilitate practice transformation on achievement of National Committee for Quality Assurance (NCQA) Level-3 PCMH recognition and assessed its impact on patients' utilization, cost, quality of care, and experiences.

METHODS: We compared changes in outcomes over time for Medicare beneficiaries attributed to 503 demonstration FQHCs relative to beneficiaries attributed to 827 comparison FQHCs using a difference-in-differences approach. To better understand the relationship between achievement of PCMH recognition and changes in beneficiary outcomes, we also conducted a post-hoc analysis—analogous to a "dose–response" analysis—that pooled demonstration and comparison FQHCs and compared changes in outcomes in FQHCs with different levels of PCMH recognition to FQHCs receiving no PCMH recognition by the end of the demonstration.

RESULTS: Seventy percent of demonstration FQHCs achieved NCQA Level-3 PCMH recognition. Beneficiaries attributed to demonstration FQHCs had 83 more FQHC visits and 30 more emergency department visits per 1000 beneficiaries per year than comparison FQHCs, 1.3 and 1.6 percentage points higher rates of diabetic eye exams and nephropathy screening, respectively, and $37 higher annual Part B expenditures per beneficiary ($p < 0.05$ for all results). Demonstration participation was associated with modest improvements in beneficiaries' perceptions of access and timeliness of care relative to comparison FQHCs but declines in specialists' knowledge of medical histories and being treated with courtesy and respect. Across both demonstration and comparison FQHCs, Level-3 recognition was associated with statistically significant increases

in primary care utilization and quality, decreases in specialty care utilization, and lower spending relative to FQHCs with Level-1, Level-2, or no recognition. Level-3 recognition was associated with 128 additional FQHC visits, 8 fewer inpatient admissions, and 40 fewer specialist visits per 1000 beneficiaries per year compared to non-recognized FQHCs. Quality of care improved on 3 of 5 process measures. Annual total Medicare expenditures were $262 lower per beneficiary in Level-3 FQHCs; inpatient and Part B expenditures were $192 and $61 lower, respectively. Changes in patient experiences were mixed.

CONCLUSIONS: While demonstration FQHCs did not consistently achieve better outcomes, PCMH implementation in both demonstration and comparison FQHCs was associated with increased primary care utilization, lower specialty and acute care utilization, and lower spending. Improvements in outcomes associated with PCMH recognition from this study provide empirical evidence to support the goal of primary care redesign in FQHCs while continuing to evaluate the effects of these efforts on patient outcomes.

IMPLEMENTATION OF A PAYER-LED, PRACTICE BASED CARE MANAGEMENT PROGRAM FOR HIGH COST, HIGH NEED PATIENTS Manik Chhabra[4]; Krisda H. Chaiyachati[1]; Anje Van Berckelaer[5]; David Grande[3]; Judy A. Shea[2]. [1]The University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA, PA; [3]University of Pennsylvania, Philadelphia, PA; [4]Veterans Affairs Medical Center, Philadelphia, PA; [5]Health Partners Plan, Philadelphia, PA. (Control ID #2705456)

BACKGROUND: Health systems and payers have struggled to manage high-cost, high-need patients. Care management programs are a popular mechanism to assist these populations. One model uses a payer-led approach that, in collaboration with a health system, embeds care teams at clinic practice sites. However, evaluations of these programs have yielded uneven results, with little to no impact on cost and quality of care. Understanding the design and implementation of these programs may help contextualize these negative findings.

METHODS: We conducted semi-structured interviews to characterize barriers and facilitators during the early implementation period of a community-based care management (CBCM) program guided by the exploration, preparation, implementation, and sustainment (EPIS) framework. The CBCM was developed, funded, and implemented by a local Medicaid managed care organization (MCO), in collaboration with Community Behavioral Health (CBH), the behavioral health MCO for Medicaid recipients in Philadelphia, and 10 primary care practice sites in Philadelphia, to target high-cost, high-need patients. The intervention integrates Nurse Navigators (NNs), Community Health Workers (CHWs), and behavioral health case managers into clinic sites to identify, address, and coordinate care based on patients' health care and social needs. The MCO employed the NNs; the clinic sites hired the CHWs; CBH employed the behavioral health case managers. Key program and clinic staff members were interviewed beginning in July 2016, 6 months after the intervention start date. Interviews were digitally recorded, transcribed, coded and analyzed using modified grounded theory.

RESULTS: 45 interviews were conducted with program staff including, 10 CHWs, 8 NNs, 10 practice administrators, 1 pharmacist, 3 behavioral health case managers, and 13 clinicians. Overall, clinic staff believed the partnership with the MCO helped identify patient needs and improved access to resources. Barriers included legal obstacles, which resulted in a) duplicative operational processes, b) delayed information sharing, c) delayed integration of NNs hired by the MCO at sites, leading to staff turnover. Facilitators included practice size, which affected clinician integration in the program. Access to electronic medical records for CHWs and NNs also improved their communication with clinical providers. Staff found behavioral health integration was the most important component of the program, and helped address previously unmet mental health needs, and that CHWs played a vital role in fostering trust with patients resulting in additional insights for the clinical management of physical health needs.

CONCLUSIONS: Payer-led care management models for high-cost, high-need patients require attention to implementation processes and outcomes. This study informs key components of the partnership between payers and clinics sites, as well as which elements may be the largest drivers of improved patient care.

IMPLEMENTING A POST-MORTEM SURVEY TO IDENTIFY AREAS FOR QUALITY IMPROVEMENT Leah Korkis[1]; Jessica Kaltman[1]; Anne M. Walling[1]; Alia Bana[1]; Neil Wenger[2]. [1]UCLA, Los Angeles, CA; [2]University of California, Los Angeles, Los Angeles, CA. (Control ID #2706912)

BACKGROUND: Clinical ethics issues often arise at the end of life suggesting a need for quality improvement, yet the principal measure of quality of care for dying patients – the post-mortem family interview – is uncommonly implemented in clinical settings. We modified the Family Assessment of Treatment at End-of-Life, Short Form by adding items about continuity and decision making, and implemented the survey to evaluate the quality of care for patients dying in the hospital in an academic health system.

METHODS: For English-speaking patients who died in the hospital between July 2015 and October 2016, we attempted to identify the appropriate caregiver to mail the post-mortem survey after excluding patients who died <2 days after admission, patients <18 years old and traumatic deaths. We also excluded respondents who might suffer harm from the survey by eliciting input from the Offices of Legal Affairs and Patient Relations. Non-responders received up to 3 telephone calls and a postcard reminder. Respondents could opt out by telephone or mail and could request bereavement materials or a referral. Surveys were mailed 6 weeks after death. Because of low response rate during the first 3 months, we initiated a 6-month post-mortem survey before settling on a 3-month window.

RESULTS: Of 1311 decedents across two hospitals, 755 caregivers were mailed surveys and 206 (27%) responded, with no difference in response rate between 6-week and 6-month mailings. No adverse effects of survey were detected. Ratings were high for overall care quality (excellent/very good 82%), communication (always/usually 89%), staff caring (always/usually 95%) and emotional support (always/usually 80%). But lower ratings were received for care continuity (definitely 66%) and spiritual support (always/usually 63%). Twenty-two percent of respondents felt that a treatment decision was made during the final month of life that the patient would not have wanted and another 20% were unsure. Care ratings at 6 weeks and 6 months were not statistically different. Many responses included actionable write-in critiques such as inadequate continuity with the patient's primary care provider, fractious interprofessional interactions as death approached distracting from attention on the dying patient, lack of awareness of outpatient decisions among the inpatient teams, or poor coordination among teams. One in ten surveys named a particular clinician for providing exceptionally good or bad end of life care.

CONCLUSIONS: Surveying families after death is a complex endeavor with a low response rate, but the survey can identify areas for targeted quality improvement.

IMPLEMENTING THE CALIFORNIA END OF LIFE OPTION ACT

Neil Wenger[1]; Anne Coscarelli[2]; Charles Reynolds[2]; Thomas Strouse[2]. [1]University of California, Los Angeles, Los Angeles, CA; [2]UCLA, Los Angeles, CA. (Control ID #2703996)

BACKGROUND: The California End of Life Option Act, effective June 9, 2016, allows a terminally-ill, capable, adult California resident to request from his or her physician a drug to end life. The law specifies steps that must be followed: Two oral requests, witnessed written request, consulting physician concurrence, possible mental health assessment and avoidance of undue influence. Participation is voluntary for patients and clinicians, and physicians are not subject to liability or sanction. However, the Act does not focus on ensuring best end of life care and is vague regarding checks on affective distress, who might prescribe, relationships between prescribing and consulting physicians, and access to aid-in-dying drugs. We developed a mechanism to implement the Act and report on 6 months' experience.

METHODS: Informed by Oregon and Washington, UCLA Health System created an infrastructure aiming to ensure all regulations of the Act were followed; patients make fully autonomous, unencumbered choices; and end of life treatment is the best it can be for anyone requesting aid-in-dying. Clinical consultants, specially-trained social workers and psychologists, are mandated to work with each patient requesting aid-in-dying to carry out psychosocial assessment, counseling, psychoeducation and interdisciplinary communication. They use original materials to promote conversations around meaning, legacies and ethical wills; address psychosocial distress in patients and families; assist in end of life planning and earlier referral to hospice and palliative care; and address challenges such as managing patient expectations and assisting when continuity physicians decide not to prescribe. Implementation included physician education and guidance on interactions with patients and clinicians, patient and family education on handling the drugs, and pharmacy compounding an affordable aid-in-dying drug.

RESULTS: Over 6 months, 62 patients (54% males, 88% White, mean age 67 years, range 33–95) requested an aid-in-dying drug. Eighty-five percent had cancer. Patients enthusiastically participated in counseling, individual and family psychoeducation and legacy building; some welcomed referral to palliative care and hospice. Fourteen patients did not complete the process because they no longer perceived a need, had rapid disease progression or became incapable. Sixteen patients filled the aid-in-dying drug; thus far 6 ingested and died, 3 died without ingesting and 7 are holding the drug while continuing treatment. Eleven patients were ineligible due to prognosis, incapacity or being outside the health system, and for 21 patients the process continues. Twenty-four different physicians have prescribed or consulted thus far.

CONCLUSIONS: This organizational change to implement the End of Life Option Act creates a new, broadly accepted psychosocial standard of care for patients at the end of life while creating a mechanism for hands-on implementation of the Act, ensuring checks, balances and access.

IMPLEMENTING TRAINING IN A PRACTICE BASED RESEARCH NETWORK: AN EXPERT PANEL "MAKES THE MEDICINE (TRAINING) GO DOWN"

Ellen F. Yee[1]; Susan M. Frayne[2]; Diane Carney[3]; Brooke DiLeone[4]; Elizabeth M. Yano[5]; Lori A. Bastian[6]; Bevanne Bean-Mayberry[5]; Anne Sadler[7]; Karen M. Goldstein[8]; Alyssa Pomernacki[3]; Yasmin Romodan[3]; Ruth Klap[5]; Dawne Vogt[9]. [1]NMVAHCS, Albuquerque, NM; [2]VA Palo Alto Health Care System/Stanford, Menlo Park, CA; [3]VA Palo Alto Health Care System, Menlo Park, CA; [4]Childrens Literacy Initiative, Philadelphia, PA; [5]VA Greater Los Angeles HSR&D Center, Sepulveda, CA; [6]University of Connecticut, Farmington, CT; [7]Iowa City VAMC, Iowa City, IA; [8]Duke University School of Medicine, Durham, NC; [9]VA Boston HCS, Boston, MA. (Control ID #2706360)

BACKGROUND: Employee training in health care organizations is an essential component of maintaining high quality standards, but the optimal way to implement such training is unclear. Mandatory training may be resented or irrelevant. An Evidence-Based Quality Improvement (EBQI) approach that involved Expert Panels (EPs) was used to identify implementation strategies to engage VHA employee learners in a gender-sensitivity training program. The study objectives were (1) to evaluate whether EPs with key stakeholders could identify local site priorities that would inform gender sensitivity training and (2) to assess whether local implementation training design elements identified by an EP could be successfully implemented at multiple sites.

METHODS: Four geographically diverse sites in the VA's Women's Health Practice Based Research Network participated in this project. Local investigators and clinical leaders at each site identified key stakeholders for the EPs. Participants were sent a questionnaire prior to the EP meeting to rate the importance and feasibility of various strategies to advance VA gender sensitivity and implement the training in their facility. Summary ratings were presented at EPs to arrive at a group consensus for designing and implementing the training. Design elements included identification of local training strategies, responsible entities, supplemental organizational resources, prioritization of target clinical workgroups (departments, target clinics and providers), and identification of local barriers.

RESULTS: Survey completion rates ranged from 52-64%, and Expert Panel stakeholder attendance ranged from 40-79% (8–14 panelists). Different implementation approaches were identified across sites. Action plans were embraced at one site but rated as unhelpful at another. One site chose to rely on a single "go to" leader while another tapped an existing group to "own" the program. Perceived barriers to training implementation included: time, availability to participate in meetings/calls; and competing program implementation. Each site identified six workgroups to receive training. The number of design elements planned (ie, group or individual training; mandatory training or not; actions plans, use of supplemental posters, brochures, flyers) ranged from 3–6. Overall, there was a 100% implementation of the 3–6 design elements identified by sites. Training was implemented at all of the six workgroups at each site, though participation likely varied across these workgroups.

CONCLUSIONS: Four different sites chose different ways to implement this training program, and all sites implemented the training. Involving stakeholders in implementation design identified strategies that accounted for local organizational culture, prioritized leadership engagement to facilitate the training intervention, integrated organizational support for implementation/monitoring, and proactively ameliorated potential barriers and competing demands.

IMPLEMENTING UNIVERSAL PHQ SCREENING AT HOSPITAL ADMISSION TO IDENTIFY DEPRESSION AND POTENTIALLY REDUCE READMISSIONS: INITIAL RESULTS FROM A LARGE RETROSPECTIVE ANALYSIS

Danny Lee[2]; Rachel Fridman[3]; Joshua Lee[1]; Joshua Pevnick[3]. [1]University of California Los Angeles, Yorba Linda, CA; [2]Virginia Commonwealth University School of Medicine, Yorba Linda, CA; [3]Cedars-Sinai Medical Center, Los Angeles, CA. (Control ID #2690436)

BACKGROUND: As readmission penalties increase, providers seek to identify risk factors for readmission. Several risk factors have been studied, but

many are not amenable to treatment (e.g. older age). Depression, however, is a modifiable risk factor that could potentially be used to target interventions to reduce readmissions. Approximately 30% of inpatients are depressed as measured by Patient Health Questionnaire (PHQ) screening data. Furthermore, meta-analysis shows elevated PHQ scores to be associated with higher 30-day readmission rates (20.4% vs. 13.7% among patient with normal PHQ scores, $p < 0.01$). We evaluated whether the prevalence of depression and the relationship between depression and readmission persisted when PHQ data was obtained for operational, rather than research, reasons.

METHODS: We used a retrospective cohort study design. For operational reasons, ward nurses had been instructed to ask the two PHQ-2 questions of all inpatients soon after hospital admission to a large teaching hospital. Patients who answered 'yes' to at least one PHQ-2 question were then to be asked nine PHQ-9 questions. We compared readmission rates among all inpatients who had PHQ data obtained during 7/1/14-6/30/16. As per other studies of readmission, we excluded patients from the analysis who died before discharge, were discharged to another health care facility or hospice, left against medical advice, or were under observation. We classified PHQ-9 data into the six categories used in prior studies: no depression (0), minimal depression (1–4), mild depression (5–9), moderate depression (10–14), moderately severe depression (15–19) and severe depression (20–27).

RESULTS: During the period analyzed, 31,418 patients were admitted and had PHQ data obtained. For PHQ2 = 0 (92.5% of patients), the 30-day readmission rate was 15.3%. This did not differ from the PHQ2 > 0 rate of 15.9% (chi-square $p = 0.48$). For PHQ-9 showing no, minimal, mild, moderate, moderately severe, and severe depression, readmission rates were 12.8, 15.0, 16.4, 15.1, 17.7, and 17.6%, respectively.

CONCLUSIONS: We studied PHQ data obtained for operational reasons to determine whether it showed the same patterns as PHQ data obtained for research. Although readmission rates generally increased with higher operational PHQ-9 scores, patients on the lower end of the PHQ-9 scale had lower readmission rates than patients in whom no depression was detected (PHQ-2 = 0). This, in combination with the low prevalence of depression we detected (7% as compared with 30% in prior studies), suggests that this operational deployment of PHQ instruments may have missed many cases of depression. We suspect this may be due to less focus on PHQ data by ward nurses who had many competing priorities, as compared to PHQ data obtained by researchers. One major limitation is that we have not yet accounted for other risk factors for readmission (this work is ongoing).

IMPOSTER PHENOMENON ACROSS THE SPAN OF MEDICAL TRAINING Kayley Swope[1]; Britta M. Thompson[2]; Paul Haidet[1]. [1]Penn State College of Medicine, Hershey, PA; [2]Penn State Hershey COM, Hershey, PA. (Control ID #2702738)

BACKGROUND: The imposter phenomenon has been described anecdotally and empirically in medical students, but it is unclear how imposter feelings may fluctuate during times of transition in medical training. The purpose of this project was to explore the imposter phenomenon during times of transition compared to stable, non-transitional points during the school year.

METHODS: We surveyed first- and second-year medical students about gender, class year, and imposter feelings using the Clance Imposter Phenomenon Scale. The surveys occurred at both transition and non-transition points of the school year. First-year students completed surveys upon entry to medical school (transition) and will be completing them again later in the school year (non-transition). Second-year medical students completed surveys at the beginning of their school year (non-transition), and will be completing surveys at the beginning of their third year (transition).

RESULTS: There were response rates of 85/150 (56.7%) for the first-year class (transition) and 78/150 (52%) for the second-year class (non-transition). Of the total 163 students, 4.3% had minimal imposter feelings, 35.4% had moderate imposter feelings, 50% had frequent imposter feelings, and 10.4% had intense imposter feelings. The overall mean imposter score was 63.66 on a scale of 0–100 (SD = 13.37) which corresponded to frequent imposter feelings. This score is comparable to or slightly greater than other medical learners reported in the literature. There was a trend toward females having higher imposter scores ($p = 0.13$). Although second-year students (non-transition) tended to have higher imposter scores on the various subscales of the instrument, there was no significant difference between students in transition and students not in transition ($p = 0.624$).

CONCLUSIONS: The imposter phenomenon is an important facet of student wellness. Because transitions in education are pivotal in setting new patterns in students' professional development, it is important for educators to know when to intervene to mitigate effects of the imposter phenomenon. At this early stage in our project, there was no difference between transition and non-transition states, but we did see a trend toward higher imposter feelings in females and second-year students. Further research is needed to understand imposter feelings and their effects on the educational experiences of medical students.

IMPROVED ICU DOCUMENTATION USING A STANDARDIZED CHECKLIST IN A COMMUNITY-BASED TEACHING HOSPITAL Rohini S. Chatterjee[1]; Peter Clardy[2]; Rasika Chepuri[1]; Carey C. Thomson[2]. [1]Mount Auburn Hospital, Cambridge, MA; [2]Mt Auburn Hospital, Cambridge, MA. (Control ID #2701924)

BACKGROUND: Checklists have been implemented in large academic centers to improve documentation of intensive care unit (ICU) performance measures. Checklists improves documentation, and has been associated with lower complication rates and better clinical outcomes. Our goal was to compare documentation before and after implementation of a physician checklist in the ICU of a community-based teaching hospital.

METHODS: This mixed methods study employed both a survey assessment and a pre-post intervention chart review. In the survey, physicians reported their impression of how often they documented ICU performance measures in their notes. ICU performance measures included documentation related to daily awakening and breathing trials, head of bed elevation, GI and DVT prophylaxis, early mobility, urinary and vascular catheter utilization, nutritional support, and code status. Structured chart review consisted of convenience sampling of representative charts over a three-month period before and after implementation of the checklist, and included collection of data on the fields above. In the first analysis, we compared self-assessed rates of documentation of ICU performance measures from the survey with actual rate of documentation from chart reviews obtained prior to checklist implementation. In the second analysis, we compared rates of documentation before and after checklist implementation.

RESULTS: Physician response rate for the survey was 73 percent. There was a significant difference between self-reported and actual documentation of performance measures. Attending physicians consistently, and in some cases dramatically, overestimated their documentation of ICU performance measures relative to their actual performance. This variance was greatest for documentation related to mobility and early mobilization and was least for documentation related to spontaneous breathing trials. There was a substantial increase in

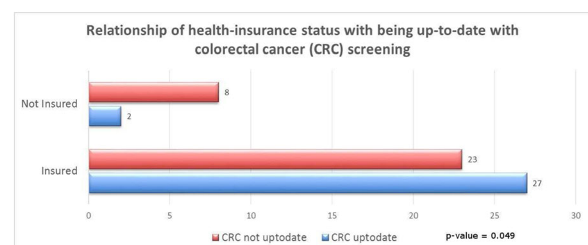
the documentation of ICU performance measures across all domains following checklist implementation. Overall, documentation of relevant domains increased from 37 to 91 percent following implementation. Improvement was noted across all domains and for all attendings. Improvement was greatest in the domains that started at lower levels, including GI prophylaxis and mobility.
CONCLUSIONS: This work demonstrates that a simple checklist-based intervention improves documentation practices of ICU staff in a community-based teaching. Future efforts will incorporate nursing-driven protocols and structured electronic documentation, and will seek to link improvements in documentation to improved clinical outcomes.

IMPROVING BURNOUT IN GENERAL INTERNAL MEDICINE: A FACULTY COACHING PROGRAM Kerri Palamara[2]; Beth Walker-Corkery[2]; Karen Donelan[2]; Mary F. McNaughton-Collins[1]. [1]MGH/HMS, Boston, MA; [2]Massachusetts General Hospital, Boston, MA. (Control ID #2703486)

BACKGROUND: Physician burnout is widespread and negatively impacting physicians, patients, and the healthcare system. The objective of our study was to develop and implement a 1-year faculty coaching program to help reduce burnout, improve resiliency, and improve workplace satisfaction, based on our successful Department of Medicine residency coaching program.
METHODS: We developed a 1-year, strengths-based, positive psychology curriculum. Existing faculty ($n = 309$) were informed of the program and encouraged to participate as coaches (if >3 years at MGH), coachees or both. New faculty for 2015–16 ($n = 40$) were automatically enrolled and assigned a coach. We obtained IRB approval to send an enrollment survey with brief demographics and to send participating faculty a baseline survey including questions from the Maslach burnout inventory (MBI), coping at work questions, workplace satisfaction, and patient safety culture metrics. Survey data was deidentified to program team. Faculty coaches ($N = 32$) were given 3 hours of training in positive psychology coaching, and assigned 2–3 coachees. Training introduced core coaching concepts and positive psychology in a dyad peer coaching model. The content of the training sessions included: #1 - What does success look like for me? What are my goals for the year, #2 - What are my strengths?, and #3 - What is the state of my work/life blend? What do I want to do about that? Faculty coach/coachee pairs will meet 3 times over 9 months (June 2016-Feb 2017). A follow-up survey will combine the above quantitative measures, as well as qualitative assessment of faculty regarding their experiences with the program.
RESULTS: Of 309 existing DGIM faculty members 13 volunteered to coach, 19 to coach AND be coached, and 13 to have a coach. 34 new faculty were enrolled automatically and assigned a coach. Total enrollment is 79 faculty, matched into 68 coach-coachee pairs. 50/79 faculty responded to the baseline survey. Among those scoring in the highest tertile (50%, $n = 25$) on a 5-question emotional exhaustion (EE) subset of the MBI, 39% reported good/excellent opportunities to reflect on their performance compared with 75% of those scoring lowest on EE (10%, $n = 5$). 44% of those with highest burnout indicators responded that they felt confident about being able to choose the best coping responses for hard situations compared to 81% of those reporting lowest burnout. In open ended questions, 42% reported administrative burden as the largest challenge faced at work.
CONCLUSIONS: Burnout in our DGIM faculty is high, on par with the national average. Those experiencing greater burnout have fewer opportunities to reflect on their performance and are less in tune with positive coping responses to stress. We demonstrated the feasibility of implementing a faculty coaching program among busy GIM faculty to address these concerns. Our follow-up survey will assess the impact of the faculty coaching program on measures of burnout and emotional well being.

IMPROVING COLORECTAL CANCER SCREENING AT A RESIDENT RUN INTERNAL MEDICINE CLINIC Maria M. Dahar[2]; Noor Khan[1]. [1]UPMC Mercy, Moon Township, PA; [2]UPMC Mercy, Pittsburgh, PA. (Control ID #2706475)

BACKGROUND: According to the American Cancer Society, the screening rate for colorectal cancer is the lowest among cancers. Barriers may include insurance, socioeconomic status, awareness, gender, ethnicity, or the facilities provided by a healthcare center and competence of the healthcare providers. In this study, we looked at the percentage of the patient population that is up-to-date with colorectal screening and how the care can be improved in an outpatient setting at our hospital
METHODS: A retrospective study was conducted at the UPMC Mercy Health Center in an outpatient setting in Pittsburgh, PA. Data was collected from 60 patients aged 50–73 years. Along with biographical information, data on prior colorectal screening, type of insurance and decision-making on ordering colorectal screening on part of residents was collected. Outcomes included evaluating if colorectal screening differed among patients on the basis of ethnicity, gender, or state of insurance, if colorectal screening and counseling was offered by the residents and to find out the main reasons of refusal on part of patients
RESULTS: Out of the 60 patients, 29 patients were up-to-date with their colorectal cancer screening, 30 were not and data for 1 patient was not found. Among patients who were not up-to-date, the screening was ordered for 10 patients. Most common modality for the screening was colonoscopy (28 patients). Among patients for whom screening was not ordered but were counselled, 4 patients lacked insurance, 10 refused to undergo screening for unknown reasons. There was significant association (p-value = 0.049) between patients lacking insurance and not being up-to-date with colorectal screening. There seems to be a trend of more chances of screening being ordered for men compared to women, p-value = 0.15. This could be because 7 out of 32 female patients lacked insurance compared to 3 out of 28 male patients. Our data shows patients were counselled without the regard for their state of insurance
CONCLUSIONS: Significant percentage of the population was not up-to-date with the colorectal screening. Counselling and patient education plays significant role in patients making decision in favor of screening. Resident physicians should be prepared to counsel every patient that is not up-to-date with their screening and be able to make them aware of the benefits of colorectal screening. Lack of insurance and awareness seem to be the most important factors for patients refusing to undergo colorectal screening



IMPROVING PROVIDER RECOGNITION AND TREATMENT OF INADEQUATE PHYSICAL ACTIVITY IN THE AGING POPULATION.

Samuel Good[1]; Kristyn Ertl[2, 1]; Jeff Whittle[2, 1]. [1]Medical College of Wisconsin, Milwaukee, WI; [2]Clement J. Zablocki Veterans Affairs Medical Center, Milwaukee, WI. (Control ID #2706145)

BACKGROUND: Most Americans do not achieve recommended levels of physical activity (PA); most doctors do not discuss PA. Studies in a few settings suggest that if intake staff routinely measure physical activity by asking the 2 item PA Vital Sign (PAVS) ("On average, how many days per week do you engage in moderate to strenuous exercise like a brisk walk?" and "On average, how many min do you engage in exercise at this level?") patients more often report discussing PA. We hypothesized that routine use of the PAVS at the time of intake would increase the likelihood of PA discussion during visits to Milwaukee VA primary care providers (PCPs).

METHODS: Four volunteer LPNs working in a Milwaukee VA primary care clinic included the PAVS in their check-in routine during the study period, while other LPNs in that clinic did not. Each Tuesday through Friday, we called a sample of patients who had seen a PCP in that clinic on the preceding day. We asked consenting patients if they had discussed PA with their PCP and/or intake LPN and whether they had received a recommendation to increase their PA.

RESULTS: We reached 196 of 332 patients (59%) who we attempted to contact. All contacts were men; the mean age was 65. Patients with documented PAVS responses were not more likely to recall discussing PA with their PCP or LPN than patients without documented PAVS (26/32, 81% vs. 113/164, 69%, $p = 0.16$ by chi-square). Among the 139 who recalled discussing PA with an LPN or PCP, 75 (38%) were advised to increase PA. Of 37 patients (19%) reporting a specific PA recommendation, the most common suggestion was to increase walking (58% of patients). Other recommended activities included biking (15%) and attending a gym (10%). Contacts who recalled discussing PA during their visit most commonly discussed PA with PCPs compared to LPNs (125/139, 90% vs. 37/139, 27% (some patients recalled PA discussion with both groups)) even when PA was assessed by participating LPNs as part of the PAVS system. Nonetheless, patients reported discussing PA with LPNs more frequently during PAVS encounters compared to non-PAVS encounters (10/32, 31% vs. 27/164, 16%, $p = 0.08$, Fisher's exact test).

CONCLUSIONS: Administration of the PAVS by intake staff did not significantly increase patient report that they had discussed PA during the clinic visit. When they recalled this discussion, it was usually attributed to the PCP, even when the LPN had clearly made the assessment, as documented in the patient note. However, the confidence intervals around the 12% increase we observed with PA assessment were wide (−5 to + 25%). Future work should assess the impact of PAVS administration on physician documentation of physical activity discussion and actual changes in patient levels of PA. Given increasing recognition of inadequate levels of PA and its health consequences, researches should also seek to identify barriers and facilitators to implementation and use of the PAVS and other approaches to increasing patient PA.

IMPROVING TELEPHONE MEDICINE EDUCATION AT A MEDICAL STUDENT RUN FREE CLINIC

Peggy Leung[1]; Linjia Jia[2]; Pamela Charney[2]. [1]Weill Cornell/NewYork Presbyterian, New York City, NY; [2]Weill Cornell Medical College, New York City, NY. (Control ID #2702705)

BACKGROUND: Outside of clinic visits, telephone communication is the primary mode of physician-patient contact. While approximately a quarter of all physician-patient interactions occur over the telephone, training in telephone medicine is at best limited, especially for medical students. Here we assessed the attitudes of and need for telephone medicine training among students in a medical student run free clinic, and then created a telephone medicine curriculum based on their responses. Subsequently, we evaluated the educational session's ability to improve confidence and comfort with telephone medicine among participants.

METHODS: We conducted pre-post educational intervention with medical student participants from the Weill Cornell Community Clinic (WCCC), a medical student-run free clinic in New York City. We initially surveyed outgoing leadership board members ($n = 21$) in efforts to create a telephone medicine intervention. From these responses we developed a 30-min educational intervention that included a lecture, interactive role-playing, and handouts for the incoming leadership board. The intervention was delivered at the WCCC annual leadership transition meeting. Pre-training surveys were collected 1 week prior to the meeting and post-training surveys were collected following the intervention at the meeting. Comparisons were performed using the chi-square test, and the significance level was set to $p < 0.05$.

RESULTS: 15 members of the incoming leadership board were surveyed. Prior to the intervention, 6 students (40%) had one or more telephone encounters with patients. Notably, only 1 (6.7%) reported a strong ability to communicate with patients. 14 out of 15 (93.3%) cited either neutral or minimal ability. 14 (93.3%) students agreed educational intervention would be useful. Interestingly, all thought telephone medicine encounters positively impacted patient care and would like to receive training on the topic. However, only 1 (6.7%) out of 15 had had telephone medicine training prior to medical school. None reported telephone medicine training in medical school yet. Following our educational intervention, medical students reported a statistically significant improvement in comfort with telephone medicine ($p = 0.01$). All thought the intervention had positive educational value. 13 students (86.7%) felt their communication skills and their ability to gather information over the phone improved while 2 (13.3%) felt neutral.

CONCLUSIONS: Analysis of the survey results reveals a robust interest and recognized value in telephone medicine. However, many have not been trained and cited concerns with their ability to communicate with patients over the phone. With a formal teaching protocol, such as our program, benefits potentially include increased comfort and confidence in communication skills with telephone medicine. We are currently planning for a 3-month follow-up survey which will be completed in February 2017.

IMPROVING USE OF POLST TO COMMUNICATE RESUSCITATION PREFERENCE FOR PATIENTS DISCHARGED FROM HOSPITAL TO NURSING HOME

Christine Haynes[3]; Cody Dashiell-Earp[2]; Robin Clarke[1]; Wendy Simon[3]; Samuel A. Skootsky[3]; Neil Wenger[4]; Frances Watts[1]; Anne M. Walling[1]. [1]UCLA, Los Angeles, CA; [2]UCLA, Venice, CA; [3]UCLA-University of California at Los Angeles, Los Angeles, CA; [4]University of California, Los Angeles, Los Angeles, CA. (Control ID #2703810)

BACKGROUND: Physician Orders for Life-Sustaining Treatment (POLST) is a legal document in many states that translates patient end-of-life treatment preferences into actionable medical orders preserved across care settings. POLST can be used to document patient preferences about resuscitation and life-prolonging interventions and then ensure continuity across healthcare settings. Yet, early data suggest inconsistent use of POLST in the hospital setting. If a decision not to receive resuscitation (DNR) reached in the hospital

is not transferred to the nursing home (NH), patients may receive undesired resuscitation leading to poor patient and family outcomes.

METHODS: We developed a measure captured in our electronic medical record and validated by chart review that reports whether patients with DNR orders at hospital discharge have an appropriately completed POLST at the time of NH transfer. We implemented an interprofessional quality improvement intervention at two hospitals: (1) education of residents and faculty on communication skills to guide discussion and use of POLST, (2) nursing huddle messages to encourage nurses on general medicine floors to discuss POLST with physicians when appropriate, and (3) case manager-driven prompts to physicians to consider POLST completion when a patient with a DNR order was discharging to a NH. To increase engagement, the intervention was augmented by (4) a small educational fund financial incentive for medical residents who appropriately completed a POLST at NH transfer of a patient with a DNR order, (5) daily emails to ward residents and attendings identifying POLST candidates, and (6) monthly emails to provide feedback to residents about their POLST completion rates. We compared POLST completion on resident general medicine teams for patients with DNR orders at discharge to NH using chi square tests at three time points: baseline (November 2014-January 2015), one year after implementation of the initial intervention (November 2015-January 2016) and 9 months after augmented intervention (August 2016-October 2016). Three months of data were used for each time point to minimize monthly fluctuations.

RESULTS: The intervention steps resulted in an 80% increase in POLST use from baseline to augmented for patients discharged to nursing home: baseline 22/56 (39%), intervention 36/71 (51%, $p = 0.2$ compared to baseline), and augmented intervention 44/63 (70%, $p = 0.003$ compared to baseline).

CONCLUSIONS: An interdisciplinary intervention can increase the use of POLST for patients with DNR orders transitioning to NHs. However, multiple components may be needed; after our initial intervention had minimal effect, a quality improvement framework guided intervention augmentation with performance feedback and targeted financial incentives, leading to statistically significant improvement. This intervention deserves testing with a control group and an assessment of how improvements in POLST utilization affect patient outcomes.

INCIDENCE OF COLORECTAL CARCINOMA FOLLOWING LUNG OR HEART TRANSPLANT - A DESCRIPTIVE STUDY USING THE UNOS DATABASE

Osama Diab[2]; Mridula Krishnan[2]; Arjun K. Theertham[3]; Lakshmi M. Chintalacheruvu[2]; Nina Zook[3]; Ryan Walters[2]; Renuga Vivekanandan[1]. [1]Creighton Medical center, Omaha, NE; [2]Creighton University, Omaha, NE; [3]Creighton University School of Medicine, Omaha, NE. (Control ID #2705914)

BACKGROUND: Post-transplant studies showed two to three fold increase in cancer incidence. These cancers tend to progress faster and have a worse response to treatment, which makes early detection crucial. Especially in lung and heart transplant patients who have a higher risk due to the aggressive and prolonged immunosuppression regimens.

METHODS: The incidence of a new colorectal cancer (CRC) diagnosis is presented for both lung transplant and heart transplant patients as frequency and percent. The cumulative (relative) risk of developing CRC was calculated using the Mantel-Haenszel test. Differences in time to a new CRC following transplant were estimated using the Kaplan-Meier method—patients were censored if they died or were lost to follow-up. SAS v.9.4 was used to conduct all statistical analyses and $p < .05$ was used to indicate statistical significance.

RESULTS: Patients included in the analysis had either a lung ($N = 4{,}203$) or heart ($N = 6{,}884$) transplant that occurred between 1987 and 2015. The overall incidence of new CRC following lung transplant was 3.4% (95% CI = 2.9 to 4.0%; $n = 143$) and 2.8% (95% CI = 2.4 to 3.2%;$n = 194$) following heart transplant. For lung transplant patient, women were twice as likely to develop CRC as men, whereas Caucasian patients were 62% less likely to develop CRC compared to non-Caucasian patients. Similar results were observed with heart transplant patients, albeit to a lesser extent, as women were approximately 1.5 times more likely and Caucasians were 40% less likely to develop CRC. The low overall incidence rate of new CRC precluded the calculation of mean or median time to new CRC via the Kaplan-Meier method. However, women developed CRC following lung transplant significantly earlier than men ($\chi 21 = 12.3$, $p < .001$), and non-Caucasian patients developed CRC following lung transplant significantly earlier compared to Caucasian patients ($\chi 21 = 23.7$,$p < .001$). In addition, women developed CRC following heart transplant significantly earlier than men ($\chi 21 = 5.7$,$p = .017$)

CONCLUSIONS: Incidence of new CRC following lung and heart transplant was 3.4 and 2.8% respectively, which is higher than the general population (0.041% per year). Currently, there is no protocol for CRC screening in thoracic transplant recipients. Further studies may be needed to determine the benefit of increased CRC surveillance, especially in non-Caucasian female patients.

Table 1. New Colorectal Cancer Incidence by Demographic Characteristics

	CRC Incidence Rate (%)	Relative risk {95% CI}	*P*
		Lung Transplant Patients (*n* = 4,203)	
Female vs Male	5.2 vs 2.5	2.12 [1.54,2.92]	<.001
White vs Non White	3.1 vs 8.1	0.38 [0.25,0.60]	<.001
Obese vs Non Obese	3.0 vs 3.5	0.87 [0.53,1.43]	0.585
Age ≥ 65 vs Age < 65	2.8 vs 3.5	0.80 [0.51,1.25]	0.259
		Heart Transplant Patients (*n* = 6,884)	
Female vs Male	4.0 vs 2.6	1.55 [1.11,2.17]	0.01
White vs Not White	2.6 vs 4.4	0.60 [0.41,0.87]	0.007
Obese vs Not Obese	2.4 vs 2.9	0.81 [0.55,1.20]	0.296
Age ≥ 65 vs Age < 65	2.9 vs. 2.8	1.03 [0.71,1.48]	0.89

INCORPORATING THE INDICATION INTO CPOE: TRANSFORMING PRIMARY CARE MEDICATION WORKFLOW

Kevin W. Kron[7]; Aaron Nathan[1]; Sara Myers[1]; Hannah Dym[1, 7]; Lynn A. Volk[5]; Pamela M. Neri[6]; Adam Wright[1, 7]; Mary Amato[2]; Alejandra Salazar[1]; Enrique Seoane-Vazquez[4]; Tewodros Eguale[1, 3]; Sarah K. McCord[3]; Rosa Rodriguez-Monguio[8]; Gordon D. Schiff[1, 7]. [1]Brigham and Women's Hospital, Boston, MA; [2]Brigham and Womens Hosptial/MCPHS, Boston, MA; [3]MCPHS University, Boston, MA; [4]Massachusetts College of Pharmacy and Health Sciences, Boston, MA; [5]Partners HealthCare, Wellesley, MA; [6]Partners Healthcare Systems, Inc., Wellesley, MA; [7]Partners Healthcare, Wellesley, MA; [8]UMass School of Public Health & Health Sciences, Amherst, MA. (Control ID #2682950)

BACKGROUND: Currently, medication orders lack information about the drug indication. Integrating indications could pave the way for a safer, more complete continuum of care for the patient and save time during prescribing

and related tasks (e.g. medication reconciliation). The goal is to design and build a prototype indications-based CPOE system that is both safer and more efficient than current CPOE systems, which limit indications to after-the-fact additions and are viewed as cumbersome by prescribers. When designing a system like this, it's critical to employ user-centered design to ensure that indications are implemented in a way that fits seamlessly into a prescriber's regular workflow.

METHODS: We have used a user-centered design process to develop an indications-driven CPOE prototype. Six expert webinars were hosted to consult high-level stakeholders on system design considerations necessary for building an indications-based CPOE system. To refine this list, we conducted 9 one-on-one contextual inquiry sessions with prescribers to observe prescribing activities and workflow, and 4 participatory design sessions to brainstorm design ideas directly with prescribers and better understand how to prioritize the information displayed. We employed iterative usability testing of new screen designs and workflow modifications with prescribers to ensure their needs and priorities are met.

RESULTS: We have developed a prototype CPOE - designed and user-tested to seamlessly integrate indications into the prescribing workflow. This includes hundreds of features designed to improve CPOE usability and safety, many of which use medication indications information to do so (e.g. providing drugs of choice for a given indication to avoid potential safety risks).

CONCLUSIONS: Indications-based prescribing has the potential to revolutionize prescribing by reengineering the prescriber workflow to incorporate indications. In addition to making prescribing more efficient, this has the potential to increase patient medication safety and adherence. Taking a user-centered design approach has helped to design a system that can meet the needs of users. Initial reactions to the prototype have been overwhelmingly positive and we have garnered widespread support for this initiative. Head-to-head testing of the prototype CPOE system is being conducted against two leading commercial vendors, Epic and Cerner, to compare satisfaction and error rate.

INCREMENTAL EFFECTS OF ANTIHYPERTENSIVE DRUGS: AN INSTRUMENTAL VARIABLE ANALYSIS OF THE SPRINT TRIAL

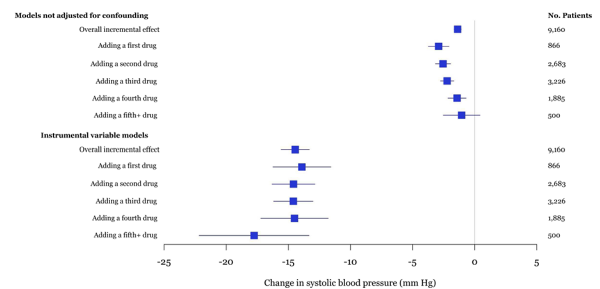
Adam A. Markovitz[2, 3]; Jacob A. Mack[2]; Brahmajee K. Nallamothu[1, 2]; John Z. Ayanian[1, 2]; Andrew Ryan[3, 1]. [1]University of Michigan, Ann Arbor, MI; [2]University of Michigan Medical School, Ann Arbor, MI; [3]University of Michigan School of Public Health, Ann Arbor, MI. (Control ID #2705598)

BACKGROUND: Nearly two-thirds of American adults with hypertension use multiple drugs to control blood pressure. Observational studies suggest that incremental effects on blood pressure and cardiovascular events diminish across successively higher numbers of drugs. However, these findings may be explained by confounding by indication, i.e., a treatment appears less effective or harmful because it is given to sicker patients. We performed an instrumental variable (IV) analysis to assess the incremental effects of antihypertensive drugs across different levels of baseline drug use while accounting for confounding.

METHODS: We analyzed secondary data collected from the SPRINT trial (n = 9,160). Our outcomes were systolic blood pressure (SBP), major cardiovascular events (myocardial infarction, other acute coronary syndromes, stroke, heart failure, or cardiovascular death), and composite serious adverse events. Our exposure was the number of antihypertensive drug classes at the study's end. Our instrumental variable was randomization status, i.e., treatment or control. We stratified by baseline number of drug classes to assess whether incremental effects varied among the first, second, third, fourth, or fifth drug class added to a patient's regimen.

RESULTS: In models that did not account for confounding by indication, adding antihypertensive drugs were associated with slightly lowered SBP (−1.4 mm Hg, 95% confidence intervals [CI], −1.7, −1.1). These effects diminished with each additional drug (Figure; interaction term P = 0.001). In these models, antihypertensive drugs were also associated with increased risk of cardiovascular events (absolute risk [AR] of events per 1,000 patient-years, 2.5; 95% CI, 0.4, 4.9). After addressing confounding in IV models, antihypertensive drugs were associated with larger SBP reductions (−14.4 mm Hg, 95% CI, −15.6, −13.3) and a decreased risk of cardiovascular events (AR, −6.8; 95% CI, −13.1, −1.1). Incremental effects on SBP (Figure) and cardiovascular events did not vary across baseline number of drugs in models that accounted for confounding. Antihypertensive drugs were not associated with adverse events in any model.

CONCLUSIONS: After accounting for confounding by indication, adding antihypertensive drugs led to significant reductions in SBP and risk of cardiovascular events but no differences in serious adverse events. These effects remained significant and similar in magnitude when adding a first, second, third, fourth, or fifth drug class.



INDUCED ABORTION AMONG WOMEN VETERANS: DATA FROM THE ECUUN STUDY

E. Bimla Schwarz[1]; Florentina Sileanu[3]; Xinhua Zhao[3]; Maria K. Mor[3]; Lisa S. Callegari[4]; Sonya Borrero[2]. [1]University of California, Davis, Sacramento, CA; [2]University of Pittsburgh and VA Pittsburgh, Pittsburgh, PA; [3]VA Pittsburgh, Pittsburgh, PA; [4]Veterans Health Administration, University of Washington, Seattle, WA. (Control ID #2700236)

BACKGROUND: Since 1976, the Hyde amendment has prohibited provision of abortion services using federal funds. We sought to describe the prevalence of induced abortion reported by women Veterans receiving VA healthcare compared to the larger US population.

METHODS: We analyzed data from women Veterans younger than 45 years, who participated in the "Examining Contraceptive Use and Unmet Need among Women Veterans" (ECUUN) study, a telephone-based, cross-sectional survey of randomly sampled women who had received VA primary care in the prior 12 months. We compared rates of abortion in ECUUN to age-adjusted data from the National Survey of Family Growth, a nationally-representative sample of US women. Among the 1485 Veterans who had been VA patients for 5 or more years, we used logistic regression to examine associations between abortion in the last 5 years and age, race/ethnicity, education, religion, marital status, parity, income, geographic region, medical and mental health comorbidities, deployment history, and housing instability. Geographic region and housing instability in the last 5 years were identified using VA administrative data.

RESULTS: ECUUN participants ($n = 2302$) were more likely to be Black (29% vs.14%) and single (50% vs. 33%) than the age-adjusted US population. Although Veterans were more likely to have college education (53% vs. 37%), they were less likely to have annual incomes over $40,000 (48% vs. 60%). Housing instability was documented for 15% of participating Veterans. Women Veterans were not less likely than age-adjusted US women to report ever having an abortion (17.6% among Veterans vs. 15.7%). In the last year, pregnancy rates were lower among Veterans than US women (67.3 vs. 87.6 per 1,000 women). However, Veterans' pregnancies were more likely to be unintended (37.0% among Veterans vs. 28.9%), resulting in similar reports of abortion in the last year (2.6 among Veterans vs. 3.3 per 1,000 women). Accounting for under-reporting, we estimate that 3% of women Veterans of reproductive age have abortions each year. Among the 1485 women who had been VA patients for 5 or more years, 1.8% reported abortion in the last 5 years. Veterans were more likely to report abortion if their annual income was less than $40,000 (3.3% vs. 0.5%; aOR:4.04, 95%CI:1.26-12.99), they had documented housing instability (4.3% vs. 1.3%; aOR:1.63, 95%CI:0.67-3.96), were single (2.9% vs. 0.8%; aOR:2.63, 95%CI:0.98-7.09), they had ever been deployed (2.5% vs. 1.1%; aOR:2.49, 95%CI:1.04-6.00), or had previously given birth (2.2% vs. 1.2%; aOR:3.08, 95%CI:1.16-8.13).

CONCLUSIONS: The Hyde Amendment, which precludes federal funding for abortion, does not result in lower rates of abortion among women Veterans compared to the general US population and likely increases vulnerable Veterans' out-of-pocket healthcare costs.

INFECTIOUS CONTROL: RAISING AWARENESS OF GERM INFESTED ACCESSORIES Gurneet Matharoo[1]; William T. Whitmire[1]; Daniel Schoolcraft[2]; Niket Sonpal[3]. [1]American University of Antigua, Osbourn, Antigua and Barbuda; [2]Medical University of Lublin, Lublin, Poland; [3]Touro College of Osteopathic Medicine, New York, NY. (Control ID #2703112)

BACKGROUND: The first thing we learn as medical professionals at any level of training is to practice high standards of infection control when interacting with patients. However, a gap in education arises when workers develop the misconception that hand hygiene alone is sufficient. In an era of fast paced health delivery, it is easy to recognize why accessories kept on hand and accessed regularly may not receive appropriate disinfection.

METHODS: Over a period of 9 days, a 31-question survey was distributed at random amongst various medical professional populations at health care centers over the United States and Canada. Results were tabulated through the online software service company, *Survey Monkey Inc.* The survey titled "How dirty are you?" engaged interest of medical professionals, and raised awareness as they answered subsequent questions. 79 responses were submitted as hard copy and uploaded manually. 52 responses were submitted directly through the web link itself. Results were then reviewed using confidence intervals of 95%(95CI) for proportions. 3 respondents failed to complete the survey completely therefore results were discarded to ensure accuracy.

RESULTS: Surveys were collected from 131 medical professionals (English). 55% of responses were males. 75% of professionals completing the surveys were third year medical students, 10% were residents, and physicians. 50/130 (38.5%; 95CI: 30.14–46.9) of workers report wearing artificial nails, hand or wrist jewelry, with 59/91(64.8%; 95CI: 55–74.6) admitting to never sanitizing their wrist-watches. When asked if one sanitizes their stethoscope after each usage, an astonishing 77/128(60.1%; 95CI: 51.6–68.6) replied sometimes, and 20/128 (15.6%; 95CI: 9.31–21.9) responded never. A significant finding amongst medical professionals was the 58/125(46.4%; 95CI: 37.7–55.1) who endorsed never sanitizing their cell phones. Data also showed 86/113(76.1%; 95CI: 68.2–84) never sanitize their clipboards, binders, and notebooks. With these replies the same professionals reported using gloves sometimes but not always 53/129 (41.1%; 95CI: 32.6–49.6) before touching the patient for any reason. An alarming 42/129 (32.6%; 96CI: 24.5–40.7) indicated they sometimes but not always wear gloves, specifically for performing physical examinations.

CONCLUSIONS: This study was performed to point out infection control errors that are not commonly discussed, can easily be made by anyone in healthcare. The survey was sufficient in determining that accessory hygiene should be critically appraised more often, since healthcare workers use personal protective equipment such as gloves inconsistently. Implementing and upholding rules involving regular stethoscope hygiene are minor changes that can provide an enhanced hygienic environment for patients and intuitions. Similar studies should be accomplished to determine personal and accessory hygiene specifics in larger health-care populations.

INFLUENZA VACCINATION BELIEFS AND PRACTICES AMONG PREDOMINATELY ELDERLY HISPANIC PRIMARY CARE PATIENTS Sharon Rikin[1]; Steven Shea[1]; Philip LaRussa[2]; Melissa Stockwell[2]. [1]Columbia University, New York, NY; [2]Columbia University, NY, NY. (Control ID #2689856)

BACKGROUND: The majority of influenza related deaths and hospitalizations are in individuals ≥65 years, yet the national influenza vaccination rate for this group is 63 and is lower in the Hispanic population (CDC, Flu Vaccination Coverage, US 2015–16). Previous studies have shown that negative predictors of vaccination include concerns for vaccine safety, efficacy, and side effects. However, there is a knowledge gap of how influenza vaccine-specific beliefs affect vaccination rates. The purpose of this study was to understand influenza vaccine health beliefs in a ≥65 year-old primary care population (with 63.1% vaccination rate in 2015–16) and investigate relationships between beliefs and vaccination.

METHODS: A questionnaire regarding influenza vaccine beliefs was administered to a convenience sample of 200 patients ≥65 years in an academic general internal medicine clinic with 88% participation rate. The study was approved by the IRB and consent obtained. A free response question regarding influenza vaccine concerns was evaluated qualitatively with predominant themes grouped into belief categories.

Logistic regression evaluated associations, adjusted for age, gender, and language.

RESULTS: Mean age was 74 years (SD 6.7), 73% female, 93% Hispanic, and 86% had high school level education or less. Influenza vaccination rate in the last year was 75%; 7.5% reported never receiving the vaccine. Only 46.5% reported the influenza vaccine was very effective; 47% that it was very safe. Many had specific concerns about the vaccine with themes emerging: general side effects (*n* = 23, 11.6%), vaccine causes the flu (*n* = 22, 11.1%), vaccine causes a cold (*n* = 12, 6%), alternative remedies are better than vaccines (*n* = 8, 4.0%), vaccine components (*n* = 5, 2.5%), get the flu despite vaccination (*n* = 4, 2.0%). Concerns for side effects, fear that the flu shot causes the flu, and believing that alternative treatments are more efficacious than vaccination were associated with reduced odds of vaccination (Table).

CONCLUSIONS: This study highlights which beliefs specific to the influenza vaccine are associated with decreased odds of vaccination. The patient-perceived distinction between cold, flu, and other symptoms warrants further exploration. This information can be used to develop targeted educational messages.

Odds of receiving influenza vaccine associated with vaccine beliefs

Belief	Category	OR	95% CI
Efficacy	Very/somewhat effective (ref)	–	
	Unsure	1.21	0.24,6.17
	Somewhat/very ineffective	0.18	0.03,1.30
Safety	Very/somewhat safe (ref)	–	
	Unsure	0.18	0.03,1.10
	Somewhat/very unsafe	0.38	0.06,2.58
Flu shot causes flu*		0.18	0.05,0.62
Flu shot causes a cold*		1.03	0.18,5.94
Other side effects*		0.15	0.05,0.50
Get flu despite vaccination*		0.61	0.05,6.95
Vaccine components*		0.61	0.07,5.14
Alternative remedies are better than vaccine*		estimate unreliable, quasi-complete separation

INITIAL CHALLENGES IN IMPLEMENTING SCREENING TOOL FOR PREGNANCY INTENTION IN A PRIMARY CARE INTERNAL MEDICINE CLINIC

Erin Murphy[2]; Carol A. Stamm[2]; Rebecca Petersen[2, 3]; Daniel Topp[2]; Christine Gilroy[1]. [1]University of Colorado Anschutz Medical Campus, Denver, CO; [2]University of Colorado Denver, Denver, CO; [3]Kaiser Permanente, Denver, CO. (Control ID #2706219)

BACKGROUND: Unintended pregnancy is a major public health issue and the ensuing social, health and economic problems have expansive societal effects. Half of the pregnancies each year in the US are unintended—higher than in other developed countries. Efforts to bolster contraceptive counseling and provision by primary care providers might potentiate this public health problem. There are no national quality assessment metrics evaluating efficacy of pregnancy intention screening and contraception use in primary care visits. For this study, we adopted the Oregon metric for pregnancy intention, asking ONE KEY QUESTION® [OKQ] (Do you wish to become pregnant within the next year?), with the aim to better prompt clinicians to address women's reproductive needs.

METHODS: This is a prospective quality improvement study utilizing chart review (EMR database query [EMR] and manual chart review [MCR]) to evaluate rates of documented contraception/preconception counseling. Inclusion criteria were all female patients age 18–50 cared for in the patient panel of 6 internal medicine interns. Prior to study initiation, all interns received a brief educational intervention for contraception/preconception counseling and coding/billing. MAs were trained to screen for pregnancy intention using OKQ during appointment intake. De-identified data obtained by independent reviewer at 5-week and 3-month intervals were compared longitudinally, examining 1) rates of OKQ asked during intake, 2) rates of documentation for contraception/preconception counseling, 3) rates of coding/billing for contraception/preconception counseling.

RESULTS: 5-week interval: −9/24 (38%) encounters documented OKQ response −5/24 (21%) encounters documented contraceptive counseling (MCR) -0/24 encounters coded for contraceptive/preconception counseling (EMR) 3-month interval: −0/16 encounters documented OKQ response −6/16 (38%) encounters documented contraceptive counseling (MCR) -0/16 encounters coded for contraceptive/preconception counseling (EMR)

CONCLUSIONS: −Consistency of MA inquiry for pregnancy intention decreased over time, yet providers proportionally increased their documentation of contraceptive/preconception counseling as seen in manual chart review. -Counseling sessions were not coded in visit bills. Speculations why include 1) providers are unaccustomed to coding for various forms of counseling (eg, weight loss and smoking cessation) even when these conversations occur (as seen in manual but not database chart review); 2) when diagnostics or prescriptions are not ordered, providers are less likely to bill for counseling session given EMR does not incentivize counseling coding. - This study is limited by small sample size, as well as general patterns and inter-provider variability of documentation by MAs and physicians.

INPATIENT ADDICTION CONSULTATION FOR HOSPITALIZED PATIENTS INCREASES POST-DISCHARGE ABSTINENCE AND REDUCES ADDICTION SEVERITY

Sarah E. Wakeman[3]; Joshua Metlay[3]; Yuchiao Chang[1]; Grace E. Herman[2]; Nancy A. Rigotti[2]. [1]Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Massachusetts General Hospital, Charlestown, MA. (Control ID #2705802)

BACKGROUND: Alcohol and drug use results in substantial morbidity, mortality, and cost. Individuals with alcohol and drug use disorders are overrepresented in general medical settings. Hospital-based interventions offer an opportunity to engage with a vulnerable population that may not otherwise seek treatment.

METHODS: Prospective, quasi-experimental evaluation comparing 30-day post-discharge substance use outcomes of patients who were or were not seen by an addiction consult team during hospitalization at Massachusetts General Hospital in Boston, Massachusetts. Participants were 399 adult patients who screened high risk for having an alcohol or drug use disorder or who were clinically identified by the primary nurse as having a substance use disorder. The intervention consisted of an addiction consultation from a multidisciplinary specialty team offering pharmacotherapy initiation, motivational counseling, treatment planning, and direct linkage into ongoing addiction treatment. Primary outcomes were the Addiction Severity Index (ASI) composite score for alcohol and drug use and self-reported abstinence at 30-days post-discharge. Secondary outcomes included 90-day substance use measures and self-reported hospital and ED utilization.

RESULTS: Among 265 participants with 30-day follow-up, the ASI composite score for drug or alcohol decreased more in the intervention group compared to the control group (mean ASI-alcohol decreased by 0.24 vs. 0.08, $p < 0.001$; mean ASI-drug decreased by 0.05 vs. 0.02, $p = 0.003$.) Days abstinent increased more in the intervention group versus the control group (+12.7 days versus +5.6, $p < 0.001$). The differences in ASI-alcohol, ASI-drug and days abstinent all remained statistically significant after controlling for age, gender, employment status, smoking status, and baseline addiction level ($p = 0.018$, 0.018, and 0.02, respectively). In a sensitivity analysis assuming that patients who lost to follow-up had no change from baseline, the differences remained statistically significant. Among the 227 with 90-day follow-up, the mean ASI composite score for alcohol decreased more in the intervention group (−0.22 vs. -0.10, $p = 0.003$). The mean change in ASI-drug was greater in the intervention group but the difference did not reach statistical significance (−0.05 vs. -0.02, $p = 0.058$). The change in days abstinent remained significantly higher in the intervention group (11 vs. 5.5, $p < 0.001$). At 30-day follow-up, self-reported substance-related hospitalizations decreased significantly in the intervention group 61% vs. 51% ($p =$ 0.001), as did substance-related ED visits 66% vs. 53% ($p = 0.002$).

CONCLUSIONS: Addiction consultation significantly reduced addiction severity for alcohol and drug use and increased the number of days abstinent in the first month after hospital discharge.

INTERACTIVE ONLINE LEARNING INCREASES MEDICAL STUDENT KNOWLEDGE RETENTION VERSUS PASSIVE LEARNING: A RANDOMIZED CONTROLLED TRIAL Thomas D. Shiffler[2]; David Feldstein[2]; Yuyen Chang[1]; Emmanuel Contreras Guzman[3]; Christopher B. Bundy[3]; Emmanuel Sampene[4]. [1]University of Wisconsin - Madison, Madison, WI; [2]University of Wisconsin School of Medicine and Public Health, Madison, WI; [3]University of Wisconsin-Madison, Madison, WI; [4]UW Madison, Madison, WI. (Control ID #2705146)

BACKGROUND: Use of distance education and asynchronous learning to educate medical students is increasing as classroom time and time spent at main campuses is decreasing. While interactive education increases knowledge compared to passive learning, there is little evidence about the role and level of interactivity for online learning. Our main objectives were to determine: 1) if interactive online learning improves student knowledge vs. passive online learning; and 2) the time required for faculty to create interactive learning sessions and for students to complete them.

METHODS: Clinical Therapeutics is an online elective course for senior year medical students at the University of Wisconsin. It teaches how to treat over 70 common conditions and runs from December through March. We invited all students enrolled in the 2015–2016 course to participate. They were randomized to interactive online lectures (intervention) for 5 of the clinical topics or recorded lectures with identical content and no interaction (control). Intervention students received interactive case-based questions 4–5 times during each lecture. A correct response was required before proceeding and feedback was provided. All students completed a 5-question, multiple-choice quiz querying the most critical content of each lecture (25 total questions). The same quiz was completed 2 weeks later. Faculty reported the time to develop interactive sessions. Student time to complete the topics was captured via video start/stop times. Differences in quiz scores and student time to complete topics were assessed by 2-sample t tests.

RESULTS: 121 of 123 students consented to participate; 60 were randomized to the intervention and 61 to control. The most common residencies to which students applied were: Internal Medicine 17.4% ($n = 21$), Family Medicine 16.5% ($n = 20$) and Pediatrics 10.7% ($n = 13$). Average immediate quiz scores were 3.72 (out of 5) for the intervention group vs. 3.64 for control (difference = 0.086, $p = 0.433$). Average 2-week quiz scores were 3.54 for the intervention group vs. 3.29 for control (difference = 0.252, $p = 0.036$) which is a small to medium effect size (Cohen's d = 0.39). The 5 faculty spent 2–12 hours building interaction into the topics. The mean time for students to complete the topics ranged from 25.4 to 55.8 min (intervention) vs. 25.9 to 53.8 min (control). There were no statistically significant differences between groups for any lecture; the largest mean difference was 4.1 min greater for the intervention group.

CONCLUSIONS: Incorporating interactivity into online learning had no immediate effect on knowledge compared to passive online learning, but intervention students showed improved knowledge retention. The time for faculty to incorporate interactivity was not extremely burdensome and the increased student time to complete interactive topics was minimal. Studies to evaluate more extensive interactivity are warranted to see if it can increase short-term knowledge and provide larger increases in long-term knowledge.

INTERNAL MEDICINE RESIDENT COMFORT WITH COMMUNICATING GOALS OF CARE WITH SURROGATE DECISION MAKERS AT END OF LIFE. Ramy Sedhom[1]; David Barile[2]. [1]Rutgers - Robert Wood Johnson, Princeton, NJ; [2]University Medical Center of Princeton at Plainsboro, Plainsboro, NJ. (Control ID #2698269)

BACKGROUND: Internal Medicine (IM) faces challenges posed by the increasing number of older Americans, many of whom are incapacitated when faced with end-of-life decisions. Few physicians are certified in geriatrics or trained in palliative care. In addition, no formal training exists for communication with surrogates at the end of life. We investigated internal medicine resident comfort with communicating goals of care with surrogate decision makers at end of life.

METHODS: A survey of surveying physician trainees at three categorical IM residency programs was analyzed. The survey, developed by the investigators, included information regarding communication with surrogates at end of life; whether formal training or education was offered; faculty resources, and educational barriers. Participation was voluntary and consent required.

RESULTS: Fifty three of eighty three surveys were returned; a response rate of 64%. No resident felt adequately trained for communication at end of life with a surrogate decision maker. All house staff reported minimal training in geriatric and end of life care, with an average of 12 hours over their medical training. When asked about barriers to communicating recommendations to surrogates at end of life, conflicts with paternalism (82%), uncertain dynamics of decisions making (73%), and difficulty prognosticating (64%) were most commonly cited. Further complicating the physician-surrogate relationship was the uncertainty residents felt regarding the ethics of surrogate decision making. Shared decision making with surrogates was interpreted by some as the physician facilitating a decision made solely by the surrogate; others felt that decisions should be made jointly by the physician and surrogate that promoted the authentic values of the patient. Of importance, less than half of residents felt comfortable navigating all aspects of the POLST form and reported using it routinely in family meetings.

CONCLUSIONS: Our study highlights difficulties in decision making and goal setting with surrogates at end of life. Recent literature suggests high rates of post-traumatic stress disorder for surrogate decision makers obviating the need to better train health care providers navigating goals of care discussions. Our data suggests that resident trainees are uncomfortable with this role and are poorly trained in end of life communication. Increased use of the POLST form has been shown to significantly decreased surrogate stress and may serve as an educational tool for physicians involved with surrogate decision makers.

INTERNAL MEDICINE RESIDENTS AND FACULTY IMPLICIT BIAS TOWARDS LESBIAN, BISEXUAL, GAY AND TRANSGENDER PATIENTS: A NEEDS ASSESSMENT Eloho Ufomata[2]; Kristen Eckstrand[3]; Peggy B. Hasley[1]; Kwonho Jeong[1]; Doris Rubio[1]; Carla Spagnoletti[1]. [1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]Western Psychiatric Institutes and Clinic, Pittsburgh, PA. (Control ID #2704257)

BACKGROUND: People who identify as LGBT have suboptimal cancer screening and increased prevalence of mental health disorders. The Healthy People 2020 includes initiatives to improve the health, wellbeing and safety of LGBT individuals by enhancing provider's abilities to inquire and be supportive of patients' gender identity and sexual orientation; and improving cultural competency. Some attitudes exist outside conscious awareness, or are implicit, and may predict behavior. For example, studies have shown implicit racial bias leading to differences in treatment of African American patients in hypothetical case scenarios. Our goal was to evaluate implicit bias among internal medicine (IM) residents by use of the widely validated Implicit Association Task (IAT) as part of a curriculum development needs assessment.

METHODS: Participants were 153 IM residents and 35 faculty at one institution in an urban setting. The use of the IAT has been described extensively; it asks participants to pair images that signify either "gay" or "straight" with words that are positive (e.g. lovely, beautiful) or negative (e.g. agony, horrible). The program calculates the response times to assign a "D score" or relative latency score, as a measure of implicit associations. Project Implicit provided a unique IAT environment to collect anonymous IAT results from our study participants who were invited to complete the IAT in January 2016. We also asked survey questions on perception of the IAT.

RESULTS: A total of 110 participants (22 faculty and 88 residents, response rate 58.5%) completed the IAT. The average "D score" was 0.27 ± 0.42, which signifies a slight preference for straight people compared to gay people (see table for specific breakdown of D scores). A total of 31.4% of respondents felt that the use of the IAT increased their awareness of their own personal bias towards gay people while 41.2% were neutral and 27.5% disagreed.

CONCLUSIONS: A cohort of IM residents and faculty practicing in an urban setting were found to have a preference for straight people. This is consistent with IAT results from the general US population and of a national study of physicians, although our cohort's preference was only slight whereas in other populations the preference was stronger. Though it is unknown whether curricular content may change implicit bias, this study reinforces the need for additional efforts aimed at educating physicians about the care LGBT patients, so that despite the implicit bias against them, such patients may receive high quality, sensitive, and non-judgmental care.

Sample Distribution of IAT Score Categories

Implicit Association Descriptor	Percent (%) of Participants ($N = 110$)
strong automatic preference for straight people compared to gay people	15
moderate automatic preference for straight people compared to gay people	25
slight automatic preference for straight people compared to gay people	24
little to no automatic preference for straight people compared to gay people	20
slight automatic preference for gay people compared to straight people	8
moderate automatic preference for gay people compared to straight people	6
strong automatic preference for gay people compared to straight people	1

INTERNAL MEDICINE RESIDENTS' PERCEPTIONS OF ERROR REPORTING: A QUALITATIVE STUDY John Szymusiak[1, 1]; Thomas J. Walk[3]; Maggie K. Benson[1]; Megan Hamm[4]; Susan L. Zickmund[2]; Alda Maria Gonzaga[1]; Gregory M. Bump[1]. [1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of Pittsburgh/VA Pittsburgh Healthcare System, Pittsburgh, PA; [3]VA Pittsburgh Healthcare System, Pittsburgh, PA; [4]University of Pittsburgh CHRC Data Center, Pittsburgh, PA. (Control ID #2698478)

BACKGROUND: Event reporting is important for recognizing types of errors occurring in a hospital and identifying ways to improve patient safety. Data show that a minority of reports are made by physicians, which has been targeted for improvement. Residents are front line providers, yet little is known about their reporting attitudes. Our study aims to identify drivers and barriers to reporting among internal medicine residents at two tertiary care, academic hospitals within our health-care system and to identify modifiable aspects of an institution's culture of safety that could encourage resident reporting. In so doing, we hope to improve patient care and promote career-long reporting in trainees.

METHODS: Four focus groups were conducted, two at each hospital of interest, with senior-level internal medicine residents as part of a larger study. Participants filled out a questionnaire with demographic information and assessing their reporting experience. They were then asked open-ended questions by a trained moderator based on a piloted focus group guide. All discussions were audio-recorded, de-identified, and transcribed verbatim. Using the "editing approach" to qualitative analysis a codebook was developed and applied independently by two trained coders.

RESULTS: The 4 focus groups varied in size from 7 to 11 participants, with a total of 35 participants. Thirty-three residents completed demographic data, 18 (55%) were PGY-3. Thirty participants (91%) rated their knowledge of how to report as fair, good, or excellent and 23 (70%) reported their likelihood of reporting an adverse event as $\geqq 50\%$. The barriers and drivers identified clustered into three categories; issues with the event itself, with the institution or its culture, and with the reporting system or process. Table 1 summarizes these themes.

CONCLUSIONS: Focus groups are useful to understand residents' attitudes about reporting. Interventions to encourage reporting can target each of the categories of drivers/barriers identified. These include showcasing system benefits of reporting others' errors, educating all members of the multidisciplinary team about the goals and process of event reporting, having reports go to neutral third party safety officers to protect anonymity, and making event reporting follow up part of existing resident conferences. Similar interventions

could prove effective at other academic institutions to improve resident engagement in patient safety.

Residents' Perceived Barriers and Drivers to Event Reporting

Domain	Barrier	Driver
Event Related Issues	Someone Else's Mistake	System Error
	"Human Error"	Harm or Potential to Harm
	Reported in Another Forum	Reckless Behavior
		Recurrent or Repeatable Event
Institutional & Cultural Issues	Differences in MD & RN Perspective	Potential for Improvement
	Blame-based System	Attending Encouragement
	"Waste of Time"/ Inefficacious	
	Culture of Low Expectations	
Reporting System/ Process Issues	Lack of Anonymity	Follow-up on Reports
	Difficult Reporting System	Visible Changes to System
	Lack of Transparency of Process & Consequences	
	Inappropriate Follow-up	
	Witnessed or Experienced Negative Consequences	

INTERNAL MEDICINE TRAINEE KNOWLEDGE, ATTITUDES, BEHAVIORS AND EXPERIENCES REGARDING PRE-EXPOSURE PROPHYLAXIS FOR HIV INFECTION

Christopher P. Terndrup[4]; Carl G. Streed[1]; Perry J. Tiberio[6]; Marissa A. Black[5]; John Davis[8]; Oni J. Blackstock[3]; E. J. Edelman[7]; Gail Berkenblit[2]. [1]Brigham & Women's Hospital, Boston, MA; [2]Johns Hopkins, Baltimore, MD; [3]Montefiore Medical Center/AECOM, New York, NY; [4]Oregon Health and Sciences University, Portland, OR; [5]University of Washington, Seattle, WA; [6]Yale New Haven Hospital, New Haven, CT; [7]Yale University School of Medicine, New Haven, CT; [8]Ohio State University, Columbus, OH. (Control ID #2707091)

BACKGROUND: Despite the proven effectiveness of pre-exposure prophylaxis ("PrEP") for HIV prevention with tenofovir-emtricitabine (Truvada), provider adoption remains low. Education and comfort with prescribing PrEP have been found to be significant barriers to prescription access. Given that adequately trained internists would provide a large pool of future PrEP prescribers, ensuring adequate training during residency is crucial to the implementation of PrEP as HIV prevention. We sought to understand current knowledge, attitudes, behaviors and experiences of Internal Medicine residents in using PrEP.

METHODS: We adapted the PCP PrEP survey, a prior survey of General Internists, and tailored it for trainees. Following a brief description of PrEP, we assessed self-reported knowledge of and prior training regarding PrEP, including side effects. Specific questions regarding residency training assessed comfort levels in prescribing PrEP. We evaluated resident attitudes towards PrEP in various contexts, and assessed their prior prescribing habits. All residents in five residency programs received recruitment emails via list serves for the online survey, sent by study coordinators at each site. Institutional review board exempt status from Johns Hopkins University School of Medicine was granted for this project prior to the release of the survey to the subjects, which was done between April and June of 2016.

RESULTS: We had a 35% response rate, with even distributions over 3 years of residency. While 96% of residents had heard of PrEP, only 25% endorsed prior training or education on PrEP. Only 19% rated their knowledge as very good or excellent, and 55% rated it as fair or poor. Only 11% had prescribed PrEP before, but 86% of those who had not indicated willingness to prescribe. Of all residents surveyed, 89% noted they would need more training before feeling comfortable doing so, and 88% identified lack of provider education as likely or extremely likely to be a barrier to prescribing. Lastly, 93% said that training during residency would be likely to facilitate their prescribing PrEP. 70% said that training all providers in the practice would be the most feasible way to implement PrEP in their primary clinics.

CONCLUSIONS: The majority of Internal Medicine residents reported a perceived need for more education before prescribing PrEP, yet only 25% had received prior training. In order to help combat the ongoing HIV epidemic, efforts to integrate PrEP education into residency training are needed.

INTERNISTS UNDERPERFORM IN PROVISION OF FIRST LINE CONTRACEPTION

Ashley H. Snyder[3]; Christiana Zhang[1]; Guodong Liu[2]; Cynthia H. Chuang[2]; Mindy Sobota[1]. [1]Brown, Providence, RI; [2]Penn State College of Medicine, Hershey, PA; [3]Penn State Milton S. Hershey Medical Center, Hershey, PA. (Control ID #2706826)

BACKGROUND: Long acting reversible contraceptives (LARCs), including intrauterine devices (IUD) and the contraceptive implant, are the most highly effective forms of birth control and are recommended as first line. However, LARC use remains low at only 7.2% of women aged 15–44. This is of importance to internists because the American College of Physicians considers contraception a "core competency" of women's health. One barrier to utilization of LARCs is a lack of primary care provider training. Although the data regarding internists is limited, a recent survey of primary care practices suggests that the majority of IUD insertions are performed by gynecologists and midwives. We aim to evaluate the variations that exist in the provision of LARCs according to provider type.

METHODS: Data from Truven Health MarketScan®, a national private insurance claims database, were used to examine LARC insertion rates among reproductive age women according to provider type. Study cohorts of women aged 13–45 were created for each calendar year between 2006 and 2014. Cohort size ranged from 3.88 million women (2006) to 7.32 million women (2012) per year. IUD and implant insertions were identified using ICD-9, CPT-4, and HCPCS codes. Provider type was identified using existing variables in the database. For claims coded as Medical Doctor, Osteopathic Medicine, MultiSpeciality Physician Group, Preventive Medicine, Pediatrician, Pediatric Specialist, Nurse Practitioner, and Physician Assistant, there was no way to further specify specialty. Therefore, we report the proportion of IUDs and implants inserted according to provider types of Internal Medicine, Family Practice, Obstetrics and Gynecology, and Midwife.

RESULTS: The rate of claims for IUD and implant insertions increased over time. For all study years, the proportion of IUDs inserted was lowest among internists (0.3–0.5%) and midwives (1.4–1.9%) and highest among family practice (5.0–6.0%) and gynecologists (76.2–83.9%). Similarly, the proportion of implants inserted was lowest among internists (stable between 0–0.5% with the exception of 2007 when it was 6.7%) and midwives (0–2.3%) and highest among family practice (increasing from 3.3% in 2008 to 9.3% in 2014 with the exception of 2007 when it was 20%) and gynecologists (72.8–77%).

CONCLUSIONS: Among reproductive age women, those who received first line contraception were far less likely to have had it inserted by an internist compared to by a family physician or gynecologist. This suggests that reproductive age women who are cared for by primary care internists may experience a disparity in accessing these standard of care contraceptive methods. The need to be referred to a specialist to obtain a LARC is an important barrier to use. Because LARCs are highly effective but underutilized, especially among women who see internists, our findings suggest that efforts to expand the training of primary care physicians in LARC provision is important in order to reduce barriers to access for women.

INTERPERSONAL VIOLENCE, POST-TRAUMATIC STRESS DISORDER, AND AGE-RELATED GENITOURINARY DYSFUNCTION IN WOMEN Carolyn J. Gibson[2]; Alison J. Huang[3]; Brigid McCaw[4]; Jun Shan[1]; Leslee Subak[3]; Stephen K. Van Den Eeden[1]. [1]Kaiser Permanente Northern California, Oakland, CA; [2]San Francisco VA Health Care System, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA; [4]Kaiser Permanente Division of Research, Oakland, CA. (Control ID #2706269)

BACKGROUND: Posttraumatic stress disorder (PTSD) and exposure to interpersonal violence are associated with genitourinary complaints among younger women, but little is known about the prevalence or impact of trauma experiences and sequelae among midlife and older women.

METHODS: We conducted the first study of the relationship of PTSD and interpersonal violence exposures to genitourinary dysfunction in midlife and older women. Data were drawn from the Reproductive Risks for Incontinence Study at Kaiser (RRISK), a prospective cohort of ethnically-diverse women aged 40 to 80 years enrolled in Kaiser Permanente Northern California, a large integrated health care system. PTSD symptoms, lifetime history of interpersonal violence exposures (physical or emotional intimate partner violence, sexual violence), and genitourinary symptoms (vaginal pain with sexual intercourse, vaginal irritation, and urinary incontinence) were assessed using standardized, structured-item questionnaire measures, including the Post-traumatic Stress Disorder Checklist-Civilian Version (PCL-C). Multivariable logistic regression models were used to predict genitourinary symptoms from PTSD and interpersonal violence exposures, adjusting for age, race/ethnicity, and body mass index.

RESULTS: In this sample of 2,016 community-dwelling women, (mean age 61 ± 10 years, 40% non-Latina White, 20% Latina White, 20% Black, and 20% Asian), 450 (22%) had clinically significant PTSD symptoms (PCL-C ≥30), 483 (24%) reported a history of physical or emotional violence, and 382 (19%) reported having experienced sexual violence. Thirteen percent reported vaginal pain with intercourse, 32% reported vaginal irritation, and 32% reported weekly or more frequent urinary incontinence. In multivariable analyses, women with clinically significant PTSD symptoms were more likely to report vaginal pain with intercourse (adjusted odds ratio [AOR] 2.12, 95% CI 1.55–2.89, $p < .001$), vaginal irritation (AOR 2.22, 95% CI 1.68–2.95, $p < .01$), and urinary incontinence (AOR 1.51, 95% CI 1.17–1.93, $p < .01$). Intimate partner violence was associated with vaginal pain with sexual intercourse (AOR 1.43, 95% CI 1.03–1.98, $p = .04$) and urinary incontinence (AOR 1.42, 95% CI 1.11–1.81, $p < .01$). Sexual violence was associated with vaginal pain with intercourse (AOR 1.46, 95% CI 1.03–2.09, $p = .04$) and vaginal irritation (AOR 1.44, 95% CI 1.05–1.98, $p = .02$).

CONCLUSIONS: Over 20% of midlife and older women in this ethnically-diverse community-based cohort reported clinically significant PTSD symptoms and exposure to interpersonal violence, which contributed to their risk of age-related symptomatic genitourinary dysfunction. These findings highlight the importance of systematic screening for PTSD and interpersonal violence among midlife and older women, and the need to determine best approaches for trauma-informed care in women across the aging spectrum.

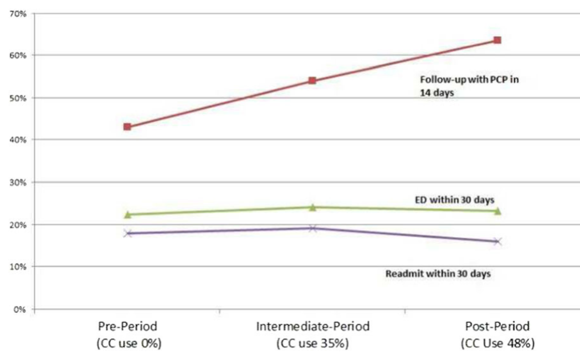
INTERVENTION TO IMPROVE POST-DISCHARGE PCP FOLLOW-UP WAS NOT ASSOCIATED WITH IMPROVEMENT IN READMISSION RATES Paawan Punjabi[1]; Lauren Doctoroff[1]; Anjala Tess[1]; Sarah O'Neil[1]; Ateev Mehrotra[2, 1]. [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Harvard Medical School, Boston, MA. (Control ID #2702499)

BACKGROUND: Driven by the Medicare Hospital Readmissions Reduction Program, hospitals are focusing significant resources to improve the transition from inpatient to outpatient care in an effort to decrease readmission rates. Some observational studies have found that patients who have early follow-up with their primary care provider (PCP) are less likely to have a readmission. Whether facilitating early follow-up with a PCP deters readmissions is unknown.

METHODS: To facilitate follow-up, the Beth Israel Deaconess Medical Center (BIDMC), an urban 651-bed tertiary care center, implemented a new system called Care Connection (CC) in October 2009. Through CC, inpatient physicians on the medicine and cardiology service can submit an electronic order to have a call center schedule the follow-up visit. This retrospective cohort study evaluated 4,225 hospitalizations on the medicine and cardiology service who were discharged home between September 2014 and September 2015 and had a BIDMC PCP. We compared rates of visits with a PCP within 14 days of discharge and hospital readmission within 30 days of discharge among those which CC was used controlling for age, diagnosis related group, and length of stay. In a sensitivity analysis, we conducted a difference-in-difference analysis comparing discharges from the medicine and cardiology service to those discharged from the neurology and vascular surgery service (where CC was not or minimally available). We compared this change before and after CC was available.

RESULTS: Among discharges from the medicine/cardiology service from September 2014–2015, 48.1% of physicians used Care Connection. Controlling for other factors, discharges with Care Connection were significantly more likely to follow-up with their primary care provider within 14 days (OR 6.65, CI (5.63-7.78), $p < .01$) but were not less likely to have a readmission (OR 0.90, CI 0.71-1.12, $p = 0.35$). These findings were echoed in the difference-in-difference sensitivity analysis, where there was a 7 percentage point greater increase in PCP follow-up among medicine/cardiology discharges but no greater decrease in readmissions.

CONCLUSIONS: While this automated scheduling intervention resulted in significantly increased rates of timely PCP follow-up, it did not reduce the rates of 30-day readmissions. Timely PCP follow-up alone may not be sufficient to deter readmissions.



CONCLUSIONS: When compared with previous research from the United States and Canada, this study suggests that readmission risk may be less sensitive to sociodemographic factors within Canadian contexts. Future research should investigate the degree to which the effects of sociodemographic factors are moderated by contextual factors of health systems such as universal health insurance coverage, and the cultural sensitivity/competence of care providers and hospital services. Attentiveness to patients' sociodemographic circumstances is an important component of patient-centered care. However, to prevent readmissions, efforts to improve standardized hospital-to-home care transition processes and follow-up care in the community should remain paramount.

INVESTIGATING THE SOCIAL DETERMINANTS OF 30-DAY UNPLANNED HOSPITAL READMISSION AMONG GIM PATIENTS IN TORONTO, CANADA. Robert W. Smith[2]; Kerry Kuluski[5, 6]; Andrew Costa[8]; Samir Sinha[1, 5]; Rick Glazier[7, 5]; Alan Forster[3, 4]; Lianne Jeffs[5, 7]. [1]Mount Sinai Hospital, Toronto, ON, Canada; [2]University of Oxford, Oxford, United Kingdom; [3]University of Ottawa, Ottawa, ON, Canada; [4]Ottawa Hospital, Ottawa, ON, Canada; [5]University of Toronto, Toronto, ON, Canada; [6]Sinai Health System, Toronto, ON, Canada; [7]St. Michael's Hospital, Toronto, ON, Canada; [8]McMaster University, Hamilton, ON, Canada. (Control ID #2671836)

BACKGROUND: Hospital readmissions remain a common and costly health system performance issue. The causal mechanisms leading to readmission are complex and not well understood—particularly the role of sociodemographic factors. The purpose of this study was to examine whether patient-level sociodemographic factors are independently associated with 30-day readmission among GIM patients at an urban teaching hospital in Toronto, Canada. This study is among the first in Canada to examine detailed patient-level sociodemographic factors in relation to hospital readmission among medical patients.

METHODS: 2058 GIM patients participated in a detailed survey (primarily in English) of sociodemographic information between the years 2012 and 2014. Survey data was linked to hospital administrative data from the Canadian Institute of Health Information (CIHI). Study inclusion and readmission ascertainment criteria were based on CIHI's 30-day medical readmission rate measure. After exclusions, 1427 adult, non-palliative patients discharged home were included in this study. Guided by a retrospective cohort design, multivariable Cox regression analyses were used to examine relationships between 13 sociodemographic variables and unplanned all-cause readmission over a 30-day timeframe. Indicators of illness-level that were controlled for include Hospital Admission Risk Prediction (HARP) index score (constituted by age, case mix group, discharge location, frequency of hospital use 6 months preceding the index admission), Charlson score, and inpatient length of stay.

RESULTS: Approximately 14.4% ($n = 205$) of patients experienced an unplanned all-cause readmission within 30 days. Patient-level sociodemographic factors did not exhibit significant associations with readmission. HARP scores from nine to 29 (compared to 0–2), were associated with 66% greater hazard of readmission (*adjusted HR* = 1.66, *95 % CI*: 1.08-2.54, $p = 0.02$). When HARP variables were analyzed as separate covariates, having experienced one previous admission (*adjusted HR* = 1.78, *95 % CI*: 1.22-2.59, $p < 0.01$) and at least four emergency department visits (*adjusted HR* = 2.33, *95 % CI*: 1.46-4.43, $p < 0.01$) were associated with increased hazard of readmission.

IS BIGGER DATA BETTER? PREDICTING READMISSIONS IN ACUTE MYOCARDIAL INFARCTION ON ADMISSION VERSUS DISCHARGE WITH ELECTRONIC HEALTH RECORD DATA Oanh K. Nguyen[1, 1]; Anil N. Makam[1, 1]; Christopher Clark[2]; Song Zhang[1]; Sandeep R. Das[1]; Ethan Halm[1, 1]. [1]UT Southwestern Medical Center, Dallas, TX; [2]Parkland Health & Hospital System, Dallas, TX. (Control ID #2697988)

BACKGROUND: Readmissions after hospitalization for acute myocardial infarction (AMI) are common, but the few available risk prediction models have poor predictive ability. We sought to assess whether an AMI-specific electronic health record (EHR) readmission risk prediction model derived and validated from data through the entire hospital course ('full stay' model) outperforms a model using data available only from the first day of hospitalization ('first day' model).

METHODS: EHR data from AMI readmissions from 6 diverse hospitals in north Texas from 2009–2010 were used to derive a model predicting all-cause non-elective 30-day readmissions which was then validated using five-fold cross-validation.

RESULTS: Of 826 consecutive index AMI admissions, 13% were followed by a 30-day readmission. History of diabetes (AOR 2.41, 95% CI 1.37–4.24), hypotension (SBP <100 mmHg) on admission (AOR 2.18, 95% CI 1.68–2.82), elevated creatinine (≥2 mg/dL) on admission (AOR 2.56, 95% CI 2.52–6.08), elevated BNP on admission (AOR 6.36, 95% CI 1.65–24.47) and lack of PCI within 24 hours of admission (AOR 1.31, 95% CI 1.02–1.69) were significant predictors of readmission. Our 'first-day' AMI readmissions model based on these predictors had good discrimination (Table). Adding three other variables from the hospital course - use of intravenous diuretics (AOR 1.58, 95% CI 1.07–2.31), anemia (hematocrit ≤ 33%) on discharge (AOR 2.04, 95% CI 1.20–3.46), and discharge to post-acute care (AOR 1.50, 95% CI 0.90–2.50) - improved discrimination of the 'full stay' AMI model but only modestly improved net reclassification and calibration.

CONCLUSIONS: A 'full-stay' AMI-specific EHR readmission model modestly outperformed a 'first-day' EHR model, a multi-condition EHR model, and the CMS AMI model. Surprisingly, incorporating more hospitalization data improved discrimination of the full-stay AMI model but did *not* meaningfully improve reclassification compared to the first-day model. Readmissions in AMI may be accurately predicted on the first day of hospitalization; incorporating more data from the hospital course did not meaningfully improve risk prediction.

Table. Model Performance and Comparison of AMI Readmission Models Versus Other Models

Model	C-statistic	p-value*	NRI† (95% CI)	Average Predicted Risk, %	
				Lowest Decile	Highest Decile
Full-stay AMI	0.78 (0.74-0.83)‡	[Ref]	[Reference]	1.6	43.9
First-day AMI	0.75 (0.70-0.80)§	0.001	-0.03 (-0.10-0.04)	2.1	41.1
Full-stay multi-condition	0.73 (0.68-0.78)	0.02	-0.12 (-0.23 to -0.01)	5.7	29.6
CMS AMI	0.74 (0.69-0.79)	0.02	-0.04 (-0.14-0.05)	7.2	24.3

Abbreviations: AMI, acute myocardial infarction; CI, confidence interval; EHR, electronic health record; NRI, net reclassification index

* p-values shown are for each model compared to the respective reference model

† The categorical NRI compares reclassification between the highest top risk quintile and the lowest four risk quintiles

‡ Optimism-corrected C-statistic 0.75, (95% CI 0.74-0.76)

§ Optimism-corrected C-statistic 0.73 (95% CI 0.71-0.74)

IS IT REALLY COST-EFFECTIVE TO RISK-ASSESS ALL HOSPITALIZED PATIENTS FOR PRESSURE INJURIES EVERY NURSING-SHIFT?

William V. Padula[1]; Uchenna Onyekwere[1]; Mary Beth F. Makic[3]; Heidi Wald[3]; Ziv Epstein[4]; David Meltzer[2]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]University of Chicago, Chicago, IL; [3]University of Colorado, Denver, CO; [4]Pomona College, Claremont, CA. (Control ID #2674789)

BACKGROUND: Hospital-acquired pressure injuries are localized skin injuries that cause significant morbidity and mortality, and are costly to treat. Following the International Guidelines for pressure injury prevention reduce rates over Standard Care, but require risk-assessment among all patients each nursing-shift using the Braden Scale. The relative value of only continually risk-assessing at-risk patients - about 7% of hospitalizations - is uncertain. Our objective was to analyze the cost-effectiveness of nursing resources to risk-assess all patients or select risk-groups identified by machine learning compared to Standard Care.

METHODS: We obtained patient-level data on 43,787 encounters from a university hospital EHR between 2011–2014, including daily Braden scores. Longitudinal arrays of adult inpatients with ≥10 Braden scores were classified into 5 risk-groups: very high-risk [6–9]; high-risk [10–11]; moderate-risk [12–14]; at-risk [15–18]; low-risk [19–23]. We constructed a 10-state Markov model using supervised machine learning to calculate age-adjusted transition probabilities between risk-groups, pressure injury states and discharge states. Costs (2015 $US) and lifetime quality-adjusted life years (QALYs) related to pressure injury outcomes were added to the Markov model to compare the cost-utility of Standard Care, continual risk-assessment in all risk-groups or only follow-up risk-assessment in higher risk-groups. Probabilistic sensitivity analysis (PSA) tested model uncertainty at $100,000/QALY willingness-to-pay from the U.S. societal perspective.

RESULTS: Risk-assessing all patients every nursing-shift was cost-effective ($5,193, 15.43 QALYs) compared to Standard Care ($5,139, 14.00 QALYs) at an increment cost-effectiveness ratio of $37/QALY. Follow-up risk-assessment only among patients with Braden scores <19 dominated Standard Care ($1,745, 14.03 QALYs) in 50.89% of PSA simulations with small QALY gains. Follow-up among patients with lower Braden scores decreased costs at fewer QALYs.

CONCLUSIONS: Our analysis using real-world data maintains that follow-up risk-assessment among all patients cost-effectively prevents pressure injuries. Hospitals should encourage nurses' adherence to International Guidelines to benefit patients instead of cost-cutting.

IS UTILIZATION AND OUT-OF-POCKET SPENDING FOR HOSPITAL OUTPATIENT CARE, HIGHER FOR LOW-INCOME MEDICARE BENEFICIARIES?

Jennifer N. Goldstein[1, 1]; Zugui Zhang[1]; J. Sanford Schwartz[2]; LeRoi S. Hicks[1, 1]. [1]Christiana Care Health System, Newark, DE; [2]University of Pennsylvania, Philadelphia, PA. (Control ID #2698137)

BACKGROUND: Hospital outpatient status, or observation status, is a Medicare billing designation for hospitalized beneficiaries whose anticipated length of stay is short, spanning fewer than 2-Midnights. Beneficiaries admitted under hospital outpatient status are subject to cost-sharing for their hospital stay under Medicare Part B, with no out-of-pocket spending limit. Low-income status has been associated with increased hospital utilization, and there is concern that such beneficiaries may be at risk for high utilization and uncontrolled out-of-pocket costs related to hospital outpatient care. The objective of this study was to assess whether low-income status is associated with high utilization and high financial liability for hospital outpatient care.

METHODS: This is a retrospective observational study of the 5% Part B Limited Data Set for Medicare Claims and county-level income and poverty data from the US Census Bureau, both from 2013. Beneficiaries were included if they were admitted under hospital outpatient status and had Medicare Part A and Part B coverage for the full calendar year. Patients were categorized into income quartiles based on the proportion of their county of residence living under the Federal poverty level. Beneficiaries in the tails of the poverty distribution were also examined to evaluate outcomes in the poorest and wealthiest counties. The primary outcomes were 1) high utilization 2) high financial liability, and 3) cost burden related to hospital outpatient care. We defined high utilization as 3 or more hospital outpatient stays in 12 months, high financial liability as an annual out-of-pocket cost greater than the 2013 Part A inpatient deductible ($1184) and cost burden as the ratio of out-of-pocket costs to estimated annual income. Logistic regression was used to assess whether poverty level was independently associated with high utilization and high financial liability.

RESULTS: Of the 56,454,361 claims, there were 132,539 hospital outpatient stays representing 67,641 unique Medicare beneficiaries. After adjustment for covariates, beneficiaries from the poorest counties were almost 2.5 times more likely to be high utilizers of hospital outpatient care compared to those in the wealthiest counties (AOR = 2.43, 95% CI: 1.88–3.14). Patients from the poorest quartile were approximately 50% more likely to sustain higher financial liability for observation care compared to those in wealthiest quartile (AOR = 1.54 95% CI 1.38–1.72). The cost burden for hospital outpatient care was 1.51% of estimated annual income among beneficiaries in the poorest counties compared to 0.58% from the wealthiest ($p < 0.0001$).

CONCLUSIONS: The poorest Medicare beneficiaries appear to utilize more hospital outpatient care and sustain higher out-of-pocket cost burden than their wealthiest counterparts. An out-of-pocket spending limit could help protect vulnerable beneficiaries from excessive costs.

ISCHEMIC ST-SEGMENT CHANGES ON ELECTROCARDIOGRAM IN ACUTE MYOCARDIAL INFARCTION- STILL COMMON?

Waleed Al-Darzi[2]; Richard Nowak[2]; Michael Hudson[2]; Michele L. Moyer[2]; Gordon Jacobsen[1]; James McCord[2]. [1]Henry Ford Health System, Detroit, MI; [2]Henry Ford Hospital, Detroit, MI. (Control ID #2699946)

BACKGROUND: Prior studies report ischemic ST-segment changes on electrocardiogram (ECG) in 40–60% of patients with acute myocardial infarction (AMI) with important diagnostic and prognostic implications. Additionally, 1 to 6% of AMI patients had normal ECG on prior studies. These findings may have changed on the era of more sensitive cardiac troponin (cTn) assays.

METHODS: In a single-center we prospectively studied 569 patients who were evaluated for possible AMI in the emergency department from May 2013 to April 2015. Diagnosis of AMI was adjudicated by 2 independent physicians in accordance with the universal definition of AMI using all clinical information and required cTnI > 0.04 ng/ml (Siemens Ultra-cTnI). In situations where there was disagreement between the adjudicators, a third Cardiology adjudicator reviewed the case for final determination. Patients with ECG findings that led to immediate reperfusion therapy were excluded.

RESULTS: There were 45 (8%) patients with a diagnosis of AMI. Among AMI patients, the most common ECG findings were T-wave inversion 13 (29%) and normal 13 (29%) while 6 (13%) ECGs demonstrated ST-Depression ≥ 1 mm. Comparing patients with and without ST-segment elevation or depression, there was non-significantly higher cTnI levels (13.2 ± 28.3 vs. 5.9 ± 15.6 ng/ml; $p = 0.355$).

CONCLUSIONS: ST-segment changes on ECG are becoming less common in AMI. This may relate to smaller AMIs identified by more sensitive cTn assays which should be verified in larger trials.

Table 1: ECG Findings in Patients with Acute Myocardial Infarction

ECG Findings	$n = 45$	Number of Percutaneous Coronary Interventions	Number of Coronary Artery Bypass Grafting
Left Bundle Branch Block	1 (2%)	0	0
Left Ventricular Hypertrophy	10 (22%)	3	0
ST-segment Depression ≥ 1 mm	6 (13%)	2	1
ST-segment Depression 0.5-1 mm	0	0	0
ST-segment Elevation ≥ 1 mm	2 (4%)	1	0
ST-segment Elevation 0.5-1 mm	0	0	0
T-wave inversion	13 (29%)	1	0
Normal	13 (29%)	8	0

IT TAKES YOUR WHOLE LIFE OVER - PCP PERSPECTIVES ON ELECTRONIC INBASKET NOTIFICATIONS Sarah L. Cutrona[4, 2]; Laura Burns[1]; Hassan Fouayzi[1]; Rajani Sadasivam[2]; Devi Sundaresan[3]; Jerry H. Gurwitz[1]; Kathleen M. Mazor[1]; Lawrence Garber[3]; Terry Field[1]. [1]University of Massachusetts Medical School and Meyers Primary Care Institute, Worcester, MA; [2]University of Massachusetts Medical School, Worcester, MA; [3]Reliant Medical Group, Worcester, MA; [4]Edith Nourse Rogers Memorial Veterans Hospital, Bedford, MA. (Control ID #2705814)

BACKGROUND: Electronic Health Record (EHR) inbasket notifications allow care teams to communicate important patient information, but high volumes of notifications may contribute to physician burnout and may limit the safety and effectiveness of this communication mode.

METHODS: We used a mixed-methods approach to assess EHR inbasket management. We analyzed data for 75 primary care providers (PCPs) across a multisite healthcare system. PCPs were chosen based on their receipt of one or more automated notifications (alerts) sent to inbaskets as part of a previous randomized controlled trial. Alerts highlighted time-sensitive medication concerns for older patients post-hospital discharge (2010–2011) and were delivered at 10 am on day 3 post-discharge. Less than 2/3 were opened by PCPs within 48 hours. In our follow-up study, we sought to characterize the number of other notifications competing for attention in the PCPs inbaskets and to understand PCP perceptions of inbasket management. We used audit and access log EHR data to calculate the number of inbasket notifications present at the time of alert delivery and the number of notifications received by the PCP in the prior 7 days. We also tracked the time of day PCPs were opening alerts. To complement this work, we conducted one focus group ($n = 5$ PCPs) addressing EHR inbasket workflow. Audio recordings were transcribed and the transcript was reviewed by two reviewers for major themes.

RESULTS: The median number of notifications in PCP inbaskets at the time of alert delivery was 68.7 (IQR 41.3, 156.3). The median number of notifications arriving in PCP InBaskets during the 7 days prior to alert delivery was 379.8, IQR (295.0, 492.0). Tracking data followed for three days post-alert delivery showed PCP opening of alerts occurring from 5 am through midnight. Themes emerging from the focus group included high numbers of notifications, duplication/redundancy, anxiety associated with risk of delayed or missed review of critical information, and use of personal time daily (including on vacations) to review inbaskets. Inbasket overload was perceived as contributing to burnout; use of personal time to manage this overload was seen as impacting perceptions of students and family (participants described watching their own and other physicians' children opting not to pursue careers in medicine due to the lifestyle). Suggested methods for improvement included use of staff to help triage inbasket notifications, protocols to minimize back-and-forth messaging and system-wide interventions to decrease redundant and inactionable notifications.

CONCLUSIONS: EHR audit and access log data supports PCP reports of managing high volumes of inbasket notifications and of regular use of after-hours time including late night and early morning. Inbasket overload is perceived by some PCPs as a risk to patient safety, a factor contributing to burnout, and a potential influence on our future primary care workforce.

IT'S THE DIFFERENCE BETWEEN LIFE AND DEATH: A QUALITATIVE STUDY ON THE VIEWS OF TRAINED MEDICAL INTERPRETERS ON THEIR ROLE IN PATIENT SAFETY EFFORTS. Margaret Wu[3]; Shail Rawal[1, 2]. [1]University of Toronto, Toronto, ON, Canada; [2]University Health Network, Toronto, ON, Canada; [3]University of Toronto Medical School, Toronto, ON, Canada. (Control ID #2702202)

BACKGROUND: Patients with limited English proficiency (LEP) experience poorer quality care and more adverse events in hospital when compared to their English-proficient counterparts. The use of trained medical interpreters improves the quality of care delivered to patients with LEP. As a result, there is interest in defining the role of medical interpreters in efforts to improve patient safety. In developing such an understanding, it is important to consider the perspectives of medical interpreters. In this qualitative study, we sought to explore the views of trained medical interpreters on their role in patient safety efforts.

METHODS: We conducted a qualitative analysis of in-depth, semi-structured interviews with 15 trained medical interpreters affiliated with the Healthcare Interpretation Network in Toronto, Ontario. Interviews were audiotaped and transcribed verbatim. Participants' views on their role in patient safety efforts were independently analyzed by the two authors and organized into themes. Data analysis was informed by grounded theory and occurred concurrently with data collection. Interviews were conducted until theoretical saturation was reached.

RESULTS: Trained medical interpreters described being uniquely situated to prevent adverse events involving patients with LEP by: 1) facilitating robust communication between patient and provider, 2) enhancing patient comprehension, 3) speaking up when patient safety issues are identified, and 4) giving voice to patient concerns. Medical interpreters highlighted several important challenges to fulfilling these functions including, the hierarchical structure of healthcare teams, the ill-defined role of interpreters within such teams, and the ethical imperative for interpreters to remain impartial when mediating communication between patients and providers. These challenges affected the ability of interpreters' to play a more active role in improving safety for LEP patients.
CONCLUSIONS: Our study found that trained medical interpreters view their work as integral to the delivery of safe and high quality healthcare to patients with LEP. Medical interpreters and healthcare providers require a mutual understanding of their roles in order to effectively engage in patient safety efforts. In addition, medical interpreters need to be thoughtfully integrated into the healthcare team to leverage their unique skillset in improving safety for patients with LEP. Medical interpreters must also be empowered by healthcare teams to speak up when they identify patient safety concerns.

IT'S COMPLICATED: PATIENT AND PHYSICIAN ATTITUDES TOWARDS LUNG CANCER SCREENING IMPLEMENTATION

Margaret Lowenstein[1]; Maya Vijayaraghavan[1]; Nancy J. Burke[2]; Leah S. Karliner[1]; Melissa Peters[1]; Celia P. Kaplan[1]. [1]University of California San Francisco, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA. (Control ID #2706666)

BACKGROUND: Based on the results of the National Lung Screening Trial (NLST), national guidelines now recommend lung cancer screening with low dose computer tomography (LDCT) in high-risk individuals after a process of shared decision-making. However, the balance of risks and benefits is complex, and screening uptake has been mixed. Our aim was to explore patient and physician attitudes towards lung cancer screening and identify challenges and facilitators for screening interventions.
METHODS: We conducted in-depth, semi-structured interviews with primary care physicians (PCPs) and patients from two academic primary care clinics, including a safety net clinic, from August 2014-May 2016. We recruited 28 patients who met NSLT eligibility criteria using a combination of PCP referral, waiting room signs, and chart review. 12 PCPs were recruited via email. We assessed patient and physician attitudes regarding lung cancer screening, barriers and facilitators to screening, and preferred methods of communication. Two independent reviewers analyzed interview transcripts to identify emergent themes using a hybrid deductive-inductive process.
RESULTS: Of the 28 patients, 11 had received LDCT and 17 had not. 36% of participants were non-white, 66% were current smokers, and 74% were male. Over 20% of the participants had completed high school or less, 32% were on disability, and 21% were employed. Of the 12 PCPs, a majority were faculty (92%), female (67%), and white (50%). Most patients reported discussing smoking cessation with physicians but less consistently understood associations between smoking and lung cancer or screening. Among those who received LDCT, patients reported brief discussions with their physicians, limited shared decision-making, and a focus on benefits of screening rather than risks. Most patients were not deterred by concerns about radiation and false positives, but did worry about transportation, cost, navigation, and potential treatment if cancer were detected. Physicians were generally aware of lung cancer screening guidelines but inconsistent in their application, citing concerns about screening risks (false positives, testing frequency, radiation) complexity of decision-making and lack of systems for testing and follow-up. Both groups favored screening interventions that identified individual risks and benefits coupled with shared decision-making conversations between patients and providers. Additionally, physicians desired systems-level interventions including reminders, health coaching, and increases in capacity for screening and follow-up.
CONCLUSIONS: Both patients and physicians value shared decision-making about lung cancer screening but report different types of concerns and variable practices for screening and communication. As lung cancer screening is scaled up, this information can inform multi-faceted interventions on the patient, physician, and system level to identify high-risk patients, promote shared decision-making and facilitate structured follow-up.

IT'S NOT YOU, IT'S ME: PATIENT FLOW AND PERCEIVED SATISFACTION IN ACADEMIC PRIMARY CARE CLINICS

Cody Mowery; Raagini Suresh; Jason Selinger; Michelle E. Guy; Brent Kobashi; Leslie Sheu. University of California, San Francisco, San Francisco, CA. (Control ID #2692582)

BACKGROUND: Patient satisfaction is a commonly used metric of clinic performance. Prior studies have shown that patient satisfaction scores are directly associated with time-with-provider and inversely correlated to wait time. We therefore sought to explore patient-reported and provider-perceived satisfaction with respect to wait times and identify bottlenecks to patient flow in our academic clinics.
METHODS: We distributed anonymous surveys to patients at two primary care clinical sites affiliated with our academic center over the course of two weeks, asking patients to 1) rate their satisfaction with wait times on a five-point scale from "very dissatisfied" to "very satisfied" and 2) record the lengths of various steps of their appointment. In parallel, we circulated an anonymous online survey to 158 physicians and clinical support staff in the same two clinics to 1) measure perceived patient satisfaction regarding wait times on the same five-point scale and 2) qualitatively solicit perceived bottlenecks to patient flow. We generated a coding schema for the provider responses a posteriori.
RESULTS: We received 40 patient and 61 (39% response) staff surveys. Thirty-one (76%) patients reported being "satisfied" or "very satisfied", whereas only 10 (19%) staff perceived patients to be "satisfied" or "very satisfied". On average, patients wait 27.3 min from time of arrival to seeing their physician (SD = 19.3 mins). Though appointments are scheduled for 20 mins, the average time-with-provider extended to 30.4 mins (SD = 12.7 mins). We found no correlation between wait time (Rsq = 0.07) nor time-with-provider (Rsq = 0.04) and patient satisfaction. Fifty-two clinic staff (85%) reported perceived bottlenecks to patient flow, the three most common being "late provider" (90%), "late patient" (23%), and "scheduling" (16%).
CONCLUSIONS: Our data reveal a discrepancy between patient-reported and provider-perceived satisfaction regarding wait times in our primary care clinics. We hypothesize that patient-reported satisfaction reflects an acceptance of unfavorable wait times, as well as appreciation for the time they are able to spend with their provider, whereas provider perceptions of patient experience serve as proxy for provider discontent regarding clinic inefficiencies. Because provider dissatisfaction is a primary contributor to burnout, our ongoing work seeks to identify and address structural factors disrupting patient flow, including optimizing scheduling and maximizing clinic space to allow for flexibility in situations of provider

and/or patient tardiness. These efforts will not only enhance patient satisfaction and overall experience even more, but also remedy provider burnout by addressing policies and procedures affecting both patient and provider satisfaction.

JOY IN PRACTICE AS AN ENABLING STRATEGY FOR QUALITY IMPROVEMENT IN CARDIOVASCULAR CARE

Anton J. Kuzel. Virginia Commonwealth University, Richmond, VA. (Control ID #2678442)

BACKGROUND: As part of the AHRQ Evidence Now initiative, the Heart of Virginia Healthcare collaborative (HVH) has designed a practice intervention initiative to improve performance on cardiovascular risk factors by 250 small to medium sized primary care practices in Virginia. Unlike most QI initiatives, HVH recognizes that widespread levels of stress and burnout amongst primary care clinicians and staff can be an obstacle to practice change for quality improvement. We designed our intervention to address those issues to help practices regain adaptive reserve as preamble to QI efforts.

METHODS: We brought practice representatives together for a "kickoff" meeting focused on sharing practical strategies for creating a positive practice environment by reducing waste, improving efficiency, and creating a supportive practice culture. They were shown how to use these gains to implement quality improvement activities such as pre-visit planning, collaborative care between clinicians and staff, and team documentation. Additional elements included meetings between practices and assigned coaches, a session on the evidence for the ABCS guidelines presented by a member of the USPSTF, and a closing session on strategies to improve personal and practice resilience.

RESULTS: Presenter ratings were consistently high [4.7 out of 5] and more importantly participants' self-rated confidence in their ability to a) Identify measurements of the ABCS of heart health for their patient populations based on recommended standards, b) Apply concepts to optimize clinical coding for the ABCS of heart health based on recommended standards, c) Identify and integrate key workflows in the primary care office or clinic based on exemplary practice models, d) Use concepts of exemplary practice research to optimize teamwork by building personal resilience and creating culture by design, and e) Define strategies for creating "joy in practice" based on exemplary practice research showed dramatic improvements when comparing pre- and post-meeting ratings [2.73 to 4.25, $p < .001$]. Finally, our practice coaches reported that practices that came to the kickoff meetings were the most engaged during the on-site portion of our practice support strategy.

CONCLUSIONS: Our experience suggests that the decision to first address factors leading to practice stress and clinician burnout created a readiness for change and quality improvement that might not have otherwise been achieved. Our ongoing practice coaching experience reinforces the importance of burnout and stress among provider teams as a key element influencing both motivation and actual ability to make meaningful and sustained changes. A consistent mindful focus on these elements by coaches, faculty and the practice teams themselves creates new opportunities, improved buy-in, and an enhanced "value proposition" in efforts to improve practice engagement.

KEEPING THE PROBLEM LIST TIDY: A PILOT STUDY OF OWNERSHIP AND CLUTTER IN AN ACADEMIC PRIMARY CARE CLINIC EMR.

James L. Wofford; Carolyn F. Pedley; Claudia L. Campos; Melanie Martin; Feben Girma. Wake Forest University, Winston-Salem, NC. (Control ID #2704712)

BACKGROUND: Avoiding disorganized and cluttered EMR documentation is an increasingly important factor in decreasing cognitive burden, improving clinician sanity, and promoting patient safety. Lack of ownership of the list, variation in diagnostic language, and coding/billing pressures contribute to undermining the value of this communication tool. In an effort to establish the value of the problem list, we sought to examine problem list characteristics and identify dysfunctional practices in problem list management

METHODS: We performed a one-week audit of outpatient EMR problem lists at our academic-affiliated primary care clinic, now 4 years into EPIC (TM) implementation. A random sample of patients with return continuity visits were chosen to systematically examine problem lists. In addition to characterizing the number of problems, list contributors (PCP versus other) and the proportion of problems entered by the PCP, documented problems were classified as true diagnoses, or "problematic" problems (symptoms without diagnosis, self-limited syndromes, administrative labels, past medical history items, family/social history items, duplicate entries).

RESULTS: Of the 194 return visits during the one-week audit period in November 2017, 87 randomly chosen visits were to 25 clinicians (11 senior clinicians, 14 resident physicians), and the average patient age was 58.8 (+12.7) years. The average number of problems documented on the problem list was 11.5 (+27.1, range 3–40), and patients aged >65 differed little from those <65 in the number of problems t (14.2 vs 11.2, $p = .10$). The designated PCP contributed on average 4.6 (+5.4) of the problems. The total number of problem list contributors averaged 3.9 (+2.6). On average, 89% (78/87) of charts reflected at last one "problematic" problem. Symptoms without a specific diagnosis represented 2.2 (+2.6) of problems, and undifferentiated pain symptoms 1.1(+1.8) of problems. Self-limited health care problems remained on the problem list in 29.9% (26/87) of charts. Items of family history/social history and past medical history were present in 28.8% (25/87), and 40.3% (35/87), respectively. Duplicate problems and administrative diagnoses were identified in 43.6% (38/87) and 18.9% (16/87) of problem lists, respectively. Problem lists were only slightly longer for senior clinicians than for resident clinicians (12.5 + 7.6 versus 10 + 5.8) and reflected no more often problematic problem lists.

CONCLUSIONS: EMR problem lists at this academic primary care clinic with a mature EMR implementation are lengthy and cluttered. Lack of ownership of the problem list is apparent, and inappropriate and irrelevant problems are prevalent. Senior clinicians are not demonstrably better than resident physicians at less cluttered, more concise problem lists. With external pressures and inadequate maintenance undermining the value of the problem list, future studies should examine the specific value of the list for clinicians and develop better guidance for physicians-in-training.

KEEPING UP WITH SOCIAL MEDIA

Zaid Shakir[1]; Tarundeep S. Grewal[1]; Sarah Sethi[1]; Olivia Onwodi[1]; Niket Sonpal[2]. [1]American University of Antigua, Brooklyn, NY; [2]Kingsbrook Jewish Medical Center, Hauppauge, NY. (Control ID #2704223)

BACKGROUND: Social media is 2nd nature in today's generation and is available for all healthcare professionals and patients. It has become a platform for networking and education, from public health programs to patient care and health care tips. There is also a risk of breaking legal and ethical grounds with health care professionals communicating with patients through social media. The average user checks their phone nearer to 150 times per day with an

average, 23 times a day for messaging, 22 times for voice calls and 18 times to get the time. This proves that social media plays a large role in the day to day lives of clinicians.

METHODS: A 33 question written survey was presented to 3rd year and 4th year medical students, Medical Residents, and Registered Nurses at 3 major hospitals in the NYC area. The survey was completed over a one-week period and the data was then analyzed. This study questions queried how medical residents, future physicians and healthcare professionals feel about using social media as a platform to engage with patients.

RESULTS: Surveys were collected from 193 participants (113 MS3, 42 Medical Residents, 28 MS4, 7 Nurses). Most were ages 25–29 (55.2%), female (54.2%), Asian (44.8%), and US IMG (59.6%). Most participants believe that social media has affected medicine in a positive way (62.2%). Nearly four in five participants who believed social media had a positive impact (80.3%) use social media as a learning tool for medicine in their daily life and majority (88%) of them use it to stay up to date with current medical information (eg, events, journals, guidelines, etc.). One in six of the same participants (16.2%) feel it is professional to communicate or connect with patients through social media; and nearly half of them (42.1%) use e-mail as the platform to communicate with their patients. The main concern regarding using social media platforms to interact with patients online (77.8%) is due to concern about privacy, followed by (48.1%) due to concern about liability. Majority of those (77.8%) would post valuable medical information (i.e. health tips, articles, resources, links to studies) on social media to be accessible for patient's health and care.

CONCLUSIONS: Healthcare professionals have different views on using social media as a platform to engage with their patients. Despite the majority agreeing that the popularity of social media in today's generation has positively impacted medicine, a large amount are still hesitant to use it to communicate with their patients due to concerns of privacy and liability. However, majority would still use social media as learning tool, staying up to date with medicine and posting valuable information for their patients.

KNOWLEDGE THAT LIFESTYLE BEHAVIORS PREVENT CANCER AND BEHAVIORAL ADOPTION

Jaya Aysola; Hairong Huo; Marilyn M. Schapira. University of Pennsylvania, Philadelphia, PA. (Control ID #2707453)

BACKGROUND: Lifestyle behaviors contribute to the majority of cancer diagnoses, yet we lack sufficient understanding if knowledge of this fact motivates behavioral change. The objective of this study is to examine if awareness that lifestyle behaviors reduces cancer risk is associated with a higher likelihood of adopting those behaviors.

METHODS: We analyzed data on a nationally representative sample of US adults without a prior diagnosis of cancer ($n = 3502$) from the 2015 Health Information National Trends Survey (HINTS). Our primary predictor was the response to a 4-point Likert scaled question, "how much do you think health behaviors like diet, exercise, and smoking, determine whether or not a person will develop cancer (a lot, somewhat, a little, not at all). Linear and logistic regression models estimated associations between our primary predictor and self-reported behavioral outcomes related to diet, exercise, sedentary activity, obesity, and smoking. In multivariable regression models, we adjusted for age, gender, race/ethnicity, household income, education level, employment, and talking to friends about health (yes, no).

RESULTS: About 47% ($n = 1648$) of the study population reported that health behaviors such as diet, exercise, and smoking had "a lot" and about 34% ($n = 1187$) reported it had "somewhat" to do with whether a person developed cancer. While about 19% ($n = 667$) reported that it had very little or nothing to do with whether a person develops cancer or not. Significant predictors of reporting that lifestyle behaviors related to cancer risk included race/ethnicity and educational level. There were no significant associations detected between knowledge that lifestyle behaviors related to cancer risk and exercise and sedentary behaviors (weekly exercise time, daily TV watching), obesity (BMI), and current smoking status. However, knowledge that lifestyle behaviors had a lot to do with cancer risk was significantly associated with increased use of menu calorie information and vegetable consumption in both unadjusted and adjusted analyses. For example, individuals that reported that lifestyle behaviors had little to do with cancer were significantly less likely to consume the daily recommended amount of vegetables [Adjusted Odds Ratio (95% Confidence Interval): 0.5 (0.4, 0.8)].

CONCLUSIONS: Our findings suggest that increased awareness that lifestyle behaviors relate to cancer risk is associated with a greater adoption of behaviors related to diet alone and highlights an opportunity for health care providers to discuss dietary modifications in the context of cancer prevention.

LEARNER EXPERIENCES WITHIN A NOVEL INTERPROFESSIONAL PRACTICE MODEL

Temple Ratcliffe[1]; Ann Ding[1]; Lauren S. Penney[2]; Erika Bowen[1]; Sean E. Garcia[1]; Christopher Moreland[1]; Kanapa Kornsawad[1]; Luci Leykum[2]. [1]Medicine, UTHSCSA, San Antonio, TX; [2]STVHCS/UTHSCSA, San Antonio, TX. (Control ID #2704083)

BACKGROUND: Poor communication is a well-documented issue with hospital care, impacting diverse outcomes from errors to poor care transitions. Numerous barriers exist to effective communication, including professional silo-ing and lack of patient engagement. Collaborative Care (CC) is a novel interprofessional practice model where patients, families, and the team of interprofessional providers partner to deliver high-quality care. Key CC elements include novel interprofessional rounding and daily team reflections. Little is known about learners' experiences on these teams in teaching hospitals. We report on their experiences on our CC team.

METHODS: Semi-structured interviews were conducted with learners ($n = 16$) and attendings ($n = 2$) at the end of their rotations on the CC team. Interview transcripts were first deductively coded using frameworks informed by complexity science and learner constructs of interest. New themes were inductively identified.

RESULTS: Common themes identified were Loss (e.g. explicit teaching moments), Uncertainty during Rounds (e.g. when to discuss sensitive topics), Adaptability and Flexibility (e.g. adjusting to novel rounding style), Workflow (e.g. perceived inefficiencies), Communication with Patients and the Team (e.g. opportunities for improved communication skills), Conceptualization of Teaching and Education (i.e. interplay of teaching and learning in patient care), and Conceptualization of Collaborative Care (i.e. key elements of CC).

CONCLUSIONS: Learner and attending experiences illustrated the tensions the CC model can pose for professional identities and hierarchies. CC was discussed as something done to patients during rounds, rather than a global

approach to care delivery. Neither group seemed to embrace key aspects of the CC model including conceptualizing the larger interprofessional team or recognizing alternative forms of learning taking place. Some learners appreciated perceived benefits for patients and improved interprofessional relationships. These findings highlight the challenges involved in instituting new models of patient care in teaching hospitals and speak to the need to better set expectations of learners and attendings.

LET'S TAKE A WALK: EXAMINING THE ATTITUDES OF OLDER AFRICAN-AMERICAN HEMODIALYSIS PATIENTS REGARDING EXERCISE Debora Afezolli[1]; Shenglin Zheng[3]; Janet Seo[1]; Haniya Syeda[1]; Jasvinder Bhatia[2]; Sara Folta[3]; Christine Liu[1]. [1]Boston Medical Center, Boston, MA; [2]Boston University Medical Center, Boston, MA; [3]Tufts University, Boston, MA. (Control ID #2706257)

BACKGROUND: Kidney failure disproportionately affects African Americans; older African-Americans are one of the fastest growing groups of hemodialysis (HD) patients. Kidney failure is associated with increased risk of muscle wasting, leading to overall poorer quality of life and physical impairment. Many older adults on HD develop difficulties with self-care activities and have trouble walking. A potential intervention to halt the physical decline in older adults with HD is increased exercise. Greater levels of exercise have been associated with decreased mortality in HD patients. Our goal was to explore the attitudes of older African American HD patients regarding exercise, in order to devise targeted strategies to improve physical function in these patients.

METHODS: A convenience sample of HD patients aged 65 or older followed at an urban academic medical center underwent 30–40 min semi-structured interviews in their homes. The interview guide included open-ended and Likert style questions about general physical function, falls, and exercise. The Falls Efficacy Scale-International (FES-I) was administered. Interviews were audiotaped and transcribed. Four research team members simultaneously reviewed interview data and determined dominant themes using data patterns facilitated by Nvivo 11. Intercoder reliability was ≥0.8.

RESULTS: A total of 10 older African-American HD patients (mean age 73.0 ± 5.0 years, 60% women, mean years on HD 4.8 ± 4.5) were interviewed between November 2015 and January 2016. Ninety percent of participants did *not* think hemodialysis was a contraindication to exercise, and 100% agreed that getting up and moving could make them feel better. Sixty percent expressed willingness to undertake exercise at least three times a week. Mean FES-I score was 22.3 ± 9.3 points, consistent with a moderate level of concern for falling. Themes that emerged as barriers to exercise (see Table below) were self-barriers (cited by 90% of the participants), health problems, and environmental restrictions. Themes that emerged as facilitators of exercise were self-motivation (cited by 80% of the participants), support from families and friends, as well as feasible means of exercise.

CONCLUSIONS: In this predominantly African-American sample, older adults on HD view themselves as capable of undertaking exercise, and are willing to do it multiple times a week. To successfully use exercise to improve physical function in older African American HD patients, future interventions should include components that address barriers, such as home modifications for safety, and leverage motivators such as family and friend support.

Barriers and facilitators to exercise in older African-American patients on HD

	Theme	Examples
Barriers	Self-barriers	"I don't have anything to motivate me to say, well let's get up and do this. Let's go take a walk." "I feel like I'll get up later, I'll get up in a few min. I keep laying there."
	Health problems	"My back pain and knee pain prevent me from moving, regardless of whether I have hemodialysis." "I feel lightheaded, and if I feel, if I get up and feel lightheaded I just sit back down and wait a few min, and then I get up and try it again."
	Environmental restrictions	"I don't do too much outside walking when there is ice on the ground." "I don't go to people's houses unless I know what kind of step they have."
Facilitators	Self-motivators	"Life motivates me to get moving… I love living" "God makes it easy for me to move" "I mean the only way I'm going to get out of this chair is to get up and start moving around. If I sit here it's just going to get harder and harder for me to do, so I have to try, I have to try"
	Family and friend support	"I have the lady downstairs that won't let me stay in bed, saying, "Come down. Come down." "Sometimes I walk downstairs, like go to the mailbox and say hi to people that is down there that you know, and then come back upstairs."
	Feasible exercise	"I'll go to the grocery store, walk around there for a while, and go shopping" "Walks to HD and walks back so that gets him exercise. Moves for about 15–20 min, takes his time."

LIFE-YEARS LOST TO PREVENTABLE CAUSES-OF-DEATH IN THE US, 2014 Glen B. Taksler[1]; Michael B. Rothberg[1]; R. Scott Braithwaite[2]. [1]Cleveland Clinic, Cleveland, OH; [2]New York University School of Medicine, New York, NY. (Control ID #2705388)

BACKGROUND: Modifiable behavioral risk factors pose a substantial mortality burden in the US. We sought to explain the number of life-years lost to modifiable risk factors in 2014.

METHODS: Based on data from the National Vital Statistics System, we developed a microsimulation model to assess the number of life-years lost to preventable disease risk factors. First, we simulated 2014 life expectancy in the US population aged ≥15 y, based on 28 competing risk factors (17 modifiable, such as hypertension, and 11 non-modifiable, such as genetics) that contributed to 19 mortality-causing conditions (which were based on the 10 leading causes-of-death for each age decile). An individual could have multiple risk factors (e.g., hypertension, obesity) and multiple mortality-causing conditions (e.g., breast cancer, heart disease) but could only die of a single cause. All individuals faced background mortality risk based on age, sex and race. To estimate the number of life-years lost to each modifiable risk factor, we

examined the change in mortality for a series of counterfactual US populations that each eliminated a single risk factor. We compared the results with the change in life-years lost for an “optimal” population that eliminated all modifiable risk factors. Recognizing that some less common factors might place substantial burden on small population subgroups, we also estimated life expectancy gained in individuals with each modifiable risk factor.

RESULTS: In 2014, the greatest number of preventable life-years were lost to obesity (303 million life-years, 22.2% of total preventable life-years), diabetes (267 million life-years, 19.6% of total), hypertension (209 million life-years, 15.4% of total), tobacco (206 million life-years, 15.1% of total) and hyperlipidemia (+130 million life-years, 9.5% of total). Fewer life-years were lost to alcohol misuse, HPV, sexual behaviors, bipolar disease, anxiety, vaccines, hepatitis B/C, illicit drug use, head trauma and environmental toxins (each 1–3% of total). However, in affected individuals, a substantial number of years were lost to alcohol misuse (+17.5 years/individual), tobacco (+10.0 years/individual), hepatitis B/C (+7.6 years/individual) and bipolar disease (+7.3 years/individual). Individual losses to obesity (+4.8 years/individual), diabetes (+2.6 years/individual), hyperlipidemia (+1.0 years/individual) and hypertension (+0.9 years/individual) were smaller.

CONCLUSIONS: We analyzed the contribution of modifiable behavioral risk factors to causes-of-death in the US population. Our findings suggest that obesity resulted in 47% more life-years lost than tobacco in 2014, but tobacco caused similar life-years lost as hypertension. Results also highlight tension between population health approaches to mortality prevention (which were influenced by both gains in life expectancy and number of affected individuals in each age group) vs. individualized goals for use in clinical practice (which were only influenced by gains in life expectancy).

LIVING ALONE IS ASSOCIATED WITH DISCHARGE TO POST-ACUTE SKILLED NURSING FACILITY CARE AFTER HOSPITALIZATION Daniel E. Lage[1]; Michael Jernigan[2]; Yuchiao Chang[2]; John Hsu[2]; Joshua Metlay[2]; Sachin J. Shah[2]. [1]Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital, Boston, MA. (Control ID #2700217)

BACKGROUND: Use of skilled nursing facility (SNF) care after hospitalization appears to vary substantially across hospitals and regions, but the association with patient outcomes is less clear. One challenge to understanding variation in SNF use and outcomes has been the lack of information on patient level determinants of SNF admission. In particular, the amount of potential home support during the post-hospitalization recovery period may be an important determinant of SNF use. We examined whether those who live alone are at greater risk to be discharged to SNF.

METHODS: We conducted a retrospective cohort study at the Massachusetts General Hospital. Eligible subjects were admitted to the medical service from the community, at least 50 years old at the time of admission, had hospitalizations of at least three days, did not have a major surgical procedure during their admission, and were discharged alive between July 2014 and August 2015. Demographic, clinical, and discharge data were extracted from the electronic medical record. Information about the living environment and activities of daily living was obtained from a standardized “Initial Nursing Assessment” that was completed on the first day of admission (missing for <1% of eligible admissions). Education and income measures were obtained from zip code-level US Census data. We performed multivariable logistic regression to assess if living alone at the time of hospitalization was associated with subsequent discharge to SNF.

RESULTS: Of the 8021 eligible subjects, 25.4% reported living alone prior to admission. Subjects living alone were more likely to be female (54.9% vs. 43.4%, $p < 0.001$), older (72.5 vs. 69.6 years, $p < 0.001$), sicker (Elixhauser Comorbidity Index = 3.7 vs. 3.5, $p < 0.001$), and more independent prior to admission [e.g. dressing (82.2% vs. 75.9%, $p < 0.001$) and bathing by themselves (79.2% vs. 73.4%, $p < 0.001$)]. Among all subjects, 15.3% were discharged to SNF. Patients living alone were more likely to be discharged to SNF (20.4% vs. 10.8%, $p < 0.001$). After adjustment for age, sex, race, income, education, insurance status, comorbidities, length of stay, and activities of daily living, patients living alone had double the odds of being discharged to SNF (OR 2.12, 95% CI 1.82 to 2.47, $p < 0.001$).

CONCLUSIONS: Patients living alone are more likely to be discharged to SNFs. This association persisted even after accounting for clinical and functional status. Future work will examine how home support (and potential compensating features such as home health services) might interact with clinical and functional measures to determine post-discharge outcomes. Further, studies that evaluate the impact of SNF admission on patient outcomes, including hospital readmission, should account for differences in home support that might confound observed differences.

LIVING BETTER BEYOND PAIN: RANDOMIZED TRIAL OF OFFICE- VERSUS COMMUNITY-BASED SELF-MANAGEMENT OF CHRONIC PAIN Barbara J. Turner[1, 1]; Zenong Yin[2, 1]; Natalia Rodriguez[1]; Raudel Bobadilla[1]; Mariza Rodriguez[1]; Maureen J. Simmonds[1, 1]; Paula Winkler[1, 1]; Yuanyuan Liang[3, 1]. [1]University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]University of Texas San Antonio, San Antonio, TX; [3]University of Maryland School of Medicine, Baltimore, MD. (Control ID #2705344)

BACKGROUND: Primary care clinicians are increasingly frustrated by the lack of available and affordable strategies to manage chronic pain. A practical, effective intervention is needed to engage and educate patients about chronic pain self-management. We developed a 6 month (mo) curriculum in Spanish and English for patients about pain management strategies such as stretching, exercise, goal setting, sleep hygiene and mindfulness. To assess how best to deliver this program, we randomized patients to receive the intervention in clinic from a trained community health worker (CHW) or in a convenient community library from clinic physicians and other experts.

METHODS: In two academic primary care clinics serving primarily low income Hispanics, eligible patients were age 35 to 70 and treated with >2 mos opioids for chronic back or leg pain. Patients were randomized to: 6 monthly meetings 1-on-1 with a CHW or 9 group lectures in a library over 6 mos. The same trial was repeated for two 6-mo cohorts and ended in 12/16. The primary outcome was change in 5X sit-to-stand test (5XSTS) from baseline to 3- and 6-mos. Change in 50-feet speed walk (50FtW) and Symbol-Digit Modalities Test (SDMT) were assessed at both times while change in 6-min walk (6 MW) and Patient Health Questionnaire-9 (PHQ-9) were assessed at 6 mos. Linear mixed effects models were estimated and adjusted for study arm, sex, age, BMI, % visits missed, and % make-up visits.

RESULTS: Among all study subjects ($N = 111$), 55% were women, 78% Hispanic, mean age 56.5 (SD = 9.01), and mean BMI 34.5 (SD = 8.43). Mean baseline measures were: 5XSTS 22.6 s (sec) (SD = 14.0), 50FtW 19.3 secs (SD =

6.39), 6 MW 948.4 ft (SD = 376.0), SDMT 30.9 (SD = 11.8) and PHQ-9 13.0 (SD = 7.4). Subjects in clinic ($N = 53$) and community ($N = 58$) arms did not differ significantly on any variable. 69 (62%) subjects completed 3 mo measures and 67 (60%) 6 mo measures. Baseline mean 5XSTS improved by 4.9 sec (SD = 13) at 3 mos ($P = 0.003$) and by 5.3 sec (SD = 10.8) at 6 mos ($p < 0.001$). After adjustment, improvements appeared for both arms in: 5XSTS at 3 and 6 mos (both $P < 0.001$); 50FtW at 3 mos ($P = 0.03$) and 6 mos ($P = 0.04$); SDMT at 3 and 6 mos (both $P < 0.001$); and PHQ-9 at 6 mos ($P = 0.001$). 6 MW improved at 6 mos only for the clinic arm ($P = 0.03$).

CONCLUSIONS: In this trial of a self-management educational intervention for chronic pain, subjects in both study arms had significant improvement in physical function and cognitive measures at both 3- and 6-mos and depression improved at 6 mos. Other than the 6 MW which improved for the clinic arm only, the equivalent benefits from the CHW-led clinic program and the community-based program suggest that this curriculum can be effectively delivered in either setting. Although longer term outcomes need to be assessed, this practical educational intervention promises to relieve the burden of chronic pain management shouldered by primary care physicians.

LOCALIZATION OF ABDOMINAL PAIN IS A USEFUL CLUE TO DIAGNOSIS OF UNDERLYING DISEASES: THE IMPORTANCE OF RIGHT-FLANK, LEFT-FLANK, RIGHT-SUBCOSTAL AND GENERALIZED ABDOMINAL PAIN Shun Yamashita; Masaki Tago; Naoko Kunami; Naoko E. Furukawa; Shu-ichi Yamashita. Saga University Hospital, Saga, Japan. (Control ID #2690785)

BACKGROUND: The relationship between the localization of abdominal pain and the diagnosis of underlying diseases has not been reported recently, in the era of highly developed diagnostic imagings. By analysis of recent data of new outpatients with abdominal pain, we elucidated the relationships between the localization of abdominal pain and the diagnosis.

METHODS: We retrospectively analyzed the new patients who visited the outpatient clinic or emergency room of the department of General Medicine, Saga University, Japan, for abdominal pain from April 2014 to July 2015. We checked their age, sex, the localization of abdominal pain and the diagnosis. The localization of pain was classified into 11 categories; right or left subcostal, right or left flank, right or left lower, epigastric, periumbilical, mid lower, generalized and undefined abdominal pain. The diagnosis was determined by a physician after later than 3 months of the first visit, and the diagnosis was divided into 11 categories by 3 physicians; esophageal and gastroduodenal, hepatic and biliary, pancreas, intestinal, urinary, gynecological, musculoskeletal, respiratory, cardiovascular, dermatological disease, and others. The relationships between the localization and the diagnosis were analyzed by Chi-squared test.

RESULTS: There were 472 patients (13%) visiting with abdominal pain of 3698 new patients during the research period. The mean age was 50 ± 20 years, and 191 patients (41%) were male. The most frequent localization of abdominal pain was epigastric (29%), followed by mid-lower (19%) and right-lower (12%). The most frequent diagnosis was intestinal disease (53%), followed by disease of the esophagus/stomach/duodenum (43%) and urinary tract (8.1%). There were some significant relationships between diagnosis and the localization of pain (Chi-squared test, $p < 0.05$); generalized abdominal pain with intestinal disease (likelihood ratio 4.4, 95% confidence interval 1.8 to 11.1), left flank pain with urinary disease (3.7, 1.8 to 7.2), right-subcostal pain with hepatic and biliary disease (3.6, 1.5 to 7.9), right flank-pain with urinary disease (3.1, 1.4 to 6.3), right gynecological disease (3.1, 1.5 to 5.4), Epigastric pain with hepatic and biliary disease (2.6, 1.8 to 3.2), epigastric pain with pancreatic disease (2.5, 1.4 to 3.3), epigastric pain with esophageal and gastroduodenal disease (2.2, 1.7 to 3.0) and mid-lower abdominal pain with gynecological disease (2.2, 1.2 to 3.6).

CONCLUSIONS: Right-flank and left-flank pain can be diagnostic clues to urinary diseases, right subcostal pain to liver and biliary diseases and generalized abdominal pain to intestinal diseases, respectively.

LONGITUDINAL ANALYSIS OF REAL-WORLD BASAL INSULIN UTILIZATION FOR TYPE I AND TYPE II DIABETES PATIENTS SWITCHING TO INSULIN GLARGINE U-300 (TOUJEO®) Yvonne Zhang[1]; Luc Sauriol[2]; Jennifer Glass[1]; Brad Millson[1]. [1]QuintilesIMS, Mississauga, ON, Canada; [2]Sanofi, Montreal, QC, Canada. (Control ID #2705079)

BACKGROUND: Background: Toujeo® (300 U/mL insulin glargine) is a long-acting insulin therapy approved for use in Canada in May 2015 for both type I and type II diabetes. Patients on basal insulin therapy that are experiencing poor glycemic control will often increase their dose to achieve glycemic targets, which can lead to increased costs to insurers and increased risk of hypoglycemic events. Besides a threefold higher concentration compared to Lantus® (100 U/mL or Gla-100), both pharmacokinetic and pharmacodynamic profiles of Toujeo® have previously been shown to be flatter and longer, with lesser intra-/inter-variability, which makes them more reproducible. Little information exists on how these changes impact patient utilization in a real world setting. The current study utilized real-world claims data to examine how average daily insulin dose changed when patients switched from a standard basal insulin, including insulin glargine 100U/mL, insulin detemir and neutral protamine Hagedorn (NPH) insulin to Toujeo®.

METHODS: Methods: The study utilized longitudinal private drug plan claims data from QuintilesIMS Canadian Private Drug Plan Database. The study was performed looking at Type I and Type II diabetes patients who switched from a standard basal insulin to Toujeo®. Patients were indexed on their first claim of Toujeo® between April 2014 and March 2016. Patients' basal insulin therapy was tracked for up to 12 months following the index date and calculated as average daily dose (ADD) in international units (IU) of insulin. Patients who did not have continuous coverage or who were inferred as potentially suffering from gestational diabetes were excluded from the analysis. To ensure a fair comparison, the first three months of dose titration were excluded from the analyses. Differences in ADD of insulin were compared pre- and post-switch to Toujeo®. Changes in use of concomitant medications pre and post-switch were also examined as an exploratory objective.

RESULTS: Results: 231 Type I and 1,028 Type II patients were identified in the study. In Type I patients, the ADD was 88 IU in the 3 months prior to switch and 73 IU following switch to Toujeo® ($p = 0.018$) Similarly, in Type II patients, the ADD was 111 IU in the 3 months prior to switch and 98 IU following switch to Toujeo® ($p = 0.010$). No change in concomitant medication use was seen with this decrease in insulin dosage.

CONCLUSIONS: Conclusion: In Canadian real-world practice, the overall basal insulin ADD was seen to be reduced once patients were switched (and titrated) to Toujeo®. The reduced dosing required for Toujeo® suggests a potential lower budget impact for payers. Further study is also needed to understand the impact on overall patient outcomes and safety.

LOWER DISCHARGE SYSTOLIC BLOOD PRESSURE (SBP) AND POOR OUTCOMES AMONG HOSPITALIZED PATIENTS WITH HEART FAILURE AND REDUCED EJECTION FRACTION (HFREF) AND STABLE ADMISSION-TO-DISCHARGE SBP Cherinne Arundel[2]; Phillip Lam[3]; Daniel Dooley[3]; Apostolos Tsimploulis[4]; Shani Weerakoon[5]; Gerasimos Filippatos[6]; Javed Butler[7]; Prakash Deedwania[8]; Michel White[9]; Ioannis Kanonidis[10]; Charity Morgan[11]; Wen-Chih Wu[12]; Wilbert Aronow[13]; Maciej Banach[14]; Gregg Fonarow[1]; Ali Ahmed[15]. [1]UCLA David Geffen School of Medicine, Los Angeles, CA; [2]Washington DC Veterans Affairs Medical Center, Washington, DC; [3]Georgetown University/Medstar Washington Hospital Center, Washington DC, DC; [4]Georgetown University/Medstar University Hospital, Washington DC, DC; [5]Georgetown University Hospital, Washington DC, DC; [6]University of Athens, Athens, Greece; [7]Stony Brook, Stony Brook, NY; [8]UCSF Fresno, Fresno, CA; [9]Montreal Heart Institute, Montreal, QC, Canada; [10]Aristotle University, Thessaloniki, Greece; [11]University of Alabama-Birmingham, Birmingham, AL; [12]Providence Veterans Affairs Medical Center, Providence, RI; [13]New York Medical College, Valhalla, NY; [14]Medical University of Lodz, Lodz, Poland; [15]Washington DC Veterans Affairs Medical Center, Washington DC, DC. (Control ID #2691263)

BACKGROUND: Heart failure (HF) is the leading cause for hospital admission and readmissions among elderly Medicare beneficiaries. Furthermore, the in-hospital and post-discharge mortality rates for HF remain high despite therapeutic advances. An SBP of <120 mm Hg has been associated with adverse short-term poor outcomes in hospitalized patients with HF. However, SBP may fluctuate between admission to discharge in decompensated hospitalized patients with HFrEF. We examined if a low discharge SBP among hospitalized patients with HFrEF with a stable admission-to-discharge SBP was independently associated with poor outcomes.

METHODS: In the Medicare-linked OPTIMIZE-HF registry, 10625 hospitalized patients with HF had EF ≤40%. A stable admission-to-discharge SBP was defined as SBP fluctuation of <20 mm Hg between hospital admission and discharge. Of the 5615 patients with stable SBP, 2812 (50%) had SBP <120 mm Hg. Propensity scores for a discharge SBP of <120 mm Hg, estimated for each of the 5615 patients, were used to assemble a cohort of 1372 pairs of patients, with a discharge SBP <120 vs ≥120 mm Hg, who were balanced on 58 baseline characteristics. The 2744 matched patients had a mean (±SD) age of 76 (±10) years, a mean (±SD) EF of 24 (±7) percent, a mean (±SD) discharge SBP of 120 (±16) mm Hg, 39% were women, and 12% African American.

RESULTS: During 2.1 years of median follow-up (max, 6.0 years), all-cause mortality occurred in 76 and 71% of matched patients with a discharge SBP <120 vs ≥120 mm Hg, respectively (HR, 1.23; 95% CI, 1.13–1.35; Figure). A discharge SBP <120 mm Hg was also independently associated with higher risk of all-cause readmission (HR, 1.16; 95% CI, 1.07–1.26), HF readmission (HR, 1.25; 95% CI, 1.13–1.39), and the combined outcome of total readmission or total death was (HR, 1.17; 95% CI, 1.09–1.27).

CONCLUSIONS: Among hospitalized patients with HFrEF and stable admission-to-discharge SBP, a low discharge SBP was independently associated with higher risk of poor clinical outcomes.

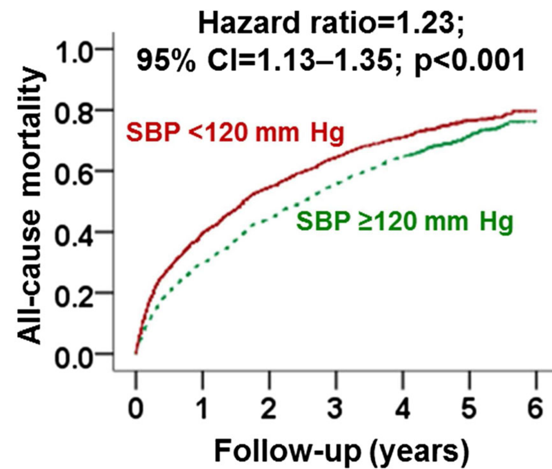


Figure Kaplan-Meier plots for all-cause mortality by discharge systolic blood pressure (SBP) in a propensity-matched cohort of patients with heart failure and reduced ejection fraction (CI=confidence interval)

M HEALTH COMMUNITY NETWORK: A PILOT STUDY IN COORDINATED CARE FOR INTIMATE PARTNER VIOLENCE SURVIVORS Mary Logeais[1]; Lynette M. Renner[2]; Cari Clark[3, 1]. [1]University of Minnesota, Minneapolis, MN; [2]University of Minnesota, St. Paul, MN; [3]Emory University, Atlanta, GA. (Control ID #2701535)

BACKGROUND: Intimate partner violence (IPV) is a significant public health concern with substantial health consequences. Though not definitive, research has shown that healthcare providers who screen for IPV and counsel patients can reduce victimization and positively impact physical and mental health. Recent clinical guidelines recommend addressing IPV, yet few patients disclose IPV to healthcare providers and few medical professionals screen for IPV. Best practices to assess and respond to IPV are incompletely understood. This study aims to better understand current practices and barriers for IPV screening, counseling and referral in one academic outpatient health system. This pilot work will inform a larger project that will investigate whether a coordinated clinical response to IPV decreases healthcare utilization, reduces victimization, improves health outcomes, and increases provider knowledge.

METHODS: Data from this mixed method study include interviews with 10 outpatient multi-specialty clinic managers utilizing the Agency for Healthcare Research and Quality's Delphi Instrument, interviews with 4 primary care clinic staff (including a medical director, nurse manager, social worker and licensed practical nurse), responses to the Physician Readiness to Manage Intimate Partner Violence questionnaire ($N = 23$) and five months of screening data captured in the electronic health record (EHR) after routine screening was implemented ($N = 9044$).

RESULTS: Overall, interviews highlighted insufficient training for staff, lack of formal policies for screening or documentation, and inadequate clinical resources to support interventions. Few primary care respondents felt they had sufficient knowledge and preparation to address IPV. Subspecialty respondents reported they did not have or were not aware of official policies for assessment or treatment of IPV; yet, 8 out of 10 respondents reported that

mandatory universal screening policies applied to their clinics. EHR data revealed that less than 50% of adult patient encounters included a screen for IPV in primary care. 83% of respondents reported a lack of or unawareness of on-site resources for IPV and only 13% reported having adequate knowledge of community-based services. Of interest, the majority of providers believed it was within their scope of practice to screen for IPV.

CONCLUSIONS: These results suggest there are considerable opportunities to improve upon not only staff knowledge, but also models of care delivery for IPV victims including connections to the community sector. This pilot study serves as a springboard to the next phase of this organizational intervention whereby routine EHR screening and referral practices will be introduced across a multispecialty outpatient practice. We anticipate this will highlight advantages and limitations of universal screening and lend insight into how these practices impact diverse patient populations beyond women of child-bearing age, including transgendered patients and cultural minorities.

MACHINE LEARNING WITH UNSTRUCTURED DATA IMPROVES IDENTIFICATION OF HOSPITALIZED PATIENTS WITH HEART FAILURE Saul Blecker[1]; David Sontag[3]; Leora I. Horwitz[1]; Gilad Kuperman[2]; Stuart Katz[1]. [1]NYU School of Medicine, New York, NY; [2]New York-Presbyterian Hospital, New York, NY; [3]MIT, Cambridge, MA. (Control ID #2705397)

BACKGROUND: Interventions to reduce readmission following hospitalization for acute decompensated heart failure (ADHF) require early identification of patients. Electronic health record (EHR)-based approaches to identify patients can range in complexity from simple algorithms based on few data elements to machine learning algorithms using big data. The purpose of this study was to compare performance of a range of algorithms to identify patients with ADHF. Given the emphasis that hospitals currently place on patients with ADHF, we developed models with high sensitivity to avoid missed opportunities for care improvement; this approach assumed secondary chart review would be necessary to confirm a diagnosis. We therefore estimated the time needed for secondary review by providers following initial screening with each algorithm.

METHODS: We performed a retrospective study of hospitalizations for patients age ≥ 18 at an academic medical center in 2013–2015. Using a random 75% development set, we developed four algorithms to identify hospitalizations with a principal diagnosis of ADHF using EHR data through the second midnight of hospitalization: 1) one of three characteristics: heart failure on the problem list, loop diuretic use, or brain natriuretic peptide ≥ 500 pg/ml; 2) logistic regression of 31 clinically-relevant data elements; 3) machine learning approach using L1-regularization logistic regression and unstructured data, including provider notes and radiology reports; 4) machine learning with both structured and unstructured data. We assessed performance of each algorithm in the 25% validation set. We also conducted a brief survey of providers who perform chart review for ADHF to estimate time needed for secondary screening following primary screening with each algorithm.

RESULTS: We included 37,229 hospitalizations in the study, of which 1,294 (3.5%) carried a principal diagnosis of ADHF. Algorithm 1 had a sensitivity of 0.98 and positive predictive value (PPV) of 0.14 for ADHF. Algorithm 2 had an area under the receiver operating characteristic curve (AUC) of 0.96 and a PPV of 0.15 when setting the sensitivity at 0.98. Both machine learning algorithms had AUCs of 0.99; with a sensitivity of 0.98, algorithms 3 and 4 had PPVs of 0.30 and 0.34, respectively. Based on survey of three providers, we estimated providers spent 8.6 min per chart review; using this this parameter, providers would spend 61.4, 57.3, 28.7, and 25.3 min on secondary chart review for each case of ADHF if initial screening was done with algorithms 1, 2, 3, and 4, respectively.

CONCLUSIONS: Traditional approaches with structured data can accurately identify nearly all patients with ADHF but are limited by a large number of false positives. Machine learning algorithms with unstructured notes and radiology reports can retain this sensitivity while significantly reducing false positives, thereby improving provider efficiency for delivery of quality improvement interventions.

MAIN FINDINGS FROM THE MYNEWOPTIONS STUDY: A RANDOMIZED CONTROLLED TRIAL OF A WEB-BASED REPRODUCTIVE LIFE PLANNING INTERVENTION Cynthia H. Chuang[1, 1]; Carol Weisman[1]; Diana Velott[3]; Erik B. Lehman[4]; Merry-K. Moos[6]; Christopher Sciamanna[2]; Richard Legro[1]; Christopher Armitage[5]; Vernon Chinchilli[1]. [1]Penn State College of Medicine, Hershey, PA; [2]Penn State Hershey, Hershey, PA; [3]Penn State Hershey College of Medicine, Hershey, PA; [4]Pennsylvania State University, Hershey, PA; [5]University of Manchester, Manchester, United Kingdom; [6]UNC Chapel Hill, Chapel Hill, NC. (Control ID #2706560)

BACKGROUND: The Affordable Care Act (ACA) requires that most private insurers cover FDA-approved contraceptive methods without cost-sharing. Thus, privately insured women may be well positioned to respond to interventions designed to assist them in making optimal contraceptive choices. A promising intervention is reproductive life planning, which is recommended by the Centers for Disease Control and Prevention (CDC), the American Congress of Obstetricians and Gynecologists (ACOG), and is required of Title X family planning programs. Reproductive life planning involves setting goals for having or not having children and making a plan to achieve those goals. How reproductive life planning affects contraceptive choices has not been evaluated in controlled trials.

METHODS: The MyNewOptions study enrolled 987 privately insured (Highmark Health), women ages 18 to 40 who were not intending pregnancy in the next year and had Internet access. After completing a baseline survey, women were randomized to one of three arms: reproductive life planning (RLP); reproductive life planning with contraceptive action planning (RLP+); or contraceptive information only. The RLP intervention was an interactive web-based tool adapted from the CDC's reproductive life planning tool. The RLP+ intervention added a contraception action planning component, which guides users to identify solutions ahead of time for challenges commonly encountered when using contraception. Women were prompted by email every 6 months for the duration of the 2-year study to complete follow-up surveys and re-visit the study website. The main outcomes were contraceptive use, long-acting reversible contraceptive (LARC) use, method adherence, and contraceptive satisfaction throughout the 2-year study period.

RESULTS: Participants completed an average of 3.5 (out of 4) follow-up surveys. Contraceptive use and LARC use increased from 88.5 and 8.4%, respectively, at baseline to 94.8 and 17.9% at 2 years. The outcome variables did not differ significantly by group allocation.

CONCLUSIONS: The null findings may be due to lack of intervention intensity, web-based intervention format, unintended intervention effect of the control condition, or a ceiling effect in our well educated, privately insured

sample. The overall increase in LARC use reflects the national secular trend. Our results suggest that reproductive life planning may not be effective at guiding privately insured women toward more effective contraceptive methods.

MANAGING COMPLEX PATIENTS IN PRIMARY CARE: WHICH PHYSICIANS HAVE ENOUGH TIME? Chinyere U. Okereke[1]; Michelle T. Vo[1]; Connie S. Uratsu[1]; Courtney R. Lyles[2]; Richard W. Grant[1]. [1]Kaiser Permanente Northern California, Oakland, CA; [2]University of California San Francisco, San Francisco, CA. (Control ID #2705372)

BACKGROUND: Complex patients often have multiple medical issues and health concerns that can be challenging for providers to effectively address during time-limited primary care visits. We surveyed primary care physicians (PCPs) about their complex patients to investigate factors associated with PCPs' perceptions that they do not have enough time during visits.

METHODS: PCPs ($n = 199$) from a single, large integrated care delivery system were enrolled into one of two clinical trials (NCT02375932 and NCT02707146) designed to help complex patients prepare for upcoming visits. At study baseline, all physicians reviewed lists of their complex patients (including patients with recent admissions, multiple medications, uncontrolled diabetes, and new [<1 year] patients with care gaps) and completed a brief survey about managing these patients. Here we report physician and patient panel factors associated with physicians reporting not having enough time during visits with these patients. This outcome was dichotomized as "Never/rarely" vs. "Occasionally/often/always" and analyzed using chi-squared tests. We also investigated factors associated with physicians reporting whether they were able to get through all the items on their agenda during these visits.

RESULTS: Physician survey respondents (response rate 93%) had a mean age of 46.8 (±8.5) years, 18.9 (±9) years of clinical practice, and 64.3% were women. More than half of physicians ($n = 105$, 52.8%) reported that they never/rarely had enough time during visits with their complex patients. These physicians were more often women (57.8% vs. 43.7% men, $p = 0.06$), new to the medical group (<5 years, 64.2% vs. 48.6%, $p = 0.05$), and working less than full time (<80% time, 70.5% vs. 50%, $p = 0.09$). We found several significant differences in the complex patient panels reviewed. Physicians reporting that they rarely/never had enough time had a greater proportion of non-white (50.5% vs. 42.4%, $p < 0.01$) and female (53.5% vs. 45.6%, $p < 0.01$) patients. Counter to our expectation, their complex patients were less likely to be on multiple medications (% of panel with >=6 medications: 26.5% vs. 39.2%, $p < 0.01$) and had similar age distributions (% >65 years of age: 35.9% vs. 38.0%, $p = 0.25$). Despite perceived lack of time, only 12% of physicians (24/199) reported never/rarely getting through all their agenda items during visits. None of the examined provider or panel factors were significantly predictive of which providers had trouble getting through their visit agendas.

CONCLUSIONS: Our results provide further insight into the challenges faced by primary care physicians. Efforts to reduce primary care burn-out should include professional training to help PCPs, particularly newer ones, grapple with time management for their complex patients. Moreover, complex patients creating these time pressures may have issues and concerns that are not be readily identified by factors such as age or medication burden.

MEASURING PROFESSIONAL IDENTITY FORMATION EARLY IN MEDICAL SCHOOL: VALIDITY EVIDENCE. Adina Kalet[1, 3]; Hyuksoon Song[2, 3]; Lynn Buckvar-Keltz[1, 3]; Verna Monson[1]; Steven Hubbard[1]; Ruth Crowe[1, 3]; Rafael Rivera[1]; Sandra Yingling[4]. [1]New York University School of Medicine, New York, NY; [2]Georgian Court University, Lakewood, NJ; [3]New York University, New York, NY; [4]University of Illinois, Chicago, Chicago, IL. (Control ID #2701253)

BACKGROUND: An evidence-based approach to understand ethical medical professional identity formation (PIF) is needed. Scored by an expert, the Professional Identity Essay (PIE) produces a developmental stage (8 potential levels) based on a constructivist-developmental methodology developed in dental, law students and military officer trainees. We assessed the validity and utility of measuring baseline PIF in a professionalism curriculum and hypothesized that PIE stage would correlate with undergraduate humanities majors, subscores on admissions Multiple Mini Interviews (MMI), and DIT2 score, but would not correlate with gender, SES, URM status, age, MCAT scores, or GPA.

METHODS: During medical school orientation, all 132 entering medical students completed 1) the Professional Identity Essay (PIE) and 2) the Defining Issues Test (DIT2), a validated measure of moral reasoning. A trained expert (VM) scored narrative responses to seven prompts (Inter-rater ICC .83, 95% CI [.57 - .96], intra-rater ICC .85, 95% CI [.50 - .93]). The DIT2 N2 score reflects the proportion of the time students used universal ethical principles to justify a response to six moral dilemma cases. Students' reflections following a debriefing were content-analyzed. Admissions data was obtained for consenting students.

RESULTS: 129 students consented (57% women, mean age 23 (range 18–34, SD 1.7). Distribution of PIF stage scores was along 4 stages (2–3: 16 (12%), 3: 59 (45%), 3–4: 49 (37%) 4: 6 (4%)). DIT2 scores indicated a strong preference for post-conventional moral reasoning (N2) relative to moral justifications based on personal interest or maintaining norms, with a mean DIT2 N2 score of 54% (range 9.7%-76.5%). PIF stage as measured by the PIE was correlated with DIT N2, $\rho = .19$ ($p < .05$), MMI-Conflict Resolution, $\rho = .26$ ($p < .05$) and MMI-Team Work, $\rho = .22$ ($p < .05$), but no other admission variable. DIT N2 score and MMI-Responsibility were correlated $\rho = .18$ ($p < .05$). Content analysis of 130 students' reflective writing on PIE stage and DIT score report revealed mostly positive reactions to the PIF curriculum (117/130, 90%). Students with mixed negative reactions (28/130, 21%) reported confusion, concern about future training, or dissatisfaction with the gap between their self-perception and the results. Students who demonstrated an analytic approach to evaluating their feedback tended not to report negative reactions, even when they were surprised by the feedback.

CONCLUSIONS: A developmental evidence grounded measure of PIF is a feasible and acceptable part of a medical professionalism curriculum for entering medical students, distributes similarly to groups in other professional training programs and correlates with a validated measure of moral reasoning and admissions MMI stations that assess relevant constructs. This approach is acceptable and intriguing to our students and may be useful as an approach to competency-based professionalism curricula.

MEASURING SKILLS IMPROVEMENT FROM A SHARED DECISION MAKING WORKSHOP FOR INTERNAL MEDICINE INTERNS Fredrik Amell[1]; Ross Merkin[3]; Darlene LeFrancois[2]. [1]Montefiore, Greenwich, CT; [2]Montefiore Medical Center, Bronx, NY; [3]Montefiore, New York, NY. (Control ID #2700845)

BACKGROUND: Shared Decision Making (SDM) is a method of patient-doctor communication that provides a framework for resolving preference-sensitive decisions, i.e. those in which a treatment or test is neither obviously effective nor harmful, in terms of absolute risk. Effective use of SDM generates a treatment plan that is consistent with patient preferences. It contrasts with the more traditional model, in which the physician builds an argument supporting his or her professional opinion with minimal patient input, and also contrasts with the completely patient-driven model, in which patients are passively presented information and left to make a decision with minimal guidance. Evidence suggests that many patients prefer SDM, and that it increases both congruence between patient values and treatment decisions, as well as informed consumption of health care. Widespread utilization of SDM is hindered by a lack of training that yields both an appreciable improvement of individual physicians' SDM skill sets, as well as a corresponding change in daily clinical practice. The workshop utilized in this study targeted novice physicians during the most formative years of their training. It contrasts with prior workshops that targeted attending physicians who are less likely to assimilate SDM than those of novice physicians. The current workshop also utilized observed standardized clinical encounters (OSCEs) to challenge common misconceptions regarding clinical scenarios appropriate for utilizing SDM.

METHODS: Forty-five Post-Graduate Year-1 (PGY1) physician interns in the categorical Internal Medicine Residency Program at Montefiore Medical Center, Bronx NY, in groups of 8–10, attended a mandatory 2-hour workshop during their ambulatory block rotation from September 2015 through December 2016. The workshop was part of a series of several interactive sessions geared toward the practice of high value care. The principles of SDM were reviewed, and the implementation of SDM was practiced using SDM barrier identification, problem-solving and role-playing in a fishbowl configuration where the instructor played role of patient and interns took turns performing SDM steps. Pre- and post-workshop video-recorded standardized clinical encounters OSCEs were performed to quantitatively assess skills improvement. These data were analyzed by an SDM expert blinded to whether the OSCE was obtained pre- or post-seminar. OSCEs were graded using the SDM-q9 scoring system on a scale of 9 to 54 evaluating sum of points from risk-benefit discussion, preference elicitation and other key components of SDM. Data were analyzed using paired student t-test.

RESULTS: 29/48 (60%) of interns completed both pre and post workshop OSCEs, who demonstrated a 57% increase in SDM proficiency (pre-workshop SDM-q9: 28/54, post-workshop SDM-q9: 44/54, $p = 0.0001$).

CONCLUSIONS: Interactive SDM workshops can improve SDM skill sets in novice physicians. Further research required to assess retention and incorporation into actual practice.

MEDIA COVERAGE OF THE HEALTH EFFECTS OF MARIJUANA

Ann Abraham[4]; Sandy J. Zhang[4]; Uche Okoye[4]; Alexandra Woodbridge[4]; Rosa Ahn[2]; Deborah R. Korenstein[1]; Salomeh Keyhani[3, 5]. [1]Memorial Sloan Kettering Cancer Center, Pelham, NY; [2]Oregon Health and Science University, Portland, OR; [3]University of California at San Francisco, San Francisco, CA; [4]San Francisco VA Medical Center, San Francisco, CA; [5]San Francisco VA, San Francsico, CA. (Control ID #2700272)

BACKGROUND: There is little data on the harms or therapeutic benefits of marijuana. Despite the gap in evidence, there has been a decline in the public perception of the harms of marijuana use. News media are large contributors to the national perspective on marijuana. It is important to determine what the media is communicating about the health effects of marijuana to the general public.

METHODS: We identified relevant articles from publications in Pew's top ten newspapers by print circulation that had articles indexed on Lexis Nexis. These papers included: The New York Times, The Daily News New York, The New York Post, The Denver Post, USA Today, and the Los Angeles Times. We selected all articles published between 1/1/12 and 5/1/2016 (date the study was initiated), whose major subject was "marijuana". If more than 100 articles were available in this time period from a particular publication, we randomly selected 100. We excluded articles less than 200 words in length, opinion pieces, and focused on synthetic marijuana. One reviewer categorized each article into one of the following topic areas: health, business, public policy, crime, entertainment or other. If the article mentioned a health effect, a second reviewer extracted reported health benefits and harms and rated the overall impression the article communicated about the benefits vs. risks of marijuana. We used the following three categories to rate the overall message of each article: 1) the benefits of marijuana outweigh the harms; 2) the harms of marijuana outweigh the benefits and 3) neutral impression of the harms vs. benefits. We compared the message content of articles focused on health to compared to those not focused on health using descriptive statistics.

RESULTS: We identified 564 articles across publications; 84 were excluded leaving a final sample of 480 articles. Articles were categorized as follows: public policy ($n = 190$, 40.0%), crime ($n = 113$, 23.5%), business ($n = 74$, 15.4%), entertainment and celebrity news ($n = 69$, 14.4%), health ($n = 31$, 6.5%), and other ($n = 1$, 0.002%). Mentions of the health effects of marijuana were found about a third of articles ($n = 151$, 31.5%), of which 89 (58.9%) described health benefits of marijuana and 105 (69.5%) described risks. Overall about half of articles ($n = 79$, 52.7%) communicated a favorable impression of marijuana, 58 (38.7%) communicated a negative impression and 13 (8.7%) communicated a neutral impression. Of the 31 articles focused on health, 19.4% ($n = 6$) communicated a favorable impression compared to 60.8% ($n = 73$) of the 120 articles not focused on health (p-value $< .001$). Articles that were not focused on health were more likely to communicate a favorable impression of the harm vs. benefit profile of marijuana compared to articles primarily focused on health (OR 6.4 95% CI 2.37–17.29).

CONCLUSIONS: Despite a lack of robust evidence on the harms risks and benefits or marijuana, a majority of lay-press articles communicate a favorable impression of the health effects of marijuana.

MEDICAL CONTRAINDICATIONS TO ESTROGEN AND CONTRACEPTIVE USE AMONG WOMEN VETERANS: RESULTS FROM THE ECUUN STUDY

Colleen P. Judge[3]; Xinhua Zhao[2]; Maria K. Mor[2]; Florentina Sileanu[2]; Sonya Borrero[1]. [1]University of Pittsburgh and VA Pittsburgh, Pittsburgh, PA; [2]VA Pittsburgh, Pittsburgh, PA; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA. (Control ID #2687727)

BACKGROUND: Women Veterans have high rates of medical comorbidities, many of which are contraindications to estrogen-containing combined hormonal contraception (CHC). Contraindications to CHC may impact eligibility for and use of effective contraceptive methods. We aimed to describe the prevalence of contraindications to CHC among women Veterans at risk for unintended pregnancy, and to characterize the relationship between contraindications and contraceptive use.

METHODS: We analyzed data from the Examining Contraceptive Use and Unmet Need Among Women Veterans (ECUUN) study, a telephone-based survey with a national sample of 2,302 women Veterans ages 18–45 who received primary care at the VA in the last year. This analysis includes women at risk for unintended pregnancy, defined as heterosexually active within three months prior to interview, not currently pregnant or trying to conceive, and with no history of hysterectomy or infertility. Seven conditions representing relative or absolute contraindications to CHC were examined: hypertension, stroke, thromboembolism, coronary artery disease, breast cancer, migraine with aura, and smoking in women over 35 years old. The primary outcome was contraceptive use in the month prior to interview. Women were classified as using no method, CHC methods (pill, patch, ring), non-CHC prescription methods (IUD, implant, Depo-Provera, sterilization) or non-prescription methods (barrier methods, withdrawal, natural family planning). Multivariable logistic regression was used to assess the relationship between contraindications to CHC and contraceptive non-use as well as CHC use among contraceptors, while controlling for age, race/ethnicity, marital status, education, income, insurance and parity.

RESULTS: Of 1169 women Veterans at risk for unintended pregnancy (mean age 33.9 years), 25% had at least one medical contraindication to CHC. The most prevalent conditions were hypertension (15%), smoking in women over 35 (7%) and history of thromboembolism (3%). Eighty-eight percent reported contraceptive use in the past month: 22% used CHC methods, 50% non-CHC prescription methods, and 16% non-prescription methods. Women with contraindications to CHC were more likely to report contraceptive non-use in the past month than were women without contraindications (16% vs. 10%, $p =$ 0.004; adjusted OR [aOR]:1.74, 95% CI:1.14, 2.66). Among 1034 women using any contraception, women with contraindications were less likely to report CHC use than women without contraindications (17% vs. 27%, $p =$ 0.001; aOR:0.68, 95% CI:0.45, 0.99).

CONCLUSIONS: In a national sample of women Veterans at risk for unintended pregnancy, women with medical contraindications to CHC were less likely to use CHC methods, but were also more likely to report contraceptive non-use. These findings suggest appropriate medical screening for CHC use in VA healthcare settings, but also draw attention to an important gap in contraceptive care for women Veterans with medical comorbidities.

MEDICAL RESIDENTS WORKING WITH VULNERABLE PATIENTS IMPROVE THEIR PSYCHOSOCIAL SKILLS: A SWISS PILOT STUDY. Pau MOTA. University of Lausanne (Switzerland), Lausanne, Switzerland. (Control ID #2701875)

BACKGROUND: Scientific literature has shown that patients at high risk of vulnerability are involved in more health care use and in more encounters, which are perceived as difficult by physicians (1–2). Physicians involved in difficult encounters denoted worse psychosocial orientation practice (1–3). Medical residents are usually not trained for dealing with socioeconomic challenge after their medical degree, and physicians who experience many of their patients as difficult are more likely to end in burnout (2–6). This study aims to take advantage of a specific setting, the outpatient clinic at the University of Lausanne, in Switzerland, a university outpatient primary care clinic, in which medical residents frequently work with patients holding high levels of vulnerability (in 2015, more than 20% of encounters in the primary care clinic were patients with no insurance or depending on social welfare). The main objective of this study was to assess the medical resident beliefs about psychosocial aspects of health care, both before and after working in a university setting dealing with patients at high socioeconomic risk.

METHODS: This is a prospective study with a 6 months follow-up. To assess medical resident beliefs about psychosocial aspects of health care we used the Physician's Belief Scale (PBS). PBS is a validated questionnaire of 32 items designed to assess the importance given by the psychosocial care to the dimension in the therapeutic process (7). We compare the PBS score of medical residents both before and after having worked 6 months in the outpatient clinic.

RESULTS: All the new medical residents were included ($n = 11$). Mean age 32.4 years (+/− 3.3 sd). 7 women and 4 men. Mean of years of training 5.3 years (+/− 1.1 sd). After 6 months, we observed a decrease on the global PBS score mean from 79.5 to 76.4 ($p = 0.47$ using a Wilcoxon rank sum test). If we analyse by gender group, we observe a PBS score decrease for women (from 75.8 to 69.8) and an increase for men (from 85.75 to 87.7). Indeed, after six months we observed that the differences between genders tended to be significant, which was not the case at enrolment ($p = 0.10$ vs. $p = 0.44$). A second wave of medical new residents ($n = 16$) is currently under study (final results are expected in march-april 2017), with which we will be able to extend the sample size to a total of 27 to perform a similar analysis.

CONCLUSIONS: We observe an improvement of the medical residents PBS score after 6 months working with patients in socio-economical adversity. Even though the observed differences are not statistical significant, probably due to the small sample size, we could conclude that working with patients in socioeconomical adversity improve the medical residents' beliefs about psychosocial aspects of health care, and that there may be gender differences in this improvement.

MEDICAL STUDENTS ON INTERNATIONAL MEDICAL TRIPS: EVALUATING THE INFLUENCE OF EXPERIENTIAL LEARNING ON CLINICAL SELF-EFFICACY AND KNOWLEDGE Alexandra Strauss[1]; Hugo Narvarte[2]. [1]University of South Florida, Tampa, FL; [2]University of South Florida Morsani College of Medicine, Tampa, FL. (Control ID #2707483)

BACKGROUND: Previous studies have documented an association between international health experiences and positive educational influences on participants' knowledge, skills, and attitudes. However, the international health experiences studied were all of several weeks duration. Many medical schools participate in shorter duration international health experiences but little evidence exists regarding the effectiveness of such trips on educational outcomes. This study sought to evaluate the educational impact of a one-week international medical trip.

METHODS: The training experience was a one-week international health experience in Jarabacoa, Dominican Republic, consisting of medical students from a southeastern university. A training expert was consulted to apply principles of experiential learning theory to the educational experience. Students were surveyed before and after the health experience regarding clinical self-efficacy and educator self-efficacy, and tested on relevant medical knowledge.

RESULTS: Paired-sample t-test results demonstrate significant improvements across all targeted objectives. Clinical self-efficacy increased significantly (pretest M = 3.71, SD = 0.95; posttest M = 4.24, SD = 0.62); t(31) = 5.69 ($p < .001$, CI95 0.33, 0.71) as did student self-efficacy regarding ability to educate patients on various diagnoses (pre-test M = 3.52, SD = 0.96; posttest M = 4.26, SD = 0.69); t(31) = 6.81 ($p < .001$, CI95 0.51, 0.95). Furthermore, medical knowledge of trained and experienced topics significantly increased (pretest M = 68.10, SD = 12.34; posttest M = 73.83, SD = 16.68); t(31) = 2.43 ($p = .02$, CI95 0.93, 10.53), whereas there was no change in non-targeted medical topics.

CONCLUSIONS: Brief international health experiences in combination with a focused preceding curriculum can have significant educational value based upon measures of medical knowledge and self-efficacy; and thus, can be a positive complement to conventional medical school curricula. We speculate that this effect occurs because of the intensive and focused nature of the clinical experience consistent with experiential learning theory.

MEDICALLY TAILORED MEAL DELIVERY FOR DIABETES PATIENTS WITH FOOD INSECURITY: A RANDOMIZED CLINICAL TRIAL

Seth A. Berkowitz[1]; Linda M. Delahanty[2]; Jean Terranova[3]; Andrea Pyke[3]; Deborah J. Wexler[2]. [1]MGH, Boston, MA; [2]Massachusetts General Hospital, Brookline, MA; [3]Community Servings, Boston, MA. (Control ID #2688398)

BACKGROUND: Food insecurity, inconsistent food access owing to cost, leads to poor health for patients with diabetes, but clinicians currently have few treatment options. We tested the feasibility of medically-tailored meal delivery (MTM). We hypothesized that MTM would improve the Healthy Eating Index 2010 (HEI) dietary quality score. Higher HEI scores are associated with improved glycemic control and reduced diabetes complications.

METHODS: In preliminary results for the Community Servings: Food as Medicine for Diabetes randomized clinical trial (NCT02426138), 29 adults (age > 18 years) with hemoglobin A1c > 8.0% who reported food insecurity (using the 2-item 'hunger vital sign') were enrolled between June 2015 and October 2016. The intervention was home delivery of freshly prepared medically tailored (by a registered dietitian) meals, from Community Servings, a non-profit organization. We used a randomized crossover design, randomly assigning the order of 'on-meals' (10 meals/week delivered for 12 weeks) and 'off-meals' (12 weeks usual care and a Choose MyPlate healthy eating brochure). HEI was assessed by three 24-hour food recalls in both the 'on-meals' and 'off-meals' periods, averaged, and adjusted for baseline HEI score. Higher total HEI score (range: 0–100) and higher sub-category scores (range: 0–5, 0–10, or 0–20) represent 'better' dietary quality. A difference of 5 points in total HEI score is clinically significant. Linear mixed models accounted for repeated measures in the analysis.

RESULTS: Participants were 69% female and had a mean age of 57.8 (SD 12.1) years. Sixty-six percent were non-Hispanic white, 24% were non-Hispanic black, and 10% were Hispanic. Over 50% had Medicaid insurance. The intervention led to large and statistically significant improvements in the mean total HEI score (69.4 when 'on-meals' and 37.5 'off-meals'; $p < .0001$), and for most sub-categories (Table).

CONCLUSIONS: Home delivery of medically tailored meals substantially improved dietary quality for food insecure patients with diabetes. Longer-term studies should evaluate the effect of MTM on clinical outcomes.

Healthy Eating Index Results

	On Meals	Off Meals	*P*
HEI Total (0–100)	69.4	37.5	<.0001
HEI 1: TOTAL VEGETABLES (0–5)	4.4	2.5	<.0001
HEI 2: GREENS AND BEANS (0–5)	3.7	0.4	<.0001
HEI 3: TOTAL FRUIT (0–5)	3.3	1.3	0.0003
HEI 4: WHOLE FRUIT (0–5)	3.7	1.3	0.0002
HEI 5: WHOLEGRAIN (0–10)	4.6	1.5	0.0007
HEI 6: TOTAL DAIRY (0–10)	5.5	4.6	0.27
HEI 7: TOTAL PROTEIN (0–5)	4.7	3.8	0.006
HEI 8: SEAFOOD AND PLANT PROTEIN (0–5)	3.4	1.4	0.0003
HEI 9: LESS FATTY ACIDS (0–10)	7.5	4.2	0.0003
HEI 10: LESS SODIUM (0–10)	1.7	2.9	0.14
HEI 11: LESS REFINED GRAIN (0–10)	8.8	6.1	0.001
HEI 12: FEWER 'EMPTY' CALORIES (0–20)	18.0	7.6	<.0001

Score range in parentheses.

Higher score represents 'better' consumption for all categories (e.g. a higher empty calories score represents lower consumption of 'empty' calories)

MEDICARE ADVANTAGE BENCHMARKS, BIDS, AND REBATES BEFORE AND AFTER THE AFFORDABLE CARE ACT

Zirui Song. Massachusetts General Hospital, Boston, MA; Harvard Medical School, Boston, MA. (Control ID #2707566)

BACKGROUND: To slow the growth of Medicare spending, changes to Medicare financing are increasingly debated. Some policymakers propose reforming Medicare from a traditional defined benefit to a fixed government contribution per beneficiary. This approach would build on the Medicare Advantage (MA) program, in which private insurers compete to administer the Medicare benefit to seniors. A third of Medicare beneficiaries are now in MA, yet little is known about the impact of federal payments to MA plans (the "benchmark") on the plans' pricing decisions (the "bid") for seniors. In 2012, MA payment rates nationwide changed under the Affordable Care Act (ACA). This study evaluates the impact of changes in plan payments on plan pricing decisions and, in turn, their implications for the benefits that beneficiaries in MA receive.

METHODS: This study used 2006–2014 MA plan payment data from the Centers for Medicare and Medicaid Services. All local plans that submit prices under the competitive bidding system in MA, including special needs plans, were included. Employer group waiver plans and regional PPO plans were excluded. This study examined the impact of changes in the benchmark on plan bids and beneficiary rebates across the time period, as well as before and after the ACA, using a longitudinal multivariable model at the county and plan level, controlling for characteristics of the market, coding intensity, contract type, and secular trend. It was also weighted by beneficiary enrollment. The benchmark, bid, and rebate were all risk-standardized to reflect a beneficiary of 1.0 risk.

RESULTS: The growth in MA benchmark payments before the ACA slowed in the years after the ACA. Across the study period, for every $1 change in the MA benchmark payment, MA plans changed their bids by an average of $0.58 in the same direction ($p < 0.001$), consistent with imperfect competition in the MA market and incomplete pass-through of federal payments or cuts to beneficiaries. In the years after the ACA, this bid response was on average $0.70 ($p < 0.001$), suggesting that the MA market was less competitive in the

later years relative to the earlier years. Plans with higher benchmark payments lowered their bids more than plans receiving lower benchmark payments, thereby buffering the decrease in rebates faced by beneficiaries.

CONCLUSIONS: After passage of the ACA, private plans in Medicare on average lowered their bids in response to decreases in federal payments. This lessened the decrease in rebates faced by beneficiaries, potentially explaining the continued growth in MA enrollment after the ACA. Competition in the MA market remained imperfect and appeared to have decreased after the ACA. As debate over the reform of the entire Medicare program towards a competitive bidding ("premium support") system intensifies, these national findings on the effect of federal payments on plan pricing and its implications for beneficiary rebates and enrollment may serve as a useful guide for policymakers and the public.

MENTAL HEALTH AND ACCULTURATION IN FIRST GENERATION CHINESE AMERICAN IMMIGRANTS IN NEW YORK CITY: A CONTEMPORARY CROSS-SECTIONAL ANALYSIS Helen Ma[3]; Martin C. Fried[1]; Johanna Hase[2]; Rachael Hayes[2]; Aiyi Zhang[2]; Colleen C. Gillespie[2]. [1]NYU, Astoria, NY; [2]NYU School of Medicine, New York, NY; [3]New York University, New York, NY. (Control ID #2704867)

BACKGROUND: Chinese Americans represent the fastest growing immigrant population in the United States, and they face unique mental health challenges. To best care for this population internists should understand the effects of acculturation, defined as the change that occurs when an ethnic minority encounters a dissimilar dominant culture. The relationship between acculturation and mental health is complex. We sought to describe this relationship in Chinese immigrants currently living in New York City.

METHODS: We analyzed data from the Chinese American Cardiovascular Health Assessment, a cross-sectional survey of foreign-born Chinese adults living in New York City ($n = 2071$). Primary outcomes included depression, stress and physical symptoms, and the primary exposure was acculturation. Rates of depression, stress, and physical symptoms were surveyed using validated tools. Acculturation was evaluated using the Stephenson Multigroup Acculturation Scale, which is an assessment of both ethnic and dominant society immersion (ESI and DSI). Mean acculturation, depression and stress scores were stratified by demographics. Differences were assessed using one-way ANOVA analysis.

RESULTS: Our population was generally middle-aged, well-educated, and employed. Younger age, female gender, shorter duration of residence in the US, single marital status and poor perceived health were associated with higher rates of depression and stress. Overall the cohort was more acculturated to China (average ESI 3.67 out of 4) than America (DSI 2.11 out of 4). Participants who were depressed had lower acculturation to ethnic society compared to those without depression (ESI 3.59 vs ESI 3.67, $p = 7.13e\text{-}5$). This difference was not seen when comparing acculturation to dominant society in depressed vs not depressed participants (DSI 2.08 vs DSI 2.11, $p = 0.53$). Higher levels of stress were associated with lower acculturation to both ethnic (ESI 3.62 vs 3.67, $p = 0.003$) and dominant cultures (DSI 2.0 vs 2.12, $p = 0.002$). Participants with depression and stress were more likely to have physical symptoms and lower self-rated health.

CONCLUSIONS: We performed a descriptive analysis of Chinese immigrants living in NYC to characterize the interaction between acculturation, depression and stress. We observed that depressed participants had lower acculturation to their ethnic society, but not dominant society, perhaps suggesting a protective effect of connection to one's home society. Future mental health interventions may target patients with low acculturation by increasing access to community events, employing Chinese community health workers, or leading group visits to targeted groups. This study is consistent with prior research demonstrating a relationship between physical symptoms and mood in Chinese immigrants. Internists should consider physical symptoms as potential indicators of underlying mood disorders in this underserved population, as early identification may lead to improved diagnosis and treatment.

MODELING PATIENT COST SAVINGS FROM ELECTRONIC CONSULTATIONS Scott Shipman; Karen Jones. Association of American Medical Colleges, Washington, DC. (Control ID #2707536)

BACKGROUND: Healthcare costs borne by patients are an insufficiently addressed aspect of patient care and high value healthcare models should strive to reduce these costs. Recent research highlights the significant time burden and opportunity costs to patients obtaining ambulatory healthcare. Referrals to specialty providers have increased dramatically, with substantial cost and access implications for patients. Some health systems have introduced an innovative alternative, electronic consultations (eConsults), which provide a high-reliability mechanism for primary care physicians to receive timely input from specialists. The eConsult often averts the need for a referral and subsequent in-person specialty visit(s). We sought to estimate the patient savings enabled by eConsults.

METHODS: Expenses associated with specialty office visits include out-of-pocket medical costs, transportation, childcare, etc. We calculated average out-of-pocket patient expense for adult specialty visits and estimated transportation costs using published travel times. Opportunity costs for adult specialty visits were derived using published ambulatory visit times and the 2015 median hourly wage to value the patient's time in foregone activities. For patients 65 and over, the comparable retiree wage was used. Since one in ten of older adults are accompanied to ambulatory visits by adult children we estimated the additional costs for that subgroup. We used our opportunity cost estimates to assess the potential overall patient savings in an eConsult model of care. Using the midpoint from earlier research showing that eConsults can substitute for 8–20 percent of specialty visits, we applied the cost per visit to the specialty visits averted.

RESULTS: The mean out-of-pocket cost for specialty visits was $36, travel costs were $12, and opportunity costs were $37. Combining direct and indirect costs, we estimate $85, $65, and $104 for adults under age 65, over 65 (alone) and over 65 (accompanied) respectively. Of the 105 million ambulatory visits resulting in referrals in 2009, 57.8 million or more were from primary care providers. eConsults could have replaced 8.1 million of those referrals, resulting in savings to patients of over $657 million.

CONCLUSIONS: eConsults that avert a specialty visit represent a considerable savings to patients, particularly when opportunity costs are considered in addition to direct costs. This is a conservative estimate, since we have considered only the minimum of direct expenses. Further, as initial specialty referrals leads to multiple visits over time, there are added savings to patients that accrue. Unnecessary specialty visits are costly to patients and impede access to care for those who require in-person care. eConsults represent a promising innovation to improve timeliness of specialist input while reducing costs of care.

MODIFIABLE COMMUNICATION FACTORS CONTRIBUTING TO HOSPITAL READMISSION RATES FOR AFRICAN AMERICAN PATIENTS IN PRIMARY CARE Jessica Valente; Natrina Johnson; Ugo Edo; Leah S. Karliner. UCSF, San Francisco, CA. (Control ID #2704445)

BACKGROUND: Many interventions have been developed to facilitate patients' transitions from the hospital back to primary care. However, disparities remain in readmission rates for vulnerable populations, including a 34% higher readmission rate for African American patients from our urban academic general medicine practice. We set out to identify modifiable factors contributing to higher readmission rates for this group.

METHODS: We recruited self-identified African American patients receiving primary care in our general medicine practice who were discharged from Medicine or Cardiology services at our tertiary care hospital between 7/2013 - 6/2014 to participate in semi-structured individual interviews. Interview transcripts were coded by two researchers using both inductive and deductive coding to identify modifiable factors contributing to high readmission rates.

RESULTS: After excluding those who had died and those whose primary care provider (PCP) preferred patient not be contacted, we identified 100 eligible patients, and interviewed 24. Thirteen (54%) had multiple admissions during the study period. Five major themes emerged: 1) Importance of continuity with a single PCP (Patient only sees cardiologist: "because too many different primary care providers, they don't do anything"), 2) Impact of patient-provider relationship ("just that ear to listen to you and literally give you constructive criticism or a solution to something is so refreshing to get sometimes. And so to get that in my life, she [PCP] was right on time, because I didn't have that outlet."), 3) Deficiencies in the discharge process (Patient unexpectedly discharged after procedure was postponed: "It was a nurse saying, 'You're gonna be leaving' after starving me all day"), 4) Obstacles to disease self-management (Patient admitted for hyperglycemia: "I was making an aggressive attempt to lose weight…then I made the mistake of getting these juices, thinking that they would curb appetite, not realizing that they had all this sugar in them."), and 5) Coordination across settings (Patient closely followed by outpatient GI: "I think if the [inpatient team] talked to my GI [doctor], they would have said, hey, this is what we usually do and the protocol. Because that's what they deal with").

CONCLUSIONS: Our interviews revealed the importance of different aspects of communication for successful discharges and readmission prevention for this vulnerable population, including building strong continuity relationships and listening skills in primary care, enhancing information-sharing between settings, improved self-management education, and adequate preparation for discharge. Our next step is to develop systems-based interventions focused on these communication areas.

MORTALITY AFTER NONFATAL OPIOID OVERDOSE: MEDICATIONS FOR OPIOID USE DISORDER ARE ASSOCIATED WITH LOWER RISK Marc Larochelle[2]; Dana Bernson[3]; Thomas Land[3]; Thomas Stopka[4]; Alexander Y. Walley[1]. [1]Boston Univ, Boston, MA; [2]Boston University School of Medicine and Boston Medical Center, Boston, MA; [3]Massachusetts Department of Public Health, Boston, MA; [4]Tufts University School of Medicine, Boston, MA. (Control ID #2706600)

BACKGROUND: Methadone, buprenorphine, and naltrexone are approved medications for opioid use disorders (MOUD) that reduce opioid craving and use, and increase opioid abstinence in randomized controlled trials. MOUD are associated with improved survival in observational studies. People who survive an opioid overdose are at high risk for subsequent fatal opioid overdose; however, the mortality benefit from MOUD among overdose survivors is not known. We hypothesized MOUD would be associated with reduced risk of opioid-related and all-cause mortality.

METHODS: We conducted a retrospective cohort study of Massachusetts residents ages 11 years and older who experienced a nonfatal opioid overdose in 2013–2014. We used individually linked state-based data from ambulance encounters, hospital treatment, the prescription monitoring program, substance use treatment programs, all payer claims, and death records. Nonfatal opioid overdose was identified from ambulance encounters with evidence of opioid overdose using a natural language processing algorithm, and from emergency department and inpatient encounters with ICD-9 codes for opioid poisoning. We examined the number and proportion of individuals who subsequently received MOUD defined as treatment in a methadone maintenance program, receipt of buprenorphine, or receipt of naltrexone in each month. We examined time to opioid-related and all-cause mortality, censoring for the end of the study period or, for opioid-related mortality, death due to another cause. We used a multivariable Cox proportional hazards model with MOUD as the monthly time varying predictor of interest. We controlled for age, sex, and receipt of prescription opioids or benzodiazepines as monthly time varying covariates.

RESULTS: We identified 11,438 individuals who survived an opioid overdose. 7,092 (62%) were male; 1,411 (12%) were between 11 and 24 years of age, 5,907 (52%) were between 25 and 44 years of age, and 4,120 (36%) were 45 years of age or older. Over a median follow-up of 10 months, 2,642 (23%) people received MOUD in one or more months [693 (6%) received methadone, 1,672 (15%) buprenorphine, 624 (5%) naltrexone]. Opioid-related mortality was 2% ($n = 240$), and all-cause mortality was 6% ($n = 649$). Compared to not receiving MOUD in a given month, receipt of MOUD was associated with a decreased risk of opioid-related mortality (adjusted hazard ratio (AHR): 0.2 [95% confidence interval (CI): 0.1–0.6]) and all-cause mortality (AHR: 0.3 [95% CI: 0.2–0.5]).

CONCLUSIONS: A minority of individuals received MOUD following nonfatal opioid overdose; however, MOUD was associated with a 70% reduction in all-cause mortality, and an 80% reduction in opioid-related mortality. Efforts to link and engage overdose survivors with MOUD may substantially improve survival and warrant study in prospective controlled trials.

MULTIMORBIDITY AND LONG-TERM DECLINE IN PHYSICAL FUNCTIONING AND ACTIVITIES OF DAILY LIVING AMONG OLDER ADULTS Melissa Y. Wei[2, 3]; Mohammed U. Kabeto[2]; Kenneth Mukamal[1]; Kenneth M. Langa[2, 3]. [1]Beth Israel Deaconess Medical Center/ Harvard Medical School, Boston, MA; [2]University of Michigan, Ann Arbor, MI; [3]Institute for Healthcare Policy and Innovation, University of Michigan, Ann Arbor, MI. (Control ID #2703648)

BACKGROUND: Multimorbidity is highly prevalent in the general population, particularly among older adults, but its optimal quantification and associations with long-term physical functioning and disability are uncertain. We aimed to quantify the associations of multimorbidity with future physical functioning and activity limitations using a newly developed and validated comprehensive multimorbidity-weighted index

(MWI) that weights 81 chronic conditions by current physical functioning, a universally-valued and patient-oriented outcome, in community-dwelling adults.

METHODS: The Health and Retirement Study (HRS) is a nationally-representative longitudinal cohort of >38,000 adults aged ≥51 years followed since 1992. In 2000, participants were interviewed about physician-diagnosed chronic conditions, from which their MWI was computed. In 2010, participants reported their physical functioning using a modified Short Form-36 physical functioning scale (range 0–100) and number of limitations with activities of daily living (ADLs, range 0–5) and instrumental activities of daily living (IADLs, range 0–6) limitations. We included participants with complete follow-up through 2010. The MWI was examined as a continuous and categorical variable. With baseline MWI as the exposure, we used multivariate linear regression to measure the longitudinal association with continuous physical functioning and the number of ADL and IADL limitations over 10-year follow-up. All models were adjusted for age, sex, race/ethnicity, and education.

RESULTS: There were 18,519 eligible respondents in the 2000 interview after excluding 93 (0.5%) adults missing ≥1 chronic condition variables. After 10-year follow-up, 6403 (34.5%) died, and 1256 (6.8%) were lost to follow-up. The final sample included 10,860 participants with a mean ± SD age of 66.6 ± 10.4 years. At baseline, participants had a weighted mean ± SD MWI of 4.9 ± 4.8, and 0.50 ± 1.2 ADL and 0.32 ± 0.95 IADL limitations. After follow-up, participants with the highest quartile MWI had 0.88 ADL limitations (95%CI: 0.74-1.01) and 0.46 IADL limitations (95%CI: 0.37–0.55), while those in the lowest quartile had 0.15 (95%CI: 0.11–0.20) ADL limitations (all $p < 0.001$) and no significant IADL limitations. Physical functioning declined by −28.6 (95%CI: −30.8, −26.4) for those in the highest versus lowest quartile MWI (−10.1, 95%CI: −11.4, −8.7) (both $p < 0.001$). There was a dose–response association between increasing MWI quartiles with physical functioning decline and number of ADL and IADL limitations.

CONCLUSIONS: In this nationally-representative cohort, a multimorbidity index weighted to current physical functioning was strongly associated with long-term decline in physical functioning and greater ADL and IADL limitations, with more than a doubling in those with the greatest MWI. Multimorbidity has profound associations with future physical functioning that are easily captured with a readily-measured index that can target older adults at higher risk for functional decline and disability.

MULTIMORBIDITY AND PHYSICAL AND COGNITIVE FUNCTION IN NATIONALLY-REPRESENTATIVE US ADULTS: PERFORMANCE OF A NEW MULTIMORBIDITY-WEIGHTED INDEX Melissa Y. Wei[2, 2]; Mohammed U. Kabeto[2]; Kenneth M. Langa[2, 2]; Kenneth Mukamal[1]. [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]University of Michigan, Ann Arbor, MI. (Control ID #2703266)

BACKGROUND: Multimorbidity is currently one of the greatest challenges facing patients and providers, but its quantification remains challenging. We recently developed a new multimorbidity-weighted index (MWI) that weights 81 chronic conditions by their impact on physical functioning in community-dwelling adults. We now assess its association with subjective and objective physical and cognitive outcomes in an independent, nationally-representative cohort of US adults.

METHODS: The Health and Retirement Study (HRS) is an ongoing, nationally-representative longitudinal cohort of ≥51 year-old US adults. In 2010, participants completed an interview on physician-diagnosed chronic conditions and physical functioning items adapted from the Short Form-36 physical functioning scale. We used multivariable linear regression to obtain coefficients for 16 chronic conditions on physical functioning and used Pearson's correlation coefficient and the Kappa statistic to validate the weights of the original, independently-derived MWI. We then used multiple linear regression to determine the association between the original MWI (continuous and quartiles) and continuous measures of grip strength (kg), gait speed (m/s), basic and instrumental activities of daily living (ADL/IADL) limitations, and cognitive performance using the modified Telephone Interview for Cognitive Status (TICS-m). All models were adjusted for age, sex, race/ethnicity, body mass index, smoking status, education, and household net worth.

RESULTS: Among 20,805 eligible participants, 184 (0.9%) missing ≥1 health conditions were excluded, leaving a final sample of 20,621 adults with a mean ± SD age of 67 ± 9 years. Associations between chronic conditions and physical functioning varied several-fold (median coefficient 7.0, range 2.0-25). MWI values based on weightings observed in the HRS and the original published cohorts were highly correlated (Pearson's r = 0.92) and had a classification agreement of 85 and Kappa statistic of 0.80 ($p < 0.0001$). The mean ± SD MWI was 5.2 ± 4.6. Participants in the highest quartile of MWI had decreased grip strength (−2.91 kg, 95%CI: −3.51, −2.30), slower gait speed (0.11 m/s, 95%CI: 0.06, 0.15), a greater number of ADL (0.79, 95%CI: 0.71, 0.87) and IADL (0.49, 95%CI: 0.44, 0.55) limitations, and decreased TICS-m score (−0.59, 95%CI: −0.77, −0.41) in adjusted models compared with the lowest quartile MWI (all $P < 0.001$). We observed a graded relationship for all outcomes with increasing MWI quartiles.

CONCLUSIONS: A multimorbidity index weighted to physical functioning performed nearly identically in a nationally-representative independent cohort of adults as it did in its original development cohorts, confirming its broad generalizability. In this independent cohort, MWI was strongly and consistently associated with subjective and objective physical and cognitive performance. Thus, the MWI appears to be a valid measure of multimorbidity in US adults.

MULTIPLE RISK FACTOR COUNSELING TO PROMOTE HEART-HEALTHY LIFESTYLES IN THE CHEST PAIN OBSERVATION UNIT: PILOT RANDOMIZED CONTROLLED TRIAL David A. Katz[1, 1]; Mark Graber[1]; Patricia Lounsbury[2]; Mark Vander Weg[1, 1]; Philip Horwitz[1]; Xueya Cai[3]; Alan Christensen[1]. [1]University of Iowa, Iowa City, IA; [2]University of Iowa Hospital and Clinics, Iowa City, IA; [3]University of Rochester Medical Center, Rochester, NY. (Control ID #2707528)

BACKGROUND: Admission to the chest pain observation unit (CPOU) may be an advantageous time for patients to consider heart-healthy lifestyle changes while undergoing diagnostic evaluation to rule out myocardial ischemia. The aim of this pragmatic trial was to assess the effectiveness of a multiple risk factor intervention in changing CPOU

patients' health beliefs and readiness to change health behaviors. A secondary aim is to obtain preliminary estimates of the intervention's effect on diet, physical activity, and smoking.

METHODS: We conducted a pilot randomized controlled trial (RCT) of a moderate intensity counseling intervention in 140 adult patients with at least one modifiable cardiovascular risk factor (CRF) who were admitted to the CPOU of an academic emergency department (ED) with symptoms of possible acute coronary syndrome (ACS). Study patients were randomly assigned to full counseling (face-to-face cardiovascular risk assessment and personalized counseling on nutrition, physical activity, and smoking cessation in the ED, plus two telephone follow-up sessions) or minimal counseling (brief instruction on benefits of modifying cardiovascular risk factors (<5 min) and informational handout) by a cardiac rehabilitation specialist. We measured Health Belief Model constructs for ischemic heart disease, stage of change, and self-reported CRF-related behaviors during 6-month follow-up using previously validated measures. We used linear mixed models and logistic regression (with generalized estimating equations) to compare continuous and dichotomous behavioral outcomes across treatment arms, respectively.

RESULTS: In both treatment arms combined, patients showed significant increases in the perceived benefits of improving CRF-related behaviors (27.7 vs. 26.6, $p = .0001$) and increased readiness to change dietary behavior and PA during follow-up: intake of saturated fat (83 vs. 49%), fruit and vegetable consumption (83 vs 56%), and regular exercise (34 vs. 14%) at 6-months and baseline, respectively ($p < .0001$ for all comparisons). Although roughly 20% more patients in the full counseling arm reported having received counseling on diet and physical activity during CPOU admission, there were no significant differences between treatment arms for any cardiovascular health beliefs, stages of change, or CRF-related behaviors during longitudinal follow-up.

CONCLUSIONS: Patients admitted to the CPOU demonstrate sustained changes in several cardiovascular health beliefs and risk-related behaviors during follow-up; this provides further evidence that the CPOU visit is a "teachable moment" for cardiovascular risk reduction. A multiple risk factor intervention that aimed to build motivation to change and problem-solving skills did not significantly improve behavioral outcomes, compared to minimal counseling. Future studies should evaluate more intensive ED-initiated counseling interventions to engage patients in changing cardiovascular risk behaviors, in coordination with primary care.

MUSIC TO MY EARS: BRIGHTENING THE DAYS OF HOSPITALIZED PATIENTS Feifei Xue; Scott Wright. jhusom, Baltimore, MD. (Control ID #2706698)

BACKGROUND: For most people, listening to music is pleasurable. This act can serve as a calming influence, it can be a satisfying distraction, and it is capable of lifting low spirits. Hospitalized patients may experience boredom, fear, and unease; these emotions may be related to both the acute illness and missing the comforts of home. In an attempt cheer up hospitalized patients and to connect them with a preferred experience from their past, we designed a brief intervention that would bring the gift of music to their hospital room. A priori, we hypothesized that such an intervention might serve to upgrade their mood and minimize their awareness of pain.

METHODS: This pilot study assessed the impact of an intervention that was delivered to 151 hospitalized adult patients that were admitted to a general medicine wards at a large academic hospital in Baltimore. After consenting to participate, the patients were asked a series of questions, including the modified HADS (Hospital Anxiety and Depression Scale), a validated pain scale (that uses response options along a 10-point Likert-scale), and assessments of their appreciation of music. Following this data collection, subjects selected 1 or 2 songs of their choice for their listening enjoyment. These favorite songs were played from an internet-based library (Spotify) and delivered through noise-cancelling headphones, uninterrupted for the length of the track. Mood and pain were reassessed immediately after listening to this music session; paired t-tests were used to assess for differences in scores.

RESULTS: A majority of the patients studied were female ($n = 86$, 57%), and their mean age was 57 years. Two thirds of patients were Caucasian (64%), and 51 patients were African American. Ninety percent of patients reported listen to music in their free time, and 89% of patients explained that they enjoy listening to music when they are alone. The patients' modified HADS score (−4.99, standard error [SE] = 0.45, $p < 0.0001$) and pain score (−0.72, SE = 1.51, $p < 0.0001$) were both significantly decreased after listening to a couple of their favorite songs. The 2 most frequently requested songs were "Sangria" by Blake Shelton, and "My Heart Will Go On" by Celine Dion. The genre of music that were selected with the greatest frequency were Rock ($n = 28$) and Country ($n = 28$). All patients (100%) enjoyed the music session. Spontaneous comments were recorded from patients and 2 representative quotes are shown here: "You truly made my day. I love that song and haven't heard it in so long", and "That was such nice treat. You should have been here the day when I was really sick; I could have used some music then."

CONCLUSIONS: This study demonstrates that bringing music to hospitalized patients and encouraging them to listen to their favorite songs are genuinely appreciated. If this intervention can enhance moods and reduce pain for patients in the hospital, directing resources to make it sustainable may be justified.

NATIONAL TRENDS IN MEDICAL COMPLEXITY OF ADMITTED EMERGENCY DEPARTMENT ADULT PATIENTS FROM 2009–2013 Matthew Basciotta; Luke Brindamour; Ivana Jankovic; Kenneth Mukamal. BIDMC, Brookline, MA. (Control ID #2706514)

BACKGROUND: In the setting of major changes to health care delivery, there is a perception that patients admitted to hospitals are increasingly complex. Although complexity, can be difficult to capture, it is generally defined by an increased number of chronic medical problems, increased severity of complications related to a chronic medical condition, or both. By understanding trends in patient complexity, hospitals will better be able to direct economic and human resources (level of nursing care, number of providers etc.) to better care for their patient populations.

METHODS: In this observational serial cross sectional study, we utilized publicly available NHAMCS emergency room data. Time period included 2009–2013 (excluding 2011, for which data was unavailable). Inclusion criteria was patients >18 years old admitted to inpatient services or transferred to another hospital from the emergency department. Using time (year) as exposure of interest, outcomes assessed included number of comorbidities, age, number of medications prescribed, and triage level at point of care. We accounted for changes in survey detail and format between 2009–2010 and 2012–2013 by capping at data points available in earlier surveys. Results were analyzed using linear regression to evaluate changes in continuous variables and ordered logistic regression to evaluate ordinal variables. All analysis were performed with Stata statistical software.

RESULTS: Age, number of medications and number of comorbidities were analyzed as continuous outcome variables with year as a continuous exposure variable. Age and number of medications were significantly correlated with year. Every increase in 1 year after 2009 was associated with an increased age of patients by 0.74 years ($p = 0.002$) and number of medications given by 0.10 ($p = 0.014$). Number of comorbidities among the five diagnoses that were surveyed across all years was not significantly correlated with year ($p = 0.38$). Triage level was recorded as 1–5 and was analyzed as an ordinal variable with ordered logistic regression. Every increase in 1 year was associated with an odds ratio of 1.08 of a more acute triage level ($p = 0.014$).

CONCLUSIONS: Over 2009–2013 we found statistically significant increases in age, triage level and number of medications prescribed to patients admitted from the ED. We did not observe a significant trend towards increased comorbidities, however this was likely limited by fewer listed comorbidities in data sets prior to 2012 (five vs 10). Despite this limitation, all other variables trended significantly towards increased medical complexity. Additional studies could be performed prospectively to confirm this trend and evaluate for factors that would better capture medical complexity. This analysis could also be extended as data from 2014–2016 becomes available. It would be interesting to evaluate how changes in access to care across this time period have effected patient complexity and stress on hospitals.

NATIONAL TRENDS IN USE OF MEDICARE'S ANNUAL WELLNESS VISIT

Ishani Ganguli[1, 2]; Jeffrey Souza[2]; J. Michael McWilliams[2]; Ateev Mehrotra[2]. [1]Brigham and Women's Hospital, Chestnut Hill, MA; [2]Harvard Medical School, Boston, MA. (Control ID #2706549)

BACKGROUND: In 2011 Medicare introduced the Annual Wellness Visit (AWV) - a form of the periodic health exam that has been a mainstay in primary care. The AWV is free for patients and has been promoted as a way for clinicians to encourage preventive care. While small studies have suggested pockets of adoption, some call visit requirements onerous and it is unclear where and how AWVs are being used across the US. We examined national growth of AWVs and characteristics of clinicians and patients who use them.

METHODS: Using a national 20% sample of 2010–2014 Medicare fee-for-service beneficiaries, we calculated AWV rates among eligible beneficiaries in hospital referral regions and across demographic and clinical characteristics, including linkage to a primary care physician (PCP; family practice, general practice, or internal medicine) affiliated with an Accountable Care Organization (ACO). We characterized clinicians performing AWVs.

RESULTS: The percent of beneficiaries getting an AWV each year grew from 7.5% in 2011 to 15.6% in 2014. In 2014, whites, urban residents, and those with higher income, few comorbidities (Table), and an ACO-affiliated PCP (25.9% vs 17.6%,$p < 0.01$) were more likely to receive an AWV. Among those who received an AWV in 2014, 53.4% had one the prior year. AWV rate varied across regions from San Angelo,TX (3.0%) to Appleton,WI (34.3%). Nearly 90% of AWVs were done by PCPs; the top 10% of all AWV providers accounted for 43.7% of AWVs.

CONCLUSIONS: AWV use has grown modestly, particularly in ACOs and certain regions. These patterns, in light of challenges with AWV documentation, suggest visit use may be contingent on physician or institution-specific availability of templates, workflows, or non-physician health workers to facilitate them. AWV use was higher among whites, higher-income, urban, and relatively healthy beneficiaries, raising concern that disadvantaged groups who might most benefit from AWVs are least likely to receive them. Further work should explore whether AWVs improve care.

NEEDS ASSESSMENT FOR SCALE-UP OF THE WOMEN'S HEALTH PRACTICE-BASED RESEARCH NETWORK

Anju Sahay[3]; Alyssa Pomernacki[3]; Diane Carney[3]; Rachel Golden[3]; Elizabeth M. Yano[1]; Alison Hamilton[1]; Ruth Klap[1]; Susan M. Frayne[2]. [1]VA Greater Los Angeles HSR&D Center, Sepulveda, CA; [2]VA Palo Alto Health Care System/Stanford, Palo Alto, CA; [3]VA Palo Alto, Palo Alto, CA. (Control ID #2702961)

BACKGROUND: The 60-site national VA Women's Health-Practice Based Research Network (WH-PBRN) focuses on improving care of women Veterans. It promotes a culture of continual organizational learning by fostering collaboration, supporting practice-based research/quality improvement (QI) initiatives, and disseminating findings. To inform its next phase of scale-up, we conducted a needs assessment of WH-PBRN Site Leads (SLs) and Co-SLs to characterize their participation and elicit their perspectives.

METHODS: In Fall 2016 we emailed a cross-sectional, 2-page, self-administered survey to all SLs and Co-SLs ($n = 65$) at 57 sites (after excluding 3 with SL in transition). It asked about recent involvement in PBRN activities, willingness to participate in future activities, and perspectives about usefulness/importance of participation.

RESULTS: The 65 respondents (response rate 78%) came from 50 sites. Among 45 SLs, 76% were clinicians and 24% researchers; among 20 Co-SLs, 85% were clinicians and 15% researchers. Most had been in the

role for at least 12 months (80% of SLs, 70% of Co-SLs). During the past 12 months, respondents participated actively by attending the monthly national calls 1–5 times/year (43%) to 6–12 times/year (48%) and read the monthly Newsletter 1–5 times/year (52%) to 6–12 times/year (40%). Going forward, 72% expressed willingness to serve as a key informant for a rapid-cycle Practice Scan survey (describing elements of local women's health clinical practices) at least quarterly, and 23% were willing to complete it 9–12 times/year. All (100%) respondents rated the monthly national calls as somewhat/very useful to hear results of research studies, for presentation about SL roles, and to learn about the structure of WH care at other facilities; 93% rated as useful the WH-PBRN's quarterly Full Community calls, open to not only SLs and Co-SLs but also clinicians, managers and researchers at the site. All (100%) reported the following as somewhat/very important to them regarding their WH-PBRN role: improve quality of care for women Veterans; strengthen local site connections; participate in multi-site research/QI; and learn about new WH research findings. There were no statistically significant differences in responses based on role (SL vs Co-SL) or duration in role (<12 months vs longer).

CONCLUSIONS: Nearly all clinicians and researchers in the national WH-PBRN community of SLs/Co-SLs participate in WH-PBRN activities, though scope of engagement varies by site. Findings have triggered modifications to WH-PBRN processes, in preparation for scale-up efforts, and provide lessons relevant to other PBRNs seeking to engage members from diverse backgrounds. The fact that SLs/Co-SLs engage in WH-PBRN activities, find value in their role, and are willing to participate in future rapid-turnaround practice characteristics surveys bodes well for the WH-PBRN's ability to support VA's efforts to be a learning healthcare system.

NON-BUPRENORPHINE OPIOID UTILIZATION AMONG PATIENTS USING BUPRENORPHINE/NALOXONE (SUBOXONE)

Matthew Daubresse[1]; Brendan Saloner[1]; Harold Pollack[2]; G. Caleb Alexander[1]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]University of Chicago, Chicago, IL. (Control ID #2705477)

BACKGROUND: Buprenorphine/naloxone is commonly used to treat opioid dependence, however, non-buprenorphine prescription opioid utilization among these patients has not been well defined. We sought to characterize patterns of opioid utilization among incident buprenorphine/naloxone (Suboxone) users in eleven states.

METHODS: We used IMS Health anonymized, individual-level, all-payer pharmacy claims to identify incident users of buprenorphine/naloxone between January 2010 and August 2013. We focused on patients 18 years of age and defined each patient's first treatment episode as the length of time from the patient's incident prescription for buprenorphine/naloxone (index fill) until the first day of a gap where the patient had no buprenorphine/naloxone on-hand for 90 or more days. We calculated measures of non-buprenorphine opioid utilization during the first treatment episode as well as during 12-month periods prior to and following this episode.

RESULTS: Of the 22655 individuals meeting inclusion criteria, 49% were female and 50% were between 25 and 46 years of age. The median length of the first treatment episode was 79 days (interquartile range [IQR], 30 to 226 days). More than half (58%) of buprenorphine/naloxone recipients filled prescriptions for other opioids following buprenorphine/naloxone treatment and 30% filled at least one opioid prescription during their treatment episode. The median total of morphine milligram equivalents (MME) 12 months prior to treatment was 250 mg/per month (IQR 38 to 1347) then declined to 221 mg/per month (IQR 39 to 1034) and 175 mg/per month (IQR 25 to 1106) during and following the treatment episode, respectively. The median MME per opioid day supplied prior to, during and following the first treatment episode remained constant at 40 mg per day.

CONCLUSIONS: Treatment with buprenorphine/naloxone is associated with reduced non-buprenorphine opioid use. However, a substantial proportion of patients fill prescriptions for non-buprenorphine opioids during and following such treatment.

NONPHARMACOLOGIC TREATMENTS FOR MENOPAUSE-ASSOCIATED VASOMOTOR SYMPTOMS

Karen M. Goldstein[3, 1]; Remy Coeytaux[2]; Megan Shepherd-Banigan[3]; Adam Goode[4]; Jennifer McDuffie[3]; Deanna Befus[5]; Soheir Adam[4]; Varsha Masilamani[3]; Megan Van Noord[6]; John Williams[3, 1]. [1]Duke University School of Medicine, Durham, NC; [2]Duke Clinical Research Institute, Durham, NC; [3]Durham VA HSR&D, Durham, NC; [4]Duke University Medical Center, Durham, NC; [5]Duke University School of Nursing, Durham, NC; [6]Duke University Medical Center Library, Durham, NC. (Control ID #2698882)

BACKGROUND: Vasomotor symptoms (VMS) are bothersome for many perimenopausal women. Use of pharmacologic and herbal treatments for VMS are limited due to safety profiles and/or uncertain efficacy. Thus, many women look to nonhormonal, nonpharmacologic treatments. We aimed to determine the effects of acupuncture, yoga, structured exercise and relaxation on VMS among perimenopausal and postmenopausal women.

METHODS: We conducted a rigorous, protocol driven (PROSPERO # CRD42016029335) review of fair-to-good quality systematic reviews (SR) and randomized controlled trials (RCTs) for each intervention. Risk of bias (ROB) was assessed for SR and RCTs using validated tools. Meta-analysis (MA) were conducted when indicated and feasible using standardized mean differences (SMD). Heterogeneity was measured with I^2.

RESULTS: Of 239 SR and 1135 RCT citations, 10 SRs and 14 RCTs were eligible. ROB was low for acupuncture and paced respiration trials, and moderate for exercise and yoga trials. Updated MAs suggest the following: acupuncture is effective at reducing VMS frequency (SMD −0.66, 95% CI −1.06 to −0.26, $I^2 = 61.7\%$, 5 trials) and severity (SMD −0.49, 95% CI −0.85 to −0.13, $I^2 = 18.1\%$, 4 trials) when compared to waitlist, though similar analyses were not significant when compared to sham acupuncture; yoga is associated with reductions in VMS severity (SMD −0.36, 95% CI −0.65 to −0.07, $I^2 = 0.0\%$, 4 trials); structured exercise was not associated with reductions in VMS frequency (SMD −0.08, 95% CI −0.33 to 0.16, $I^2 = 0.0\%$, 4 trials) or severity (SMD 0.06, 95% CI −0.21 to 0.10, $I^2 = 0.0\%$, 5 trials); and paced respiration is not associated with a decrease in VMS frequency (SMD 0.04, 95% CI −0.73 to 0.82, $I^2 = 56.6\%$, 3 trials) or severity (SMD 0.06, 95% CI −0.69 to 0.80, $I^2 = 65.1\%$, 3 trials).

CONCLUSIONS: Low to moderate quality evidence supports acupuncture and yoga when compared to control for reducing VMS. Structured exercise and relaxation do not appear beneficial. Larger, high quality trials are needed to further support the use of these interventions.

Strength of Evidence for Effects of Interventions on Vasomotor Symptoms

Comparison	#RCTs (Patients)	Findings	Strength of Evidence
Acupuncture vs Waitlist	4 (501)	SMD 0.66 lower (1.06 lower to 0.26 lower)	Moderate
Acupuncture vs sham acupuncture	8 (644)	SMD 0.35 lower (0.70 lower to 0.01 higher)	Moderate
Yoga vs control	4 (157)	SMD 0.36 lower (0.65 lower to 0.07 lower)	Low
Structure exercise vs control	4 (431)	SMD 0.08 lower (0.33 lower to 0.16 higher)	Moderate
Paced respiration vs control	3 (161)	SMD 004 higher (0.73 lower to 0.82 higher)	Low

NUMERACY, HEALTH LITERACY, COGNITIVE IMPAIRMENT AND 30-DAY READMISSIONS AMONG PATIENTS WITH HEART FAILURE: THE VANDERBILT INPATIENT COHORT STUDY (VICS)

Madeline R. Sterling[2]; Monika M. Safford[2]; Kathryn Goggins[1]; Samuel K. Nwosu[1]; Jonathan Schildcrout[1]; Ken Wallston[1]; Amanda S. Mixon[3, 1]; Russell L. Rothman[1, 1]; Sunil Kripalani[1, 1]. [1]Vanderbilt University Medical Center, Nashville, TN; [2]Weill Cornell Medical College, New York, NY; [3]VA Tennessee Valley Healthcare System, Nashville, TN. (Control ID #2689396)

BACKGROUND: Numeracy has emerged as an important skill in chronic disease management and prior studies have found low numeracy to be associated with adverse patient outcomes. Yet, little research has focused on numeracy in the context of heart failure (HF), a condition which requires patients to use numerical skills to monitor their weight, fluid intake and dietary salt, especially in the immediate post-hospitalization period. Here, we examined the relationship between numeracy, health literacy, and cognitive impairment with 30-day readmissions among patients hospitalized for acute decompensated heart failure (ADHF).

METHODS: The Vanderbilt Inpatient Cohort Study (VICS) is a prospective longitudinal study of adults hospitalized with acute coronary syndromes and/or ADHF. We studied 883 adults hospitalized with ADHF. During hospitalization, a baseline interview was performed in which demographic characteristics were obtained. Numeracy was assessed with both objective (serial subtraction task from the Short Portable Mental Status Questionnaire [SPMSQ]) and subjective measures (shortened Subjective Numeracy Scale [SNS-3]), as was health literacy (Brief Health Literacy Screen [BHLS] and the Short Form of the Test of Functional Health Literacy in Adults [sTOFHLA]). Cognitive impairment was assessed with 9 items of the SPMSQ. Through electronic chart review, medical comorbidities and the severity of illness during the index hospitalization were determined. The outcome of interest was any 30-day readmission to an acute care hospital. Poisson regression was used to examine the association between numeracy, health literacy, and cognitive impairment and readmission within 30 days, while adjusting for demographic and clinical characteristics.

RESULTS: Of the 883 patients admitted for ADHF, 23.7% ($n = 210$) were readmitted within 30 days. Overall, 36% of the study sample had low objective numeracy skills, 24% had low objective health literacy skills and 32% were cognitively impaired. In both unadjusted and adjusted analyses, (objective) numeracy and cognitive impairment were not associated with 30-day readmissions. Objective health literacy was associated with 30-day readmissions in unadjusted analysis, but not in adjusted analyses. A history of diabetes, a greater number of comorbidities and a higher number of prior hospitalizations the year before index admission were independently associated with 30-day readmissions in fully adjusted models.

CONCLUSIONS: Low numeracy, low health literacy and impaired cognition were present in more than one in three patients, but were not associated with 30-day readmissions in adjusted analyses. Our findings suggest that other influences may play a more dominant role in determining 30-day readmission rates among patients hospitalized for ADHF.

OBESITY AND BREAST DENSITY INCREASE ESTROGEN RECEPTOR NEGATIVE BREAST CANCER RISK IN PREMENOPAUSAL WOMEN

Yiwey Shieh[1]; Christopher G. Scott[2]; Matthew R. Jensen[2]; Aaron D. Norman[2]; Kimberly A. Bertrand[3]; Vernon S. Pankratz[4]; Kathleen R. Brandt[2]; John Shepherd[1]; Rulla M. Tamimi[5, 6]; Celine M. Vachon[2]; Karla Kerlikowske[1, 7]. [1]University of California, San Francisco, San Francisco, CA; [2]Mayo Clinic, Rochester, MN; [3]Boston University, Boston, MA; [4]University of New Mexico Health Sciences Center, Albuquerque, NM; [5]Harvard Medical School, Boston, MA; [6]Harvard T.H. Chan School of Public Health, Boston, MA; [7]San Francisco Veterans Affairs Medical Center, San Francisco, CA. (Control ID #2700978)

BACKGROUND: Understanding the relationship between risk factors and estrogen receptor (ER) subtypes of breast cancer is essential to risk prediction and prevention counseling in primary care. Breast density and obesity increase breast cancer risk, with differential effects across ER subtypes. Moreover, obesity is inversely associated with the percentage of breast density and confounds its association with breast cancer risk. Thus, we evaluated whether ER subtype-specific effects of breast density vary by body mass index (BMI).

METHODS: We conducted a case–control study of women in the Mayo Mammography Health Study and the San Francisco Mammography Registry. Breast density was measured on digitized film mammograms as dense area (DA) and nondense area (NDA) using a computerized threshold technique. Percent density (PD) was calculated as DA/(DA + NDA). BMI (kg/m^2) was categorized as normal/underweight (<25), overweight (25–30), and obese (>30). We evaluated the association between density measures and ER subtype using logistic regression, adjusted for age and study and stratified by BMI and menopausal status. For density measures, odds ratios (OR) were estimated per standard deviation (SD). We used a Wald chi-squared test to assess for interactions between BMI and density measures. Contrasts were constructed to test for heterogeneity of association by subtype.

RESULTS: The study consisted of 1823 invasive breast cancers (1538 ER-positive, 285 ER-negative) and 4720 controls. Mean time from mammogram to diagnosis was 4.4 years. PD and DA were positively associated, and NDA inversely associated, with invasive breast cancer across all BMI categories. In premenopausal women, there was a statistically significant interaction between BMI and PD for subtype-specific risk ($P_{interaction} = 0.03$). This was driven by heterogeneity of association between PD and subtype in overweight and obese women where a one-SD increase in PD was associated with a higher risk of

ER-negative cancers, $P_{heterogeneity} = 0.08$ and 0.09, respectively (Table). In postmenopausal women, a one-SD increase in PD was associated with increased risk of both ER-positive and negative cancers, without BMI-density interactions.

CONCLUSIONS: Premenopausal overweight/obese women with dense breasts have an elevated risk of ER-negative cancer. While prior studies have shown obesity and breast density are individually associated with ER-negative cancer in this demographic, ours is the first to show an interaction between these risk factors. Premenopausal overweight/obese women should be counseled on weight reduction and their increased risk of ER-negative breast cancer.

Associations of percent density with subtype-specific breast cancer risk in premenopausal women, by BMI category

	BMI < 25 per-S.D. OR (95% CI)	**BMI 25-30** per-S.D. OR (95% CI)	**BMI > 30** per-S.D. OR (95% CI)
ER-positive	1.90 (1.57, 2.29)	1.23 (0.95, 1.59)	1.69 (1.23, 2.32)
ER-negative	1.51 (1.04, 2.21)	1.93 (1.19, 3.13)	3.04 (1.57, 5.89)
$P_{heterogeneity}$	*0.27*	*0.08*	*0.09*

$P_{interaction} = 0.03$ for interaction between BMI and PD

OBSERVATION UNIT UTILIZATION IN DECOMPENSATED HEART FAILURE AND CLINICAL PREDICTORS FOR APPROPRIATE TRIAGE

Vincent Lipari; Michael Mashiba; Vivek Mendiratta; Scott Lawler; Joseph Gibbs. Henry Ford Hospital, Detroit, MI. (Control ID #2702869)

BACKGROUND: Acutely decompensated heart failure (ADHF) represents a significant financial and health burden in the United States with more than 1 million hospitalizations annually and 3% of annual health care expenditure. Currently, 75% of patients presenting to Emergency Departments (ED) are admitted to the hospital, however, estimates suggest as many as 50% may be safely treated in Observation Units (OU). The use of OUs is a cost-effective alternative to inpatient admission for ADHF, however, data to support appropriate triage of patients is sparse. We sought to isolate clinical data indicative of Length of Stay (LOS) greater than 48 hours that is readily available to the ED physician.

METHODS: We performed a retrospective cohort study with patients admitted from the ED with ADHF. Patients with end-stage renal disease, heart transplant, or ventricular-assist device were excluded. Demographic and clinical data pertinent to the evaluation of heart failure in the ED were collected. We compared patients with LOS < 48 hours to those with longer stays using Chi-Square analysis, Two-Sample T-Test, Cochran Armitage Trend Test, as well as Wilcoxon Rank Sum Test.

RESULTS: Of the 553 patients included in the study, 234 (42%) had LOS > 48 hours. The mean age was 70.3 years (standard deviation, 14.8 years) and 53% were female. Patients were more likely to require >48 hours of care if they had a higher Charlson Comorbidity Index (4.4 vs 3.9, $p = 0.014$), had systolic pressure <90 mmHg (3.8% vs 0.9%, $p = 0.021$) or had BNP >200 pg/mL (72.8% vs 60.9%, $p = 0.006$). Chest x-ray findings of pulmonary vascular congestion (21.6% vs 15.0%), pulmonary edema (6.3% vs 4.1%), or pleural effusion (21.2% vs 14.3%) were likewise associated with increased LOS ($p = 0.003$). Patients with LOS > 48 hours were also more likely to be anemic (hemoglobin 11.8 vs 12.2, $p = 0.005$), have a lower lymphocyte percentage count (19.7 vs 22.1, $p = 0.009$), and have higher troponin (0.07 vs 0.05, $p = 0.042$).

CONCLUSIONS: The Observation Unit is a growing care modality for ADHF. Our study identifies clinical characteristics readily available to the ED physician suggestive of the need for inpatient care. Multivariate analysis and prospective validation will be necessary to further develop our findings into a clinically useful triage tool.

OLDER ADULTS PERCEPTIONS ABOUT OVERUSE OF HEALTHCARE SERVICES

Ariel Green[1]; Monica Tung[1]; Jodi B. Segal[1, 2]. [1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD. (Control ID #2704957)

BACKGROUND: The U.S. spends more on health care than other high-income nations, but has worse health outcomes. This has led many experts to suggest that health care is overused in the U.S., exposing patients to harm with little likelihood of benefit. Older Americans may be particularly vulnerable to overuse. Despite national initiatives to encourage clinicians and patients to talk openly about overuse, it is unknown whether patients believe that overuse is a problem and have insights as to its causes and consequences. Our goal was to illuminate the experiences and perspectives of older adults with respect to overuse of healthcare, in order to begin developing a framework for understanding overuse in older adults.

METHODS: People 65 years of age and older were recruited from senior centers in Baltimore, Maryland. We conducted five separate focus groups of 8 people each using guiding questions that had been pilot tested with individual older people. Four groups included participants from lower-income black neighborhoods and one from a mixed-income white neighborhood. Audio recordings were transcribed and analyzed using conventional and directed qualitative content analysis.

RESULTS: Virtually all participants expressed that they or an acquaintance had experienced some overtesting or overtreatment, expressing agreement that terms such as "unnecessary," "wasteful" and "overdoing it" characterized these encounters. Major themes that were expressed as contributing to overuse were: (1) poor quality of communication between patients and doctors; (2) treating individual complaints instead of "the whole person"; (3) few efforts to engage patients in shared decision-making; (4) inadequate communication between different health care providers involved in a patient's care; and (5) little trust in the clinician. Yet, many participants also expressed concern that they had received too little care.

CONCLUSIONS: Although overuse of healthcare seems not to be a primary concern of older people, we learned what they perceive to be drivers or determinants of overuse of healthcare. The next step will be to explore whether or not these perceived drivers do, in fact, contribute to overuse, using observational research and survey methods. Engaging patients in the decision process and enhancing communication between patients and doctors and between health care providers may be effective at reducing overuse, but this remains to be proven.

OLDER ADULTS' VIEWS AND COMMUNICATION PREFERENCES AROUND CANCER SCREENING CESSATION

Nancy Schoenborn[5]; Kimberley Lee[4]; Craig E. Pollack[5]; Sydney M. Dy[2]; Antonio C. Wolff[3]; Cynthia M. Boyd[1]. [1]JHU, Baltimore, MD; [2]Johns HOpkins, Baltimore, MD; [3]Johns Hopkins Kimmel Cancer Center, Baltimore, MD; [4]Johns Hopkins School of Mediicine, Baltimore, MD; [5]Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #2688308)

BACKGROUND: Research and clinical practice guidelines recommend against cancer screening in patients with limited life expectancy because the benefits of screening may take years to accrue but the harms may be immediate. Older adults with limited life expectancy still frequently receive cancer screening. Patient preferences may be an important contributor to continued screening.
METHODS: We conducted individual interviews with 40 community dwelling adults 65+ years of age. We examined their views on the decision to stop cancer screening when life expectancy is limited and to their preferences for how clinicians should communicate recommendations to cease cancer screening. The interviews were audio-recorded and transcribed verbatim. Two investigators independently coded the transcripts using qualitative content analysis and results are summarized as major themes.
RESULTS: The participants' mean age was 75.7, 23 participants were female, and 25 were white. We identified three major themes: First, participants were amenable to stopping cancer screening especially in the context of a trusting relationship with their clinician. Second, although many participants supported using age and health status to individualize the screening decision, they were more skeptical of the role of life expectancy. All except two participants objected to a Choosing Wisely statement about not recommending cancer screening in those with limited life expectancy, often believing that clinicians cannot accurately predict life expectancy. Third, participants preferred that clinicians explain a recommendation to stop screening by incorporating individual health status but were divided on whether life expectancy should be mentioned. Specific wording of life expectancy was important; many felt the language of "*you may not live long enough to benefit from this test*" was unnecessarily harsh compared to the more positive messaging of "*this test would not help you live longer*".
CONCLUSIONS: Although research and clinical practice guidelines recommend using life expectancy to inform cancer screening, older adults may be skeptical of the role of life expectancy in screening and may not prefer to hear about life expectancy when discussing screening. The described communication preferences can help inform future screening discussions. The mismatch of patient preference and guideline language needs to be reconciled to enable implementation of guidelines.

OPIOID PRESCRIBING AT INITIAL ENCOUNTERS FOR PAIN IN UNITED STATES PRIMARY CARE SETTINGS Mallika Mundkur[1, 2]; Kathryn Rough[1, 2]; Krista Huybrechts[1, 2]; Raisa Levin[1, 2]; Joshua Gagne[1, 2]; Rishi Desai[1, 2]; Elisabetta Patorno[1, 2]; Niteesh K. Choudhry[1, 2]; Briain Bateman[1, 2]. [1]Brigham and Women's Hospital, Lexington, MA; [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA. (Control ID #2705386)

BACKGROUND: Prescriptions by primary care clinicians account for nearly half of all opioids dispensed in the United States. Recent guidelines issued by the Centers for Disease Control and Prevention (CDC) have specifically targeted this group of clinicians, yet opioid-prescribing patterns in primary care settings are not well documented. The main objective of this study was to characterize variation in opioid prescribing at initial encounters for ten pain conditions commonly managed by primary care clinicians.
METHODS: We used insurance claims data from the Optum Research Database, from January through December of 2014, to evaluate individuals 18 years or older with an initial presentation to a primary care setting for one of ten common pain conditions: joint pain, non-radicular back pain, back pain with radiculopathy, muscular sprains/strains, musculoskeletal injuries (e.g. ligamentous tears), nephrolithiasis, headache, dental pain, tendonitis/bursitis, and neck pain. Patients with history of opioid use or a prior visit for the pain condition were excluded, as were those with a history of cancer, hospice/palliative care, recent surgery or hospitalization. The main outcomes assessed were: (1) the proportion of initial encounters for pain associated with an opioid prescription fill and (2) the proportion of dispensed opioid prescriptions with >7 days' supply. We used multivariable logistic regression to determine whether a number of covariates, such as age, comorbidities, recent medications and substance abuse history, were significant predictors for our primary outcome. We also used a mixed linear regression model to determine adjusted rates of our primary and secondary outcome by state.
RESULTS: We identified 205,560 individuals who presented to a primary care setting in an initial encounter for pain. Overall, 9.1% of encounters were associated with an opioid fill, ranging from 4.1% (headache) to 28.2% (dental pain). The median days' supplied was 7 [IQR 5,12], and 10% of prescriptions supplied ≥30 days of opioids. Recent use of benzodiazepenes, history of smoking and male gender were significant predictors of opioid use ($p < .05$). States with the highest rates of opioid use following initial pain encounters, adjusting for case-mix and other measured differences, were Alabama (16.6%) and Arkansas (15.9%), while the lowest rate of use was observed in New York (3.7%).
CONCLUSIONS: Opioid prescribing occurs in nearly one of ten initial encounters for pain in primary care settings with a wide range of inter- and within-condition variation. Primary care clinicians should consider further reducing days' supplied at initial encounters, as the total quantity dispensed may pose risk to patients or household members. We expect that policies enforcing the CDC's recently recommended 7-day limit on initial opioid supplies will have a drastic impact on prescribing within primary care.

OPIOID TAPERING IN PATIENTS WITH CHRONIC PAIN: A QUALITATIVE STUDY OF PATIENT AND PROVIDER EXPERIENCES Nicole Johnson[4]; Cleveland Shields[5]; Stewart C. Alexander[5]; Matthew J. Bair[1, 3]; Palmer MacKie[3]; Monica Huffman[3]; Marianne S. Matthias[2, 3]. [1]Center for Health Information and Communication, Indianapolis, IN; [2]Roudebush VAMC, Indianapolis, IN; [3]Indiana University, Indianapolis, IN; [4]Indiana University Purdue University Indianapolis, Indianapolis, IN; [5]Purdue University, West Lafayette, IN. (Control ID #2698023)

BACKGROUND: In response to increases in opioid use and misuse in chronic pain treatment, state laws and institutional policies have increasingly focused on reducing opioid doses. However, little is known about the impact of mandated dose tapering on patients or their primary care providers (PCPs). Such an understanding is essential to optimize outcomes for patients and mitigate potential harms.
METHODS: Qualitative interviews were conducted with patients and their PCPs in a large safety-net hospital system as part of a larger study on opioid management. We used constant comparative methods to analyze the data.
RESULTS: To date, 6 PCPs and 12 of their patients completed interviews. Descriptions of experiences with opioid tapering centered around 3 key themes: Theme 1: Relationships and Trust Provide Safety Nets. Relationships and support were critical during tapering. One PCP stated, "I said [to the patient], this is a trial. I'm not leaving. I'm with you. We've been together a long time. I'm not going to disappear on you" (PCP1). A patient described a similar feeling. "Dr. X said… we'll try cutting you back. If you don't feel that you can do that, we'll move it back [to the original dose]… and

I'm happy with that" (P20). Theme 2: Patients Need to Understand Reasons for Tapering. For many patients, their understanding of why they were being tapered affected their attitudes toward tapering. One patient who did not understand said, "I asked [my doctor] and she said that a lot of people was OD'ing on pain medication and getting addicted. I told her I was in a lot of pain and this was not addiction" (P6). In contrast, a PCP described helping a patient with severe lung disease to understand why she was being tapered. "We were able to… directly talk about the [opioid] medication's effects on her respiratory system. So I think having that tangible [risk] helped her to buy into it" (PCP2). Theme 3: Policies Legitimize Tapering. Some patients believed that institutional policies are warranted. One patient stated of being tapered, "I think she's being reasonable. It's the hospital that wants her to cut back. Well, they've got a point. They probably have a helluva lot of addicted people out there" (P3). PCPs identified the importance of policies in supporting tapering, particularly when there is patient resistance. "This is law. I'm not going to break that" (PCP1). Another PCP noted, "Once I hit that wall with a patient, it is nice to say, honestly, it is out of my control" (PCP2).

CONCLUSIONS: Successful opioid tapering while maintaining a positive patient-provider relationship is critical for effective patient care. This study highlights the importance of trust and effective communication during opioid tapering, while also pointing to the importance of institutional policies to facilitate tapering decisions.

OPIOID TAPERING IS NOT ASSOCIATED WITH GREATER RISK OF LOSS TO FOLLOW-UP IN PATIENTS ON CHRONIC THERAPY

Hector R. Perez[1]; Michele J. Buonora[2]; Yuming Ning[1]; Joanna L. Starrels[1]. [1]Albert Einstein College of Medicine, Bronx, NY; [2]Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, NY. (Control ID #2706851)

BACKGROUND: There is emerging consensus that tapering chronic opioid therapy (COT) may be beneficial when the risks of continuing the same dose exceed the benefits. However, it is possible that reduction in COT dose could be associated with loss to follow-up if dissatisfied patients terminate care, but this association has not been examined. We sought to determine whether COT patients who were tapered were more likely to be lost to follow-up compared to other COT patients.

METHODS: Using electronic medical record data from 7/2009 to 7/2015, we conducted a retrospective cohort study of patients receiving COT in an urban health system in Bronx, NY. To be eligible, patients: 1) were prescribed COT (>3 opioid prescriptions in two consecutive six-month periods from 7/2009 to 7/2010 [baseline period]); 2) had a stable COT dose (<20% change in mean morphine equivalent daily dose [MEDD] within the baseline period); and 3) did not have an ICD-9 code for cancer. Patients were classified as having "tapered" if they had a 30-90% reduction in mean MEDD from the baseline dose in two consecutive six-month time periods between 7/2010 and 7/2014. We identified each patient's final outpatient encounter during the study time frame, and patients were considered lost to follow-up (LTFU) if their final encounter occurred prior to 1/2015. To estimate the time to loss, we determined the number of six-month time periods to the final encounter, starting from the end of either the baseline period if no tapering occurred, or, if tapering occurred, from the end of the first tapering period. We used X^2 to compare the proportions LTFU in the tapered and non-tapered groups. Separately, we calculated rates of loss to follow-up in both groups and a hazard ratio using Cox regression, adjusting for patient age, race and ethnicity, and baseline COT dose.

RESULTS: Of the 679 COT patients who met eligibility criteria, 181 (26.7%) were tapered and, of those tapered, 56 (30.9%) were LTFU. Patients who were tapered were significantly less likely to be LTFU (OR 0.54, $p < 0.001$). Among those tapered, 17 (9.4%) were LTFU at one year after tapering (vs 46 [9.2%] in the non-tapered group). Overall, patients were LTFU at similar rates in both groups, which was not statistically significant (10.3% LTFU per person-year in the tapered group versus 10.6% in the non-tapered group). In Cox regression, those who tapered had no greater risk of being LTFU over time (HR 1.08, CI 0.8-1.5) compared to those in the non-tapered group.

CONCLUSIONS: In this cohort, tapering was not associated with greater risk of loss to follow-up. A limitation is the lack of a standardized definition for tapering; ours is conservative but may exclude patients with faster opioid tapers. Nonetheless, our findings are reassuring given the health consequences of being lost to follow-up. Further research is needed but these findings may have important implications for the millions of patients on COT in primary care for whom tapering could be an appropriate option.

ORGANISED PROGRAMME AND SOCIAL INEQUALITIES IN MAMMOGRAPHY SCREENING: A 22-YEAR POPULATION-BASED STUDY IN GENEVA, SWITZERLAND

José Luis Sandoval[1]; Jean-Marc Theler[1]; Stéphane Cullati[1]; Christine Bouchardy[4]; Orly Manor[5]; Jean-Michel T. Gaspoz[2]; Idris Guessous[1, 3]. [1]Geneva University Hospitals, Geneva 14, Switzerland; [2]University Hospitals, Geneva 14, Switzerland; [3]University of Lausanne, Lausanne, Switzerland; [4]University of Geneva, Geneva, Switzerland; [5]Hebrew University-Hadassah, Jerusalem, Israel. (Control ID #2704466)

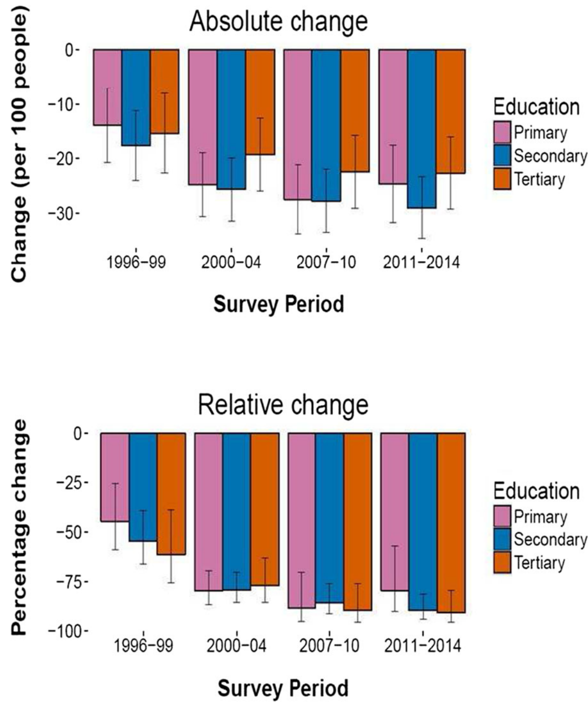
BACKGROUND: Breast cancer (BC) mortality decreased in developed countries due, at least in part, to generalisation of mammography screening. Organised programmes aim to increase participation and decrease social inequalities in screening access. We characterised the evolution of socioeconomic disparities in mammography screening before and after the implementation of an organised programme in Geneva, Switzerland.

METHODS: We included 5345 women aged 50-74ys with no past history of BC who participated in a cross-sectional study between 1992–2014. Outcome measures were: 1) never had a mammography (1992–2014) and 2) never had a mammography. Educational attainment was divided in 3 groups (primary, secondary and tertiary) and period in two groups (before the introduction of screening programme in 1999 and after). We calculated measures of relative and absolute change, including the relative (RII) and slope (SII) indexes of social inequality adjusted for age and nationality. We compared screening prevalence before and after screening programme implementation using Poisson models.

RESULTS: The proportion of unscreened women decreased during the study period from 30.5 to 3.6%. Women with lower education more probably never had a mammography (RII = 2.39, $p < 0.001$; SII = 0.10, $p < 0.001$). Introduction of organised screening decreased the proportion of unscreened women independently of education (prevalence ratio before vs after = 4.41, $p < 0.001$), but absolute and relative inequalities persisted (RII = 2.11, $p < 0.01$; SII = 0.04, $p < 0.01$). The observed discrepancies between relative and absolute measures reinforce the need of using both measures to characterise changes in inequality (Figure).

CONCLUSIONS: Introduction of an organised programme increased women adherence to mammography screening but did not eliminate social disparities in screening participation.

Absolute and relative changes (95%CI) in proportion of women that never had a mammography during surveyed years with 1992–1995 period as reference



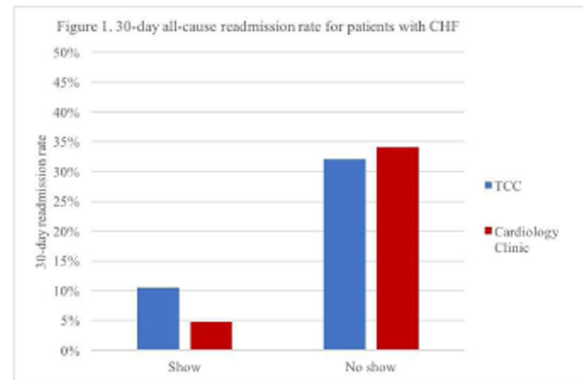
OUTCOME OF A TRANSITIONAL CARE CLINIC TO REDUCE HEART FAILURE READMISSION IN HIGH-RISK INNER CITY POPULATION Justin S. Lee; Felix M. Reyes; Miguel A. Ramirez; Mafuzur Rahman. SUNY Downstate Medical Center, Brooklyn, NY. (Control ID #2705538)

BACKGROUND: In the US, the cost of healthcare expenditure on heart failure (HF) treatment is estimated to increase up to $69.7 billion by 2030. Black population with low socioeconomic status has significantly higher rates of HF than other ethnicities in the US. Central Brooklyn consists of 80% black ethnicity, with 31% living below poverty level. Managing patients with chronic medical conditions in this area is particularly challenging as many of them do not fully understand the importance of adherence with medical treatment plan. Reasons for hospital admissions for HF exacerbation include not only medication non-compliance, but also failure to follow up with primary care appointments. Our institution has established a transitional care clinic (TCC) in May 2015, with aims to aid patients with chronic medical conditions by providing early post-discharge follow up regardless of patient's financial or insurance status.

METHODS: Retrospective review was conducted for patients who were scheduled for TCC with a diagnosis of HF, from May 2015 to October 2016. Our TCC model includes, follow up appointment within 7 days post-discharge, pre and post-clinic phone calls and additional TCC clinic visits as needed to bridge patient over to his or her primary care clinic. A 30-day readmission rate was calculated and compared between patients who followed up with our TCC and who did not by Fisher's exact test. Also, readmission rates were compared for patients who followed at TCC vs. cardiology clinic.

RESULTS: Total of 204 admissions for HF were identified in the study period. Majority of patients were black (91%) with a mean age of 65 years and median length of stay of 5 days. Out of 137 patients who did not follow up with our TCC, 44 were readmitted (32.12%). From the 67 patients who followed with our TCC, 7 were readmitted (10.45%).

CONCLUSIONS: Our transitional care clinic model demonstrates early success with 21% decrease in 30-day all-cause HF readmission in patients who were followed up at the clinics. Rate of readmission did not differ significantly on patients who were followed at TCC vs. those who were followed by their cardiologists. Future study design can be directed towards cost analysis, comparison to historical data from other inner-city population and interventions focused on ways to increase compliance with TCC appointment.



OUTCOMES AFTER BREAST CANCER SURGERY IN NURSING HOME RESIDENTS: A NATIONAL STUDY Victoria Tang[1]; Ken Covinsky[2]; Rebecca L. Sudore[2]; W. John Boscardin[2]; Emily Finlayson[2]. [1]UCSF/VASFMC, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA. (Control ID #2702769)

BACKGROUND: Over 60% of cancer-related operations in nursing home residents occur for breast cancer and can cause significant functional disability, especially in frail older adults. We aim to study the functional and mortality outcomes after inpatient breast cancer surgery in long-term care nursing home women.

METHODS: We used data from the 2003–2012 Medicare Files and the Minimum Dataset for Nursing Homes to identify long-term stay nursing home residents age ≥67 who underwent inpatient breast cancer surgery. We examined 30-day mortality and hospital re-admission rates, stratified by procedure type (lumpectomy, mastectomy, and axillary lymph node dissection with either lumpectomy or mastectomy [LND]). In multivariate analysis, we examined factors associated with 1-year mortality and functional trajectories. Functional status was measured by assessing the degree of dependence in seven activities of daily living (on the Minimum Data Set-Activities of Daily Living [MDS-ADL] scale of 0 to 28 points, with higher scores indicating greater functional difficulty and 2 point difference as clinically significant).

RESULTS: We identified 5,969 nursing home residents who underwent inpatient breast cancer surgery (age: 82 ± 7, 83% white, 57% dementia). On average, residents experienced significant functional decline that persisted 1 year after surgery (MDS-ADL score worsened 2.8 points after lumpectomy, 4.1 points after mastectomy, and 4.6 points after LND). Thirty-day readmission and mortality were also high after surgery: 23 and 9% after lumpectomy, 13 and 4% after mastectomy, and 16 and 2% after LND, respectively. The 1-year all-cause mortality was high, in all treatment groups: 42% for lumpectomy,

31% for mastectomy, and 30% for LND. In a multivariate analysis, poor baseline MDS-ADL score before surgery was strongly associated with death at 1 year in all treatment groups - HR 1.7, 95%CI 1.2–2.4 after lumpectomy, HR 2.1, 95%CI 1.6–2.7 after mastectomy, and HR 1.7, 95%CI 1.4–2.1 after LND.

CONCLUSIONS: Among nursing home women residents who undergo breast cancer surgery, 30-day hospital readmission and mortality are high, as is 1-year all-cause mortality. Poor baseline function prior to surgery was strongly associated with 1-year mortality. Individualized goal-oriented care, such as hormonal therapy or symptom management only, should be considered in nursing home residents, particularly those with poor baseline function.

OUTCOMES FOR HIP FRACTURE PATIENTS ON HOSPITALIST VS. NON-HOSPITALIST SERVICES

Carlton R. Moore[1]; John Stephens[1]; Mukhtar Adem[1]; Jamison Chang[2]; Edmund A. liles[1]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Univeristy of North Carolina at Chapel Hill, Chapel Hill, NC. (Control ID #2703539)

BACKGROUND: Hip fractures are a major health problem in the geriatric population in the United States, with estimated costs of $18billion annually. Hip fractures are highly morbid in the elderly, as deconditioning and acute complications compound chronic comorbidities. To improve care for this high-risk population, hip fracture patients are preferentially admitted to our medicine hospitalist service with co-management from the orthopedics consult service. The hospitalist service developed a clinical pathway that facilitates evidence-based care processes such as initiating venous-thromboembolism prophylaxis, physical therapy and removal of urinary catheters on post-operative day #1. However, due to a variety of factors, some hip fracture patients are admitted to non-hospitalist services (e.g., orthopedics). The purpose of our study is to compare outcomes for hip fracture patients on hospitalist vs. non-hospitalist services.

METHODS: We included all discharges from UNC Hospitals from July 2014 - June 2015 with a primary ICD-9 diagnosis of hip fracture. We excluded patients if they were ≤18 years old or if the hip fracture was caused by "high energy" trauma (e.g., motor vehicle accident). We conducted univariate analyses using t-tests for comparison of continuous variables and Pearson chi-squared for categorical variables. Multivariate logistic regression was used to assess for independent associations with LOS ≤ 7 days and 30-day readmission.

RESULTS: Two hundred patients were included in the study (Table). Patients on the hospitalist service had significantly shorter LOS compared with patients on non-hospitalist services (5.6 vs. 6.7 days, $p = 0.038$). In adjusted analyses (controlling for race, gender, insurance, admission day of the week, Charlson comorbidity index, and administered blood transfusion), patients on the hospitalist service were more likely to have LOS ≤ 7 days (OR: 2.28, 95%CI: 1.05–4.95, $p = 0.039$). The 30-day readmission rates on the hospitalist and non-hospitalist services were not significantly different.

CONCLUSIONS: Our study shows that hip fracture patients admitted to a hospitalist service that uses clinical pathways have reduced LOS. Future studies will evaluate if the reduced LOS is associated with improved care processes.

Table. Patient Characteristics (n=200)

Characteristic	Value			p-value
	Overall (n=200)	Hospitalist (n=138)	Non-Hospitalist (n=62)	
Female, %	73.0	76.8	64.5	.085
Age, years (sd)	*77.5 (13.3)*	*80.0 (10.8)*	*71.9 (16.2)*	<.001
Charlson comorbidity index (sd)†	5.7 (2.3)	5.7 (2.0)	5.6 (2.7)	.678
Received blood transfusion, %	19.5	22.6	12.9	.114
Admitted to hospital on Thursday, Friday or Saturday, %	46.5	45.7	48.4	.720
Length of stay, days (sd)	***5.9 (3.4)***	***5.6 (3.1)***	***6.7 (4.0)***	***.038***
Length of stay ≤ 7 days, %	***80.5***	***85.5***	***69.4***	***.008***
30 Day Readmission, %	8.5	7.3	11.3	.412
White race, %	83.5	84.1	82.3	.628
Insurance, %				
Medicare	73.5	77.5	64.5	.059
Medicaid	12.5	8.7	21.0	.021
Private	24.5	23.2	27.4	.594
Self pay	0.5	0.7	0.0	.502

†measure of disease severity based on patient age and comorbidities

OVERUTILIZATION OF THE OBSERVATION UNIT FOR DECOMPENSATED HEART FAILURE

Michael Mashiba[3]; Scott Lawler[2]; Vivek Mendiratta[2]; Vincent Lipari[3]; Fawaz Georgie[2]; Paul Nona[1]; Joseph Gibbs[3]. [1]Henry Ford Health System, West Bloomfield, MI; [2]Henry Ford Helath System, Detroit, MI; [3]Henry Ford Hospital, Detroit, MI. (Control ID #2705904)

BACKGROUND: Acutely decompensated heart failure (ADHF) remains a significant health burden in the United States, with high mortality and cost. To promote quality care, the Centers for Medicare and Medicaid Services have decreased reimbursement for hospital systems with high readmission rates. Observation Units (OU) are a less-costly option for treatment of ADHF, however outcome data beyond 30 days is sparse. We sought to evaluate long-term outcomes and utilization for patients treated in the OU for ADHF.

METHODS: We performed a retrospective cohort study with patients admitted from the Emergency Department (ED) with ADHF. Patients with heart transplant, ventricular-assist device, or end-stage renal disease were excluded. Demographic and 12-month outcomes were collected. Patients discharged from the OU were compared with those admitted using Chi-Square Analysis, Fisher Exact Test, and Two-Sample T-Test. OU patients later admitted were also compared with those admitted from the ED.

RESULTS: Of the 535 patients included in the study, 427 were triaged to OU. Of these, 156 (37%) had LOS > 48 hours and required admission. The mean age was 71.4 years (standard deviation, 14.9 years) and 52% were female. OU patients converted to admission had higher Charlson Comorbidity Index (4.5 vs 3.9, $p = 0.012$) and higher 12-month mortality (17.3% vs 9.2%, $p = 0.014$) compared to those discharged. When converted patients were compared to those admitted from the ED, mortality (17.3% vs 10.3%, $p = 0.210$) and Charlson (4.3 vs 4.5, $p = 0.552$) were comparable. Patients triaged to OU showed no difference in readmissions, downstream OU visits, or adverse cardiac events. However, OU patients later admitted had shorter time to death compared to patients triaged directly to inpatient units (137.3 vs 257.9 days, $p = 0.023$). Patients cared for in the OU were more likely to follow-up outpatient (41.0% vs 25.9%, $p = 0.041$).

CONCLUSIONS: The OU is a venue for high-quality care for ADHF. Our study showed overutilization of the OU, commonly defined as over 15% conversion. A possible difference in time to death exists due to suboptimal triage, but multivariate analysis is needed to confirm. Enhanced risk-stratification for patient triage is needed.

PAIN AND SUBSTANCE USE AMONG PERSONS LIVING WITH HIV: ASSOCIATIONS WITH CO-MORBID ILLNESS AND VIRAL SUPPRESSION

Daniel J. Hindman[1]; Jeanne C. Keruly[2]; Richard D. Moore[1]; Geetanjali Chander[2]. [1]Johns Hopkins, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD. (Control ID #2706135)

BACKGROUND: Pain has been shown to be common in persons living with HIV (PLWH). Our objectives were to investigate the relationships between pain and substance use, depressive, anxiety, and post-traumatic stress symptoms among PLWH and to examine the association between pain and viral suppression.

METHODS: We performed a prospective cohort study of PLWH in the Johns Hopkins HIV Clinical Cohort who underwent an Audio-Computer Assisted Self-Interview (ACASI) at 6 month intervals querying drug and alcohol use, pain and mental health symptoms. Our primary outcome was the presence of moderate to severe pain obtained from the EuroQuol. HIV viral load was obtained from laboratory data. Alcohol and drug use were ascertained via the AUDIT and the NIDA ASSIST. Anxiety, depressive and trauma symptoms were obtained using the GAD-7, PHQ-8 and Primary Care PTSD, respectively. We performed bivariable and multivariable analysis, using generalized estimating equations to account for repeated measures, to examine the relationship between variables. Analyses were adjusted for age, sex, and race.

RESULTS: Between September 2013 and June 2016, 1431 individuals underwent 1967 ACASIs. 62.3% were male, 84.2% African American, median age 40.8. 576 out of 1431 (40.3%) reported moderate to severe pain at baseline. In univariate analysis, being female ($p = 0.026$), PTSD ($p < 0.01$), anxiety ($p < 0.01$) depression ($p < 0.01$), current cocaine use ($p < 0.01$), current heroin use ($p < 0.01$), prescription opioid use ($p < 0.01$), and current tobacco use ($p < 0.01$) were associated with pain. 95% of patients with symptoms of PTSD also met criteria for at least mild depression. Multivariable analysis of factors associated with pain is in table 1.

CONCLUSIONS: Depressive symptoms, anxiety symptoms, female sex, current cocaine use, and current or prior prescription opioid use were associated with patient report of pain. Pain was not associated with lower rates of viral suppression. Our results indicate that pain occurs in a complex milieu of substance use and mental illness. Effectively treating pain may require that clinicians also treat associated mental health and substance-related comorbidities.

Table 1

Characteristic	OR	95% CI
Sex (female=reference)	0.79	0.63-0.99
Age (per year older)	1.02	1.01-1.03
Current heroin use	0.85	0.49-1.50
Moderate alcohol use (none=reference)	0.86	0.69-1.07
Hazardous alcohol use (none=reference)	0.77	0.53-1.08
Current cocaine use	1.71	1.15-2.54
Prescription opioid use prior to last 3 months (none=reference)	1.81	1.30-2.51
Prescription opioid use within the last 3 months (none=reference)	2.74	1.55-4.86
No PTSD + mild depression*	2.98	2.35-3.79
No PTSD + moderate to severe depression*	4.82	2.81-8.25
PTSD without depression*	2.38	0.66-8.55
PTSD + mild depression*	3.91	2.29-6.69
PTSD + moderate to severe depression*	6.05	3.01-12.15
GAD (per 1 unit increase in score)	1.03	1.01-1.07
Viral Suppression	0.86	0.65-1.13]

*Reference = neither PTSD nor depression.

PATIENT AND CAREGIVER UNDERSTANDING OF PROGNOSIS AFTER HIP FRACTURE Rachel Eikelboom[1]; Anna Gagliardi[2]; Rajiv Gandhi[4]; Paul Kuzyk[3]; Peter Cram[5]. [1]University of Toronto, Toronto, ON, Canada; [2]Toronto General Research Institute, Toronto, ON, Canada; [3]Mount Sinai Hospital, Toronto, ON, Canada; [4]Toronto Western Hospital/University Health Network, Toronto, ON, Canada; [5]University Health Network and Mt. Sinai Hospitals, Toronto, ON, Canada. (Control ID #2703837)

BACKGROUND: Hip fracture (HF) is common among the elderly and mortality and morbidity are high. Patient and surrogate understanding of the seriousness of HF is unclear. We interviewed older patients hospitalized with HF, or their surrogate decision makers (SDMs), to explore their understanding of HF treatment options and prognosis.

METHODS: We used mixed methods to conduct interviews consisting of both open- and closed-ended questions that explored understanding of HF prognosis, treatment options, and recovery. We approached older patients (>65 years) hospitalized with HF, or their SDMs, at two academic hospitals in Toronto, Canada between August 2015 and July 2016. All interviews occurred within 72 hours of hospital admission, either pre- or post-operatively. All participants had provided informed consent for surgery at time of interview. We asked all participants to estimate probability of mortality and probability of living independently within 30 days of surgery (range 0-100%). Interviews were audio-recorded, transcribed, and analyzed using thematic content analysis. We gathered supplementary data from medical records including patient demographics, medical history and pre-fracture functional status. We compared participant assessment of HF mortality and likelihood of living independently to estimates from the American College of Surgeons National Surgical Quality Improvement Program (ACS NSQIP) risk calculator.

RESULTS: We conducted 12 interviews (9 patients, 3 surrogates) before reaching thematic saturation (mean age for patients 83 years, 75% women). The mean mortality estimated by participants was 6.7% (range 0–20%) and mean mortality calculated from NSQIP was 7.5% (range 0.1–27.8%). The mean probability of living independently within 30 days of surgery estimated by participants was 90.8% (range 65–100%), and mean probability calculated from NSQIP was 33% (range 23.4–64.4%). We identified four major themes from our interviews: nature of injury; treatment; recovery expectations; and patient experience. Many patients were unclear about risk factors for or predisposition do HF. Though all participants had received HF surgery or provided informed consent for surgery, they had difficulty describing treatment options. Participants expressed uncertainty about recovery timeline and probability of complete return of function, as well as content and duration of rehabilitation.

CONCLUSIONS: Older patients and their SDMs seem to understand the mechanism of HF, but lack understanding of prognosis, outcomes and functional recovery even after providing informed consent for surgery. Interventions are needed to ensure that older patients with HF and family members understand the seriousness of the injury and prolonged recovery trajectory.

PATIENT AND STAFF PERCEPTIONS OF A MOBILE INSULIN TITRATION INTERVENTION FOR UNCONTROLLED DIABETES PATIENTS: A QUALITATIVE STUDY Erin Rogers[1]; Sneha Aaidisani[1]; Rebecca Friedes[1]; Dana Moloney[1]; Natalie K. Levy[2]. [1]NYU School of Medicine, New York, NY; [2]NYU School of Medicine, Bellevue Hospital, New York, NY. (Control ID #2701934)

BACKGROUND: In the Spring and Summer of 2016, a text-messaging intervention to titrate basal insulin in patients with type 2 diabetes and poor glycemic control was implemented at two safety net health care systems in New York City. The goal of the current study was to conduct a qualitative evaluation assessing barriers to, and facilitators of, implementation of the mobile insulin titration intervention (called "MITI").

METHODS: We conducted in-depth qualitative interviews with patients ($N =$ 36) and physician, nursing and administrative staff ($N = 19$) at the two health care systems implementing MITI. Interviews were transcribed and coded by two study investigators using a codebook guided by the Consolidated Framework for Implementation Research and through iterative, consensus-driven content analysis.

RESULTS: Patients and staff perceived MITI as convenient and time-saving for patients, easy to use, and effective at achieving its clinical goals. Patients were comfortable sharing health information via text, and felt good about communicating with their health team remotely. Interviewees across stakeholder groups felt that MITI was helpful beyond insulin titration by reminding and motivating patients to engage in healthy behaviors and improving medication adherence. Staff felt MITI worked well with existing workflows and expressed a desire to see MITI expanded to other chronic conditions. Nurses responsible for weekly titration reported initial concerns over safety/liability, time required to deliver the program, difficulties reaching patients for titration calls and the need for ongoing support/training in using the online texting platform. Perceived barriers to MITI implementation reported by providers included perceived lack of patient cell phone access or texting capabilities and patient language barriers. There was also a theme that emerged across interviewees of an unmet need for additional diabetes management support among this population, beyond insulin support provided by MITI. The project team made several modifications to MITI operations in response to these findings.

CONCLUSIONS: Patients and staff were overwhelmingly supportive of MITI and believed it had many benefits. Initial implementation of MITI should address nurse comfort, workload and training, and sites should provide ongoing support and training for nurses after implementation. Future research should explore options for integrating additional diabetes support for patients enrolled in MITI or after they are discharged from the program.

PATIENT CHARACTERISTICS ASSOCIATED WITH LEAVING A USUAL SOURCE OF CARE DESPITE IMPROVED INSURANCE COVERAGE AFTER MASSACHUSETTS HEALTH REFORM

Elena Byhoff[3, 4]; Nancy R. Kressin[2]; Amresh D. Hanchate[1]; Norma Terrin[3]; Alejandro Moreno-Koehler[3]; Amy LeClair[3]; Karen M. Freund[4]. [1]Boston University School of Medicine, Boston, MA; [2]Dept of Veterans Affairs and Boston University, West Roxbury, MA; [3]Tufts Medical Center, Boston, MA; [4]Tufts University School of Medicine, Boston, MA. (Control ID #2706431)

BACKGROUND: Massachusetts Insurance Reform has allowed for expanded insurance coverage. Little is known about the characteristics of patients who switch or lose primary care despite increasing access through stable insurance coverage. Frequent changes in care, particularly related to changes in insurance coverage, may lead to suboptimal chronic or acute disease management. By understanding which patients are at risk of leaving their usual source of care (USOC), we can identify those who might benefit from outreach.

METHODS: Longitudinal cohort study to describe significant patient characteristics associated with staying in continuous care despite insurance switches. We use electronic medical and billing data from two large Academic Medical Centers in Boston to identify a cohort of patients and their USOC from 2004 through 2014. USOC is defined as ≥2 visits per year at the same clinic. We define two populations of patients who are identified as using the medical centers as their USOC beginning in 2004: (1) Those lost from USOC within 2 years for insurance reform (by 2010) (2) those who stay with USOC through 2014. We excluded patients who aged into Medicare during this time period. We identify those who left USOC adjusting for insurance changes, including loss of insurance, site of care, comorbidities, and socio-demographic factors. We then compare these covariates between groups using ANOVA, Chi Squared and Student's T tests.

RESULTS: Of the 80,610 total patients included in our cohort, 66,330 patients remained with their USOC through 2014. Of those that continued to visit their USOC, 15,826 (24%) had switches in insurance coverage, including loss of insurance. 14,280 patients (17.7%) left their USOC, of those, 3,178 (22.3%) experienced loss of insurance. There was no significant difference in the gender of those who stayed with their USOC compared to those who left (17.8% of men vs 17.7% of women, $p = 0.26$). Non-Hispanic white patients were more likely to leave their USOC compared to Black or Asian/Pacific Islander (19.3% vs 16.3% vs 14.0%, $p < 0.0001$). The mean Charlson Comorbidity Index was similar in patients who stayed vs left (1.78 vs 1.79, $p = 0.031$). Using census-track level data, the median income was $55,116 for those who stayed in USOC vs $59,039 for those who left (IQR $44,395-$77,276).

CONCLUSIONS: We show that in two large academic medical centers, insurance coverage loss was common despite insurance reform. Non-Hispanic white and higher income patients were more likely to leave their USOC controlling for changes in insurance status. Understanding characteristics of this population may help target patients who may have changes in USOC to prevent potential gaps in care.

PATIENT CHARACTERISTICS ASSOCIATED WITH VARIABLE LEFT VENTRICULAR RECOVERY IN TAKOTSUBO SYNDROME

Jae Kim[1]; Charan Yerasi[2]; Alaa Azzouqa[1]; Itsik Ben-Dor[1]. [1]Medstar Washington Hospital Center, Washington, DC; [2]St Joseph's Hospital and Medical Center, Phoenix, AZ. (Control ID #2705492)

BACKGROUND: Takotsubo syndrome (TTS) is an acute and usually reversible heart failure syndrome. The degree of recovery of left ventricular systolic function is variable and in this study we sought to identify determining factors and compare adverse event profiles.

METHODS: We conducted a retrospective analysis of the medical records of 90 TTS patients treated at our institution from 2006 to 2014. All presented with acute cardiac symptoms, left ventricular regional wall motion abnormalities, and absence of culprit atherosclerotic coronary artery disease. Patients were grouped based on degree of left ventricular ejection fraction (LVEF) evidenced on follow-up echocardiography, namely LVEF <50% (partial group) or LVEF ≥ 50% (full group). Various demographic characteristics and comorbidities, as well as laboratory, electrocardiography and echocardiography data were analyzed. Medication profiles were also compared between groups.

Adverse events analyzed included cardiogenic shock, use of mechanical ventilation, development of intramural thrombus and new onset arrhythmias.

RESULTS: Compared with full recovery patients, partial group patients were older (76.7 ± 12 years vs. 70.3 ± years; $P = 0.04$), with a higher prevalence of co-morbid endocrine disorder (25.9% vs. 7.9%; $P = 0.02$). All patients that were initially dentified as having endocrine disorder had a specific diagnosis of hypothyroidism. A greater portion of partial group patients were on levothyroxine replacement therapy (22.2% vs. 3.2%; $P = 0.003$). Use of ACEi/ARB was 18.5% in partial vs. 36.5% in full group ($P = 0.09$). We found no significant between-group differences in type of triggering event or peak cardiac biomarker levels. Initial electrocardiographic abnormalities differed in QT duration which was longer in partial group (540.6 ± 70.7 ms vs. 460.7 ± 34.4 ms; $P = 0.01$). Mean LVEF on initial echocardiogram was lower in partial group, but this was not statistically significant (25.0 ± 5.8% vs. 32.5 ± 9.5%; $P = 0.08$). Follow up LVEF was 37.9 ± 7.6% in partial group and 58.0 ± 4.2% in full group ($P < 0.005$). Follow up time did not statistically differ between groups ($P = 0.26$). There was no statistically significant difference between groups in length of hospital stay or rate of adverse events.

CONCLUSIONS: TTS typically presents with characteristic transient left ventricular dysfunction with variable degree of recovery after the acute episode. Those with partial recovery were older and had a longer QT duration on initial EKG. Triggering event did not differ between groups. Co-morbid endocrine disease (i.e. hypothyroidism) and levothyroxine replacement both associated with partial LV recovery.

PATIENT COMFORT WITH WHICH PROVIDER CAN RECOMMEND MEDICATION DISCONTINUATION Amy Linsky[2, 3]; Steven R. Simon[2]; Kelly Stolzmann[2]; Barbara Bokhour[4]; Mark Meterko[1]. [1]VHA Office of Analytics and Business Intelligence (OABI), Bedford, MA; [2]VA Boston Healthcare System, Boston, MA; [3]Boston Medical Center, Boston, MA; [4]ENRM Bedford VA, Bedford, MA. (Control ID #2699358)

BACKGROUND: Patients often receive care from multiple providers and may be given different advice about whether to discontinue medications. Patients may trust recommendations from one provider over another. We assessed patients' level of comfort with having pharmacists, primary care providers (PCPs) and/or specialists advise them to stop medicine and the characteristics associated with those patterns of comfort.

METHODS: We conducted a national mail survey using the Patient Perceptions of Discontinuation (PPoD) instrument of 1600 randomly sampled Veterans receiving Veterans Affairs (VA) primary care prescribed ≥ 5 medications. To create four outcome groups for patterns of comfort, we combined responses to two yes/no items: 1) "Imagine that a specialist…prescribed a medicine for you. Would you be comfortable if your PCP told you to stop taking it?" and 2) "Imagine that your VA PCP prescribed a medicine for you. Would you be comfortable if a VA clinical pharmacist told you to stop taking it?" The primary predictors were eight validated attitudinal scales. Other predictors included demographics, health status, and health care experiences. Multinomial regression modeling associated patient factors with patterns of comfort.

RESULTS: Respondents ($n = 803$; adjusted response rate, 52%), were predominantly male (85%); non-Hispanic white (68%), age ≥ 65 years (60%), with generally poor (16%) or fair (45%) health. There were 281 (38%) respondents who said "no" to both questions (PCP-N/Pharm-N) and 146 (20%) who said "yes" to both (PCP-Y/Pharm-Y). There were 155 (21%) respondents who said "no" to the PCP stopping a specialist's medicine but "yes" to the pharmacist stopping the PCP's prescription (PCP-N/Pharm-Y). There were 153 (21%) who said the pharmacist could not stop a PCP's medicine, but the PCP could stop the specialist's (PCP-Y/Pharm-N). In adjusted multinomial regression models with PCP-N/Pharm-N as the reference, those with chronic obstructive pulmonary disease were less likely to be PCP-Y/Pharm-N (OR 0.52, CI 0.31–0.88). Respondents with greater medication concerns were more likely to be PCP-Y/Pharm-Y (OR 1.45, CI 1.09–1.92). Those with more interest in shared-decision making were more likely to be PCP-N/Pharm-Y (OR 1.41, CI 1.04–1.92). Finally, if one had greater trust in their PCP, they were less likely to be PCP-N/Pharm-Y (OR 0.52, CI 0.34–0.81), but more likely to be PCP-Y/Pharm-N (OR 2.16, CI 1.31–3.56) or PCP-Y/Pharm-Y (OR 1.83, 1.13–2.98).

CONCLUSIONS: Patients have varying patterns of whom they feel comfortable to make deprescribing decisions about their medicines. Those with more concerns about medicines were more amenable to anyone telling them to stop taking them, and trust in one's PCP was associated with allowing the PCP to supersede the specialist. As multidisciplinary models of care expand, understanding how patients perceive the roles of various providers is important as it may influence adherence to recommendations.

PATIENT EMPOWERMENT PROGRAM (PEP) HAS A LASTING IMPACT: PATIENT REPORT OVER A YEAR LATER Nadiya Pavlishyn[2]; Lisa Altshuler[2]; Kayla Maloney[2]; Rebecca Deng[2]; Sondra Zabar[2]; Joseph Plaksin[2]; Adina Kalet[2]; Andrew B. Wallach[1]. [1]Bellevue Hospital, New York, NY; [2]NYU School of Medicine, New York, NY. (Control ID #2702503)

BACKGROUND: The shift toward a Patient Centered Medical Home has redefined healthcare delivery to be a patient centered affair. While this is beneficial, it also calls for patients to be more activated in the doctor's office and responsible in their self-directed care outside of the office. For patients with chronic diseases, the burden of illness is even higher and requires significantly more effort in disease self-management. We developed 4 hour Patient Empowerment Program (PEP) to bridge that gap through a program training patients with diabetes in the skills necessary to communicate effectively with providers and engage in shared decision making (SDM). Previously, we reported improved diabetes self-care behaviors at 6 months post intervention based on standardized questionnaires. This study examined participants' perspectives on PEP from 1–2 years post intervention.

METHODS: 71 patients with type 2 diabetes mellitus were recruited from 2 urban safety-net hospitals to participate in PEP. 33 patients completed the intervention and 28 patients completed a 6-month follow-up assessment. Participants were predominantly low-income, racial minorities, with limited health literacy (Newest Vital Sign M = 2.21, SD = 1.67). We reached 22 of those 28 participants, at 11 to 20 months post intervention (M = 16, SD = 2.31). They were interviewed via telephone, with structured open-ended questions asking them to reflect on what they took away from the classes, and whether they'd behaved differently during doctor visits or cared for their diabetes differently since the classes. A qualitative analysis was made of these responses, using Dedoose software to assist in analysis.

RESULTS: All 22 patients recalled PEP and could identify key concepts from it. Participants referenced the doctor-patient relationship, from "how to improve relationship with my doctor" to "practicing role of doctor and patient in interaction and relationship". 86% of participants identified changes in their behavior since PEP- 36% identifying that they share more information with their doctor now than they did before, 18% reporting that they ask more questions, and another 18% reporting that they are more proactive in their diabetes care. When asked about their diabetes self-management, prevalent themes were better diet/food choices, exercise, and adherence to medication. 3 patients reported losing weight since the classes.

CONCLUSIONS: Despite follow up occurring almost a year later for some, and almost 2 years for others, the message of PEP was clear and compelling. Participant's perspective on their role as a patient changed from a passive recipient of healthcare to a more engaged and activated one. They felt empowered to participate in SDM with their doctors and more comfortable speaking up for their preferences. While further validation is necessary, PEP offers an important way to prepare patients to become true partners with their providers.

PATIENT EXPERIENCE WITH INTER-HOSPITAL TRANSFER: A QUALITATIVE STUDY Stephanie Mueller[1]; Evan Shannon[1]; Jeffrey L. Schnipper[2]; patricia dykes[2]. [1]Brigham and Women, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA. (Control ID #2703707)

BACKGROUND: Inter-hospital transfer (IHT) exposes patients to risks of care fragmentation and remains a largely unstudied care transition. In this study, we investigated patient experience with IHT.

METHODS: We developed interview guides to investigate patient experience with IHT using themes extracted from prior research along with stakeholder input. We conducted semi-structured interviews on a purposeful sample of patients transferred within the previous 48 h to the General Medicine, Cardiology or Oncology services at Brigham and Women's Hospital (Boston, MA). We used Content analysis to interpret data obtained from transcribed interviews. Using an *a priori* analytic framework, two independent reviewers coded data into discrete categories, meeting regularly for analytic discussions to iteratively modify themes and interpretations.

RESULTS: Interviews were conducted with 10 recently transferred patients (2 medicine, 6 cardiology, 2 oncology). Analysis yielded three primary themes: (1) "Decision to transfer," (2) "Communication regarding transfer," and (3) "The transfer process" (Table). Patients often described a joint decision to transfer between themselves and the referring care team, most often to receive more specialized care, and expressed satisfaction with the transfer. Most patients expressed dissatisfaction with the timing of transfer, including time of day, delay, and lack of notice, with less focus on communication between providers. Patients often focused on the physical transfer process (ambulance ride, hospital room) (Table).

CONCLUSIONS: Appreciating patients' experience with IHT is an essential step towards understanding of the impact of IHT on primary stakeholders. Notably, patients focused on elements of IHT that more directly impacted them, including timing of transfer, and the physical transfer process, with less focus on communication between providers of which they might be less directly aware. These identified themes may provide important patient-centered targets in improving this care process.

Table. Themes of Patient Experience with IHT

Theme	Patient Example
Decision to Transfer	
Reason for transfer	"I was at [Outside Hospital] for about a week and a half for my latest stint. I went in with pancreas issues. The recommendation after a week and a half was that they would send me to...a hospital that have actual specialists that deal with the pancreas, whether it be surgery wise or nutrition wise. There they weren't well-equipped enough at [Outside Hospital] to deal with my condition basically, so they wanted me to go to...Brigham" (Patient 3)
Expectations of care	"I didn't wanna sit there for weeks for no reason. They could only keep me alive for so long. What's the point? Yeah, I was happy that I was transferred over here. Yeah... I feel a lot more comfortable here." (Patient 8)
Communication Regarding Transfer	
Timing of transfer	"They transferred me at, like, midnight." (Patient 8) "The only downside was that I really didn't know any time really, when I'd be transferred, so I'm guessing that's something that you get complaints about or concerns about from people... so I was told Wednesday, so I was planning on Wednesday... I was telling my family, I'm like, "Oh, if you're not busy, you can come by before Wednesday cuz I'm getting transferred"... it was just kind of difficult because they switched it up last minute. I think I found out at 6:30 last night that a bed opened up at Brigham and Women's, they'll be here in an hour and a half... so I had an hour and a half to basically pack up all my stuff." (Patient 3) "Three times my uncle was already on his way here from [his house]. Three times I had to call him. I don't know if you should stop where you are because they just cancelled the ambulance." (Patient 5) "Well, let's put it this way. I found out that we were being transferred at 8:00—I don't—maybe 9:00. We didn't leave by ambulance until 1:00 in the morning. Getting here was just unreal. Once we got here, you know, they were ready for us." (Patient 9)
Information exchange between transferring and receiving treatment teams	"I didn't have any concerns about it, but a lot of what was going on was behind, quiet behind the scenes. I didn't know too much about what was going on." (Patient 1) "Well, yeah, they use the same computer system now, so all my stuff is in the computer—all my meds, everything. It's all there. I don't even think they really need to talk." (Patient 8)
The Transfer Process	
The physical transfer process	"They called an ambulance team out in [transferring location], and they came up with a stretcher, got me all set up on that. Got me in the ambulance. It was pretty quick. I kept dozing off, so it was really quick. There was three paramedics with me. The one in the back kept giving me my medication every two hours, and they gave me the medication maybe three times. My two hour pain med and then an anxiety pill, and then there was another pill I was due while I was in the ambulance ride; she gave me those, which I guess that's what was making it where it seemed so quick. I was dozing in and out quite a bit." (Patient 4) "The ambulance drivers are very good. They covered me up in the ambulance and one sat there and talked if I wanted to talk, and I had no problem whatsoever. I got over here safe and sound, no problem." (Patient 10) "The ambulance ride was awful...Maybe she smoked or maybe the guy that was taking care of me smoked. I smelled cigarettes, and I can't handle that. A whiff of that and I'm like "oh my God". It was on adults and everything. I felt like it was on my skin. I just showered. After six days, I just showered. It felt like it was on my skin. Then when [the ambulance] was just going, rocking back and forth, I had very low blood pressure. Maybe I'm just running low, and I'm laying down, and I'm scared to death. You guys obviously are speeding and I didn't have my glasses on, so I didn't see anything." (Patient 5)
Impressions on arrival	"I was really surprised to see how nice the room was, and how roomy a room it was, as compared to [Outside Hospital]." (Patient 1) "When I got here, I went by the nurse's station, so I was aware that they knew that who I was and I was coming in and what room I was gonna be in and all that." (Patient 7) "I mean, as soon as I got here—the nurses are awesome. As soon as I got here, they got right on the computer, checked it out, got my meds right away." (Patient 8)

PATIENT EXPERIENCE: COMPARISON OF PRIMARY CARE PATIENTS' AND UNANNOUNCED STANDARDIZED PATIENTS' PERCEPTIONS OF CARE Lisa Altshuler[4, 4]; Michelle E. Carfagno[6]; Nadiya Pavlishyn[4]; Anne Dembitzer[4]; Kelly J. Crotty[5]; Richard E. Greene[4, 1]; Andrew B. Wallach[1, 1]; Reina Smith[1]; Barbara Porter[3, 1]; Kathleen Hanley[2]; Sondra Zabar[4]; Mark D. Schwartz[4]. [1]Bellevue Hospital, New York, NY; [2]NYU, New York, NY; [3]NYU SOM, New York, NY; [4]NYU School of Medicine, New York, NY; [5]New York University, NY, NY; [6]NYU School of Medicine, Dix Hills, NY. (Control ID #2707245)

BACKGROUND: Patient experience is an important quality indicator, and healthcare organizations spend considerable resources assessing patient satisfaction. Yet a view of patient experience gleaned from patient satisfaction measures tends to show high levels of reported satisfaction, with little variation. Unannounced standardized patients (USPs) have been used to assess providers' clinical skills, but can also provide other information about the healthcare encounter. This study examined the concordance between USP and patient reports of care at the same site.

METHODS: Data was gathered at Bellevue Hospital Primary Care Clinic, a city safety-net hospital. USPs assess internal medicine residents training there, and complete a behaviorally anchored checklist of resident skills and interactions with other staff, wait times, ease of clinic navigation, and perceptions of team functioning. Data from 155 USP visits from July 2015-Oct 2016 was used in this study. Independently, as part of team-training efforts in the Primary Care Clinic, patient satisfaction surveys were collected, addressing similar issues. At the end of a clinic visit, research assistants unrelated to patient care asked patients to complete a 30-item survey. 118 surveys were completed between July-November 2016. 11 items appeared on both scales (though worded slightly different) and were used in this comparison. These included questions about clerical (CA) and patient care associates (PCA), and providers (MDs, NPs, PAs), provision of information, team functioning and clinic environment. Of the 11 items, 4 had the same response choices. 7 had differing

numbers of responses (eg 4 vs 3 point Likert scales), evenly distributed across patient and USP scales. For each of these items, we collapsed items so to maximize positive ratings (eg. on a 4 point scale from poor to excellent, "good" and "excellent" were combined rather than "good" and "fair"). Chi-square analyses were computed to examine group differences.

RESULTS: On chi-square analyses, 9 of the 11 items significantly differed between the USP and patient groups, with patients more likely to have positive ratings. These included rating PCAs as friendlier ($x^2 = 8.67(1,206)$, $p = .003$) and providers better at answering questions ($x^2 = 11.75$ (2,265), $p = .003$); reporting that they received sufficient/clear instructions about medication refills and follow-up ($x^2 = 29.5(2,264)$, $p = .0001$); finding the clinic atmosphere calmer than did USPs ($x^2 = 10.5$ (2,265), $p = .005$) and noting that the team functioned better ($x^2 = 7.31(2,268)$, $p = .026$). There were no significant differences in willingness to recommend the clinic or on clarity of CAs' communication.

CONCLUSIONS: Results of this study document the differing perspectives of patients and USPs. Consistent with previous work, patients in our study tended to rate most items higher than did the USPs. USPs provide a different, and likely a more critical look at the clinical setting and this information can enhance efforts to improve patient experience.

PATIENT KNOWLEDGE OF RISKS AND BENEFITS OF PERCUTANEOUS CORONARY INTERVENTION DOES NOT INFLUENCE PATIENT PREFERENCE FOR TREATMENT FOR STABLE CORONARY ARTERY DISEASE

Neal Yuan; Nadra Lisha; R. Adams Dudley; W. John Boscardin; Grace A. Lin. University of California San Francisco, San Francisco, CA. (Control ID #2706818)

BACKGROUND: In patients with stable coronary artery disease (CAD), percutaneous coronary intervention (PCI) may help with more rapid relief of anginal symptoms but does not reduce mortality or risk of cardiovascular events when compared with optimal medical therapy (OMT) alone. Nevertheless, many patients who may not benefit continue to receive PCI. Prior studies have found that patients are not well informed and preferences are not well incorporated into the treatment decision. Increasing patient knowledge has been promoted as a key intervention for improving shared decision-making for stable CAD treatment. It is unknown how significantly patient knowledge influences both patient preference and the treatment received for stable CAD. We sought to understand the relationships among patient knowledge, preferences, and treatment received.

METHODS: We surveyed patients with stable CAD referred for elective cardiac catheterization for CAD evaluation across four large U.S. academic centers. Patient completed surveys either immediately pre- or post-cardiac catheterization. The survey consisted of 23 questions covering the three primary domains of decision-making: knowledge, communication, and preferences. Self-reported demographics and medical history were collected. Treatment received was verified by chart review. Knowledge score was calculated using the number of correct responses to knowledge questions. We used linear regression to evaluate the relationship between knowledge score and patient preferences. We used logistic regression to study the association of patient preference with treatment received.

RESULTS: Of the 101 patients surveyed, 52.0% agreed or strongly agreed that they would prefer receiving OMT over PCI. More knowledge did not predict a patient's treatment preference (OMT or PCI), even after adjustment for age, gender, race, education, desired level of decision-making involvement, and degree of symptoms ($\beta = -0.04$, $p = 0.74$). The majority (80.8%) of patients desired a substantial role in the decision-making process. Expressing a preference for OMT over PCI did not correlate with receiving OMT. Only 24% of patients stating that they strongly would prefer medications over PCI actually received OMT alone. In contrast, patients expressing an ultimate preference for PCI were nine times more likely to receive PCI (OR 9.05, 95% CI 2.32–38.94).

CONCLUSIONS: Greater knowledge of the risks and benefits of stable CAD treatment did not appear to affect a patient's preference for treatment. While the vast majority of patients desired a substantial role in forming the treatment decision, treatment received was associated with patient preference only in patients who preferred PCI. Thus, interventions aimed only at improving knowledge may not substantially influence patient preference for treatment or treatment received.

PATIENT MORTALITY DURING UNANNOUNCED ACCREDITATION SURVEYS AT US HOSPITALS

Michael L. Barnett[2]; Andrew Olenski[1]; Anupam B. Jena[1]. [1]Harvard Medical School, Boston, MA; [2]Harvard T.H. Chan School of Public Health, Boston, MA. (Control ID #2705841)

BACKGROUND: The Joint Commission (TJC) performs week-long unannounced on-site surveys at US hospitals as an integral part of their accreditation process. The stakes for performance during TJC surveys are high since a citation can significantly affect a hospital's reputation. To date, no research has addressed whether this heightened vigilance during survey weeks is associated with patient outcomes. If surveyors' presence improved outcomes, it would imply that the survey-week scramble to improve staff compliance has a safety impact worth further study. We hypothesized that surveyors' presence would improve safety outcomes, with a larger effect in major teaching hospitals, which have both greater resources and reputational incentives to ensure survey compliance.

METHODS: Observational analysis of Medicare admissions at 1,984 TJC-surveyed hospitals from 2008–2012. We identified survey weeks using historical dates extracted from the TJC website. We measured rates of 30-day mortality, and secondary outcomes (*C. diff.*infections, in-hospital cardiac arrest mortality and the composite Patient Safety for Selected Indicators (PSI)-90 measure) from 3 weeks before to 3 weeks after surveys. We then compared rates of these outcomes during survey weeks vs. average rates in the ±3 week period with logistic regression, adjusted for beneficiary characteristics. Additional sub-analyses were conducted for major teaching hospitals. Standard errors were clustered at the hospital-level.

RESULTS: There were 244,787 admissions during 3,417 survey weeks and 1,462,339 admissions in the ±3 week period during 2008–2012. Patient characteristics, admission diagnoses and procedures were similar across survey and non-survey weeks. Across all surveyed hospitals, there was a significant decrease in 30-day mortality for admissions occurring during a survey week vs. the surrounding 3 weeks (7.03% vs. 7.21%, adjusted difference 0.11%, $p = 0.032$), with stable rates during non-survey weeks ($p > 0.13$). This observed decrease was larger than 99.5% of mortality changes among 1,000 random permutations of hospital-survey date combinations. Larger effects were observed among major teaching hospitals, where 30-day mortality fell from 6.41% on non-survey weeks to 5.93% during survey weeks (adjusted difference 0.39%, $p = 0.027$), a 6.1% relative decrease. We did not find any

significant differences between survey and non-survey weeks among safety-related secondary outcomes.

CONCLUSIONS: Admissions during TJC survey weeks have significantly lower 30-day mortality than non-survey weeks, particularly in major teaching hospitals. These results are unlikely explained by confounding given that patient/admission characteristics were indistinguishable between survey and non-survey weeks and surveys are unannounced. Though the mortality effects we observed were modest, these results suggest that changes in practice occurring during periods of surveyor observation may meaningfully impact patient mortality.

PATIENT NAVIGATION TO PROMOTE SMOKING CESSATION IN PRIMARY CARE: PRELIMINARY FINDINGS FROM AN ONGOING RANDOMIZED CONTROLLED TRIAL Karen E. Lasser[1]; Lisa M. Quintiliani[2, 3]; Ve Truong[1]; Ziming Xuan[3]; Lori Pbert[4]. [1]Boston Medical Center, Boston, MA; [2]Boston University, Boston, MA; [3]Boston University School of Public Health, Boston, MA; [4]University of Massachusetts Medical School, Worcester, MA. (Control ID #2700692)

BACKGROUND: Primary care practices are implementing patient navigation widely to promote smoking cessation. Little is known about the reach and effectiveness of such programs.

METHODS: We analyzed data from an ongoing trial of patient navigation and financial incentives to promote smoking cessation among primary care patients who are daily smokers at an urban safety-net hospital; smokers in the precontemplation stage were excluded. 177 participants were randomized to the intervention arm and received up to four hours of patient navigation over six months and financial incentives for biochemically confirmed cessation. Two navigators delivered the intervention; each worked twenty hours per week. Navigators were given flexibility in how to reach participants (in-person, text, and/or by phone). The navigators' goal was to link participants to tobacco counseling; navigators were not formally trained as tobacco treatment counselors. We analyzed process data (e.g. ability to contact patients by phone, complete motivational interviewing calling script), receipt of the minimum intervention dose (at least one in-person meeting) and outcome data (linking patients to counseling and pharmacologic therapy). We used chi square tests to compare differences between groups, and multivariable logistic regression to examine predictors of having a nicotine replacement therapy (NRT) prescription sent to the patient's pharmacy via the EMR. We controlled for variables of a priori clinical significance and those with $p < 0.1$ in bivariable analyses.

RESULTS: Navigators contacted 86% of participants by phone (navigator 1 contacted 93%; navigator 2 contacted 78%; $p = 0.004$). Stage of change with respect to smoking cessation was not associated with ability to contact participants; navigators contacted 92% of participants in contemplation stage vs. 84% in preparation stage ($p = 0.14$). Navigators completed a motivational interviewing calling script with 53% of participants and met 24% of participants in person. Very few participants accepted referrals to counselling (quit line or hospital smoking cessation resources) or pharmacotherapy other than NRT. Navigators sent NRT prescriptions to 34% of participants (60/177). In multivariable analyses limited to participants who received at least one in-person meeting or navigation by phone, meeting the navigator in person was associated with an increased odds of receiving NRT (OR 3.7, 95% CI 1.6–8.4). Black participants were less likely to receive NRT compared to non-black participants (OR 0.3, 95% CI 0.15–0.71).

CONCLUSIONS: Meeting participants in person may help navigators connect with and link smokers to NRT. Given the limited acceptance of referrals to tobacco treatment, navigators should be trained in tobacco treatment counselling. Further interventions are needed to increase uptake of NRT by black smokers.

PATIENT PERCEPTION OF BEDSIDE FIRM ROUNDS: MIXED METHODS STUDY OF A NOVEL APPROACH TO BEDSIDE ROUNDS Allen Shih[1]; Nana Addo-Tabiri[2]; Andre N. Sofair[1, 2]. [1]Yale School of Medicine, New Haven, CT; [2]Yale New Haven Hospital, New Haven, CT. (Control ID #2705161)

BACKGROUND: Transition of care between medical teams represents a juncture critical for patient safety and quality, yet often occurs without patient involvement. Concerns over patient privacy, understanding, and comfort helped to drive the decline in bedside rounding in favor of hallway and conference presentations. Our institution recently introduced 'Firm Rounds' during which one outgoing night team and two accepting day teams jointly transition care using 3 pillars: a patient-centered presentation of the history and physical at the bedside, a 'warm handoff' including introductions of the accepting team by name and role, and discussion of a teaching point by the resident. Our project seeks to explore patient perceptions regarding patient involvement in transitions of care at the bedside.

METHODS: Semi-structured interviews were conducted with 38 English-speaking adults admitted to the general inpatient medical floor at Saint Raphael's Campus of Yale New Haven Hospital between November 2014 to March 2015. Conducted within 48 hours of admission, this mixed methods study comprised a quantitative portion with a 5-point Likert scale and a qualitative interview. Questions included the experience with rounds, interactions with doctors, patient comfort level with the process, and degree of understanding of their care. Interviews were audiotaped, transcribed, analyzed using the constant comparative method, and conducted until thematic saturation was reached. Chi-squared test assessed answer independence.

RESULTS: Patients described the following positive attributes of bedside rounds: meeting the medical team, helping teach the medical team, and understanding more about their illness. Patients found importance in listening to presentations, asking questions, and engaging with the medical team. Although patients enjoyed undivided attention from physicians, distractions included too many participants in rounds, confusion about team member's roles, and apparent boredom by several listeners. 68% of patients felt that rounding in a 2-bed hospital room was acceptable. Although physicians sought to use patient-centered language, 53% of patients stated that medical jargon was still used. After bedside rounds, 58% of patients stated that they had a better understanding of their condition and treatment plan. Patients commonly viewed bedside rounds as educational to themselves and round attendees.

CONCLUSIONS: Our study suggests that patients hold positive views regarding bedsides rounds and prefer it to rounds taking place outside the room. While patient hold a variety of preferences for how bedside rounds are conducted, the majority found rounds to be informative, personable, and beneficial. Concerns over patient privacy or use of medical jargon weighed less heavily than the perceived benefits of team communication and education. We found that well-conducted, patient-centered bedside rounds such as Firms Rounds can enhance patient-physician rapport and foster patient understanding and satisfaction.

PATIENT SATISFACTION WITH A LARGE PRIMARY CARE TELEMEDICINE SERVICE Kathryn A. Martinez[1]; Mark N. Rood[2]; Nikhyl Jhangiani[1]; Adrienne Boissy[1]; Michael B. Rothberg[1]. [1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Foundation, Chagrin Falls, OH. (Control ID #2702118)

BACKGROUND: Interest in use of telemedicine for primary care delivery is increasing, however information regarding patient satisfaction is limited. The objective of this study was to characterize factors associated with patient satisfaction with telemedicine encounters.

METHODS: We analyzed all completed primary care encounters between January 2013 and August 2016 from the Online Care Group telemedicine service, one of the largest telehealth companies in the US, serving patients in 48 states. Patient characteristics, including age, sex, and geographic region were provided by the user when accessing the system. Encounter characteristics, including time of day, wait time, visit length, and whether patients used a coupon for a free or reduced-cost visit were recorded by the telemedicine system. Patient diagnosis and prescription receipt were recorded by the visit provider. At the completion of the encounter, users were asked to rate their satisfaction (on scales of 0 to 5 stars) with 1) the telemedicine system overall, and 2) their telemedicine provider. We dichotomized satisfaction measures as 5 stars versus less than 5 stars. Using multivariable logistic regression, we evaluated the association between patient characteristics, encounter characteristics, and patient diagnosis and prescription receipt with satisfaction with 1) the telemedicine service overall and 2) with the visit provider.

RESULTS: There were 56,863 completed encounters during the study period with 601 providers; 60% of patients were female and 64% were under 40 years. Eighty-five percent rated their satisfaction with the provider 5 stars, and 78% rated their overall experience 5 stars. Mean wait time was 5.1 min (Interquartile Range (IQR): 1.2–6.1 min) and the mean visit length was 7.1 min (IQR: 3.4–8.8 min).In the multivariable model regarding the telemedicine service overall, receipt of a prescription (Odds Ratio (OR):3.30; 95%Confidence Interval (CI):3.04–3.59), and coupon use (OR: 1.39; 95%CI:1.24–1.57) were associated with greater odds of rating satisfaction 5 stars. In the adjusted model regarding visit providers, greater satisfaction was also associated with both prescription receipt (OR: 3,72; 95%CI: 3.38–4.09) and coupon use (OR: 1.55; 95%CI: 1.34–1.79). In both models, longer visit length was associated with higher satisfaction and longer wait time was associated with lower satisfaction, but these effect sizes were small. Neither call time of day nor patient diagnosis was associated with satisfaction in either model.

CONCLUSIONS: In this large nation-wide cohort of telemedicine patients, satisfaction with both service overall and individual providers was high. However, satisfaction varied significantly by both coupon use and prescription receipt. Patient expectations of telemedicine may differ from those of traditional outpatient care, and be more heavily influenced by consumer-oriented demands.

PATIENT SATISFACTION: “ACCENTUATING THE POSITIVE” IN PATIENT CARE Garrett Oberst; Abigail Lawson; Christina Fahey; Dylan Woolum; Stephanie A. Rose; David Rudy. University of Kentucky, Lexington, KY. (Control ID #2705382)

BACKGROUND: Process improvement is a vital component of health organizations. Hospitals commonly identify areas of strengths and weaknesses through patient satisfaction surveys. Normally, areas of weakness are identified and plans are made to rectify these deficiencies. While sometimes successful, it can lead an organization to overlook its strengths and focus on weaknesses which may lead to a “blame and shame” organizational culture. Appreciative Inquiry (AI) is an alternative to this method. AI works by promoting positive successes. The aim of this project is to identify positive aspects of patient care in the cancer center in an academic medical center.

METHODS: Interviews were conducted in the outpatient chemotherapy infusion and inpatient bone marrow transplant units in a large, university-based cancer center. All patients were over 21 years of age. No identifying information was collected other than the date and setting of the interview. Patients were asked about a time that they were a part of excellent patient care. Patients were asked to identify people who contributed or helped during this experience and why these individuals were so impactful. Additionally, patients were asked to name three wishes that could enhance their experience. Researchers took written notes of patients’ responses. Notes were analyzed qualitatively, reviewed by the authors, and thematic areas were identified. An operational definition was developed for each theme to decrease subjectivity. Two iterations of theme development were performed. Patient responses could fall into more than one category. Discrepancies were assigned final codes based on simple majority ratings.

RESULTS: 102 interviews were conducted, with 78 (77%) conducted in outpatient chemotherapy infusion and 24 (23%) in inpatient bone marrow transplant. The four common themes identified in patients’ responses regarding their positive experiences were caring (68% of patients), personalized care (50%), communication (41%), and professionalism (38%). The themes of the responses regarding improvements were wait time (28% of patients), facilities (15%), scheduling (10%), availability of staff (10%), and staff performance (8%). 49% of patients could not identify an improvement.

CONCLUSIONS: Patients at the cancer center most appreciated the way in which they were treated by their healthcare providers rather than the level of healthcare that they received. Additionally, the improvements in care that most patients suggested tended to be related to operational improvements such as wait time and facility improvements rather than to the performance of their healthcare providers or the way that they were treated. Surprisingly, nearly half of patients interviewed were unable to identify an improvement. Future goals include review of these findings with the cancer center, which will allow us to focus on both strengths and weaknesses.

PATIENT-CENTERED PRIMARY CARE, SOCIAL NETWORKS, AND CANCER PREVENTION KNOWLEDGE AND BELIEFS IN US ADULTS Jaya Aysola; Hairong Huo; Marilyn M. Schapira. University of Pennsylvania, Philadelphia, PA. (Control ID #2707630)

BACKGROUND: We lack understanding about whether patient-centered primary care and social networks predict cancer prevention knowledge and beliefs among US adults. The primary objective of this study was to evaluate if factors such as having patient-centered primary care and discussing health with social ties were associated with cancer prevention knowledge and beliefs.

METHODS: We analyzed data on a nationally representative sample of US adults without a prior diagnosis of cancer ($n = 3502$) from the 2015 Health Information National Trends Survey (HINTS). Our first predictor was whether one had a regular source of care that was patient centered (yes or no). To have patient-centered care, one would have to have a regular provider, excluding psychiatrists and other mental health professionals, and have answered “Always” or “Usually” to several questions that assessed patient-centeredness. (Cronbach’s alpha 0.86). Our second predictor was the response

to the question, “Do you have friends or family members that you talk to about your health?” (yes or no). Our primary outcomes were awareness of the relationship between lifestyle behaviors and cancer risk (yes or no) and the following beliefs about cancer: everything causes cancer (agree or disagree), prevention is not possible (agree or disagree), and there are too many recommendations about cancer (agree or disagree). With logistic regression models, we estimated associations between our two predictors and cancer knowledge and belief outcomes. In multivariable regression models, we adjusted for age, gender, race/ethnicity, household income, education level, and employment.

RESULTS: About 81% of the study sample had knowledge that lifestyle behaviors influence cancer risk and about 60% agreed with the belief that everything causes cancer, about 30% agreed with the belief that prevention was not possible, and about 73% agreed with the belief that there were too many recommendations about cancer. We found no significant associations between both our predictors (having patient-centered care, discussing health with social ties) and knowledge that cancer behaviors influence cancer risk. However, we found significant associations between discussing health with social ties and cancer-related beliefs. For example, talking with your friends about health meant you were less likely to belief that everything causes cancer [(Adjusted Odds Ratio (95% Confidence Interval): 0.6 (0.4, 0.9)]and that prevention is not possible [(Adjusted Odds Ratio (95% Confidence Interval): 0.4 (0.3, 0.6)]

CONCLUSIONS: Our findings suggest currently social networks influence cancer knowledge and beliefs more so than having patient-centered care and highlights a need for primary care providers to discuss cancer prevention with their patients.

PATIENTS' PERCEPTIONS ABOUT PARTICIPATION IN ONLINE HEALTH RESEARCH IN AN URBAN SAFETY-NET SETTING

Sneha Thatipelli[1]; Gato I. Gourley[1]; Madelaine Faulkner[3]; Hannah Gittleman[2]; Gregory Marcus[2]; Urmimala Sarkar[1]. [1]Division of General Internal Medicine and Center for Vulnerable Populations at San Francisco General Hospital, University of California, San Francisco (UCSF), San Francisco, San Francisco, CA; [2]Division of Cardiology, Medicine, UCSF, San Francisco, CA; [3]Department of Epidemiology and Biostatistics at UCSF, San Francisco, CA. (Control ID #2673274)

BACKGROUND: As smartphone usage grows among low SES groups and ethnic minority populations, mHealth has the potential to improve health and reduce disparities. However, low-income, diverse populations have lagged in adoption of information technology for health. Formative work is needed to design online interfaces that address the needs and concerns of diverse populations.

METHODS: We conducted a 2-hour focus group with 11 participants to understand their ideas regarding sharing personal data via smartphone apps. Participants had either participated in prior studies and given consent to be contacted about upcoming studies or were recruited via flyers posted in ambulatory clinics. Inclusion criteria included age over 18, ambulatory care patients in the safety-net setting, English-speaking, and ownership of a smartphone with weekly or daily use. Participants were excluded if they had significant cognitive or visual impairments. The two audio recordings set up in opposite areas were transcribed using a digital transcription service. Two researchers separately analyzed the transcripts to inductively identify themes in the participant's responses and agreed upon a common set of themes.

RESULTS: Four themes regarding individuals' willingness to participate in data sharing applications on their smartphones were identified: accountability and trust, fear of data misuse, usability, and altruism. Participants were very concerned about jeopardizing their personal information through data sharing; they were only willing to share health information with trusted sources (i.e. their doctors and known health institutions), but were hesitant to share with others. Individuals also heavily stressed that knowing the reason for the research study would influence their decision to share their personal data. Three specific fears regarding data misuse frequently arose during the focus group: fear of geographic tracking, financial harm, and medical information privacy breach. Participants also highlighted the importance of usability of mobile platforms, emphasizing ease of use as an important factor Many wanted to participate in research that would lead to public good (altruism).

CONCLUSIONS: Concerns about participation in online health research echo known concerns about research participation in general and about overall internet data sharing. These concerns appear to be particularly acute in our sample drawn from a safety net healthcare system. This formative work informed iterative design of our planned mobile application for online health research. The next step will be to conduct individual interviews and usability testing of the mobile app research platform with diverse populations, with the goal of enhancing the diversity of research participation in online studies.

Patients' Perceptions about Mobile Data Sharing

Accountability and Trust	“I have to be able to trust them with my information, whatever they're going to do it stays with them and no one else gets involved in it that don't need to know about it” “I don't like to give out personal information, but it really depends on who's asking. If it's a doctor, that's different.”
Fear of Data Misuse	“The only thing I don't dig is somebody being able to track me minute by minute, day by day around each block, no, that's not happening. Everything else I could care less about.” “What if you're looking for a job? Any hacker can get that information. If you have some disease that's going to impair your job, your job search is going to be pretty screwed, if they have access to your medical records.”
Usability	“Basically the reason I don't use the phone for emails, or Facebook, or just any apps or whatever…I will go to the bus stop, I will dial 511, departure times puts you in the bus stop, and it will tell you within so many min this bus is coming, blah, blah, blah. I don't need a frigging app, okay?…It isn't worth the drama.”
Altruism	“…to help somebody else, sure, I'm all right with that. I mean it's all about trying to help someone else.”

PATIENTS' PERSPECTIVES ON REASONS FOR READMISSION

Amy LeClair[1]; Megan Sweeney[1]; Grace H. Yoon[1]; Jana C. Leary[3]; Saul N. Weingart[1]; Karen M. Freund[2]. [1]Tufts Medical Center, Boston, MA; [2]Tufts University School of Medicine, Boston, MA; [3]Floating Hospital for Children at Tufts Medical Center, Boston, MA. (Control ID #2701183)

BACKGROUND: Readmissions increase costs for hospitals, patients and their families. We examined patient perspectives on the reasons behind readmissions in one urban academic medical center.

METHODS: Between June and August 2016, semi-structured interviews were conducted with patients with unplanned readmissions to the medicine services within 30 days of inpatient discharge. Patients and/or proxies were

asked about original discharge experience, the reasons for returning to the hospital, adequacy of care post-discharge (either in-home or at a facility), and access to socioeconomic resources. Interviews were conducted in English, Spanish, and Mandarin Chinese, transcribed verbatim, and de-identified. A team of four coders conducted thematic analysis using Dedoose® software.

RESULTS: 36 interviews were conducted with 35 participants, who ranged in age from 21 to 90 with a median age of 59 years. 49% were women, 69% were non-Hispanic white, and 94% completed the interview in English. 60% of the participants were covered by Medicare or Medicaid almost half were originally discharged to a post-acute care (skilled nursing, long term acute care, rehabilitation) facility. Three common themes emerged regarding patient perceived reasons for readmission: (1) problems with post-acute facilities, (2) language barriers, and (3) communication issues. Patients reported a mismatch between their clinical care needs and services available at some post-acute facilities, with some describing regret after selecting a facility based primarily on proximity to home or family. Some non-English speaking patients and their families reported an inability to obtain written discharge instructions in a language they could read and understand, even if an interpreter provided verbal instructions at the time of discharge. Poor communication between members of the care team, the hospital and post-acute care facilities, and patients/families and providers was identified by patients as contributing to readmissions, particularly when parties failed to relay information about topics such as plan for discharge or timeline for follow-up appointments.

CONCLUSIONS: Patients identified three factors that contributed to readmissions. Future interventions could aim to: improve networks of post-acute care focusing on the medical capabilities of individual facilities; heighten access to materials in the languages most prevalent in the local patient population; and improve patient care transition communication among members of the care team, with post-acute facilities, and with patients and families.

PEER REVIEW OF VIDEOED TEACHING ENCOUNTERS: A NOVEL METHOD FOR CONTINUING TEACHING EDUCATION

Sarah B. Merriam[1]; Megan Hamm[2]; Melissa McNeil[1]; Deborah DiNardo[1]. [1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA. (Control ID #2705273)

BACKGROUND: Practicing clinicians are held to well-established standards for the ongoing maintenance of clinical knowledge through CME requirements. While no such standard exists for cultivation of teaching skills, this is an equally critical component of professional development for medical educators. In this qualitative study, we evaluated the acceptability and efficacy of a novel method for teaching skills development. Faculty reviewed self-selected video segments of peer teaching during small group sessions. Monthly sessions were moderated by a master educator who guided direct observation of and reflection upon observed teaching, including highlighting efficacious teaching methods.

METHODS: Semi-structured post-curriculum telephone interviews were conducted with 20 of the 40 total participating faculty during summer 2016. We created an open-ended question script that was used by an experienced interviewer. The 20-min interviews were audio-recorded, de-identified, and transcribed verbatim. Using the editing approach of qualitative analysis developed by Crabtree and Miller, a codebook was developed and refined. Two coders independently applied the codes to interview transcripts using ATLAS.ti (Scientific Software, Berlin Germany) software. After coding, discrepancies between coders were adjudicated until agreement was achieved. Original coding files prior to adjudication were used to calculate intercoder reliability. The mean Kappa statistic was 0.66, which is characterized as "substantial agreement."

RESULTS: Seven senior faculty, 7 junior faculty and 6 medical education fellows were interviewed. Generally, interviewees viewed the curriculum positively. The most frequently cited advantages of participation included 1) exposure to new teaching strategies, 2) the ability to give/receive direct feedback, 3) gaining a new perspective on individual teaching behavior, and 4) the "safety" of the learning environment. Despite an overall endorsement of the curriculum, the following criticisms emerged: 1) discomfort reviewing video 2) difficulty giving feedback across hierarchy 3) technology challenges. None described the curriculum as unsafe, critical or evaluatory. Most faculty reported incorporating (12/20) or planning to incorporate (6/20) a new teaching behavior into their practice. Twelve described an increase in self-reflective behaviors outside of curricular sessions. All interviewed would recommend the curriculum to other faculty and endorsed a plan for continued participation.

CONCLUSIONS: Though faculty development for the maintenance of teaching skills is effective, formal programs are underutilized. This novel curriculum which focuses on direct observation of and reflection upon individual teaching encounters, is an effective, acceptable and efficient means to improve and expand the teaching practice of medical educators. This longitudinal, self-directed curriculum serves as a model for similar interventions at other academic institutions.

PEER-DELIVERED COGNITIVE BEHAVIOR INTERVENTION REDUCED DEPRESSION AND STRESS

Monika M. Safford[3]; Susan J. Andreae[2]; Joshua S. Richman[2]; Andrea Cherrington[1]. [1]University of Alabama Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Weill Cornell Medical College, New York, NY. (Control ID #2704892)

BACKGROUND: As many as 70% of individuals with diabetes people report chronic pain, increasing risk for depression and stress, both linked to poor long-term health outcomes. While professional-delivered cognitive behavioral therapy (CBT) improves mood in individuals with chronic pain, many underserved communities lack resources for such programs. We examined whether a CBT-based program delivered by trained community members can improve depressive symptoms and stress in individuals with diabetes and chronic pain immediately following a 12-week intervention, and 1 year later.

METHODS: This community-based, cluster-randomized, controlled trial engaged individuals with diabetes and chronic pain. Community members were trained and certified on each session of the 8-session program. They then delivered the intervention entirely by telephone over 12 weeks. The intervention incorporated adaptive coping skills, setting diabetes self-management behavioral goals, stress reduction techniques, and cognitive restructuring. Controls (C) received supportive general health advice with an equal number of contacts. Depressive symptoms and stress were assessed using the PHQ-8 and Cohen's Perceived Stress validated instruments, and participants were asked about use of specific stress-reducing strategies. Assessments occurred at baseline, 3 months, and 1 year.

RESULTS: The 177 participants had mean age 59 ± 10 years, 96% were African Americans, 79% were women, 45% used insulin, and baseline mean physical functioning scores from the Short Form 12 were 38 ± 9. At baseline, 3-month, and 12-month follow-up, the proportion at risk for moderate or greater depression was 41%, 17%, and 20% for the intervention group (INT) (51% relative change between baseline and 12 months, $p < 0.01$) and 52%,

33%, and 36% for C (31% relative change, $p < 0.01$), respectively (change difference $p = 0.02$). Compared with baseline, stress improved 2.3 ± 5.8 points more in INT than in C participants at 3 months ($p < 0.01$) and 1.4 ± 5.7 points more at 12 months ($p = 0.11$). At 3 and 12 months, 98 and 89% of INT participants and 67 and 63% of C participants reported use of deep breathing, and 96 and 87% (INT) and 72 and72% (C) used exercise to reduce stress, respectively ($p < 0.01$ for all).

CONCLUSIONS: This peer-delivered CBT program resulted in clinically important immediate post-intervention and sustained improvements in depressive symptoms, stress, and stress reduction practices. Community members may be mobilized to improve depression and stress in individuals with chronic pain.

PERCEIVED DISCRIMINATION AND CONTRACEPTIVE USE AMONG WOMEN VETERANS IN THE ECUUN STUDY

Serena MacDonald[1]; Leslie R. Hausmann[3]; Florentina Sileanu[3]; Xinhua Zhao[3]; Maria Mor[3]; Sonya Borrero[2, 3]. [1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of Pittsburgh and VA Pittsburgh, Pittsburgh, PA; [3]VA Pittsburgh Healthcare System, Pittsburgh, PA. (Control ID #2699423)

BACKGROUND: Perceived discrimination has been linked to use of less effective (i.e., non-prescription) contraceptive methods in non-VA settings. Our objective was to describe experiences with perceived race-based discrimination in the VA healthcare setting and assess its association with contraceptive use in a national sample of women Veterans.

METHODS: We analyzed data from the Examining Contraceptive Use and Unmet Need Among Women Veterans (ECUUN) study, a national telephone-based survey of 2,302 women Veterans ages 18–45 who had received care at VA in the prior 12 months. This analysis included women who were at risk of unintended pregnancy, defined as having had heterosexual intercourse within the past year, not pregnant or trying to conceive, and no history of hysterectomy or infertility. Participants were asked about experiences with race-based discrimination when receiving care in VA, using the 7-item Perceived Discrimination in Healthcare Scale, and about their contraceptive use at last heterosexual intercourse. Discrimination was dichotomized as any versus none. Contraceptive methods were classified as prescription and non-prescription methods. Prescription methods were further categorized as: sterilization, IUD/implant, and hormonal methods (pill, patch, ring, and injection). Rates of discrimination were examined for the overall sample and by race/ethnicity. Logistic and multinomial regression analyses were used to examine associations between discrimination with use of any prescription contraception and type of prescription method compared to non-prescription plus no method.

RESULTS: In our sample of 1,341 women Veterans, 52.3% were white, 27.8% black, 12.6% Hispanic, and 7.2% “other” race/ethnicity; mean age was 33.9 years. Overall, 12.8% reported ever experiencing race-based discrimination when receiving care in VA. Blacks, Latinas, and women from “other” racial/ethnic groups reported higher levels of discrimination than whites (18.5%, 19.5 and 21.7% vs. 7%; $p < 0.001$). In unadjusted analyses, women who reported discrimination were less likely to use any prescription contraception than women who reported no discrimination (66.3% vs. 73.9%, $p =$ 0.04 and OR:0.68, 95% CI:0.48–0.96), with the largest difference in rates of IUD/implant use (15.1% vs. 22.9%, $p = 0.05$ and OR:0.51, 95% CI:0.31–0.83). After adjusting for race/ethnicity, age, income, marital status, parity and insurance, the association between race-based discrimination and use of any prescription method was no longer statistically significant (OR:0.79; 95% CI:0.55–1.14) and was borderline significant for IUD/implant use (OR:0.62, 95%: CI:0.37–1.04; $p = 0.07$).

CONCLUSIONS: While we did not find significant associations between perceived race-based discrimination and contraceptive use in adjusted models, about 20% of non-white women reported experiencing race-based discrimination when receiving VA care. These rates are concerning and warrant further investigation to ensure high-quality, respectful health care for all Veterans.

PERCEIVED DISCRIMINATION BY HEALTHCARE PROVIDERS AMONG INDIVIDUALS WITH A HISTORY OF INCARCERATION

Nicole Redmond[1]; Jenerius Aminawung[4]; Diane Morse[2]; Shira Shavit[5]; Emily A. Wang[3]. [1]National Heart Lung and Blood Institute, Bethesda, MD; [2]University of Rochester School of Medicine, Rochester, NY; [3]Yale School of Medicine, New Haven, CT; [4]Yale University School of Medicine, New Haven, CT; [5]UCSF, San Francisco, CA. (Control ID #2700259)

BACKGROUND: An estimated 65 million US adults have a criminal record. Discrimination based on criminal history has been documented in employment, housing and receipt of other social services, but has not been examined in health care settings. Perceived discrimination in healthcare settings based on race and/or sexual identity has been associated with poor health outcomes. This study examines the prevalence of perceived discrimination by health care providers due to criminal history and its association with self-reported general health status.

METHODS: The Transitions Clinic Network (TCN) is a national network of primary care clinics that aim to engage individuals with chronic diseases into care within six months of release from prison. Baseline surveys of TCN patients upon clinic enrollment measured demographics, medical history, and general health status. Perceived discrimination due to criminal history was defined as a “yes” response to the question “Have you ever felt that you were treated unfairly by healthcare providers (doctors, nurses, etc.) because of your criminal record?” Univariate and bivariate analyses determined the prevalence of perceived discrimination and other covariates. The association or perceived discrimination with self-reported health status were explored using logistic regression modeling adjusted for covariates where $p < 0.2$ in bivariate analyses (age, race/ethnicity, marital status, employment status, and TCN clinic region [Atlantic, New York, California, and Alabama/Puerto Rico]).

RESULTS: Of the 751 participants completing the baseline survey, 203 (27%) reported perceived discrimination due to criminal history by health care providers. There was high prevalence of self-reported chronic health problems including mental health conditions (71%), cardiovascular disease (47%), metabolic disorders (37%), infectious disease (24%), respiratory conditions (22%), and other health conditions (59%) and 46% reported fair or poor general health status. When compared to those not reporting discrimination, those who reported discrimination due to criminal history were slightly older (mean age 47.9 ± 10.64 yrs vs. 45.6 ± 11.35 yrs; $p = 0.01$), and there were significant differences across TCN region ($p = 0.01$). In logistic regression models controlling for age, race/ethnicity, marital status, employment status, and TCN clinic region those who reported perceived discrimination by health care providers due to criminal history had higher odds of reporting fair/poor health status (OR 1.56, 95%CI 1.12–2.21).

CONCLUSIONS: Perceived discrimination by health care providers due to criminal history was associated with significantly higher odds

of fair to poor self-reported general health status. Screening for criminal history, while important clinically, has the potential to contribute to patients perceived discrimination. Future studies could examine how to promote non-stigmatizing patient-care strategies for the one in four potential patients who are US adults with criminal histories.

PERSPECTIVES OF CLINICIANS AT SKILLED NURSING FACILITIES ON 30-DAY HOSPITAL READMISSIONS

Bennett Clark[1]; Baron Katelyn[2]; Kathleen Tynan-McKiernan[2]; Meredith Campbell Britton[3]; Karl E. Minges[3]; Sarwat Chaudhry[3]. [1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Yale-New Haven Health System, New Haven, CT; [3]Yale School of Medicine, New Haven, CT. (Control ID #2705131)

BACKGROUND: Skilled nursing facilities (SNFs) play an important role in the readmission process. Few studies have examined the factors that contribute to readmissions from SNFs, leaving hospitalists and SNF clinicians with limited evidence on how to reduce SNF readmissions.

METHODS: We prospectively identified consecutive readmissions from SNFs to a tertiary-care hospital. Using a root cause analysis instrument, semi-structured interviews were conducted with SNF clinicians who cared for the readmitted patients. A total of 24 cases were reviewed from 15 SNFs across Connecticut. Interviews were conducted from August, 2015 to November, 2015. Transcripts of the interviews were inductively analyzed using grounded theory methodology.

RESULTS: The SNFs in our study included 12 for-profit and 3 non-profit facilities. The number of licensed beds in each facility ranged from 73 to 360. Nurses involved in direct patient care comprised 21 of 28 (75%) participants. Administrators (14%) and advanced-practice nurses (11%) made up the remainder of participants. The average age of patients in our study was 74.1 years. (SD = 13.4 years) Common comorbidities included polypharmacy (79%), congestive heart failure (42%), dementia (38%), and chronic obstructive pulmonary disease (21%). The most frequent index admission diagnoses were acute decompensated heart failure (ADHF) (13%), acute kidney injury (13%) and urinary tract infection (13%). The most frequent readmission diagnoses were ADHF (13%), hypoxemic respiratory failure (13%) and pneumonia (13%). Five main themes emerged from our analysis: (1) Mismatches between patient clinical needs and facility disposition, (2) Incomplete coordination of care, (3) Incompletely addressed goals of care, (4) Barriers to obtaining necessary information, and (5) Challenges in SNF processes and culture. (Table 1)

CONCLUSIONS: SNF clinicians perceived a strong link between patient acuity at the time of transfer and readmissions. As SNFs work to expand their clinical capabilities, they struggle to win buy-in from physicians and families, many of whom view SNFs as incapable of managing acute illness. Our findings underscore a fundamental tension between hospitals and SNFs: Which facility is responsible for services that may prevent a readmission? SNF clinicians expressed near unanimity that fragmented models of care and barriers to communication made it difficult to design solutions to this dilemma. This study highlights the clinical, system-related, communication and cultural challenges that contribute to readmissions from SNFs. Successful interventions for reducing SNF readmissions will require a multifaceted approach to these problems.

Themes and representative quotes on SNF readmissions

THEME	QUOTE
Wrong patient, wrong place: Mismatch between patient clinical needs and facility capabilities	He was respiratory compromised from day one of admission [to our SNF]… (Nurse Manager)
Bedeviling details: Incomplete coordination of care	What ends up sometimes sending them back [to the hospital] is that they're waiting for an outpatient follow-up. Urology's a big one… They come with hematuria. I have to send them back to the hospital. (Director of Nursing)
Code status: Incompletely defined goals of care	I know working in long-term care or short-term rehab, the palliative talks in the hospital outweigh our talks by a lot. (Administrator)
Missing links: Communication errors about important clinical information	We just had a patient come in who used to get IV Lasix twice a week, and we weren't updated on that. (Advanced Practice Nurse)
Change starts at home: Challenges in SNF processes and culture	I don't know if there's quite the good handoff between the doctors that are on-call and the doctors that are here. There could be a thousand patients they're covering for. That's something they can work on better. (Administrator)

PHARMACOLOGIC TREATMENT OF HYPERTENSIVE URGENCY IN THE OUTPATIENT SETTING: A SYSTEMATIC REVIEW

Claudia L. Campos[2]; James L. Wofford[2]; Deanna Jones[2]; Asima Ali[3]; Charles Herring[3]; Augustus Caine[2]; Janine Tillett[2]; Robert Bloomfield[2]; Lisa Porter[2]; Karen S. Oles[1]. [1]Wake Forest Baptist Health, Winston-Salem, NC; [2]Wake Forest University, WInston-Salem, NC; [3]Campbell University, Winston Salem, NC. (Control ID #2704766)

BACKGROUND: Acute severe uncontrolled hypertension without end-organ damage (hypertensive urgency), is common. Despite its long-term morbidity and mortality, guidance regarding immediate management is sparse. Objectives: To summarize the evidence examining the benefits and harms of different antihypertensive medications to treat hypertensive urgency in adults.

METHODS: Data sources: PubMed, Cochrane Central Register of Controlled Trials (CENTRAL), Database of Abstracts of Reviews of Effects (DARE), Cochrane Database of Systematic Reviews, Web of Science, Google Scholar, and Embase. Study selection: We evaluated prospective controlled clinical trials, case–control studies, and cohort studies of hypertensive urgency in emergency department or clinic settings. Data extraction: We initially identified 11 223 published articles. We reviewed 10 748 titles and abstracts (after removing duplicates) and identified 538 eligible articles. We assessed the full text for eligibility and included 38 articles written in English that were clinical trials or cohort studies and provided blood pressure data within 48 h of treatment. For each, we extracted the author, country, year, study type, setting, sample size, demographics, medications, details of treatment, primary outcome, adverse effects, and initial and subsequent blood pressures. Quality assessment: Studies were appraised for risk of bias using components recommended by the Cochrane Collaboration. The main outcome measured was blood pressure change with antihypertensive medications. Mean arterial pressures were calculated when not explicitly calculated by the authors. Length of follow-up and medication dosages varied widely. Data analysis: Since studies were too diverse both

clinically and methodologically to combine in a meta-analysis, tabular data and a narrative synthesis of studies are presented.

RESULTS: We identified 20 double-blind randomized controlled trials and 13 cohort studies, with 262 participants in prospective controlled trials. However, we could not pool results of studies.Most of the medications evaluated in this review were short acting and the studies were not long enough to evaluate longterm morbidity of mortality.

CONCLUSIONS: To this date, longitudinal studies are still needed to determine how best to lower blood pressure in patients with hypertensive urgency.

PHYSICIAN BURNOUT AND JOY OF PRACTICE: EARLY MIXED-METHODS FINDINGS FROM THE IMPLEMENTATION OF STANFORD PRIMARY CARE 2.0 Jonathan G. Shaw; Cati Brown-Johnson; Garrett Chan; Megan Mahoney; Marcy Winget. Stanford School of Medicine, Stanford, CA. (Control ID #2699151)

BACKGROUND: With 73% of physicians in a recent survey reporting they would not choose the same profession again, burnout and lack of Joy of Practice (JoP) are critical risks for primary care and healthcare systems. In 2016, Stanford launched an ambitious team-based primary care redesign, "Primary Care 2.0" (PC 2.0), with the goal of addressing the Quadruple Aim of healthcare (ie. the Triple Aim plus reducing workforce burnout) with following components: 1. An expanded "Care Coordinator" (CC) role for medical assistants including scribing, population health management, and between-visit care management; 2. Health coaching and Motivational Interviewing; 3. "Lean" quality improvement to support a Learning Health System; 4. Telehealth; 5. Protected provider time for care coordination; and 6. An onsite extended interdisciplinary care team (i.e., mental health, pharmacy, physical therapy). The objective for this research was to assess early indications that PC 2.0 might reduce burnout and improve JoP for MDs and CCs.

METHODS: Mixed methods were used to assess the impact of PC 2.0 on burnout and JoP. Validated surveys were fielded at key milestones in the project (pre "go-live" 5/2016, and early sustainability 10/2016). Change from baseline in professional fulfillment (burnout) and perceived meaningfulness of work (JoP) were calculated overall and by provider type. Interviews were conducted with providers (immediately post "go-live" 7/2016), coded using Nvivo software, and analyzed for emerging themes.

RESULTS: In qualitative interviews, some MDs reported highly positive JoP experience with CC in-exam scribing. One MD described it as "a dream come true… I can just sit with a patient and I can just talk." There was a perception reported by MDs and CCs that EHR interferes with meaningful physician-patient interaction. Identified barriers to supporting MDs with in-visit CC scribing involved challenges in co-scheduling MD + CC slots, which brought up new needs for IT support and redesign. Quantitative results supported qualitative observations, showing positive, albeit not statistically significant, improvements in professional fulfillment for all providers (MD: May 3.4 ± 0.5 95%CI -> Oct 3.7 ± 0.3; CC: May 3.6 ± 0.3 -> Oct 4.0 ± 0.2). CCs also experienced marginal improvements in perceived meaningfulness of work with patients, reflecting our qualitative findings that CC fulfillment and sense of meaning in PC 2.0 exceeds previous experience in more traditional medical assistant roles (May 4.2 ± 0.6 -> Oct 4.6 ± 0.4).

CONCLUSIONS: Initial evidence suggests that the Primary Care 2.0 model may positively impact burnout prevention for multiple levels of clinic care roles. Specifically, one element that may support physician JoP is CC scribing, which allows MDs to connect directly with patients without EHR interference. CCs also appear to gain meaning and fulfilment from this increased exam room involvement.

PHYSICIAN CHARACTERISTICS AND LOW-VALUE SERVICE USE Aaron L. Schwartz; J. Michael McWilliams; Anupam B. Jena. Harvard Medical School, Boston, MA. (Control ID #2705979)

BACKGROUND: Recent advances in measuring low-value service use have confirmed that such services are common. However, it is unknown whether physicians exhibit substantial variation in use of such services, or whether physician characteristics predict use. Using claims-based measures, we estimated (1) across-physician variation in low-value service use, (2) associations between physician characteristics and low-value service use, and (3) associations between physician characteristics and reduction in use of a low-value service after a recent guideline publication.

METHODS: Counts of 18 primary care-oriented low-value services were tallied for 14.9 million Medicare patients of 85,234 primary care physicians in 14,125 provider organizations from 2008–2013. Physician characteristics obtained from claims and Doximity datasets included age, gender, MD vs DO credential, foreign vs domestic medical school, USNews top 20 medical school, publication authorship, clinical trial participation, professorship, receipt of drug/device payments, and patient count. Multilevel modeling was used to estimate within-organization-across-physician and across-organization variation, controlling for patient clinical, sociodemographic and geographic characteristics. Cross-sectional and difference-in-difference regressions were used, respectively, to assess for physician characteristics associated with (1) overall service use, and (2) differential reduction in colonoscopies for elderly patients after a USPSTF D recommendation.

RESULTS: Average frequency of low-value services was 31.7 low value services per 100 patients per year (unadjusted SD = 15.9). Multilevel modeling with covariate adjustment yielded an across-physician SD of 6.7 (ratio $90^{th}/10^{th}$ percentile use = 1.74), and an across-organization SD of 8.3. Physician characteristics associated with lower levels of low-value service use ($p < 0.05$) included educational characteristics (MD credential, domestic training, top ranked medical school), academic affiliation (professorship status), smaller patient panel, demographic characteristics (younger age, male gender), and no receipt of pharmaceutical/device company payments. Associations were similar when comparing physicians within the same provider organization. However, associations were generally minimal in magnitude (e.g. 1.2 more low-value services per 100 patients per year associated with foreign medical study). Professorship was the only characteristic associated with greater reductions in colonoscopy following USPSTF recommendations.

CONCLUSIONS: Variation in physicians' low-value service use is substantial even within organizations. However, physician characteristics predict only minimal differences in service use. Thus, efforts to identify more wasteful physicians (e.g. for quality-improvement interventions or

to guide patients' choice of physician) would benefit from direct measurement of service use rather than prediction based on physician characteristics.

PHYSICIAN EMPATHY IS NOT ASSOCIATED WITH DIABETES OUTCOMES IN PRIMARY CARE Kathryn A. Martinez[1]; Richard M. Frankel[2]; Amy K. Windover[3]; Anita D. Misra-Hebert[1, 1]; Leonard Calabrese[1]; Michael B. Rothberg[1, 1]. [1]Cleveland Clinic, Cleveland, OH; [2]Indiana University School of Medicine, Indianapolis, IN; [3]The Cleveland Clinic, Cleveland, OH. (Control ID #2701881)

BACKGROUND: Physician empathy is a key component of patient-centered care. The association between empathy and patient outcomes, however, is not well-established. One small study of 29 physicians (Hojat et al., 2011) found a positive association between physician empathy and clinical outcomes in diabetes. The objective of this study was to evaluate this relationship using a larger, more diverse sample of physicians and their diabetic patients.

METHODS: We used physician empathy data collected during a required communication skills course conducted at the Cleveland Clinic Health System between August 2013 and May 2014. Course participants included all full and part-time physicians in Internal and Family Medicine. At the start of the course, each physician completed the Jefferson Scale of Empathy (JSE), a validated 20-item measure of physician empathy. Scores range from 20 to 140 with higher values indicating greater empathy. Diabetic patients in each physicians' panel were identified via the electronic health record. Patients' HbA1c and LDL values closest to the date on which their physician completed the JSE were used for analysis. Mixed effects linear modeling was used to assess the association between physician empathy and their patients' HbA1c and LDL. Models controlled for patient sociodemographic and clinical characteristics, including body mass index (BMI) and Charlson comorbidity score. Models also adjusted for a number of physician characteristics, including sex, age, years of experience, specialty (Internal Medicine versus Family Medicine), and whether they were an MD or a DO. Analyses were restricted to those patients who had at least two visits with their assigned physician in the past year. As a sensitivity analysis, we reproduced the methods of Hojat et al. (2011), stratifying JSE scores into tertiles and using dichotomous HbA1c and LDL outcomes.

RESULTS: The sample included 150 physicians and 11,542 patients. Seventy percent of physicians were in Internal Medicine, 57% were male and mean (SD) physician age was 50 years (9.5). The mean physician empathy score was 117.5 out of 140 (12.5). Most (80%) patients were white, average patient age was 66.4 years (13.4) mean BMI was 33.3(7.7), and mean Charlson score was 1.6(1.3). The mean HbA1c value was 7.1(1.4) and mean LDL was 87.6(32.2). In the adjusted linear models, there was no significant association between physician empathy scores and patients' HbA1c ($\beta = 0.01$; $p = 0.892$) or LDL ($\beta = -0.04$; $p = 0.369$). Likewise, in the sensitivity analyses, there was no association between physician empathy and their patients' HbA1c or LDL.

CONCLUSIONS: In a large diverse sample of diabetic primary care patients and their physicians, we found no association between physician empathy and diabetes-related outcomes. While interventions to increase physician empathy may result in better patient-centered care, the impact of such interventions on clinical endpoints is unclear.

PHYSICIAN IDENTIFIED BARRIERS TO CARE FOR HIGH RISK PATIENTS AT PRIMARY CARE PRACTICES SEEKING NATIONAL COMMITTEE FOR QUALITY ASSURANCE RECOGNITION MARIA MCGURRIN, BA, CATHERINE L. LIANG, MBA, HANNAH ARNOW, BA, TAYLOR WILLIAMS BS, JUSTIN LANZAFANE BA, MAI LE BA CENTER FOR POPULATION HEALTH, PARTNERS HEALTHCARE, SOMERVILLE, MA, USA Maria L. McGurrin; Catherine Liang; Justin John Lanzafane; Taylor Williams; Hannah Arnow; Mai Le. Partners Healthcare, Somerville, MA. (Control ID #2706033)

BACKGROUND: The Patient Centered Medical Home (PCMH) model of care seeks to improve care quality by enhancing care coordination and the patient's ability to self manage their condition, particularly for patients with complex and chronic diseases. The Center for Population Health and Partners Healthcare provides support to practices applying for PCMH recognition from the National Committee for Quality Assurance (NCQA). As part of the application the practices are required to identify patients who they consider 'high risk' and who they believe could benefit from additional care management. The practice then creates a structured care plan containing the patient's preferences for care and lifestyle goals, the provider's treatment goal, a self management plan, and any identified barriers to care. This study aims to characterize through qualitative analysis what types of barriers were recorded by providers in the 'barriers' section of the care plan.

METHODS: The text entered into the 'Barriers' section of the care plan from 45 different practices applying for recognition was analyzed and sorted into categories based on an established rubric. The NCQA application process involves a chart review in which the care plans for 30 of the most recently seen patients from the practices 'high risk' list are reviewed for completeness. Provider entries into the 'Barriers' section which did not meet the NCQA intent and thus did not 'pass' chart review, or patients who had no barriers identified were excluded.

RESULTS: Of the 1,350 patients included in the chart reviews, 607 patients (44%) had a barrier recorded. As shown in Table 1 there was a large distribution of barrier types. Patient 'Lifestyle Barriers', including patient diet, exercise level, substance use, motivation level and the presence of environmental stressors were the most common type of barriers (39.82%). 'Difficulty Managing Symptoms of Complex Conditions' including patient mental health status, acute illnesses, difficulty accessing specialty care, comorbidities, advanced disease state, advanced age, and chronic pain were the second most common type of barrier (30.78%). In contrast Patient Medication or Treatment Regimen Compliance and Patient/Caregiver Declining Care were the two least common barrier types at 4.15 and 1.5% respectively.

CONCLUSIONS: This analysis of provider reported patient barriers serves to illustrate the most common challenges chronically ill, high utilization patients face when seeking care. Understanding which barriers chronically ill patients at different types of primary care practices continue to face could allow us to adjust the PCMH model to better meet their needs or create targeted programs to address

those barriers being faced such as difficulty accessing specialty care, communication barriers or challenges related to the patient's health literacy.

Barrier Type Distribution- All Practices

Medication/ Treatment Regimen Compliance	Difficulty Managing Symptoms of Complex Conditions	Lifestyle Barriers	Socioeconomic Barriers	Health Literacy	Communication Barriers	Patient/ Caregiver Declines Care	Patient Doesn't Tolerate Medication /Treatment
4.15%	30.78%	39.82%	7.16%	4.77%	7.04%	1.5%	4.77%

PHYSICIAN KNOWLEDGE AND VIEWS ABOUT MAMMOGRAM BREAST DENSITY REPORTING Jenny J. Lin; Jordonna Brown; Laurie Margolies; Lina Jandorf. Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #2700486)

BACKGROUND: Women with dense breasts may be more likely to develop breast cancer than women with less dense breasts, and dense breast tissue makes it harder for radiologists to interpret mammogram results so that mammograms may be less accurate. Further imaging with breast ultrasound or MRI may be ordered in addition to mammograms for women with dense breasts. Many states have required that mammogram reports sent to patients also include information about breast density. However, there are currently no consensus screening guidelines or recommendations for women with dense breasts, and it is not clear how breast density affects counseling about breast screening.
METHODS: An anonymous self-administered survey about knowledge, attitudes and practices regarding breast cancer screening for women with dense breasts was sent to primary care providers (PCPs), radiologists and gynecologists. The survey items were developed based on iterative discussions with PCPs and radiologists. Descriptive and univariate analyses were used to assess differences between PCPs and specialists.
RESULTS: A total of 151 surveys have been returned. Of the respondents, 74% were female, 75% were attending-level physicians, 42% were PCPs, 28% were radiologists and 18% were gynecologists. Most (65%) practiced in an academic setting, 18% practiced in the community and 17% were in private practice. Almost half of the respondents did not know if their state had a law mandating breast density reporting. More than half (56%) reported that they always or often discussed normal mammogram results with their patients, but only 25% reported that they always or often discussed breast density with patients. Only 28% felt "very comfortable" answering patients' questions about breast density, 37% were able to correctly identify that very dense breasts can increase risk for breast cancer by 2–5 fold, and two-thirds felt they needed more education about breast density and supplemental screening. Compared to gynecologists and radiologists, PCPs were less likely to know about breast density laws in their state (31% vs. 69%, $p < 0.001$) and to correctly identify increase in breast cancer risk with very dense breasts (18% vs. 81%, $p < 0.001$). PCPs were more likely to be uncomfortable answering questions about breast density (65% vs. 35%, $P < 0.001$) and to want more education about breast density (57% vs. 43%, $P < 0.001$).
CONCLUSIONS: PCPs are uncertain about how to counsel women with dense breasts regarding mammography and/or supplemental screening. There is a clear need for more education about and guidelines on how to best manage women with dense breasts.

PHYSICIAN TRAINEES' EXPERIENCES OF MORAL DISTRESS REGARDING POTENTIALLY FUTILE TREATMENTS AT THE END OF LIFE IN THE UNITED KINGDOM: A QUALITATIVE STUDY Elizabeth Dzeng[1]; Rachel Weiss[1]; Sophie Vergnaud[2]. [1]University of California, San Francisco, San Francisco, CA; [2]National Health Service, London, United Kingdom. (Control ID #2693814)

BACKGROUND: Moral distress, the inability to act in accordance with one's ethical beliefs due to hierarchical or institutional constraints, has been associated with burnout and poor well-being. Significant moral distress amongst American physician trainees might occur when they feel obligated to provide treatments at the end of life that they believe to be futile or harmful. In contrast to the US, policies in the United Kingdom permit physicians to make a decision to withhold or abort resuscitation that they believe would be inappropriate following discussions with the family. The aim of this study was to explore whether moral distress surrounding resuscitation at the end of life occurred in the UK, a country whose health policies surrounding end of life care are notably different than those in the US.
METHODS: We conducted semi-structured in-depth interviews with 14 physician trainees in the UK regarding moral distress and attitudes surrounding do-not-resuscitate (DNR) decision-making. Interviews, which were audio-taped and professionally transcribed, lasted an average of 60 min. Transcripts were analyzed and double coded using thematic analysis. Themes and patterns emerged from initial interviews and analysis, and were refined and validated in subsequent interviews through questions added to the interview guide and probing of key themes during the interviews.
RESULTS: UK trainees infrequently experienced feelings of ethical conflict surrounding resuscitation, though some respondents did note one or two rare but notable cases of resuscitation they felt were inappropriate. Themes that arose included a feeling of shared attitudes around providing care that was in a patient's best interest. Please see Table 1 for example quotations of UK junior doctors. Distress instead appeared to arise from other areas such as insufficient resources or personnel to provide optimal care and a lack of control over the nature of their work.
CONCLUSIONS: Along with the US data previously described in Dzeng, *et al.*, 2016, we describe different degrees of moral distress surrounding potentially futile resuscitation at the end of life between US and UK trainees. We hypothesize that UK policies and culture allow physicians to withhold inappropriate or ineffective resuscitation, allowing physicians to act in ways that are in accordance with their ethical beliefs. Different policies surrounding resuscitation at the end of life in the US and UK might contribute to different degrees of moral distress amongst physician trainees regarding potentially futile treatments at the end of life.

US and UK trainee responses surrounding moral distress regarding resuscitation provided at the end of life

UK trainees (in response to question of whether they have experienced moral distress after defining the term in the interview prompt)	US trainees (from Dzeng, et al., 2016)
"Probably not actually. I think I've been lucky in that my seniors, my hospital are of an attitude that I share about quality of life not too invasive procedures." "I don't think so. Nothing that I would consider to be at that level as you phrase it. I don't think it's ever been a massive ethical dilemma for me. I can't really think of any situations where I've had to do something or been asked to do something that I've so strongly disagreed with I felt uncomfortable about it."	"It felt horrible. I felt like I was torturing him. Absolutely torturing him. He was telling us we were torturing him. I didn't think we were necessarily doing [the right] thing for the patient. I think that a lot of times that's what happens when we go aggressive care all the way." "A lot of things happen when you

Dzeng E, Colaianni A, Roland M, et al. Moral Distress Amongst American Physician Trainees Regarding Futile Treatments at the End of Life: A Qualitative Study. J Gen Intern Med. 2016;31(1):93–99. doi:10.1007/s11606-015-3505-1.

PILOT OF QUALITATIVE COMPARATIVE ANALYSIS (QCA) TO STUDY COMPLEX OUTCOMES C. Scott Smith[2]; Bridget O'Brien[5]; Pete Spanos[1]; Anne P. Poppe[4]; Brent A. Moore[6]; nancy Harada[7]; Rebecca Brienza[3]; Anais Tuepker[8]. [1]Louis Stokes Cleveland VA Medical Center, Cleveland, OH; [2]University of Washington, Boise, ID; [3]VA Connecticut Healthcare System, West Haven, CT; [4]VA Puget Sound HCS, Seattle, WA; [5]UCSF, San Francisco, CA; [6]Yale University, West Haven, CT; [7]Coordinating Center, Centers of Excellence in Primary Care Education, Long Beach, CA; [8]Posrtland VA Medical Center, Portland, OR. (Control ID #2705149)

BACKGROUND: Evaluation of complex outcomes, such as choosing a primary care career, can be difficult due to non-linear causative pathways. QCA is a realist evaluation method that may be well suited to this task.[i] It is based on set theory, using AND, OR, and NOT to specify relationships. QCA can be performed using dichotomous crisp sets (csQCA), or partial inclusion 'fuzzy sets' (fsQCA). The purpose of this study was to assess QCA as a method for enterprise evaluation. [i] Thygeson NM, Peikes D, Zutshi A. Mixed Methods: Fuzzy Set Qualitative Comparative Analysis and Configurational Comparative Methods: Powerful Methods to Study and Refine Patient-Centered Medical Home Models. Rockville, MD: Agency for Healthcare Research and Quality. February 2013. AHRQ Publication No. 13-0026-EF.
METHODS: Interested representatives from our group used a csQCA to analyze primary care career data for physicians and NPs. They brainstormed characteristics that could influence the outcome, reduced the number by multi-voting, and set dichotomization cut points for the data. Initial subset/superset analysis was performed on these characteristics. Only those with consistency ≥ 0.8 were included in the crisp set algorithm unless no characteristic reached that threshold, in which case the highest consistency characteristic(s) were included. The csQCA analysis was performed using fsQCA 2.5 for Windows.
RESULTS: The analysis team initially identified 18 potential characteristics that might influence choice of primary care career. These were reduced to four each for the MD and NP analyses with multi-voting. Things associated with physicians going into primary care (consistency 1.0, coverage 0.67-modest effect) were: high co-training time; *OR* Primary care track *AND* adequate staffing ratio. Things associated with NP going into primary care (consistency 1.0, coverage 1.0-strong effect) were: training for collaboration *AND* high rating of clinical experience; *OR* high co-training time *AND* high rating of clinical experience; *OR* high co-trianing time *AND* inadequate staffing ratio.
CONCLUSIONS: We conclude that QCA shows great promise as an enterprise evaluation method. The ability of this technique to function with small sample sizes and to suggest multiple possible pathways to an outcome seem to match our program developmental stage well. The method suggests several interesting facts about the primary care practice decision. Co-training time, time spent together working with other professions, seems particularly important. This could suggest that limited resources be spent on coordinating schedules rather than developing new curriculum. Beyond that, physician trainees appear to be more influenced by structural characteristics (staffing ratio, academic track), while NP residents seem more influenced by process issues (rating of the clinical experience, whether they learned to work collaboratively in teams).

PILOT RCT OF A TECHNOLOGY-ASSISTED WEIGHT MANAGEMENT INTERVENTION WITHIN PRIMARY CARE AT THE VA NEW YORK HARBOR HEALTHCARE SYSTEM Clare M. Viglione[1, 2]; Srishty Amarnani[1, 2]; Dylaney Bouwman[1, 2]; Katja Lazar[1, 2]; Yixin Fang[3]; Scott Sherman[1, 2]; Adina Kalet[2]; Craig Tenner[1, 2]; Melanie Jay[1, 2]. [1]VA New York Harbor Healthcare System, New York, NY; [2]NYU School of Medicine, New York, NY; [3]New Jersey Institute of Technology, Newark, NJ. (Control ID #2705319)

BACKGROUND: Obesity is under-treated and primary care teams find it difficult to provide effective lifestyle-based weight management counseling. Further, only 10% of eligible patients attend MOVE!, the VA weight management and health promotion program. We developed an intervention called *Goals for Eating and Moving* (GEM) to improve counseling within primary care (PC) and increase attendance in intensive weight management programs such as MOVE!.
METHODS: Veterans with a Body Mass Index of greater than or equal to 30 or between 25 and 29.99 with at least one comorbidity were recruited by phone and randomized to GEM or "Enhanced Usual Care" (EUC). GEM utilizes the Patient Aligned Care Teams (PACTs) within the VA to deliver 5As counseling (Assess, Advise, Agree, Assist and Arrange) to promote modest weight loss and behavior change. Participants use a goal-setting tool to generate tailored materials, which facilitates in-person and phone counseling with health coaches. Coaches support PACT counseling during regular PC visits and encourage participants to join VA weight management services. Veterans in GEM received the intervention and Veterans in EUC met with a coach to receive the VA "healthy living messages" pamphlet. At baseline and 3 months, participants had weight measurements and completed surveys. We used the Paffenbarger Physical Activity Questionnaire and a 17-item screener to derive fruit and vegetable intake, energy from fat, and dietary fiber. Vegetable intake (leafy greens/salad) and sugar-sweetened beverage were measured as individual items. We performed per-protocol analyses (Wilcoxon Rank sums test and Spearman Correlation) to assess the relationship between GEM and different variables.
RESULTS: Thirty-one Veterans (mean age = 53.48, 63% male, mean BMI = 31.72) enrolled and 25 returned at 3-months (1 dropped out and 5 were lost-to-follow up). Those in GEM lost significantly more weight at 3-months (−1.59 kg, SD = 1.76) than those in EUC (−0.63 kg, SD = 3.42, $p = 0.03$).

There were no statistically significant differences in diet and physical activity. For Veterans that received GEM, higher number of phone coaching sessions was correlated with weight loss (Spearman Correlation −0.58, $p = 0.09$).
CONCLUSIONS: This early analysis indicates that GEM promotes small but significant ($p = 0.03$) weight loss at 3-months and identified the need for high patient retention and engagement, since the number of health coaching calls may correlate with weight loss. Based on this we have refined protocols for phone coaching to ensure that scheduling and reminder calls are patient-centered. This pilot study informed the development of a multi-site cluster-RCT of GEM to begin in June 2017 (NIH # 1R01 DK111928-01).

PILOTING A MOBILE APPLICATION TO ASSIST IN DIABETES PREVENTION IN EAST HARLEM, NEW YORK Victoria L. Mayer[1]; Emily Hanlen-Rosado[1]; Daphne Brown[1]; Crispin N. Goytia[1]; Carol R. Horowitz[2]. [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Mount Sinai School of Medicine, New York, NY. (Control ID #2705717)

BACKGROUND: While low-income and racial/ethnic minoritiy individuals have traditionally been on the access poor side of the “digital divide,” with low access to the internet and mobile technology, growing evidence shows that the gap is narrowing rapidly. The East Harlem Partnership for Diabetes Prevention, an 11-year old community-academic collaboration, utilized community-based participatory research to develop and pilot test a mobile application (app) aimed at assisting members of the East Harlem community in making lifestyle changes. The mobile app has three different components: a newsfeed (articles related to diabetes prevention, diet, and exercise), challenges/achievements (tailored to user-selected goals), and resources (locations for healthy food and free to low-cost physical activity in the area).
METHODS: We recruited participants at 3 community organizations in East Harlem and asked them to engage with the app 15 min a day, 3 days a week, for 4 weeks. After 4 weeks, participants were asked to complete a survey and participate in a focus group. Research coordinators took notes during focus groups. We analyzed count data for each survey item and examined themes discussed during focus groups.
RESULTS: We obtained consent from 53 participants (of 106 approached). 43 participants downloaded and engaged with the app for 4 weeks. 40 participants completed the survey and 23 participated in focus groups. Participants were largely racial/ethnic minorities; 45% identified as Black; 80% identified as Hispanic/Latino. After engaging with the app, 57.5% of participants “liked the app a lot.” 90% of users identified the app as helpful in learning about health topics and 85% as helpful in achieving their overall health goals. 70% found the newsfeed component to be very useful while 45% of users found the resources to be very useful. Users responded that the app was useful in changing aspects of their behavior; 80% said the app helped them improve their diet and 77.5% said the app helped them improve their activity/fitness level. Participants were interested in the following additional features: 70% in a food tracker, 62.5% in an exercise tracker, and 60% in a tool to connect with an exercise or cooking buddy. 75% of participants would recommend this app to a friend or family member, and 75% of users said that they would like to continue using the app once the pilot was complete. Focus group participants reported feeling “motivated” by the app and “looked forward” to using it daily. Participants felt that they learned health content that they did not know prior to using the app.
CONCLUSIONS: Participant are interested in a mobile app that is community-specific and helps them to improve diet and increase physical activity. Participants sought ways to connect with other community members and resources. As users in low-income communities gain more access to mobile technology, community-based technology development has the potential to provide new tools for health promotion.

POLICE-REPORTED CRIME AND GEOGRAPHIC DISPARITIES IN OBESITY AND HYPERTENSION IN CHICAGO Elizabeth L. Tung; Jennifer A. Makelarski; Kelly Boyd; Kristen Wroblewski; Chenab Navalkha; Monica E. Peek; Stacy T. Lindau. University of Chicago, Chicago, IL. (Control ID #2706040)

BACKGROUND: Violent crime is an endemic public health crisis in U.S. cities. Communities with a high prevalence of violent crime may experience psychosocial stress and trauma, which prior studies have linked to higher rates of metabolic and cardiovascular disease. In prior studies, however, health conditions are typically self-reported and subjective measures (e.g., “How safe is your neighborhood?”) are commonly used as proxies for violence exposure. The purpose of this Chicago-based study is to examine the relationship between police-reported crime and objectively measured obesity and hypertension status.
METHODS: We analyzed cross-sectional data for 15,173 patients seen in at least one of 3 primary care clinics at an urban academic medical center. Patient-level health data were obtained from the electronic health record using each patient’s first visit between 6/2014 and 5/2015, including body mass index (BMI) and blood pressure (BP) measurements. Obesity was defined as BMI ≥ 30 kg/m2 and hypertension was defined as systolic BP ≥ 140 mmHg or diastolic BP ≥ 90 mmHg. These data were linked to contemporaneous geocoded crime counts (total crimes, drug-related crimes and violent crimes) obtained from the City of Chicago Police Data Portal. Crime counts were aggregated to the census tract level and calculated as an annual crime rate per 1000 population. Census tracts were classified into 4 crime exposure risk quartiles, each containing 81 census tracts. We used generalized linear mixed models (logit function, clustered by census tract) to assess obesity and hypertension status as a function of crime exposure risk quartile, controlling for patient demographic characteristics (age, gender, race/ethnicity, insurance status), clinic site, and neighborhood characteristics (median household income, educational attainment, and poverty level).
RESULTS: In a 324 census tract region of Chicago, median total crime rates in each quartile ranged from 54 to 240 crimes per 1000 population. Of patients included in this study, 41% were obese and 33% had hypertension. Compared to patients living in the lowest quartile, patients living in the highest quartile for total crime had 73% higher adjusted odds of obesity (95% CI, 1.39–2.15) and 24% higher adjusted odds of hypertension (95% CI, 1.03–1.49); patients living in the highest quartile for drug-related crime had 63% higher adjusted odds of obesity (95% CI, 1.28–2.08) and 25% higher adjusted odds of hypertension (95% CI, 1.08–1.46); patients living in the highest quartile for violent crime had 84% higher adjusted odds of obesity (95% CI, 1.46–2.32) and 24% higher adjusted odds of hypertension (95% CI, 1.03–1.50).
CONCLUSIONS: In a densely-populated, high-poverty region in Chicago, exposure to total, drug-related, and violent crime was consistently associated with obesity and hypertension. Interventions to mitigate the harmful health effects of crime, particularly in high crime communities, may be critical to population health improvement.

POSITIVE ASPECTS OF PATIENT CARE Dylan Woolum; Abigail Lawson; Christina Fahey; Garrett Oberst; Stephanie A. Rose; David Rudy. University of Kentucky, Lexington, KY. (Control ID #2705457)

BACKGROUND: Traditional approaches to reforming physician satisfaction in the healthcare environment involve focusing on areas of dissatisfaction, leading to inadvertently accentuating negative aspects and overlooking shared motivations. An alternative to the focus on the negative is Appreciative Inquiry (AI). AI challenges traditional negative-based approaches by instead focusing on the positive successes noted in an environment and working to promote those successes. This study assessed positive aspects of patient care (Discovery phase) from the viewpoint of Internal Medicine (IM) physicians at an academic medical center.

METHODS: A confidential online survey was emailed to all IM faculty at our institution. Study participants were voluntarily asked to think of a time when they were a part of providing exceptional patient care, who contributed to this care, and what, if any, contribution they had provided to this care. They were asked to describe what qualities and characteristics stood out about these contributors. Finally, participants were asked to describe three ideas for future improvement that would encourage a positive environment. Responses were qualitatively reviewed, and thematic areas were identified. Operational definitions for each theme were developed with responses falling into one or more categories in order to decrease subjectivity. Discrepancies were assigned final codes based on simple majority ratings.

RESULTS: 11 IM faculty physicians participated at the time of submission. When describing the contributors to a time of exceptional patient care, 64% of physicians mentioned nursing/clinic staff, 73% mentioned physicians, 9% mentioned patients, and 45% mentioned other hospital staff. Regarding their own contribution to the experience, faculty gave three themes: coordinating care (45%), making an important decision (36%), and being accommodating to patients' needs (55%). They described four common themes regarding the qualities and characteristics of contributors: personalized care (45%), professionalism (36%), communication (45%), and were caring (82%). Finally, when asked what three improvements would lead to a more positive environment, responses were categorized into four common themes: positive attitude (73%), scheduling (36%), administrative resources (55%), and communication (36%).

CONCLUSIONS: IM faculty valued caring as an important characteristic contributing to a time of exceptional care. The majority of members in the clinical practice were included as contributors to the experiences. Having a positive attitude was the most common improvement suggested to create a more positive environment. With appropriate progression to the latter stages of AI, this method creates an avenue for innovative changes to delivering exceptional care. Our intervention may help to begin to change the typical negative nature of such conversations to include the rewarding aspects of practice. Future objectives are to encompass physicians in family medicine and obstetrics/gynecology.

POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDER AFTER HEART TRANSPLANT- A DESCRIPTIVE STUDY OF THE UNITED NETWORK OF ORGAN SHARING DATABASE Jai D. Parekh[1]; Shweta P. Kukrety[1]; Ryan Walters[1]; Mahesh Anantha Narayanan[2]; Renuga Vivekanandan[1]. [1]Creighton University Medical Center, Omaha, NE; [2]University of Minnesota, Minneapolis, MN. (Control ID #2692906)

BACKGROUND: Post-transplantation lymphoproliferative disorder (PTLD) is the second most common malignancy in adults who receive solid organ transplants. Thoracic organ transplant recipients have the highest incidence rates of PTLD due to higher level of immunosuppression needed with these transplants. Despite this there is paucity of data describing the incidence and characteristics of PTLD in heart transplant recipients. We sought to determine the incidence, time to diagnosis, risk factors and mortality associated with PTLD in a large nationwide database of heart transplant recipients. Characterisation of these factors can help guide the timing and intensity of post heart transplant PTLD surveillance.

METHODS: We conducted a retrospective analysis of the United Network for Organ sharing (UNOS) database to determine the incidence, median time to PTLD diagnosis and mortality associated with PTLD amongst heart transplant recipients. We also evaluated the association between the incidence of PTLD and age, gender, recipient Ebstein-Barr virus(EBV) and Cytomegalovirus(CMV) status at the time of transplant. Categorical variables are presented as percentages and analysed using the Fischer's exact test.

RESULTS: Among 9,777 heart transplant recipients, 876 (9%) developed PTLD. Median time to PTLD diagnosis was 105.9 months (95% Confidence interval 97.7 to 111.1). Mortality rate in patients who developed PTLD was 73.7%. Increased incidence of PTLD was seen in recipients < 55 years vs recipients > 55 years (12.3% vs 7%; $p < 0.001$) and in recipient with EBV seronegative vs EBV seropositive status at transplant (14.3% vs 7%; $p < 0.001$). The gender and CMV serostatus of the recipient at the time of transplant did not affect the incidence of PTLD (Table 1).

CONCLUSIONS: We conclude the following- 1) Incidence of PTLD amongst heart transplant recipients is 9 and mortality associated with PTLD after heart transplant is very high (73.7%) 2) Heart transplant recipients present with late onset PTLD (>1 year after transplant) 3) Recipient EBV seronegative status is associated with a statistically significant increased incidence of PTLD. Pre-transplant determination of recipient EBV serostatus can help identify a subgroup of patients who have increased risk of post-transplant PTLD and may benefit from increased surveillance.

Table 1

Variable	PTLD incidence (percentage)	*p*
Age < 55 vs. Age ≥ 55	12.3 vs. 7	<.001
Female vs. Male	9.9 vs. 8.8	0.176
Recipient EBV seronegative vs seropositive at time of transplant	14.3 vs. 7	<.001
Recipient CMV seronegative vs seropositive at time of transplant	8.9 vs 7.6	0.154

POSTPARTUM HIV CARE AMONG HIV-INFECTED WOMEN IN ATLANTA, GEORGIA, 2011–2016 Christina M. Meade[1]; Martina Badell[1, 2]; Lisa Haddad[1, 2]; Andres Camacho-Gonzalez[1, 2]; Susan A. Davis[3]; Jessica L. Tarleton[4]; Emily Grossniklaus[5]; Stephanie Hackett[2]; Joy Ford[2]; Jeronia Blue[2]; Cyra C. Mehta[6]; Ryan Quigley[6]; Gabriel Vece[6]; Anandi Sheth[1, 2]. [1]Emory University School of Medicine, Atlanta, GA; [2]Grady Health System, Atlanta, GA; [3]University of Texas Austin, Austin, TX; [4]University of Pittsburgh, Pittsburgh, PA; [5]University of Washington, Seattle, WA; [6]Emory University, Rollins School of Public Health, Atlanta, GA. (Control ID #2702253)

BACKGROUND: Pregnancy provides a unique opportunity for HIV treatment, with increased health care engagement and motivation for adherence to antiretroviral therapy (ART) to prevent perinatal transmission. Continuity in HIV care after the immediate postpartum period generally requires transition

from obstetrical to HIV primary care, and though critical for maternal health, has been reported to be suboptimal in many populations. We characterized factors associated with long-term postpartum HIV care outcomes in a large urban health system in the Southern US, the region where most new HIV infections occur.

METHODS: We reviewed medical records of HIV-infected women who delivered at Grady Memorial Hospital in Atlanta, Georgia from 2011–2016 to estimate retention in HIV care (two HIV care visits or viral load measurements separated by >90 days) and viral suppression (<200 copies/mL) at 12 and 24 months postpartum. Multivariate logistic regression models assessed factors associated with 12 and 24 month retention and viral suppression. In cases of multiple deliveries per woman, only the first delivery was included in analysis.

RESULTS: Among 207 HIV-infected women, the mean age was 28.1 years (SD 6.2). 78.3% were African-American, 22.7% were diagnosed with HIV during pregnancy, and 63.2% were off ART at the time of pregnancy diagnosis. The women attended a mean 8.1 ± 3.7 prenatal care visits. 71.0% had HIV RNA <200 copies/mL at delivery, and 76.5% attended their postpartum obstetric visit. A HIV primary care visit was attended in 157 (79.7%) in a mean 130 days (SD 111) after delivery. Retention in care at 12 and 24 months postpartum occurred in 86 (46.5%) and 52 (34.0%) women, and viral suppression in 76 (41.3%) and 46 (30.1%) respectively. In multivariable analysis attending an HIV care visit within 90 days postpartum (aOR 3.90, CI 1.85-8.19; aOR 4.89, CI 2.10–11.38) was associated with 12 and 24 month retention, and having fewer previous live births (aOR 0.73, 95% CI 0.56–0.95) and older age (aOR 1.08, 95% CI 1.005–1.15) were associated with 12 month retention. Viral suppression at 12 months was associated with taking ART at pregnancy diagnosis (aOR 2.25, CI 1.09–4.63), viral suppression at delivery (aOR 3.52, CI 1.43–8.67), and attending an HIV care visit within 90 days postpartum (aOR 2.26, CI 1.8–4.72). Viral suppression at 24 months did not have significant predictors on multivariable analysis.

CONCLUSIONS: Despite high healthcare engagement during pregnancy, long-term postpartum retention in HIV care and viral suppression were low in this population of HIV-infected women. Prompt transition to HIV primary care in the postpartum period was associated with improved 12 and 24-month outcomes, suggesting that the postpartum transition from obstetric to HIV primary care may be a critical window for cross-disciplinary intervention between obstetrical and HIV primary care providers to improve long-term HIV care outcomes

POSTTRAUMATIC STRESS SYMPTOMS AND TOBACCO OR CANNABIS USE AMONG A SAMPLE OF URBAN WOMEN

Anika A. Alvanzo[2]; Sarah Jabour[1]; Alexis A. Page[1]. [1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #2707499)

BACKGROUND: Blacks and women are disproportionately affected by posttraumatic stress disorder (PTSD) with higher rates than Whites and men, respectively. PTSD symptoms are associated with comorbid health problems, including substance use. The aim of this analysis was to investigate associations between PTSD symptoms and tobacco or cannabis use among predominantly Black women in a mid-Atlantic city.

METHODS: Women were recruited from 5 urban social services centers through the PERMSS Project: Promoting Education and Research on Mood, Stress, and Substances. Women were eligible to participate if they were 21–65 years old and English speaking, and were excluded if pregnant or currently enrolled in substance use treatment. Participants completed an Audio Computer-Assisted Self-Interview (ACASI) survey which included the National Institute on Drug Abuse (NIDA)-modified Alcohol, Smoking and Substance Involvement Screening Test (ASSIST) and the Posttraumatic Stress Disorder Checklist (PCL-5). Frequencies, means and standard errors were used to describe the sample. Cannabis use was dichotomized as any use in the past 3 months (current) vs. no use. Tobacco use was assessed using two dichotomized variables: daily/almost daily use vs. non-daily use and current (any use in the past 3 months) vs. no use. Mann–Whitney U tests were used to analyze the association between PCL scores and tobacco or cannabis use. A PCL score ≥ 33 classified women as having probable PTSD. We analyzed the relationship between probable PTSD and tobacco or cannabis use using Pearson Chi-Square tests.

RESULTS: The sample consisted of 204 women with a mean age of 45.8 (SD: 11.8) years. The majority of the sample was Black (84.8%) and over half (51.2%) reported annual household incomes of less than $10,000. The mean PCL score was 15.8 (SD: 17.0). Mann–Whitney U tests found a significant association between higher PCL scores and past 3-month cannabis use (Md*n* = 9.00 (IQR = 1.50–22.00) vs. 16.50 (IQR = 4.25–31.25); U = 3051.00, $P = 0.022$); past 3-month tobacco use (Md*n* = 7.00 (IQR = 1.00–17.00) vs. 19.00 (IQR = 10.50–34.00); U = 2644.50, $P = 0.000$); and daily tobacco use (Md*n* = 8.50 (IQR = 1.00–19.75) vs. 18.00 (IQR = 10.00–35.50; U = 2523.00, $P = 0.001$). Probable PTSD was significantly associated with past 3-month tobacco use ($\chi^2 = 4.122$, df = 1, $P = 0.042$). There was no significance between probable PTSD and ever using cannabis ($\chi^2 = 1.274$, df = 1, $P = 0.259$) or daily tobacco ($\chi^2 = 3.275$, df = 1, $P = 0.070$).

CONCLUSIONS: Higher scores on the PCL, reflecting greater PTSD symptom severity, were associated with current cannabis use and daily tobacco use in predominantly Black women recruited from urban community settings. Probable PTSD was also associated with current tobacco use. Further research is needed to investigate the possibility of cannabis and tobacco use for self-medication of PTSD symptoms as well as the effectiveness of interventions that combine tobacco cessation and posttraumatic stress management.

POTENTIAL COST SAVINGS IN PE PATIENTS WITH LOW SPESI SCORES

Adam Tawney; Paul Nona; Scott Kaatz; Vinay Shah; Syed T. Ahsan; Chad Klochko; Deepthi Tirunagari; Stacy Ellsworth. Henry Ford Hospital, Detroit, MI. (Control ID #2705899)

BACKGROUND: Risk stratification tools have been validated to determine the risk of mortality with acute pulmonary embolism (PE) and low risk patients may be candidates for outpatient treatment. The Pulmonary Embolism Severity Index (PESI) and shorter simplified (sPESI) form are commonly used models. We sought to identify the proportion of low risk sPESI scores that were admitted and the potential cost savings if they were treated as outpatients.

METHODS: Retrospective review of 385 patients presenting with acute PE from May 2015 to May 2016. The sPESI score (age, history of chronic lung disease or cancer, heart rate, systolic blood pressure, and oxygen saturation) was calculated and the proportion of low risk patients (score of 0) that were admitted was determined. Published estimates that analyzed hospital room, board and inpatient nursing costs associated with inpatient treatment of pulmonary embolism of $5101 were used to evaluate potential cost savings.

RESULTS: Of the 385 patients identified with acute PE, 139 (36.1%) had low risk sPESI scores. Of those 139 patients, 133 (95.6%) were admitted for inpatient treatment. Low risk patients that were admitted had a median hospitalization of 4 days, mean inpatient hospitalization of 4.7 days with a standard deviation of 3.8 days and accounted for 641 total days of hospitalization. Treating these low risk patients as outpatients, thereby eliminating nursing costs, could be associated with approximately $678,443 in potential savings during our study period.
CONCLUSIONS: Patients with a low risk sPESI score at our institution are commonly admitted for treatment of acute PE. This accounts for a substantial economic burden that could be alleviated by use of risk stratification to determine appropriate candidates for outpatient management. The proportion of PE patients at low risk for mortality that are capable of outpatient treatment using tools like the Hestia criteria are needed to estimate the true potential cost savings.

PRE-EXPOSURE PROPHYLAXIS (PREP) FOR HIV PREVENTION: ATTITUDES, BEHAVIORS AND KNOWLEDGE AMONG PRIMARY CARE PROVIDERS FOLLOWING AN EDUCATIONAL INTERVENTION Susan Maya[1]; Keith M. Sigel[2]; Sabrina J. Gard[1]; Antonio Urbina[1]. [1]Mount Sinai Hospital, New York, NY; [2]Mount Sinai School of Medicine, New York, NY. (Control ID #2704237)

BACKGROUND: Daily oral tenofovir/emtricitabine has been shown to be effective for prevention of HIV transmission among men who have sex with men (MSM), IV drug users, and heterosexual couples, among others. To reach all at-risk populations, PrEP must be made available in a variety of clinical settings, including general primary care clinics. A number of studies have assessed the baseline attitudes, knowledge and behaviors of primary care providers with regards to PrEP. However no studies to-date have demonstrated successful improvement in knowledge of PrEP and comfort with prescribing it. We conducted an assessment of attitudes, behaviors and knowledge relating to PrEP among a group of internal medicine residents at a single academic institution following a brief educational intervention.
METHODS: We administered a 15 item questionnaire before and after a 50 min lecture given in small group sessions to all second and third year residents within the Mount Sinai Hospital Internal Medicine training program. Survey items included 5 knowledge based questions, current PrEP prescribing practices, perceived barriers to PrEP prescribing, and comfort with prescribing PrEP. Survey items were adapted from recently published surveys, and were reviewed by current PrEP prescribers in a Mount Sinai affiliated HIV clinic. The educational intervention was case based, interactive and involved practical applications such as how to order appropriate tests in the Electronic Medical Record (EMR), screenshots of a note template and a review of taking a relevant sexual history and appropriate HIV testing guidelines. We then compared pre- and post- test responses using the Wilcoxon signed-rank test.
RESULTS: Of eligible second and third year residents, 35 completed both the before and after surveys. At baseline, 1 respondent reported previously prescribing PrEP (3%). Following the educational intervention, knowledge scores improved on items including correct identification of recommended time-frame for follow up (94% vs 43%, $p < 0.001$), time to therapeutic levels (86% vs 31%, $p < 0.001$), and contraindications to PrEP (100% vs 74%, $p = 0.001$). Comfort level with prescribing PrEP increased (median 8 vs 5 on a 10 point Likert scale, p <0.001) and respondents were more likely to feel PrEP could be easily integrated into existing primary care (median 7.5 vs 5 on a 10 point Likert scale, $p < 0.001$).
CONCLUSIONS: Our educational intervention resulted in improved knowledge scores and comfort levels with prescribing PrEP. A majority of residents in general internal medicine felt that PrEP can be integrated into existing primary care delivery systems. Taken together, these results suggest that there is a willingness among general internist trainees to provide PrEP and that the necessary skills can be easily taught. Further research is needed to understand the best mechanisms for implementing this vital tool throughout resident-based primary care clinics.

PREDICTING HEPATITIS B VIRUS INFECTION AMONG PATIENTS WITH CANCER UNDERGOING SYSTEMIC ANTI-CANCER THERAPY: A PROSPECTIVE COHORT STUDY Jessica P. Hwang[1]; Anna S. Lok[3]; Michael J. Fisch[4]; Scott B. Cantor[1]; Andrea Gabriela Barbo[2]; Heather Y. Lin[2]; Jessica T. Foreman[1]; John M. Vierling[5]; Harrys Torres[1]; Bruno Granwehr[2, 1]; Ethan Miller[1]; Maria Suarez-Almazor[1]. [1]The University of Texas MD Anderson Cancer Center, Houston, TX; [2]UT MD Anderson Cancer Center, Houston, TX; [3]University of Michigan, Ann Arbor, MI; [4]Aim Specialty Health, Chicago, IL; [5]Baylor College of Medicine, Houston, TX. (Control ID #2697543)

BACKGROUND: Most patients with cancer are not screened for HBV infection prior to anti-cancer therapy, and optimal screening strategies have not been determined. We sought to identify and compare selective HBV screening strategies using predictors of HBV infection in a cohort of patients with cancer who had universal testing at the onset of anti-cancer therapy.
METHODS: We conducted a prospective study of cancer patients >18 years old at MD Anderson Cancer Center (7/2013 - 12/2014). Patients had hepatitis B surface antigen (HBsAg), hepatitis B core antibody (anti-HBc total Ig), and hepatitis B surface antibody (anti-HBs) testing and completed a CDC-based questionnaire of 19 HBV risk factors. We considered HBsAg+/anti-HBc + patients to have chronic infection and HBsAg-/anti-HBc + patients to have past infection. A multivariate logistic regression model predicting chronic or past HBV infection which was developed and validated using bootstrapping methods with 500 samples to calculate a bias-corrected area under the curve (AUC). We generated several models from which we selected a final model of 7 questions. From this final model, we selected subsets of having at least one affirmative response to any of the predictors and compared their false negative rate (FNR).
RESULTS: Of 3534 eligible patients approached, we enrolled 2206 patients (response rate 62.4%). Of these, 2124 completed both the HBV risk survey and screening tests and constituted our final study cohort. Mean age was 58 ± 13 years (SD), and 54% were women. The study population was 77% non-Hispanic white, 11% Hispanic, 8% black, and 4% Asian. Nearly 20% had a hematologic malignancy, and 79% had a solid tumor other than liver cancer. Over 12% of patients were born outside the US. The prevalence of chronic HBV infection was 0.3% ($n = 7$ patients), and that of past HBV infection was 6% ($n = 128$). Stepwise variable selection method showed 7 predictors (odds ratio [OR]; 95% CI) of a positive HBsAg or anti-HBc test: men who had sex with men (27; 6–136), black race (5; 3–9) or Asian race (3; 2–6), birthplace outside US (2; 1–5), parents' birthplace outside US (2; 1–5), household HBV contact (2; 1–4), age >50-64 (2; 1.1–3) or >65 (3; 2–5), and history of injection drug use (10; 5–22). The AUC of the model was 0.79 (95% CI: 0.73, 0.82). The FNR for the CDC-based 19 questions survey was 0% while strategies involving 6–7 questions had FNR of 0%-1.5% (Table).
CONCLUSIONS: Selective screening models based on HBV risk factors and demographics performed as well as the 19-questions CDC-based survey. These

brief tools may be used in clinical practice to identify patients at risk of HBV reactivation due to anti-cancer therapy.

PREDICTION OF FUTURE CHRONIC OPIOID USE AMONG HOSPITALIZED PATIENTS: A MACHINE LEARNING APPROACH

Susan L. Calcaterra[1, 2]; Sharon Scarbro[2]; Ingrid A. Binswanger[2, 3]; Kathryn L. Colborn[2]. [1]Denver Health, Denver, CO; [2]University of Colorado, Aurora, CO; [3]Kaiser Permanente Colorado, Denver, CO. (Control ID #2706828)

BACKGROUND: Opioids are commonly prescribed in the hospital yet little is known about which patients will continue on to chronic opioid use following discharge. Predictive tools to identify hospitalized patients at risk for future chronic opioid use could have clinical utility to improve patient education and prescribing behaviors. Logistic regression analyses are the standard method used to develop prediction models. Machine learning methods examine all potential predictors simultaneously in an unbiased manner to provides a data-driven method to identify useful predictors for health-related outcomes. We developed and compared various machine learning algorithms to predict future chronic opioid use one year following hospital discharge.

METHODS: This was a retrospective cohort study of all hospital discharges from January 2008 to December 2014. The study outcome was chronic opioid use one year following hospital discharge. We defined chronic opioid use as an opioid episode lasting >90 days or >10 opioid prescriptions dispensed over one year. Key exclusion criteria included the use of chronic opioid therapy for pain or opioid replacement therapy for addiction. We constructed a logistic regression model using variables identified by clinical expertise and informed by the literature. We compared the logistic regression model to three machine learning algorithms including the adaptive least absolute shrinkage and selection operator algorithm (LASSO), a random forest algorithm and a balanced random forest algorithm. Models predictive performance was measured using area under the receiver operator curve (AUC), accuracy, sensitivity and specificity.

RESULTS: We identified 159,574 discharges. After applying our exclusions, 27,705 patients remained. Of these, 1,457 were using chronic opioid therapy one year following discharge. All models predicted future chronic opioid use with an AUC of > 0.70. The balanced random forest model predicted chronic opioid use with the highest sensitivity (0.700), specificity (0.700) and accuracy (0.750). The logistic regression model had a poor sensitivity (0.014) and a high specificity (0.999). The balanced random forest algorithm ranked variables of importance to predict future chronic opioid use. Of the twenty variables tested, age range 40–60 years old ranked as the most important predictor with a one year probability of chronic opioid use of 1.5%. Other high ranking variables were receipt of non-opioid analgesics one year preceding the discharge (NSAIDS, neuropathic agents), opioid receipt at discharge, longer length of hospital stay and higher Charlson Comorbidity Index.

CONCLUSIONS: A machine learning approach could be used to predict future chronic opioid therapy among patients and outperformed the traditional logistic regression predictive model. Applications for such predictive models among patients discharged from the hospital include decision support tools to prompt hospital staff to provide additional education or to modify prescribing, when appropriate.

PREDICTION OF SPONTANEOUS REMISSION BY 18 F-FDG PET OR PET/CT IN CLASSIC FEVER OF UNKNOWN ORIGIN

Motoki Takeuchi[2]; Anat Gafter-Gvili[4]; Francisco Javier García-Gómez[3]; Emmanuel Andres[5]; Daniel Blockmans[1]; Teruhiko Terasawa[2]. [1]University Hospital Gasthuisberg, Leuven, Belgium; [2]Fujita Health University, Nagoya, Japan; [3]Virgen Macarena University Hospital, Seville, Spain; [4]Davidoff Cancer Center, Rabin Medical Center, Petah-Tikva, Israel; [5]Medical Clinic B, University Hospital of Strasbourg, Strasbourg, France. (Control ID #2703599)

BACKGROUND: Despite recent advances in diagnostic technologies, classic fever of unknown origin (FUO) is still a diagnostic challenge. Because not a few patients in whom FUO remains undiagnosed after intensive work-up have a possibility to resolve spontaneously, reliable predictive factors of a spontaneous regression could avoid unnecessary diagnostic tests or empiric treatment. Recently, studies of ^{18}F-FDG PET or PET/CT (PET or PET/CT) have reported a good diagnostic yield in identifying a source of fever in undiagnosed FUO cases. In this study, we systematically reviewed the ability of negative results in PET or PET/CT to predict a spontaneous remission in patients with classic FUO.

METHODS: This systematic review was performed as extended part of a broader review conducted by our team. We searched PubMed and Scopus through Oct 31, 2016 with no language restrictions. We included studies that evaluated PET or PET/CT in at least 10 adult patients (>18 years of age) with classic FUO, and followed up undiagnosed cases for at least 3 months after PET or PET/CT. Two independent reviewers screened abstracts, perused full-text publications for eligibility, and performed data extraction. We extracted the reported scan results (as positive or negative), and the number of spontaneous remissions. We contacted the study authors for unpublished data when the relevant information was not reported. We performed the Knapp-Hartung-corrected REML random-effects meta-analysis to calculate summary risk ratios and their 95% confidence intervals.

RESULTS: We included 8 studies of PET/CT (391 patients) and 4 studies of PET (128 patients). No studies were designed for evaluating prognostic ability of these imaging tests. After the evaluation with PET/CT or PET scan, 108 (28%) or 46 (36%), respectively, remained undiagnosed. Except for two prospective studies, studies retrospectively reviewed data derived from clinical practice, and failed to employ prespecified work-up strategies or follow-up protocols. Studies of PET/CT observed significantly more spontaneous remissions in patients with a negative scan than in those with a positive scan (76/144 vs. 21/247; summary RR = 5.36; 95% CI: 3.20–8.98; $p < 0.001$; $I^2 = 0\%$). In contrast, studies of PET found no evidence that either a positive or a negative scan was associated with more spontaneous regressions (8/46 vs. 18/82; summary RR = 0.83 favoring a positive scan; 95% CI: 0.14-4.98; $p = 0.77$; $I^2 = 32\%$).

CONCLUSIONS: Limited evidence suggests that a negative PET/CT can be predictive of spontaneous remission in classic FUO after a routine fever work-

up. Given the limitations in the primary studies and its high cost, future PET/CT studies should use a multivariable approach taking account of other important factors to validate these promising results.

PREDICTIVE VALUE OF THE PRESENT-ON-ADMISSION INDICATOR FOR HOSPITAL-ACQUIRED BLEEDING EVENTS

Roxanne Ghazvinian[1]; Richard H. White[2]; Brian F. Gage[4]; Margaret Fang[3]; Raman Khanna[3]. [1]Emory University, Atlanta, GA; [2]UC Davis, Sacramento, CA; [3]UCSF, San Francisco, CA; [4]Washington University, St. Louis, MO. (Control ID #2705801)

BACKGROUND: Hemorrhage is both an important reason for admission to the hospital and a complication of hospitalization; thus, distinguishing when a hemorrhage occurred is important to quality improvement. The present-on-admission (POA) indicator could be useful in distinguishing hospital-acquired bleeding from bleeding precipitating admission; however, its accuracy for hemorrhage diagnoses codes is unknown. We aimed to determine the predictive value of POA indicators for hemorrhage among hospitalized patients.

METHODS: We used administrative data from the Vizient database to identify all adult non-pregnant patients at our academic medical center with at least 1 secondary diagnosis of intracranial hemorrhage (ICH) or gastrointestinal bleed (GIB) based on ICD-10 diagnosis codes over a period of 9 months. We then obtained a stratified sample of patients with ICH and GIB diagnosis codes, with and without POA flags, and reviewed their medical records. The positive predictive value of the POA flag for bleeding was calculated as the number of events with a particular POA flag (Yes vs. No) divided by whether or not the event occurred as determined by chart review.

RESULTS: From January 1 to September 30 of 2016, we identified 397 charts with at least one secondary diagnosis code for GIB (79% POA = Y) and 147 for ICH (80% POA = Y). We sampled a total of 40 charts in each category except ICH POA = N, where we included all 29 available cases. After reviewing the charts, 11 of the sampled GIB cases (5 POA = Y, 7 POA = N) were excluded for inaccurate coding. We found that of the 35 patients with a GIB code flagged POA = Y, 31 were found on chart review to have GIB preceding the hospitalization (PPV = 89%). Of 33 patients with a GIB flagged POA = N, 27 were found on chart review to have a hospital-acquired GIB (PPV = 82%). For ICH, of 40 patients flagged POA = Y, 34 were found to have ICH on or preceding hospitalization (PPV = 85%). Finally for the 29 patients with ICH flagged POA = N, 28 were found to have a hospital acquired hemorrhage (PPV = 97%) (Table 1).

CONCLUSIONS: At our institution, the POA indicator was reasonably accurate in differentiating between hemorrhages that occurred prior to hospitalization and those that were hospital-acquired, suggesting that these indicators could be useful for quality improvement and research purposes.

Table 1. Overall PPV for each diagnosis code group and POA flag.

Diagnosis/POA combination	Total number	Sampled	Accurate upon chart review	PPV
GI Hemorrhage; POA = Y	313	35	31	89%
GI Hemorrhage; POA = N	84	33	27	82%
IC Hemorrhage; POA = Y	118	40	34	85%
IC Hemorrhage; POA = N	29	29	28	97%

PREDICTORS OF HOSPITAL LENGTH OF STAY AMONG PATIENTS WITH LOW-RISK PULMONARY EMBOLISM

Li Wang[1]; Onur Baser[2]; Phil Wells[3]; W F. Peacock[4]; Craig I. Coleman[5]; Gregory Fermann[6]; Jeff Schein[7]; Concetta Crivera[7]. [1]STATinMED Research, Plano, TX; [2]Columbia University, New York, NY; [3]University of Ottawa and the Ottawa Hospital Research Institute, Ottawa, ON, Canada; [4]Baylor College of Medicine, Houston, TX; [5]University of Connecticut, Hartford, CT; [6]University of Cincinnati, Cincinnati, OH; [7]Janssen Scientific Affairs, LLC, Raritan, NJ. (Control ID #2708353)

BACKGROUND: Increased hospital length of stay (LOS) is an important driver of costs in hospitalized patients. Low-risk PE (LRPE) patients can benefit from abbreviated hospital stays or outpatient therapy, which could substantially reduce health care costs. We sought to measure the predictors associated with LOS among LRPE patients within the Veterans Health Administration (VHA).

METHODS: Adult patients with ≥1 inpatient diagnosis for PE (index date) between October 2011 and June 2015 and continuous enrollment in the VHA health plan for ≥12 months pre- and 3 months post-index date were included. PE risk stratification was performed using the simplified Pulmonary Embolism Stratification Index (sPESI). Patients scoring 0 points on the sPESI were considered at low risk and all others were defined as high risk. LRPE patients were further stratified, based on their LOS, into short (≤2 days) and long (>2 days) LOS cohorts. Logistic regression was used to identify the predictors of LOS among LRPE patients.

RESULTS: Of 6,746 PE patients, 95.4% were men, 67.7% were white, 22.0% were African American, and 1,918 were LRPE. Of LRPE patients, 688 (35.9%) had a short and 1230 (64.1%) had a long LOS. LRPE patients with computed tomography angiography (OR: 4.8, 95% CI: 3.8–6.0), ventilation perfusion scan (OR: 3.8, 95% CI: 1.9-7.8), and venous ultrasound (OR: 1.4, 95% CI: 1.1–1.9) in the pre-index period had an increased probability of having a short LOS. LRPE patients with troponin I (OR: 0.7, 95% CI: 0.6–0.9) or B natriuretic peptide (OR: 0.6, 95% CI: 0.5–0.8) obtained during the index hospitalization had a decreased probability of having a short LOS. Additionally, LRPE patients with left ventricular dysfunction (OR: 0.2, 95% CI: 0.1–0.6), hospitalization for deep vein thrombosis (OR: 0.7, 95% CI: 0.6–0.9), or peptic ulcer disease (OR: 0.3, 95% CI: 0.1–1.0) had a decreased probability of having a short LOS. Demographics including sex, race, and body mass index did not have any significant effect on the hospital LOS in LRPE patients.

CONCLUSIONS: Understanding the predictors of LOS can help providers to deliver efficient treatment and reduce the LOS for LRPE patients, which may reduce the overall burden of PE.

PREDICTORS OF INSULIN INITIATION IN PATIENTS WITH TYPE 2 DIABETES

Scott J. Pilla; Hsin-Chieh Yeh; Jeanne M. Clark; Nisa Maruthur. Johns Hopkins University, Baltimore, MD. (Control ID #2703071)

BACKGROUND: The decision to initiate insulin therapy in patients with type 2 diabetes is complex and requires an individualized approach, yet the drivers of this decision are not known. We sought to identify patient sociodemographic and clinical factors that were independent predictors of insulin initiation.

METHODS: We retrospectively examined 1,943 participants from the Look AHEAD (Action for Health in Diabetes) clinical trial of overweight and obese adults with type 2 diabetes who were not using insulin at baseline and were

randomized to the Diabetes Support and Education (control) arm. We used data from enrolment beginning in 2001 through 10 years of follow-up. Participants' personal physicians managed their medications during the study period. The Cox proportional hazards model was used to estimate the association between participant characteristics and initiation of insulin therapy which was assessed yearly. We performed time-varying adjustment for HbA1c measured 8 times over 10 years, as well as for clinical and socioeconomic factors including age, sex, race, diabetes duration, medical comorbidities, insurance status, and source of medical care. The results of the fully adjusted model are presented here.

RESULTS: During a median follow-up of 7.4 years, 632 participants initiated insulin for an incidence rate of 4.80 events/100 person-years, and 9.54 events/100 person-years in those with baseline HbA1c > 8.5%. We found a lower risk of insulin initiation in black (HR 0.57, 95% CI 0.44–0.74) and Hispanic (HR 0.54, 95% CI 0.41–0.73) relative to white participants, global $P < 0.001$. Older age was associated with a lower risk of insulin initiation (HR 0.83 per 10 years, 95% CI 0.72–0.96), and BMI with a higher risk (HR 1.12 per 5 kg/m^2, 95% CI 1.05–1.19). Comorbid conditions that were independently associated with a higher risk of insulin initiation were tobacco use ($P = 0.021$), hypertension ($P = 0.010$) and cardiovascular disease ($P = 0.006$). Source of medical care was associated with insulin initiation (global $P = 0.008$), with those receiving care at a hospital affiliated clinic at higher risk relative to care at a private office (HR 1.50, 95% CI 1.17–1.92).

CONCLUSIONS: We identified multiple independent predictors of insulin initiation in patients with type 2 diabetes, suggesting that the decision to initiate insulin is influenced by factors including patient age, race, comorbidities, and source of medical care. This study used rigorously collected clinical trial data which allowed adjustment for potential confounders including HbA1c with a high degree of granularity. These findings highlight the need for further research to inform evidence-based guidelines for individualized use of insulin that is targeted to a patient's characteristics and needs. The finding of a lower risk of insulin initiation in black and Hispanic participants requires further study to determine the drivers of this disparity.

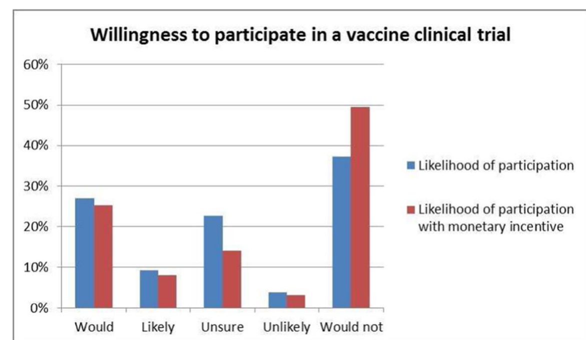
PREDICTORS OF PARTICIPATION IN PRIMARY CARE-BASED VACCINE CLINICAL TRIAL IN A PRIMARILY ELDERLY HISPANIC POPULATION Sharon Rikin; Philip LaRussa; Steven Shea; Melissa Stockwell. Columbia University, New York, NY. (Control ID #2697985)

BACKGROUND: Minorities and the elderly are underrepresented in clinical research. Motivations to participate in preventive clinical trials are not as evident as for disease-specific trials. Population-specific barriers to recruitment are also not fully understood. This study aimed to understand a) how knowledge of and previous participation in clinical trials are associated with willingness to participate in vaccine clinical trials; b) how incentives affect willingness to participate.

METHODS: A survey on participation in an influenza vaccine clinical trial was administered to a convenience sample of 200 patients ≥65 years in an academic general internal medicine clinic (88% participation rate). The study was IRB approved and consent obtained. Logistic regression evaluated associations, adjusted for age, gender, and language. Wilcoxon signed rank sum test compared 5-point Likert scale on willingness to participate with and without monetary incentives.

RESULTS: Mean age was 74 years (SD 6.7), 73% female, 93% Spanish speaking, and 86% had high school education or less. Approximately half (54.4%) responded *yes* to previously hearing about clinical trials; 17.6% reported previous participation in a trial. Those with previous knowledge were more likely to report they would/would likely participate vs. those without prior knowledge (aOR 2.18, 95% CI (1.09, 4.38)). Those who had previously participated were also more likely to report they would/would likely participate vs. those without participation, although not significant after adjusting (aOR 1.24, 95% CI (0.53, 2.88)). When asked about willingness to participate if there was monetary compensation, there was a 12.2% absolute increase in those who reported they would *not* participate (Figure), with a significant difference in distribution of responses before and after mention of monetary incentive (Wilcoxon signed rank test, $p = 0.001$).

CONCLUSIONS: Increased willingness to participate in clinical trials for those with prior knowledge or participation suggests increased public information on clinical research could improve recruitment in this population. Offering incentives unexpectedly reduced participants' willingness to participate, warranting further investigation. The study highlights the importance of pre-testing recruitment materials and incentives in key group populations prior to implementing a primary care interventional study.



PREDICTORS OF PERIOPERATIVE OPIOID PRESCRIBING AND CONSUMPTION Christopher W. Shanahan[1]; Olivia Gamble[4]; Inga Holmdhal[4]; Julia Keosaian[4, 5]; Ziming Xuan[5]; Marc Larochelle[3]; Jane M. Liebschutz[2]. [1]Boston University/Boston Medical Center, Boston, MA; [2]Boston University School of Medicine, Boston, MA; [3]Boston University School of Medicine and Boston Medical Center, Boston, MA; [4]Boston Medical Center, Boston, MA; [5]Boston University School of Public Health, Boston, MA. (Control ID #2704968)

BACKGROUND: Overprescribing of opioids for post-operative pain may lead to diversion and misuse. We analyzed data from a prospective observational study of patients undergoing elective ambulatory surgery to assess predictors of surgeons' prescribing and patients' use of opioid analgesic medications.

METHODS: We surveyed patients one week prior to and 10–14 days after ambulatory surgery at an academic safety-net hospital. Seven surgical specialties performed the procedures. We excluded cancer-related surgeries and procedures not expected to require post-operative pain management (e.g. endoscopies). Baseline data included socio-demographics (age, gender, race/ethnicity), chronic pain severity and function in the past three months (Graded Chronic Pain Scale), and high-risk alcohol and drug use (AUDIT and DUDIT). Primary outcomes were total opioids prescribed and consumed (morphine milligram equivalents (MMEs)), and percent of unused opioids. We used multivariable linear

regression, adjusted for surgical specialty, to analyze associations of socio-demographics, chronic pain, and high-risk substance use with all outcomes. We calculated intra-class correlations to partition variance in each outcome attributable to surgical specialties.

RESULTS: Eighteen surgeons performed surgery on 150 patients (54% female, 44% white, 34% black; mean age: 49 years). Surgeons prescribed opioids for post-operative pain to 95% of patients, 85% of whom received oxycodone. Surgeons prescribed a mean of 242 MMEs per patient; however, patients reported using a mean of 116 MMEs per patient (48%). On average, a 10-year increase in patient age was associated with 12 MMEs fewer prescribed opioids ($p < 0.01$). Intra-class correlations attributed for 19% of the variance in opioid prescribing to surgical specialty with significant differences between specialties ($F = 5.8$, $p < 0.001$). Surgical specialty accounted for 4.1 and 4.5% of the variance in the amount of opioids consumed and percent unused, respectively. Each one-point increase in the pre-operative Graded Chronic Pain scale was associated, on average, with an 18 MME increase in opioid consumption ($p < 0.01$), and 5% fewer unused opioids ($p = 0.03$). Prior opioid prescription was associated with a 55 MME increase in opioid consumption ($p = 0.03$), and 19% fewer unused opioids ($p = 0.03$). High-risk drug use, on average, trended towards 9% fewer unused opioids ($p = 0.05$).

CONCLUSIONS: Patients use less than 50% of opioid analgesic medications prescribed for post-operative pain control. Patient age predicts post-operative opioid prescribing. Chronic pain, risky drug use, and prior opioid prescription predict higher post-operative opioid consumption. Surgical specialty accounts for a substantial portion of variance in post-operative opioid prescribing when compared to other variables. Opportunities to improve post-operative opioid prescribing include system changes among surgical specialties, and targeted patient education and monitoring.

PREDICTORS OF SOCIAL SUPPORT AMONG NEWLY DIAGNOSED BREAST CANCER PATIENTS SEEKING CARE AT AN URBAN SAFETY NET ACADEMIC MEDICAL CENTER Naomi Y. Ko[1, 2]; Christine Gunn[1]; Sharon Bak[1]; Na Wang[3]; Kerrie Nelson[3]; JoHanna Flacks[4]; Samantha Morton[4]; Tracy A. Battaglia[1, 2]. [1]Boston University School of Medicine, Boston, MA; [2]Boston Medical Center, Boston, MA; [3]Boston University School of Public Health, Boston, MA; [4]Medical Legal Partnership Boston, Boston, MA. (Control ID #2705996)

BACKGROUND: Disparities in breast cancer care are a worsening problem, requiring effective interventions that seek to address the delivery of high quality cancer care. Evidence from interventions designed to improve timeliness of care routinely identify lack of social support as one of the biggest barriers to care. And, the presence of social support is associated with adherence to treatment and survival. This study explores predictors of social support in a diverse population of newly diagnosed cancer patients seeking care at an urban safety net medical center.

METHODS: This is a descriptive analysis of baseline preliminary data from participants enrolled in Project SUPPORT, a randomized controlled comparative effectiveness trial designed to evaluate the impact of patient navigation with or without legal support and services, among women diagnosed with Stages 0–4 breast cancer between 2014–2016. Upon enrollment (within one month of a cancer diagnosis) we administered the Medical Outcomes Survey (MOS) of social support to all participants. This validated survey measures functional support, including an overall score (range 0–95) and 4 distinct domains: Emotional/Informational, Tangible, Affectionate and Positive Social Interaction. Using chi-squared and t-tests we compared MOS scores across socio-demographic variables: age, race, language, insurance, health literacy and marital status.

RESULTS: Of the 139 participants, mean age is 54.5 (SD = 10.6); 54% Black, 23% White, 21% Hispanic, and 2% identified as other; the majority had public insurance 76%; 65% speak English, 21% Spanish and 14% Haitian Creole. Only 35% have adequate health literacy as measured by the BRIEF. Only 32% are currently partnered. The overall mean total score for social support is 75.3 (+/− 25), median of 81.6 (range 60.5 - 98.7). Participants scored lowest in tangible support (mean score 67.4 +/− 34.1) and highest in affective support (mean score 82.7 +/− 26.3). Non-White participants scored lower across all domains (mean overall MOS score 73.5 +/− 2.4) when compared with Whites (mean overall MOS score 81.4 +/− 4.4). There were no significant differences in MOS scores by language, insurance, literacy or marital status.

CONCLUSIONS: This is the first study to describe social support scores (overall and specific domains) from the validated MOS survey tool among a racially diverse, low income urban cancer patient population. Preliminary findings suggest non-white women are most at risk for low social support, and can thus benefit from targeted interventions.

PREECLAMPSIA: A CRUCIAL BUT UNDER-RECOGNIZED RISK FACTOR FOR CARDIOVASCULAR DISEASE AMONG INTERNISTS Jennifer Mackinnon; Alina Brener; Irene Lewnard; Cresta Jones; Jacquelyn Kulinski. Medical College of Wisconsin, Milwaukee, WI. (Control ID #2687131)

BACKGROUND: Cardiovascular disease (CVD) is the number one killer of American women. Numerous population-based cohort studies have concluded that women with a history of preeclampsia have increased future CVD risk compared to women with uncomplicated pregnancies. Since 2011, the American Heart Association has recognized that women with preeclampsia have an increased risk for CVD equal to diabetics and smokers. Since 2013, the American College of Obstetricians and Gynecologists (ACOG) has recommended early screening for these patients. Unfortunately, there are no guidelines in the internal medicine literature for CVD screening in women with prior preeclampsia, leading to missed opportunities to identify these women and optimize primary prevention strategies. Our aim was to determine whether internists at our institution inquire about preeclampsia during the medical interview.

METHODS: We performed a retrospective chart review of 89 women ages 18 to 48 with at least one prior delivery who presented for a well-woman visit after 2013, when the ACOG guidelines were released. We assessed documentation of preeclampsia versus traditional risk factors for CVD (smoking, diabetes, and hypertension).

RESULTS: The mean age of our cohort was 35.4 years +/− 6.4. 23.6% of women were asked about preeclampsia while 98.9% were asked about diabetes or smoking and 100% were asked about hypertension. Our data was analyzed using a test of two proportions to compare how often providers asked about preeclampsia versus smoking, diabetes, and hypertension. The P value was statistically significant at 0.0002 in each individual comparison group. The mean age of patients who were asked about preeclampsia was 34.6 +/− 4.8 and the mean age of patients who were not asked was 35.6 +/− 5.3 ($p = .093$). Interestingly, a sub-analysis revealed that there was no gender difference among providers who inquired about preeclampsia during the medical interview (50% of female providers and 54.5% of male providers, $p = .80$).

CONCLUSIONS: We identified a screening gap at our institution among internists regarding preeclampsia as an important risk factor for CVD when compared to traditional risk factors. Further research is needed to identify causes for this screening gap, including education of providers and alterations to the electronic medical record and patient history collection processes. While there are currently no screening guidelines in internal medicine, it is vital to identify these at-risk patients early in order to optimize primary prevention strategies, including lifestyle modification. Furthermore, research is needed to determine appropriate blood pressure goals for women with prior preeclampsia. We hope that our research will encourage specialties to collaborate on creating screening guidelines reflective of current research progress in cardiovascular disease.

PRELIMINARY ANALYSIS OF LIFE EXPECTANCY AND COMMON CAUSES OF DEATH AMONG VETERANS WITH MENTAL ILLNESSES Ranak Trivedi[3]; Edward P. Post[2]; Rebecca I. Piegari[6]; Joseph A. Simonetti[7]; Edward J. Boyko[4]; Steven Asch[5]; Alaina M. Mori[6]; Bruce A. Arnow[5]; Stephan D. Fihn[6]; Karin M. Nelson[6, 1]; Charles Maynard[6, 1]. [1]University of Washington, Seattle, WA; [2]VA Ann Arbor Healthcare System and University of Michigan, Ann Arbor, MI; [3]VA Palo Alto Health Care System/Stanford University, Menlo Park, CA; [4]VA Puget Sound, Seattle, WA; [5]VA/Stanford, Menlo Park, CA; [6]Department of Veterans Affairs, Seattle, WA; [7]Department of Veterans Affairs, Denver, CO. (Control ID #2700411)

BACKGROUND: Veterans Health Administration (VHA) is the largest primary care and mental health care provider in the US, and Veterans enrolled in VHA primary care have a high burden of both mental and physical illnesses. We sought to assess life expectancy and common causes of death among Veterans with mental illness, compare life expectancy among Veterans with and without mental illness, and examine patterns of healthcare utilization.

METHODS: Veterans who received primary care in VHA between 2000 and 2011 were included. Patient records from Corporate Data Warehouse (CDW) were merged with cause and date of death information from the National Death Index. Patients were determined to have depression, post-traumatic stress disorder (PTSD), an anxiety disorder, or serious mental illness (SMI; bipolar disorder, schizophrenia) if they had at least 1 inpatient or 2 outpatient visits coded with the respective diagnosis during the prior year. Patients were determined to have a substance use disorder (SUD) if they had at least 1 inpatient or outpatient visit in the prior year. We used the direct standardization method to calculate gender and cause-specific death for patients with depression, anxiety, PTSD, SUD, SMI, any mental illness (at least one of the 5), or no mental illness (none of the 5).

RESULTS: 1,763,982 death records were matched to VHA files. Of these, 556,489 listed at least one of the 5 categories of mental illness. In unadjusted analyses, patients without mental illness age at death was approximately 7 years greater than those with one (78 ± 10 y vs.71 ± 13 y). Patients with SUD had the lowest mean age at time of death at 64 ± 12 y, followed by SMI (66 ± 13 y), PTSD (67 ± 13 y), depression (72 ± 13 y), and anxiety (72 ± 13 y). The most common cause of death across all groups was ischemic heart disease (IHD), with 15-18% of patients with mental illness dying of IHD. The most common mental illness among those who died of IHD was anxiety (18%); for lung cancer, SUD (9.2%), for diabetes, PTSD (3.7%), and for suicide, SMI (3.2%). Among the 13,881 who completed suicide with firearms, 52% ($N = 7263$) did not have a diagnosis of mental illness. Compared with Veterans without mental illnesses, a greater proportion of those with mental illness had made an outpatient visit for primary care (68.5 vs. 77%), specialty medical care (41.2% vs. 60.9%), specialty mental health care (5.3% vs. 38.6%), an emergency (9.7% vs, 22.9%), or had been hospitalized in VA (17.2% vs, 35.8%) during the 1 year prior to death. The number of mental illness diagnoses was strongly associated with a higher age adjusted death rate among both men and women.

CONCLUSIONS: As has been observed in other populations, mental illness among Veteran receiving care from VA was strongly associated with use of health care resources as well as a higher risk of mortality which increased sharply with the number of mental health diagnoses.

PREP PRESCRIBING IN PRIMARY CARE CENTERS IN A LARGE URBAN HEALTH CARE SYSTEM IN THE BRONX, NEW YORK Cedric Bien-Gund[2]; Viraj V. Patel[1]; Oni J. Blackstock[3]; Uriel Felsen[4]. [1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, New York, NY; [3]Montefiore Medical Center/AECOM, New York, NY; [4]Montefiore Medical Center, Bronx, NY. (Control ID #2707265)

BACKGROUND: HIV pre-exposure prophylaxis (PrEP) has been recently established as an effective tool for HIV prevention. However, existing studies have been limited to demonstration projects and specialized PrEP programs, and little is known about PrEP prescribing in primary care settings where a significant amount of HIV preventative health care occurs. We sought to describe individuals prescribed PrEP in primary care centers in the largest health care system in the Bronx, a racially diverse borough in New York City that has one of the largest HIV epidemics in the United States.

METHODS: We used an integrated electronic medical record database to identify adult individuals who had a negative HIV test and were prescribed Emtricitabine-Tenofovir (FTC-TDF) between January 2011 and November 2015. We excluded all patients prescribed FTC-TDF as HIV post-exposure prophylaxis or as Hepatitis B treatment, and conducted a chart review to confirm that individuals received FTC-TDF for PrEP, and then extracted socio-demographic and clinical information. We included all individuals prescribed PrEP at primary care sites, which included adolescent medicine, family medicine, internal medicine, and women's health centers. We categorized clinic sites as either teaching sites, where care was provided by resident physicians and other trainees with attending physician oversight, or non-teaching sites.

RESULTS: 108 individuals were prescribed PrEP between January 2011 and November 2015, of whom 64 (59%) were prescribed at primary care sites. Out of a total of 32 primary care sites in the health care system, 14 had ever prescribed PrEP. Five of those sites were teaching clinic sites, which comprised almost two thirds (60%) of all prescriptions in primary care. The median age of patients prescribed PrEP was 28 (IQR 23–32), over half (52%) had an HIV positive partner, 36% were Hispanic, and 25% were non-Hispanic Black. Sixty-three percent were men, of whom 80% were MSM, 32% were cisgender women, and 5% were male-to-female transgender women.

CONCLUSIONS: Within a large urban health care system in an area with high HIV burden, we found that PrEP prescribing in primary care settings appears feasible in reaching key populations with diverse risk factors. However, most prescriptions were clustered among a handful of primary care centers, and less than half of all clinics had ever prescribed PrEP. Teaching clinic sites offering a majority of PrEP prescriptions. In order to expand PrEP adoption among primary care providers, efforts should be made to increase provider knowledge, experience, and comfort with PrEP prescribing.

PRESCRIBING MUSEUMS FOR PSYCHOSOCIAL STRESSORS: A SYSTEMATIC REVIEW OF APPROACHES AND EFFECTIVENESS

Kevin Liou[1]; Rebecca Boas[1]; Drew Wright[2]; Ramin Asgary[1]. [1]Weill Cornell Medicine/NewYork-Presbyterian Hospital, New York, NY; [2]Weill Cornell Medicine, New York, NY. (Control ID #2703676)

BACKGROUND: The prevalence of psychosocial stressors in primary care is high. Time and resources to address psychosocial issues are typically limited in routine office visits. Physicians have explored "social prescribing" as complementary options. Social prescribing refers to the practice in which patients are referred to non-medical community organizations that may offer beneficial programs or classes. An increasing number of museums have developed programs in collaboration with medical providers to address the psychosocial needs of patients. This systematic review aims to identify the types of arts-based interventions being implemented in museums for patients with psychosocial stressors and to synthesize the available evidence on the effectiveness of these interventions.

METHODS: A comprehensive search of PubMed, Scopus, CINAHL, SocINDEX,and PsycINFO electronic databases was conducted. Further articles were identified through cross-referencing and hand-searching. The inclusion criteria were English-language articles, research studies of any design, adult patients with any type of psychosocial stressor, and arts-based interventions implemented in museum settings. There were no date restrictions. Data extraction and quality appraisal was undertaken. Narrative synthesis was used to analyze data.

RESULTS: Eight studies satisfied the inclusion criteria: one quantitative, two qualitative, and five mixed. Study participants included patients with dementia, substance abuse, work-related stress, or mental health issues; some studies also included patients' caregivers. Most interventions involved art-viewing exercises and group discussions; some also incorporated art-making exercises. Measures used were scales, questionnaires, patients' artwork, salivary stress markers, observations and recordings of live museum sessions, and in-depth interviews of patients, patients' caregivers, and museum educators. Interventions generally received positive reviews from participants. Some studies reported that interventions were effective at improving participants' mood, self-confidence, resilience, social functioning, and other psychosocial measures. However, methodologic limitations make it difficult to evaluate these claims.

CONCLUSIONS: Health-related collaborations between medical and museum professions appear feasible. Art-based interventions are used in museum settings to address a wide range of psychosocial issues in primary care. Research in this area is still in its infancy. Control or comparison groups would allow for better assessment of clinical impact and cost-effectiveness. Additional research is needed to evaluate how the effectiveness of arts-based interventions may be influenced by the setting (clinical versus museum) and activity components (art-viewing versus art-making). It may also be worthwhile to further explore how similar arts-based interventions can be applied to physicians and other care providers to prevent burnout.

PRESCRIPTION OF ANTIBIOTICS IN A PRIMARY CARE TELEMEDICINE SERVICE: ASSOCIATION WITH PATIENT SATISFACTION AND VISIT LENGTH

Mark N. Rood[2]; Kathryn A. Martinez[1]; Nikhyl Jhangiani[1]; Adrienne Boissy[1]; Michael B. Rothberg[1]. [1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Foundation, Chagrin Falls, OH. (Control ID #2702058)

BACKGROUND: Many physicians believe that prescribing antibiotics for upper respiratory infections (URI) requires less time and increases patient satisfaction, but data supporting these beliefs is lacking. The objective of this study was to evaluate antibiotic prescribing for URI, visit length and patient satisfaction in a large national cohort of telemedicine patients.

METHODS: We analyzed all completed primary care encounters between January 2013 and August 2016 from the Online Care Group telemedicine service. Patient characteristics, including age, sex, and geographic region were provided by the patient. Encounter characteristics, including time of day, wait time, and visit length were recorded by the system. Patient diagnosis and antibiotic prescription were recorded by the provider. At encounter completion, users rated their satisfaction (on scales of 0 to 5 stars) with 1) the telemedicine system, and 2) their individual provider. We dichotomized satisfaction measures as 5 stars versus less than 5 stars. We used multivariable logistic regression to assess the association between antibiotic prescription and satisfaction with the 1) telemedicine system and 2) visit provider among URI patients. We then used multivariable linear regression to assess the difference in visit length by antibiotic prescription. Models adjusted for patient and encounter characteristics as noted above.

RESULTS: Of the 45,675 appointments during the study period with 381 providers, 31% ($n = 14{,}301$) resulted in a URI diagnosis (52% sinusitis, 16% pharyngitis, 10% bronchitis, and 22% other URI). Overall, 64% of URI patients received an antibiotic prescription, and the mean prescribing rate among individual providers was 49% (Interquartile Range: 11%-75%). Prescribing varied by URI type: 83% for sinusitis, 76% for pharyngitis, 68% for bronchitis, and 17% for other URI. Ninety-one percent of URI patients prescribed an antibiotic rated their provider 5 stars compared to 80% who were not ($p < 0.001$) and 84% prescribed an antibiotic rated the system 5 stars compared to 73% of those who were not ($p < 0.001$). Mean visit length was 6.6 min for those resulting in antibiotic prescriptions compared to 7.9 min for those which did not ($p < 0.001$). In the adjusted models, antibiotic prescription was significantly associated with rating the telemedicine service 5 stars (OR:1.89; 95%CI:1.65, 2.17), as well as rating the provider 5 stars (OR:2.47; 95%CI:2.10, 2.90). Appointments resulting in an antibiotic prescription were, on average, 0.45 min shorter (95%CI: −0.60, −0.30) compared to those which did not ($p < 0.001$).

CONCLUSIONS: Antibiotic prescription among URI patients was highly associated with satisfaction with both the telemedicine system and individual providers and was also associated with shorter visit length. Quality measures emphasizing evidence-based antibiotic prescribing may be needed to offset prescribing incentives resulting from patient satisfaction and productivity pressures.

PREVALENCE AND DETERMINANTS OF PHYSICIAN BURNOUT IN A LARGE HEALTH SYSTEM

Amy K. Windover[2]; Kathryn A. Martinez[1]; Mary Beth Mercer[2]; Katie Neuendorf[2]; Adrienne Boissy[2]; Julie Rish[2]; Michael B. Rothberg[1]. [1]Cleveland Clinic, Cleveland, OH; [2]The Cleveland Clinic, Cleveland, OH. (Control ID #2706176)

BACKGROUND: Physician burnout is associated with depression and suicide, and is a major challenge facing the physician workforce. Burnout also negatively impacts patient care. Our objective was to assess correlates of physician burnout in a large health system.

METHODS: We analyzed data from a communication skills course conducted at the Cleveland Clinic Health System between August 2013 and May 2014. Course participants included all physicians in all specialties except pathology. At the start of the course, physicians completed the Maslach Burnout Inventory- Human Services Survey (MBI-HSS), a validated measure of

work-related feelings and attitudes. Scores were dichotomized into burnout versus no burnout based on established methods. Participants also completed the Jefferson Scale of Empathy (JSE). Information on physician characteristics and employment factors was provided by the Office of Professional Staff Affairs. This included race/ethnicity, age, marital status, number of dependents under 18 years, FTE status, clinical FTE percentage, inpatient vs. outpatient practice, number of used vacation and meeting days (past year) and years in practice. We used multivariable logistic regression to assess the adjusted association between these factors and burnout. We also assessed the adjusted association between physician burnout and those who subsequently left the organization; and contemporary productivity based on RVU percentile; and patient satisfaction, as measured by the Consumer Assessment of Healthcare Providers and Systems (CAHPS).

RESULTS: The sample included 1,145 physicians; 32% were female, 21% were non-white, and the most common specialty was Internal Medicine (38%) followed by Surgery (13%). Thirty-five percent met criteria for burnout on the MBI-HSS. In the adjusted model of predictors of burnout, a greater percentage of clinical FTE (OR 2.99; 95%CI 1.63–5.48) was associated with higher odds of burnout, as was being Caucasian (OR 2.14; 95%CI 1.38–3.31) and identifying 2 or more race/ethnicities (OR 4.72; 95%CI 1.37–16.29) compared to being African American. Greater empathy was associated with lower odds of burnout (OR 0.986; 95%CI 0.975–0.997), as was older age (OR 0.982; 95%CI 0.967–0.997). Inpatient practice was associated with lower burnout, but the association did not reach statistical significance (OR 0.63; 95% CI 0.33–1.19). No other factors were significantly associated with burnout in this model. In adjusted analyses, burnout was associated with higher odds of leaving the organization (OR 2.24; 95%CI 1.20–4.19), but not with productivity or inpatient or outpatient satisfaction.

CONCLUSIONS: Burnout was less common in our physician population than reported by others and strongly related to clinical FTE and Caucasian race. Burnout was associated with leaving the organization but not with patient satisfaction or productivity. Greater levels of empathy and age were associated with lower odds of burnout.

PREVALENCE OF AVASCULAR NECROSIS, SUBSTANCE AND ALCOHOL ABUSE AND DEPRESSION DIAGNOSES IN SICKLE CELL CRISIS PATIENTS Keri Holmes-Maybank[1]; William P. Moran[1]; Kit N. Simpson[2]. [1]Medical University of South Carolina, Charleston, SC; [2]Medical Universityof South Carolina, Charleston, SC. (Control ID #2705733)

BACKGROUND: Sickle cell disease (SCD) affects 70,000 - 100,000 African Americans in the United States. Patients with SCD suffer from chronic pain and acute pain crises. Survival into adulthood has increased therefore, SCD patients are experiencing more complications including avascular necrosis (AVN). AVN is bone death from severe and prolonged ischemia. A study found significantly higher rates of pain crises/year in SCD patients with AVN. Our research revealed AVN in SCD doubles the number of hospitalizations, hospital days, and hospital cost per year. Pain is the number one reason for presentation to healthcare in SCD. Depression is the most common reaction to chronic pain in SCD. Rates of depression in SCD vary from 25.6 to 56.5%, greater than the national rate of 7.5% in African Americans. The 2013 National Survey on Drug Use and Health found higher rates of substance abuse (21%) and alcohol use (16.9%) in individuals with depression compared to those without (7.6 and 6.3% respectively). Few studies describe co-occurrence rates of AVN, depression, and substance abuse in SCD.

METHODS: We examined the 2011 Agency for Healthcare Research and Quality's Healthcare Cost and Utilization Project (HCUP) State-specific Inpatient Databases for New York, California, Mississippi, and Iowa. The HCUP contains administrative data with encounter-level information including all listed diagnoses and patient demographics regardless of payer. We describe the comorbidity rates of substance abuse (SA), alcohol abuse (AA), and depression in patients age 18 and over admitted with sickle cell crisis with and without AVN.

RESULTS: We found 4357 patients with at least one hospitalization for sickle cell crisis. The mean age was 33 years and 55% were female. Of these patients, 14.8% had an AVN diagnosis, 6.4% had a diagnosis of SA, 4.5% had depression, and 1.7% had a diagnosis of AA. Presence of an AVN diagnosis was associated with a higher rate of depression (6.8% vs. 4.1% $p = .0020$) and SA (8.5% vs. 6.5% $p = .0640$), but not with AA (2.3% vs. 1.6% $p = .1796$). However, the prevalence of SA and AA was much higher among all patients admitted with a comorbid diagnosis of depression with an SA rate 12.8% vs. 6.6% ($p = .0008$) and AA of 7.1% in depressed patients compared to 1.4% in those without a depression diagnosis ($p < .0001$).

CONCLUSIONS: AVN was present in approximately 15% of the sample population. AVN in sickle cell crisis patients had a significant impact on observed depression diagnoses. SCD patients with AVN experienced an increased rate of SA but not of AA. However, both AVN and depression diagnoses were predictors of increased risk for SA and AA. Thus, individuals experiencing sickle cell crisis should undergo screening for depression, SA, and AA. Further study should characterize the interactive effects between AVN and depression and between depression and substance use in SCD.

PREVALENCE OF BURNOUT AND PSYCHOLOGICAL DISTRESS IN AN INTERNAL MEDICINE RESIDENCY PROGRAM Julia Loewenthal[2]; Jacob Mirsky[2]; Douglas Mata[2]; Barbara Gottlieb[1]; Darshan Mehta[3]. [1]Brigham and Women's Hospital, Jamaica Plain, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Massachusetts General Hospital, Boston, MA. (Control ID #2706272)

BACKGROUND: The prevalence of depressive symptoms in resident physicians is elevated compared to that in similarly aged individuals in the general population. Depression is intertwined with burnout, a work-related syndrome involving emotional exhaustion, depersonalization, and a sense of reduced personal accomplishment. Notably, 51.5% of internal medicine trainees met criteria for burnout in a national study. We measured the prevalence of symptoms of depression, anxiety, and burnout in the Brigham and Women's internal medicine residency program to develop programs to address this important problem.

METHODS: We performed a cross-sectional study with an e-mail survey, which included the PHQ-4, a validated 4-item screen for anxiety and depression, and the 2-item Maslach Burnout Inventory (MBI), a validated instrument for measuring burnout in physicians. Burnout was scored on a scale of 1, indicating a frequency of "never," to 7, indicating a frequency of "every day," with a total maximum score of 14. The PHQ-4 total score is determined by adding together the scores for each of the four items and using reported cutoffs of 3 for mild, 6 for moderate, and 12 for severe psychological distress.

RESULTS: Overall, 67 of 135 individuals (49.6%) screened positive for symptoms of anxiety, depression, or burnout with a survey response rate of over 80%. The prevalence of burnout was 40.8%, with an average score of 7.5 (SD 3.0), and 37.7% of residents scored greater than 6 on the PHQ-4, indicating at least a

moderate degree of psychological distress. Seven residents (5.2%) screened positive for burnout, depression, and anxiety concurrently. Although interns had an average MBI score of 7.7 (SD 3.2), this was not significantly greater than upper level residents, who scored 7.2 on average ($p = 0.31$). However, interns did have a significantly higher degree of psychological distress as compared to upper level residents (7.1 vs 6.1, $p = 0.02$). Males reported a higher degree of both burnout and psychological distress (8.2 vs 6.8, $p = 0.007$; 7.2 vs 6.0, $p = 0.006$). Residents who were rotating on an inpatient rotation at the time of the survey were more likely to screen positive for burnout (8.2 vs 6.8, $p = 0.008$) and have a higher degree of psychological distress (7.2 vs 6.0, $p = 0.007$) as compared to residents on non-inpatient rotations.

CONCLUSIONS: Our study demonstrates that residents in this program have a lower prevalence of burnout as compared to national averages. To our knowledge, it is the only study to report concurrent rates of burnout and symptoms of depression and anxiety. Interestingly, males had higher rates of burnout and psychological distress than females, which is contrary to national trends. On average, residents on inpatient rotations had higher levels of burnout and psychological distress than residents on non-inpatient rotations, which is similar to trends in other studies. We plan to use these data to inform program design for residents at our institution.

PREVALENCE OF CELIAC DISEASE IN FIBROMYALGIA PATIENTS: THE MAYO CLINIC EXPERIENCE Timothy McKenna; Ayra Mohabbat; Bradley Salonen; David Raslau; Connie Luedtke. Mayo Clinic, Rochester, MN. (Control ID #2683256)

BACKGROUND: Fibromyalgia is a centralized pain sensitivity syndrome characterized by chronic musculoskeletal pain, fatigue, and sleep disturbance. Studies have demonstrated that gastrointestinal (GI) symptoms are common in this population. Celiac disease is an autoimmune disease characterized by small bowel inflammation due to antibody formation in response to gluten. It is known that the prevalence of celiac disease in the general population is around 1%. It has been found that individuals with celiac disease frequently present with symptoms similar to fibromyalgia, suggesting a link between the two. To determine the extent for which concomitant screening should be undertaken, we sought to better delineate the concomitant prevalence rate of celiac disease in our fibromyalgia cohort.

METHODS: This study was a retrospective chart review comprised of all patients evaluated at our tertiary referral Fibromyalgia clinic from 11/22/2014 until 12/31/2015. Patient records were assessed for a validated diagnosis of fibromyalgia (as defined by the 1990 and/or 2010 American College of Rheumatology Fibromyalgia Classification Criteria). Patients who met the criteria were then assessed for celiac disease. Patients were considered positive for celiac disease if findings on small bowel biopsy were consistent with celiac disease, if our institution's celiac disease serology cascade was positive, or if the diagnosis was previously given at an outside institution along with corresponding clinical features. The prevalence of celiac disease was computed using a ratio of the total number of fibromyalgia patients with celiac disease as the numerator and the number of total fibromyalgia patients with available information about celiac disease as the denominator. A two sided chi square test was used to determine statistical significance.

RESULTS: In total 1,133 charts were reviewed. Of these, 955 met the diagnostic criteria for fibromyalgia and 542 had information regarding celiac disease. Sixteen patients were found to have celiac disease. The prevalence of celiac disease in our fibromyalgia cohort was 3%; 3-times higher than previously reported within the general population (*P*-value <0.0001).

CONCLUSIONS: We found a threefold increase in the comorbid prevalence rate of celiac disease in our fibromyalgia cohort compared to the general population. To our knowledge, this is the first study to show an increased prevalence of celiac disease in individuals with concomitant fibromyalgia. Celiac disease serologic tests are readily available and provide high sensitivity and specificity. With the demonstrated increased prevalence of celiac disease in patients with fibromyalgia and their respective though vastly different treatment strategies, screening for celiac disease in the fibromyalgia population is not only feasible, but more so, necessary.

PREVALENCE OF SPIN IN RANDOMIZED CONTROLLED TRIALS
Alexandra Woodbridge[4]; Ann Abraham[4]; Rosa Ahn[5]; Susan Saba[6]; Erin Madden[2]; Deborah R. Korenstein[1]; Salomeh Keyhani[3, 4]. [1]Memorial Sloan Kettering Cancer Center, Pelham, NY; [2]NCIRE, SAn Francisco, CA; [3]University of California at San Francisco, San Francisco, CA; [4]San Francisco VA Medical Center, San Francisco, CA; [5]Oregon Health & Science University, Portland, OR; [6]Stanford University School of Medicine, Palo Alto, CA. (Control ID #2699838)

BACKGROUND: Randomized controlled trials (RCT) are the gold standard for evaluating drug safety and efficacy of results. Thus, accurate representation of trial results in the published literature has important implications for practice and the health and safety of patients. Spin, defined as reporting that distorts results or misleads the reader, threatens appropriate evidence interpretation and application by clinicians. We examined the prevalence of spin in abstracts.

METHODS: We examined the prevalence of spin in abstracts from a sample of RCTs of drug efficacy. We randomly selected 496 papers of which 190 were drug efficacy trials and met inclusion criteria. Two reviewers independently abstracted the following trial characteristics from each paper: source of trial funding, financial ties of principal investigators (PI) related to the study drug, specialty focus of trial, sample size, trial design (superiority analysis, comparator, phase, blinding), author country of origin, and trial primary efficacy outcome as reported in the Results section (positive or negative). Two clinician reviewers blinded to trial outcomes reviewed the abstracts of all 190 papers and determined whether the abstract suggested positive, negative, or mixed results. We defined the presence of spin as a mixed or positive abstract rating by clinician reviewers for a paper that had a negative primary efficacy outcome. We also examined the prevalence of spin by RCT characteristics.

RESULTS: Among the 190 papers meeting inclusion criteria, 59 RCTs had a negative outcome. Thirty-six (61.0%) were funded by industry and 29 (49.1%) had at least one PI with a financial tie with the manufacturer of the drug of interest. The majority of these trials had less than 400 patients enrolled (43, 72.9%). Most first authors were from North America (27, 45.8%) and Europe (22, 37.3%). Most were double-blinded (46, 78.0%), placebo-controlled (49, 83.1%), superiority analysis (58, 98.3%), and examined clinical outcomes (45, 76.3%). Phase III (26, 44.1%) and Phase II (21, 35.6%) trials were most common. Cardiology (9, 15.3%) and Oncology (9, 11.9%) were the specialties most represented in this sample. Among abstracts from the 59 negative papers, 25 (42.4%) had evidence of spin. Of the 25 abstracts where spin was present, 8 (32.0%) were categorized as positive and 17 (68.0%) were categorized as mixed by the clinician reviewers. Of the papers with spin, 15 (60.0%) were industry funded and 10 (40.0%) had no industry funding. There was no

association between spin and industry funding (p-value = 0.89) or between spin and PI financial ties (p-value = 0.08).

CONCLUSIONS: The prevalence of spin among RCTs is high. Spin is not associated with industry funding or PI financial ties. Given that many clinicians may obtain information from the abstract of a published trial, more scrutiny of abstracts prior to study acceptance is needed.

PREVALENCE, SEVERITY, AND FACTORS ASSOCIATED WITH MULTI-DIMENSIONAL SYMPTOMS IN OLDER HOMELESS ADULTS: RESULTS FROM THE HOPE HOME STUDY Maria Y. Patanwala[1]; Lina Tieu[2, 1]; Claudia Ponath[2]; David Guzman[2, 1]; Christine Ritchie[1]; Margot Kushel[2, 1]. [1]University of California, San Francisco (UCSF), San Francisco, CA; [2]Zuckerberg San Francisco General Hospital (ZSFGH), San Francisco, CA. (Control ID #2692932)

BACKGROUND: The homeless population is aging. As people age, their symptom burden often increases. Higher symptom burden is associated with functional impairment, healthcare utilization, and mortality. We describe the prevalence of symptoms in older homeless adults, analyze factors associated with higher somatic symptom burden, and identify symptom clusters.

METHODS: HOPE HOME is a 3-year prospective cohort study of 350 homeless adults aged 50 and older, recruited using population-based sampling. Trained interviewers asked about demographic information, physical and mental health, and health-related behaviors. At the 18-month or, if missed, next-attended follow-up interview, we administered the Patient Health Questionnaire 15 (PHQ-15) to measure somatic symptoms and the Center for Epidemiologic Studies Depression Screening (CES-D), Primary Care Post-Traumatic Stress Disorder Screen (PC-PTSD), and the Addiction Severity Index (ASI) to measure psychological symptoms. We determined loneliness or social symptoms using the 3-item Loneliness Scale and regret or existential symptoms using a 6-item regret scale. We examined symptom prevalence and severity, determined factors associated with moderate-high somatic symptom burden (PHQ-15 ≥ 10) using multivariate logistic analysis, and identified symptom clusters using cluster analyses.

RESULTS: 283 participants completed symptom interviews; 24.4% were female, 82.3% were African American, 41.3% were homeless at time of follow-up interview, and 49.5% had 2 or more chronic conditions (multi-morbidity). Over a third (34.0%) of participants had moderate-high symptom burden. The most prevalent somatic symptoms were joint pain (65.4%), fatigue (65.2%), back pain (59.0%), and sleep trouble (46.5%). Over half (57.6%) of participants had psychological symptoms; 47.0% reported depression and 36.0% reported anxiety. Over a third (38.2%) of participants were lonely and a quarter (24.7%) had high regret scores. In a multivariate model, anxiety (AOR 5.86, 95% CI 3.02–11.39), cannabis use (AOR 2.94, 95% CI 1.51–5.75), multi-morbidity (AOR 2.86, 95% CI 1.52–5.38), female sex (AOR 2.32, 95% CI 1.13–4.75), childhood abuse (AOR 2.09, 95% CI 1.09–4.00), recent abuse (AOR 1.98, 95% CI 1.05–3.72), and inadequate health literacy (AOR 1.38, 95% CI 1.08–1.77) were associated with moderate-high somatic symptom burden. We identified 4 symptom clusters: minimal overall symptoms, moderate overall symptoms, high somatic and high psychological symptoms, and high somatic and low psychological symptoms. There was no cluster with psychological symptoms only.

CONCLUSIONS: Older homeless adults have a higher prevalence of symptomatology than general population adults aged 20 years older. High somatic symptom burden is associated with physical, mental, and behavioral health factors. Understanding symptom burden may help in designing appropriate, multi-disciplinary health interventions for older homeless populations.

PREVENTABILITY OF ADMISSIONS TO SAFETY-NET HOSPITALS IN THE ERA OF HEALTH REFORM: THE MASSACHUSETTS EXPERIENCE. Danny McCormick[3]; Lisa Quintiliani[1]; Nancy R. Kressin[2]. [1]Boston University, Bostin, MA; [2]Dept of Veterans Affairs and Boston University, West Roxbury, MA; [3]Harvard Medical School/Cambridge Health Alliance, Cambridge, MA. (Control ID #2706929)

BACKGROUND: A lack of health insurance compromising access to outpatient care has been identified as a key reason for preventable hospitalizations. Long after Massachusetts' health insurance reform (expansion), we assessed the preventability of hospitalizations and patient perspectives on factors leading to hospitalization at Massachusetts' 2 largest safety net hospital systems.

METHODS: We identified a random sample of 803 patients, age 18–64, admitted to general medical wards in 2013–2014. We conducted a face to face standardized survey to measure patient demographics and socioeconomic disadvantage as well as an open-ended interview about the events and circumstances leading to the hospitalization. Board certified hospitalist physicians determined the preventability of (and factors that could have prevented) hospitalization by reviewing the interview transcript and admission/discharge notes using a pre-specified coding rubric. We assessed whether socio-demographic and social disadvantage were independently associated with preventability using multivariable logistic regression models. Then, using a sequential mixed methods approach, we conducted a qualitative analysis of the transcripts from patients deemed to have a highly preventable admission and for whom a patient-level factor (defined as non-adherence or delays in seeking care) was implicated ($n = 48$). Two coders systematically coded emerging themes and applied the coding scheme to all transcripts.

RESULTS: Most patients were insured (98%), male (55%), not currently married/partnered (75%), unemployed (68%), non-white (54%), and 41% had incomes < $10,000/year. Alcohol or substance abuse was determined to be a primary or contributing cause of 27.8% of all admissions. 12.1% of admissions were determined to be highly preventable, 35.7% somewhat preventable and 52.2% not preventable. Among hospitalizations deemed preventable, patient factors were most commonly responsible (59.1%), followed by health care system (27.1%), financial (7.7%) and clinician (6.1%) factors. Factors independently associated with having a highly preventable hospitalization included income (<$10 k/yr. vs > $50 K/yr.) (odds ratio [OR], 95% CI; 3.1 [1.1–9.1]), being worried about the safety and condition of housing (OR, 95% CI; 2.5 [1.3–4.9]) or meeting basic needs (OR, 95% CI; 2.1 [1.1–3.9]. Qualitative analyses revealed that contextual issues often underlie patient non-adherence and delays in seeking care, including: life chaos (addiction, e.g.), unstable housing, transportation issues, and mental health.

CONCLUSIONS: Preventable hospitalizations remain common in safety net hospitals after reform. Although most were due to patient non-adherence or delays in seeking care, patients' self-care behaviors were often constrained by social circumstances. Safety net hospitals providing care under "shared-risk" insurance arrangements may be financially vulnerable if social complexity of patients is not considered in reimbursement schemes.

PRIMARY CARE AND THE QUALITY OF OUTPATIENT CARE AMONG ADULTS IN THE UNITED STATES, 2002–2014 David M. Levine[2]; Bruce E. Landon[3]; Jeffrey A. Linder[1]. [1]Brigham and Women's Hospital, Boston, MA; [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [3]Harvard Medical School, Boston, MA. (Control ID #2706874)

BACKGROUND: Primary care is foundational to health systems and individual health, but it is unknown the degree to which having primary care is associated with receiving high-value care, avoiding low-value care, and improving patient experience.

METHODS: We analyzed 2002 to 2014 data from the Medical Expenditure Panel Survey, a nationally representative annual survey of Americans and their respective clinicians, hospitals, pharmacies, and employers. Participants were non-institutionalized US adults 18 years or older (annual sample: 20,679-26,509; annual response rate: 49%-65%). We examined previously published composites based on 46 individual quality measures: 5 "high-value" care composites; 4 "low-value" care composites; an overall patient experience rating; a physician communication composite; and an access-to-care composite. We compared participants with (annual range, 15,042-19,504) and without (annual range, 5,637-8,370) primary care. Participants self-reported having primary care by naming a specific clinician's name who was not based in an emergency department to which "you usually go if you are sick or need advice about your health." In a preliminary sensitivity analysis not shown, we did not observe important differences when adjusting for PCP specialty, utilization, and sociodemographics.

RESULTS: In each year (2014 values as example), Americans with primary care were older (50 years vs 39 years), more likely to be white (69% vs 52%), female (55% vs 43%), and privately insured (72% vs 57%; all $p < 0.05$). Over the study period, Americans with primary care received consistently more high-value care. In 2014, compared to those without primary care, Americans with primary care had higher rates of recommended cancer screening (78% vs 64%); diagnostic and preventive testing (82% vs 64%); diabetes care (58% vs 42%); counseling (53% vs 32%); and medical treatments (43% vs 31%; all $p < 0.05$). Over the study period, Americans with and without primary care had similar rates of low-value imaging (in 2014, 10% vs 15%) and low-value antibiotic use (in 2014, 59% vs 47%; both $p > 0.05$). In contrast, Americans with primary care had more low-value cancer screening, although this gap narrowed over time (in 2002, 54% vs 32% [$p < 0.05$]; in 2014, 47% vs 37% [$p > 0.05$]). Americans with primary care had more low-value medical treatments over the entire study period (in 2014, 11% vs 7%; $p < 0.05$). Over the study period, Americans with primary care rated their care experience highly more than those without primary care. In 2014, those with primary care reported better overall care (82% vs 70%), physician communication (66% vs 59%), and access to care (61% vs 51%; all $p < 0.05$).

CONCLUSIONS: From 2002–2014 Americans with primary care received more high-value care and better patient experience, the same low-value imaging and low-value antibiotic use, but more low-value medical treatments and low-value cancer screening, although the gap in low-value cancer screening narrowed over time.

PRIMARY CARE CLINIC AND WALK-IN CLINICS: UNDERSTANDING THE DIFFERENCE IN VISIT CHARACTERISTICS Parth Parikh; Aditi Patel; Xiaobo Liu; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Control ID #2706407)

BACKGROUND: Urgent care/walk in clinics offer patients convenience and may decrease ED visits, at a lower cost than primary care offices. Many primary care offices also offer same day/walk-in appointments. Providing urgent care services in the primary care setting could improve continuity and address additional problems, thereby justifying higher costs. Previous comparisons of these settings have focused on treatment of specific acute problems, but have not assessed the visit as a whole. Our objective was to compare the patient and visit characteristics of urgent visits in both settings.

METHODS: We performed a retrospective analysis of adult patients with same day office visits to either a primary care center or an urgent/walk in clinic. Of the 19,864 patients screened, we randomly chose 600 primary care visits and 600 urgent care visits for manual chart review. Patient demographics (age, sex, race, insurance type) were extracted electronically. Two team members extracted the following visit-related variables addressing complexity: visit complexity (simple problems that may be addressed by following algorithms or complex problems requiring diagnostic acumen), duration of complaint (acute vs. chronic), number of additional problems addressed, number of prescription and non-prescription medications prior to the visit and groups requiring extra attention (i.e. patients on insulin, opiates, warfarin and oral hypoglycemics). Two sample t-test or the Wilcoxon rank sum test was used to evaluate the relationship between continuous measures and setting (described as Median, IQR). Pearson's chi-square or Fisher's exact test was used for categorical measures.

RESULTS: After excluding 9 repeat visits within the study period, our sample contained 1191 unique visits. Patients coming to urgent care were more likely to be under 45 years of age (46.9% vs 39.3% $p = 0.017$), and have non-commercial insurance (63.9% vs 65.4% $p < 0.001$). Compared to urgent care, primary care visits were less likely to be classified as simple (53.7% vs, 73.3%, $p < 0.001$) to be focused on an acute problem (74.2% vs. 98.0%, $p < 0.001$) and have a medication prescribed (Median of 1, IQR 0–1 vs 1, IQR 0–2 $p < 0.001$), but addressed more problems (Median 0 additional problems, IQR 0–1 vs 0, IQR 0–0 $p < 0.001$). Compared to patients seeking urgent care, those coming to primary care took more medications (Median of 6, IQR 3–9 vs 4, IQR 1–7 P value <0.001) and were more likely to be on opiate medications (14.3% vs 10.3% $p = 0.035$).

CONCLUSIONS: The patients seen for urgent appointments at primary care centers appear to be more complex and to have more complex problems addressed, suggesting the need for a higher level of skill. Future studies may address the impact of care setting on patient outcomes.

PRIMARY CARE PHYSICIAN PERSPECTIVE ON CURRENT ADULT PNEUMOCOCCAL VACCINE RECOMMENDATIONS Laura P. Hurley[3, 8]; Mandy Allison[6]; Tamara Pilishvili[1]; Sean T. O'Leary[4]; Lori A. Crane[4]; Michaela Brtnikova[2]; Brenda Beaty[7]; Megan C. Lindley[1]; Allison Kempe[5]. [1]Centers for Disease Control and Prevention, Atlanta, GA; [2]Children's Outcomes Research Program, Aurora, CO; [3]Denver Health, Denver, CO; [4]University of Colorado Anschutz Medical Campus, Aurora, CO; [5]University of Colorado and Children's Hospital Colorado, Aurora, CO; [6]University of Colorado, Anschutz Medical Campus, Aurora, CO; [7]Unviersity of Colorado, Aurora, CO; [8]University of Colorado, Aurora, CO. (Control ID #2699792)

BACKGROUND: In 2012, the Advisory Committee on Immunization Practices recommended 13-valent pneumococcal conjugate vaccine (PCV13) in a series with 23-valent pneumococcal polysaccharide vaccine (PPSV23) for certain adults ≥19 years-old at increased risk for pneumococcal disease, and, in 2014, expanded this recommendation to all adults ≥65 years old. Our objective

was to assess primary care physicians' practices, knowledge, attitudes and beliefs regarding current adult pneumococcal vaccine recommendations.

METHODS: We administered an Internet and mail survey from 12/2015 to 1/2016 to a national network of general internists (GIM) and family physicians (FP). Multivariable analysis was conducted with the dependent variable being respondents who answered six to eight out of eight (the top quartile of respondents) knowledge questions pertaining to current ACIP adult pneumococcal vaccine recommendations correctly. Independent variables included physician characteristics and practice characteristics and whether the practice had a computer-based way to identify patients under 65 who need either PCV13 and/or PPSV23.

RESULTS: The overall response rate was 66% (617/935). Over 95% of respondents routinely assessed their adult patients' vaccination status and recommended both vaccines. Eighty-eight percent stocked PCV13 and 92% stocked PPSV23. A majority of physicians found the current ACIP recommendations to be clear (50% 'very clear', 38% 'somewhat clear') and easy to implement (48% 'very easy', 34% 'somewhat easy'). Approximately 1/5 of physicians found the upfront cost of purchasing PCV13, patient's insurance not covering the vaccines, inadequate reimbursement and difficulty determining pneumococcal vaccination history to be 'major barriers' to giving PCV13 and PPSV23 in series. Knowledge of recommendations was quite variable with 83% correctly identifying the PCV13 recommendation for seniors and only 21% correctly identifying the recommended interval between PCV13 and PPSV23 vaccination in an individual under 65 at increased risk. Characteristics associated with greater knowledge of the recommendations included GIM vs. FP specialty (adjusted RR = 1.45; 95% CI 1.09–1.88), younger vs. older provider age (adjusted RR = 1.41; 95% CI 1.04–1.88), and perceiving the recommendations to be 'very clear' vs, other perceptions (adjusted RR = 1.50; 95% CI = 1.15–1.96).

CONCLUSIONS: While it is encouraging that almost all primary care physicians reported recommending and stocking both pneumococcal vaccines for their patients, a disconnect exists between perceived clarity of the recommendations and knowledge of the recommendations. Optimal implementation of adult pneumococcal vaccine recommendations will require addressing reported barriers and knowledge gaps, particularly for FP and older physicians.

PRIMARY CARE PHYSICIANS' ATTITUDES ON THE IMPACT OF MEDICAL SCRIBES ON PATIENT-DOCTOR RELATIONSHIP, PHYSICIAN SATISFACTION AND PATIENT EXPERIENCE

Lauren D. Feld[2]; Neda Laiteerapong[1]; Anna Volerman[1]; Felipe Fernandez del Castillo[2]; Wei Wei Lee[1]. [1]University of Chicago, Chicago, IL; [2]University of Chicago Medicine, Chicago, IL. (Control ID #2703248)

BACKGROUND: A novel approach to address issues of electronic health record (EHR) utilization interfering with the doctor-patient relationship and contributing to physician burnout is to utilize medical scribes to complete EHR documentation. This study assesses attitudes of primary care physicians (PCPs) towards using scribes.

METHODS: We developed a 35-item survey with Likert-scale and multiple-choice questions to explore faculty perceptions of medical scribes in the faculty primary care clinic at the University of Chicago. The survey included questions related to burnout, time spent on EHR documentation outside of clinic hours, and the impact of scribes on workflow, satisfaction, and patient interactions. Those interested in working with scribes answered additional questions on duties they wanted scribes to perform. Analysis PCP's perspectives was performed on how scribes may affect workflow, satisfaction, and patient interactions. Likert responses at the high end of the scale were grouped to dichotomize data (i.e. agree/strongly agree); data was summarized using descriptive statistics.

RESULTS: Thirty-five (35/39, 90%) GIM faculty responded to the survey. 66% of respondents were female and 54% completed training over 15 years ago. One-quarter reported active symptoms of burnout. The majority (79%) of respondents reported insufficient time for EHR documentation and 36% reported that clinic was chaotic. Only 33% of physicians were satisfied with the EHR. Physicians were divided in their attitudes about scribes. About half of respondents (58%) were interested in piloting scribes in clinic and agreed that scribes would decrease their stress at work (57%) and at home (49%), allow them to be better focused (48%), increase work satisfaction (49%), and make the clinic less hectic (48%). Many respondents thought that scribes would add value to their interactions (46%) and allow them to be better connect with patients (49%). Some physicians reported concern about documentation accuracy (44%) and patient privacy (38%). Only 32% of physicians who were interested in scribes were willing to see an additional patient per clinic session to work with a scribe. Among physicians interested in working with scribes, the top five activities faculty wanted scribes to perform were allergy review (91%), reconcile medications (86%), remind them about medications refills (86%), review best practice alerts (77%), and navigate the patient through clinic (82%). Providers in practice for ≤15 years had a 5.5 greater odds (95% CI 1.1-28.4) of being interested in working with a scribe.

CONCLUSIONS: Faculty had mixed perceptions of scribe use. About half of respondents were interested in working with scribes and reported potential for scribes to decrease stress at work and improve workplace satisfaction, which can potentially decrease physician burnout. A pilot program targeting interested primary care faculty should be explored to better understand the impact of scribes on primary care physician satisfaction and burnout.

PRIMARY CARE PROVIDERS PREFER THE PEG TO COMPETITOR PAIN SCREENING MEASURES

Karleen Giannitrapani[3]; Roger T. Day[2]; Matthew McCaa[2]; Sangeeta Ahluwalia[4]; Steven Dobscha[1]; Karl Lorenz[2]. [1]Portland VAMC, Portland, OR; [2]VA Palo Alto Healthcare System, Menlo Park, CA; [3]Veterans Health Administration, Menlo Park, CA; [4]Rand, Santa Monica, CA. (Control ID #2707125)

BACKGROUND: In VA primary care, there are various measures used for screening patients for chronic pain including: 1) the numeric rating scale (NRS), a 0–10 one item assessment of pain intensity 2) the PEG a three item assessment of pain intensity, pain interference with function, and pain interference with enjoyment in life, and 3) the Defense and Veterans pain rating scale (DVPRS) a 5 item assessment including pain intensity and pain interference with sleep, mood, stress, and general activity. Our study aims to understand providers' perceptions of the PEG, now recommended by the Surgeon General, when compared to the other pain screening tools.

METHODS: We conducted nine multidisciplinary focus groups (60 providers) using a semi-structured interview guide. Using content analysis methods, we coded transcripts and compared codes across transcripts to understand provider perceptions of pain screening methods. We conducted an additional 15 phone interviews with VA providers using a semi-structured guide and asked the providers to compare screening measures.

RESULTS: Overwhelmingly, providers indicated that capturing pain intensity alone, as in the NRS, is not enough. Arguments for PEG over NRS centered around PEG including additional pertinent information: "I'd rather the patient tell me how it's [pain's] interfering with their general activity and enjoyment than me trying to figure out." Arguments for NRS over PEG included 1) parsimony/use of provider time: "*another piece of my reaction*, *though*, *is who's going to do this* [*PEG*] *and when*" and 2) interference has less meaning specific patients populations i.e. those who have already modified their activities to accommodate their pain: "'Well, I can do everything that I do because I've already modified my life.' So what's the answer [to the how does pain interfere question]? I mean, compared to if they had no pain? If they had no pain they could do a ton more things."Arguments for PEG (3-item) over DVPRS (5-item) typically centered around parsimony. "*shorter is better*, *so PEG is shorter- I like it better*." Arguments for DVPRS over PEG include the comparative abstractness of the specific items: "*They* [*patients*] *can answer question one* [*of the PEG*} *but they really stumble over two and three*." The DVPRS domains include comparatively similar constructs: "*I suspect how does pain interfere with sleep is easier for patients to understand than how does pain interfere with enjoyment in life*."
CONCLUSIONS: Most providers endorse use of the PEG for pain screening for its added information over NRS and shorter length than DVPRS. Limitations of the PEG as a screening tool do include the time it takes to complete and the abstractness of the concepts included in items (ie enjoyment in life instead of stress or mood). When using the PEG it should be understood that asking about interference with function is nuanced and may not be appropriately captured via a screening tool for all chronic pain patients.

PROMOTING WALKING AMONG AFRICAN AMERICANS WITH PERIPHERAL ARTERY DISEASE Tracie C. Collins[1]; Kelsey Lu[2]; Jianghua He[3]. [1]KU School of Medicine - Wichita, Wichita, MN; [2]University of Kansas School of Medicine, Wichita, KS; [3]University of Kansas Medical Center, Kansas City, KS. (Control ID #2706401)

BACKGROUND: African Americans are two times more likely than non-Hispanic whites to have peripheral artery disease (PAD). Walking therapy improves walking distance in patients with PAD but patients require motivation to adhere to therapy. We sought to determine the efficacy of motivational interviewing (MI) versus a scripted counseling approach (Patient-centered Assessment and Counseling for Exercise [PACE]) versus control to improve walking distance among African Americans with PAD.
METHODS: We completed a 5-year NIH funded clinical trial, one-year trial. Trial eligibility included self-identifying as African American and screening positive for PAD as defined by an ankle-brachial index (ABI) < 0.99 Participants were excluded if they had undergone lower extremity amputation, leg revascularization (open or endovascular) within the preceding 3 months, or had contraindications to walking for exercise. Participants completed a baseline visit and two follow-up visits at 6- and 12 months. All participants received a handout about PAD. The two counseling interventions were delivered bi-weekly for 3 months and monthly for 3 months followed by a 6-month maintenance in which there was no intervention. Control participants received a mailing at 3 and 9 months. We assessed baseline characteristics using the Lifestyle and Clinical Survey. Walking distance was assessed based on the 6-min walking test. We used linear regression modeling for the analysis.
RESULTS: Among the 174 African Americans enrolled, 74% were women and the mean age of the cohort was 63.7 years (SD 11.1). The prevalence of major atherosclerotic risk factors was as follows: hypertension 84.5% diabetes mellitus 63.9% (36.1%), and current/past history of smoking 60.9%. There were no differences between the three groups in baseline characteristics. Mean walking distance by group, measured in feet, was as follows: MI 1203.16 (SD 31.12), PACE 1148.80 (SD 31.12), and control 1167.50 (SD 30.33). At 6 months, mean walking distance by group was as follows: MI 1188.91 (SD 32.47), PACE 1157.51 (SD 32.33) and control 1170.05 (SD 31.68). At 12 months, mean walking distance by group was as follows: MI 1175.08 (SD 33.45), PACE 1192.27 (SD 34.62), and control 1168.05 (33.87). For within group changes, there was a statistically significant increase in mean walking distance at 6 months among participants randomized to PACE with a change of 43.47 (SD 20.59), $P = 0.038$. For between group changes, there was a statistically significant decline in walking distance at 12 months among participants randomized to MI versus PACE (−66.13 [SD 27.69]), $P = 0.019$. There was a trend towards a statistically significant improvement in walking distance at 12 months comparing PACE to control at 41.06 (SD 29.57), $P = 0.170$.
CONCLUSIONS: In a cohort of African Americans with PAD, a scripted counseling approach, PACE was efficacious to improve walking distance at 6- and 12 months. Efforts are needed to assess the implementation of this intervention in clinical practice.

PROVIDER ATTITUDES TOWARDS BREAST CANCER SCREENING IN OLDER WOMEN: RESULTS FROM A NATIONAL SURVEY Archana Radhakrishnan[1]; Sarah Nowak[4]; Andrew M. Parker[3]; Kala Visvanathan[2]; Craig E. Pollack[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]RAND Corporation, Pittsburgh, PA; [4]RAND Corporation, Santa Monica, CA. (Control ID #2704765)

BACKGROUND: Various organizational guidelines disagree on whether to screen women 75 years and older for breast cancer. The benefit from screening in this age group may be limited compared to the risk for potential harms. However, many older women continue to have routine breast cancer screening. Drawing upon a national survey of providers, we sought to describe provider attitudes towards breast cancer screening in women ages 75+.
METHODS: We performed a mailed survey of PCPs (including internists (IM), family and general practioners (FM/GP) and gynecologists). Providers were asked whether they recommended routine mammography to average-risk women ages 75+. Providers rated their agreement with a series of statements on screening older women using a 5-point Likert scale. We used exploratory factor analysis to identify underlying themes among items and to construct summary scores of provider attitudes. Bivariate and multivariable linear regression analyses were used to evaluate provider attitudes by specialty. We then performed multivariable logistic regression analysis to determine associations between provider attitudes and screening older women.
RESULTS: Our adjusted response rate was 52.3% (871/1665). Overall, 66.7% of providers recommended mammography screening to women ages 75+; gynecologists were the most likely to recommend screening compared to IM and FM/GP (81% vs. 65% vs. 59% respectively). Factor analyses revealed four provider attitudes towards screening older women: dread, concern for adverse effects, structural limitations and uncertainty, and rationing care (Table 1). Compared to internists, FM/GP had lower dread scores (−0.17, $p = 0.02$) whereas gynecologists had higher dread scores (0.37, $p < 0.001$). FM/GP had lower concern for structural limitations and uncertainty compared to IM

(−0.16, $p = 0.04$). In adjusted analysis, providers who had increasing levels of dread were more likely to recommend mammography to older women (Odds Ratio 4.71; 95% Confidence Interval 3.52-6.30) as compared to providers who did not recommend screening. Contrastingly, increasing concern for adverse effects was associated with decreased odds of recommending screening mammography to older women (OR 0.67; 95% CI 0.55-0.80) in adjusted models.

CONCLUSIONS: Providers endorsing high levels of dread towards screening women 75+ years for breast cancer were more likely to recommend mammography. Addressing provider fears of missing cancer diagnoses and malpractice may be an important opportunity in future approaches to reduce over-screening among older women.

Description of provider attitudes based on factor analysis results

Provider attitudes (factor)	Items comprising factor	Mean scores (SD)
Dread	-fear of malpractice -fear of missing lethal cancer -patient expectations for mammograms -lack of guidelines concordance	3.5 (0.9)
Concern for adverse effects	-need for additional, unnecessary testing -overdiagnosis of cancers	2.3 (0.9)
Structural limitations and uncertainty	-lack of time to discuss with patient during visit -previous provider's recommendation for screening and difficulty going against their recommendation -personal uncertainty about whether to screen	3.1 (1.1)
Rationing care	-not ordering mammogram to be cost efficient -not ordering mammogram due to 'giving up' on patient	2.4 (1.2)

PROVIDER COMFORT AND PATIENT ACCESS TO PREP IN INTERNAL MEDICINE PARTH KUMAR1, KARA TANAKA1, LESLIE SHEU, MD2, BRENT KOBASHI, MD2 Parth Kumar[2]; Kara Tanaka[2]; Brent Kobashi[1]; Leslie Sheu[2]. [1]UCSF, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA. (Control ID #2708812)

BACKGROUND: There are approximately 14,700 people in San Francisco living with HIV, with an estimate of 255 new HIV infections in San Francisco in 2015. Pre-exposure prophylaxis (PrEP), was approved by the FDA in 2012. However, at the University of California, San Francisco (UCSF), there are still no systematic protocols for PrEP management. In addition, there is no standardized protocol for documenting "high-risk" sexual behaviors in the electronic health record (EHR), so there is no easy way to identify patients who might benefit from PrEP. Only 109 of DGIM's 25,000 adult patients currently take PrEP, indicating that a large portion of patients may not be well informed of the drug's health benefits for high-risk populations.

METHODS: We conducted an anonymous online survey inviting all UCSF Division of General Internal Medicine (DGIM) providers (attending physicians, residents, nurse practitioners, and medical students). Participants were asked general questions about their role in clinic, and asked specific Likert-scaled questions about their comfort level and interactions with patients in regards to sexual history and PrEP. In addition, providers were asked an open-ended question about barriers to discussing PrEP.

RESULTS: Fifty-six providers (42%) completed the survey, comprised of 26 (46%) attendings and 26 (36%) residents. Thirty-four (61%) had engaged in a discussion about starting PrEP with a patient. Fifty seven percent of providers were comfortable discussing starting PrEP with patients. However, only 25% "always" or "most of the time" discussed sexual health during office visits. When comparing attendings to residents, 96% of residents learned about PrEP in medical school and/or residency, while only 23% of attending physicians learned about PrEP in medical school and/or residency. However, only 46% of DGIM residents reported being comfortable talking about starting PrEP, while 73% of attending physicians reported being comfortable. Some barriers that were mentioned in open-ended questions include: lack of knowledge, lack of comfort, patient's own hesitancy, and lack of a screening tool that depends on the provider.

CONCLUSIONS: Our findings suggest that there is still significant provider discomfort around discussing PrEP with patients, particularly among residents. This may be due to the relative lack of emphasis providers place on discussing sexual health during patient visits, thus limiting opportunities to discuss PrEP. Some DGIM providers were previously educated about PrEP, however the survey suggests that their education was not adequate in building the confidence or skills to have open discussions about discussing PrEP. Future work should be two-pronged, with 1) a focus on exploring ways to increase patient-provider discussions about sexual health, such as through accessible tools in an EHR, and 2) equipping providers with skills to identify patients who are appropriate candidates for PrEP and to discuss initiating PrEP.

PROVIDER INTEREST IN LIFESTYLE TRACKING WITHIN THE EHR: DATA FROM THE MAINTAIN-PC STUDY Jonathan Arnold[2]; Dana L. Tudorascu[1]; Kathleen M. McTigue[1]; Cindy L. Bryce[4]; Kimberly A. Huber[1]; Laurey R. Simkin-Silverman[1]; Rachel Hess[3]; Gary Fischer[1]; Molly B. Conroy[1]. [1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]University of Utah, Salt Lake City, UT; [4]University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA. (Control ID #2700926)

BACKGROUND: Primary care providers (PCPs) can play a critical role in supporting patients' ongoing weight maintenance. PCPs may lack time and resources to support patients, many of whom use wearable devices and/or smartphone apps to monitor their progress toward lifestyle goals. There is increasing capability to integrate patient-collected lifestyle data into the electronic health record (EHR), but less understanding of PCP interest in and potential use of these data.

METHODS: Maintaining Activity and Nutrition through Technology-Assisted Innovation in Primary Care (MAINTAIN-pc) is an RCT of an EHR-based intervention for weight loss maintenance. Referring PCPs have access to flowsheets with patient-reported lifestyle data (i.e. weight, nutrition, physical activity) and received periodic reports on patient progress. We solicited feedback from PCPs with participating patients via an anonymous web-based survey asking about their use of and interest in continuing to use the study tools and their interest in other patient lifestyle data sources. Survey links were emailed in December 2016, after all subjects had completed at least 21 study months. Survey respondents were not paid but could choose to enter a prize drawing.

RESULTS: To date we have received 18 responses to 65 surveys sent (28% response rate) across 6 different outpatient medicine practices; data collection continues through January 2017. Respondents are 59% female and 94% white. Most (93%) have completed training over 10 years prior. 50% are full time

clinicians, 44% clinician educators, and 6% clinician researchers. 72% of respondents "agree" or "strongly agree" that they are satisfied with MAINTAIN-pc. Most express interest in continuing to use the EHR-based tools with patients in MAINTAIN-pc after the study has completed (61% "yes," 33% "maybe") and will consider using them with new patients (11% "yes," 67% "maybe"). 76% will refer patients to a similar weight management program again. Most PCPs are interested in the EHR integration of patient-collected lifestyle data from other devices and/or apps (50% "yes," 33% "maybe"), specifically for physical activity (83%), weight (67%), and nutrition (61%). PCPs prefer to view summary reports of these data (56%) rather than reviewing all patient-collected data personally (22%) or by ancillary staff (6%). Few want to receive regularly scheduled reports (11%); most want to review reports on demand, prior to or during patient appointments (78%).

CONCLUSIONS: PCPs are largely satisfied with the MAINTAIN-pc EHR-based weight management intervention and tools. They are interested in integrating patient-collected lifestyle data into the EHR and prefer to review summary reports around the time of patient appointments, which is likely less time consuming than raw data review. This survey provides insight into how PCPs with experience using EHR-based tools for lifestyle management value the experience and their interest in future developments to support their patients' lifestyle efforts.

PROVIDER USE OF THE AFTER VISIT SUMMARY IN ACADEMIC CLINICAL PRACTICES Angela M. Sanchez Munoz[2]; Alex Federman[2]; Mary Gover[1]; Joseph Deluca[1]; Joseph Kannry[2]; Lina Jandorf[2]. [1]Montefiore, Brooklyn, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #2706706)

BACKGROUND: The after visit summary (AVS) was designed as an EHR tool to promote patient-centered care. Although physician perspectives on AVS design have been explored, little is known about physician use of the summary and integration in patient care.

METHODS: We surveyed physicians ($n = 136$) in two academic adult primary care practices in New York City, NY (one hospital- and one community-based) serving socioeconomically disadvantaged communities to learn about their use and preferences regarding the after visit summary. Physicians were recruited during faculty/staff meetings and via emails sent by practice leadership. In meetings, Research Assistants provided clinicians with a study information sheet and asked them to complete a short one-time self-administered questionnaire, if interested in participating. They were given the option to complete the anonymous survey on paper or online. Physicians were asked how often they 1) give a copy of the AVS to patients, 2) review the AVS with patients, and 3) add typed/written information to the AVS. Additionally, physicians rated the AVS on clarity of information and overall quality of the document on a 7-point Likert scale (ranging from very poor to exceptional). Responses were dichotomized as good/fair/poor/very poor (low ratings) to very good/excellent/exceptional (high ratings). We also did bivariate associations of a chi-squared test.

RESULTS: We enrolled 103 (76%) physicians from the hospital-based practice and 33 (24%) from the community-based practice; 59% of physicians were male; 25% were attendings and 75% were residents. Most physicians rated the clarity of information on the AVS and the overall quality of the AVS as good/fair/poor (80 and 88%, respectively; $p < 0.0001$), as opposed to very good/excellent/exceptional. 80% of physicians reported that they always/usually print out the document, 79% give patients a copy of the document, 71% reported reviewing the document with the patient and 61% of physicians include additional typed or handwritten information on the AVS. Physicians who rated the quality of the AVS highly were not more or less likely to provide it to patients than were those who rated it poorly ($p = 0.31$) when adjusted for site, gender, and training level in a bivariate analysis.

CONCLUSIONS: Most physicians in two academic primary care practices believed that the AVS they provided to patients was of poor quality, yet the majority of them continue to provide it to patients. These findings indicate that physicians value these documents and improvements in their design are warranted.

PUBLIC SERVICE LOAN FORGIVENESS PARTICIPATION AND FINANCIAL OUTCOMES AMONG US MEDICAL GRADUATES PURSUING A CAREER IN HOSPITAL MEDICINE Justin Grischkan[3, 1]; Benjamin P. George[2]; E. Ray Dorsey[2]. [1]University of Rochester School of Medicine and Dentistry, Rochester, NY; [2]University of Rochester Medical Center, Rochester, NY; [3]Penn Medicine Center for Health Care Innovation, Philadelphia, PA. (Control ID #2707465)

BACKGROUND: The field of hospital medicine has experienced tremendous growth over the past twenty years, increasing from a few hundred hospitalists in the early 1990s to more than 50,000 by 2016. Approximately 75% of hospitals in the United States now have hospitalists caring for patients. Although hospital medicine is now the largest subspecialty field in internal medicine, little is known about the indebtedness and loan forgiveness participation plans among medical school graduates who intend to enter this field of medicine. We sought to analyze future hospitalists planned participation in Public Service Loan Forgiveness (PSLF), a program which offers physicians complete loan forgiveness after 120 qualifying monthly payments while employed at a public or non profit medical institution, including payments made during residency. We also examined the financial implications of utilizing this program, which is particularly important given recent policy proposals to limit the PSLF program.

METHODS: We assessed trends in planned participation in the PSLF program using de-identified individual level data from the Association of American Medical Colleges Graduation Questionnaire. Data regarding medical education debt, plans to enter hospital medicine, and intended loan forgiveness program participation were available for medical school graduates from the classes of 2015 and 2016. Missing data were excluded from our analysis. We estimated the average hospitalist's loan repayment and forgiveness amounts under PSLF using financial modeling based on reported starting salary, residency length and income, and average debt among survey respondents ($205,000). Financial data were adjusted to 2016 dollars.

RESULTS: Among graduates from the classes of 2015 and 2016 responding to the Graduation Questionnaire, 20%($n = 5532$) of US medical gradates were identified as pursing a career in internal medicine and 31%($n = 1711$) of these graduates subsequently identified hospital medicine as their intended specialty. Among future hospitalists providing loan forgiveness plans, 27%($n = 193$) and 33%($n = 215$) of graduates from the classes of 2015 and 2016, respectively, intended to utilize the PSLF program. For a 2016 graduate pursuing hospital medicine as an employee of a non-profit hospital for at least ten years, the

federally funded PSLF program will forgive an estimated $143,000 after making $181,000 in repayment.

CONCLUSIONS: Graduates from US Medical Schools pursuing a career in hospital medicine are becoming increasingly and substantially reliant on the PSLF program for relief of educational debt. Since most academic medical centers are non-profit entities, the generous forgiveness amounts available to PSLF participants may provide a financial incentive to pursue a career in academia. However, recent policy proposals suggest capping the level of forgiveness at $57,500. Given the uncertain future of this program, policymakers should provide guidance due to the strong interest among young physicians.

PURSUING INCIDENTAL PULMONARY NODULES IN A SAFETY-NET COHORT: LOST TO FOLLOW-UP

Jonathan S. Lee[1]; Sarah Lisker[1]; Roy P. Cherian[1]; George Su[1]; Alex Rybkin[2]; David McCoy[2]; Raman Khanna[1]; Urmimala Sarkar[1]. [1]University of California San Francisco, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA. (Control ID #2695720)

BACKGROUND: Completing guideline-recommended follow-up of incidental pulmonary nodules is important for timely and accurate diagnosis. However, appropriate follow-up requires longitudinal care and tracking. Our objectives were to describe pulmonary nodule follow-up and to identify targets for intervention in a safety-net setting.

METHODS: This was a retrospective cohort study of 699 adults (≥35 years) with incidental 5–8 mm pulmonary nodules requiring radiographic follow-up by Fleischner Society guidelines at San Francisco General Hospital between 9/2008 and 12/2014. We included patients with at least one primary care, specialty care, or non-trauma ED visit within 24 months after the index CT scan. We abstracted subsequent nodule evaluation until stability, a final diagnosis or a decision to stop follow-up was documented. We also abstracted documentation of nodule management in primary care visit notes. We categorized overall follow-up as complete if all successive recommended testing was performed and evaluated differences in follow-up by demographics and engagement in care.

RESULTS: Patient mean age was 59, 370 (53%) were current or former smokers, 159 (23%) had a history of homelessness, and 245 (35%) had a history of substance abuse. Over half of patients (394, 56%) saw a primary care physician within 24 months of the index CT, and nodules were documented in clinic notes in 190 (48%) of these patients. Overall, 369 (53%) patients completed follow-up, 111 (16%) had incomplete partial follow-up and 219 (31%) had no follow-up. Amongst patients completing follow-up, 8 (2%) were diagnosed with lung cancer. Only 64-70% of patients needing follow-up completed each successive follow-up step (Figure). Follow-up completion was highest amongst patients with primary care visits and lower amongst those with only specialty care visits or only ED visits (73% vs 35% vs 18%, $p < .0001$) and did not differ by patient demographics.

CONCLUSIONS: Nearly half of patients with higher risk incidental pulmonary nodules did not complete follow-up; nearly one-third had no follow-up at all, despite ongoing visits in the health system. These findings suggest that in a safety-net population, access to primary care alone is not sufficient to meet recommended follow-up guidelines for incidental pulmonary nodules. Specific interventions for tracking/monitoring these patients should be developed and tested.

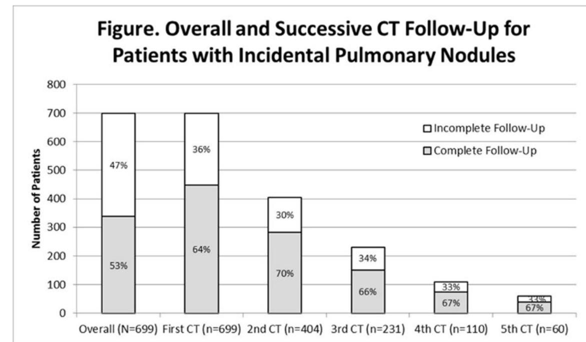


Figure. Overall and Successive CT Follow-Up for Patients with Incidental Pulmonary Nodules

PUTTING OUT THE FLAME: OUR TRAINEES NEED TO LEARN PATIENT ACTIVATION SKILLS

Amanda Watsula-Morley[1]; Colleen Gillespie[1]; Lisa Altshuler[1]; Kathleen Hanley[1, 3]; Adina Kalet[1]; Barbara Porter[2, 3]; Andrew B. Wallach[2, 3]; Sondra Zabar[1]. [1]NYU School of Medicine, New York, NY; [2]Bellevue Hospital, New York, NY; [3]Gouverneur Healthcare Services, New York, NY. (Control ID #2705438)

BACKGROUND: Effective smoking cessation counseling improves smokers' health and quality of life. As part of our assessment program, an Unannounced Standardized Patient (USP) case was developed to measure residents' performance in a routine visit with a smoker.

METHODS: The USP was a 40 year-old male new patient presenting with heartburn. He began smoking up to two packs/day at 22 years old; at the time of the visit, he reports having cut down to one pack/day and quitting cold turkey twice in the past only to return to smoking. If the resident engages him, he discusses his relationship with smoking and the possibility of quitting. The USP received 6 hours of character and checklist training to ensure standardized portrayal and evaluation. Data was collected using 2 forms of assessment: a post-visit USP checklist and a systematic review of the EMR (lab orders, prescriptions, and referrals). The 170-item USP checklist measured communication, patient education, assessment skills, and case-specific items. Each response option included descriptive behavioral anchors and was rated as not done, partly done, or well done.

RESULTS: Data was examined from 73 USP visits from 2009–2015. Mean visit length = 37 min, SD = 15 min (range: 15 to 95 min). Overall communication scores ranged from 17 to 100% with an average of 62% (Cronbach's alpha = 0.75). All residents documented History of Tobacco Use or Tobacco Use Disorder in the EMR, and the majority (82%) prescribed smoking cessation medication. There was variation in the sophistication of smoking cessation-counseling approach. While most residents (78%) discussed the risks of smoking and/or the benefits to quitting, significantly fewer (48%) explored the patient's view of the pros and cons of his smoking ($p = 0.00$). Residents who prescribed smoking cessation medication and discussed risks/benefits to smoking/quitting ($N = 31$) were compared to residents who did the same but also invited the patient to discuss his personal pros and cons of smoking ($N = 29$). Groups were not significantly different by PGY or gender. Patients who were asked to discuss their pros/cons rated the resident higher on patient activation questions (0–2 point scale), including "Helped you understand the importance of quitting smoking" (1.38 vs 0.90, $p = 0.00$), "Made you want to change your smoking" (1.10 vs 0.52, $p = 0.00$), and "Made you feel like you would be able to quit smoking" (1.07 vs 0.35, $p = 0.00$). There were no significant differences in labs ordered, referrals to a smoking cessation program, or quality of documentation.

CONCLUSIONS: While all residents ask about tobacco use and most appropriately prescribe medication, fewer than half demonstrate the skills known to motivate patients to quit smoking. Curricula needs to reinforce the importance of a patient discussing their personal relationship with smoking in order to feel activated and willing to engage in cessation.

QUALITY AND OUTCOMES AT A STUDENT-RUN PRIMARY CARE CLINIC: SHIFTING THE DISCUSSION TOWARDS VALUE-BASED HEALTHCARE Anjali Thakkar[2]; Rachael Williams[3]; Jonathan R. Abraham[4]; Steven Atlas[4]; Marya J. Cohen[3]; Bonnie B. Blanchfield[1]. [1]Brigham & Womens Hospital, Weston, MA; [2]Harvard Medical School, Cambridge, MA; [3]MGH, Boston, MA; [4]Massachusetts General Hospital, Boston, MA. (Control ID #2701704)

BACKGROUND: While the number of student run clinics (SRC) has increased rapidly, a key concern involves the quality of care they provide. Given the vulnerability of the population served by SRCs and the shift towards value-based care, SRCs must be held to the same standard of care as traditional clinics. Yet, few have published quality and outcomes data. To address this gap, we will study the quality of care at the Crimson Care Collaborative (CCC), a network of six student-faculty primary care clinics in Massachusetts. Because many CCC patients come to clinic with a chief complaint, preventative care screenings are frequently foregone. As a result, we hypothesize that CCC provides high quality care for chronic disease management, but may fall short on preventative and screening measures.
METHODS: A retrospective analysis will compare quality and outcome measures of patients at two CCC clinic sites affiliated with Massachusetts General Hospital (MGH) ($n = 1{,}120$) to their respective host clinics (MGH-Chelsea and MGH-Internal Medicine Associates) ($n = 49{,}035$) on breast, colorectal, and cervical cancer screening, and diabetes and coronary artery disease (CAD) risk management and control. Data from the MGH Primary Care Practice-Based Research Network, which biannually reports each physician's clinical performance at 18 hospital-affiliated primary care practices, will be used. We will assess statistically significant differences in quality and outcome measures attained at the CCC clinics as compared to the host clinics using aggregate sample t-tests.
RESULTS: Average age, racial, and language composition between cohorts was similar; the CCC cohort had more patients insured by Medicaid (62.41% vs 60.39%) and commercial insurers (17.5% vs 11.17%), and fewer patients insured by Medicare (15.63% vs 24.94%). Preliminary results show that CCC-Chelsea generally underperformed on cancer screenings, diabetes and CAD disease management testing, and diabetes control (defined as HbA1c <9% on most recent clinic visit) as compared to its host site. However, CCC-Chelsea outperformed on CAD control (defined as LDL < 100 mg/dL on most recent clinic visit.) CCC-IMA performed comparably on cancer screenings and chronic disease management testing, while CCC-IMA underperformed on diabetes and CAD control.
CONCLUSIONS: Understanding quality of care at SRCs is critical to support the validity of the clinic model and to drive targeted quality improvement initiatives. Preliminary results suggest the need for initiatives to improve rates of cancer screening and diabetes control at CCC-Chelsea, and to improve diabetes and CAD control at CCC-IMA. Contrary to our hypothesis, results did not suggest that CCC performs better on chronic disease management compared to preventative screening. As healthcare delivery shifts towards value-based care, measurement along quality outcomes will be imperative; holding SRCs accountable to quality can a foster a quality-driven mentality early on among future health professionals.

QUALITY IMPROVEMENT INTERVENTION ON INTERNAL MEDICINE HIGH UTILIZER INPATIENTS Marc Heincelman[2]; Samuel O. Schumann[2]; Patrick D. Mauldin[2]; Jingwen Zhang[1]; Justin Marsden[2]; Don Rockey[2]; William P. Moran[2]. [1]MUSC, Charleston, SC; [2]Medical University of South Carolina, Charleston, SC. (Control ID #2705976)

BACKGROUND: The value based care movement places considerable pressure on healthcare systems to deliver high quality medical care while decreasing costs. Studies have demonstrated that the top 10% high cost patients, labeled high utilizers (HU), disproportionately consume an exceedingly large amount of resources. For unclear reasons, the attrition rate for patients meeting HU status is high (>70% at one year) and an individual HU patient's extreme resource utilization is likely to be short lived. Thus, efforts to reduce utilization based on intensive case management of a fixed population may not impact the majority of high utilizer patients who access a health system. Using predictive modeling, inpatients at risk for a high utilizer hospitalization can be identified early based on admission variables. Historically nursing charges, a surrogate for length of stay (LOS), has been the most costly resource during a high utilizer admission. The objective of this study is to develop a quality improvement (QI) guideline intervention aimed at decreasing length of stay and the unnecessary utilization of other inpatient resources for patients identified at risk for a high utilizer admission.
METHODS: A QI guideline intervention study was performed on all patients admitted to internal medicine services from October 2015 - April 2016. An established predictive model (AUROC = 0.80) was used to analyze admission variables and identify patients at risk for a HU admission. A predictive model estimator score of ≥ 0.15 was used to define patients at risk for a high utilizer admission, giving the model a specificity of 84%. All patients with a predictive model estimator score of ≥ 0.15 were considered to be at risk for a high utilizer admission. On a daily basis, patients with the top two highest estimator scores that did not have a pre-specified exclusion criteria were enrolled in our study arm. The remaining patients with a HU estimator score ≥ 0.15 were placed in our control arm. Patients enrolled in the study arm received intervention in three areas: early palliative care consultation, early pharmD medication reconciliation, and recommendations to follow Choosing Wisely guidelines for lab tests. Primary outcome was a reduction in length of stay. Secondary outcomes included total hospital costs, pharmaceutical charges, and laboratory charges.
RESULTS: 373 met criteria for being at risk for a HU admission. 130 patients were enrolled in the QI guideline intervention study arm and received all 3 areas of intervention. 243 patients were included in the control arm. The mean LOS for HU patients enrolled in the guideline intervention was 10 days compared to a mean LOS of 14 days in the control ($p = .01$). The median LOS for HU patients enrolled in the guideline intervention was 6 days, compared to 8 days in the control.
CONCLUSIONS: Patients at risk for a HU admission can be identified in real-time based on admission variables. Guideline based interventions can then be deployed early to decrease length of stay.

QUALITY OF PHARMACOLOGIC CARE BY PHYSICIANS, NURSE PRACTITIONERS AND PHYSICIAN ASSISTANTS IN THE UNITED STATES Shiyin Jiao[2]; Irene Murimi[2]; Randall S. Stafford[1]; Ramin Mojtabai[2]; G. Caleb Alexander[2]. [1]Stanford, Stanford, CA; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. (Control ID #2705737)

BACKGROUND: Nurse practitioners (NPs) and physician assistants (PAs) have increasingly broad prescribing authority in the United States, yet little is known regarding whether they deliver the same quality of pharmacologic care as physicians. We compared the quality of ambulatory pharmacologic care provided by NPs, PAs and physicians

METHODS: The design was a serial cross-sectional analysis of the 2006–2012 National Ambulatory Medical Care Survey (NAMCS) and National Hospital Ambulatory Medical Care Survey (NHAMCS). Analyses included ambulatory care services in physician offices, hospital emergency departments and outpatient departments among a nationally representative sample of patient visits to physicians, NPs and PAs. Main outcome measures were thirteen validated outpatient quality indicators focused on pharmacological management of chronic diseases and appropriate medication use.

RESULTS: A total of 701,499 sampled patient visits were included during the study period, which represented an estimated 8.33 billion visits nationwide. Physicians were the primary provider for 96.8% of all outpatient visits examined, while NPs and PAs each accounted for 1.6% of these visits. The proportion of eligible visits where quality standards were met ranged from 34.1% (angiotensin converting enzyme [ACE]-inhibitor use for congestive heart failure) to 89.5% (avoidance of inappropriate medications among elderly). The median overall performance across all indicators was 58.7%. On unadjusted analyses, there were statistically significant differences in quality of care between non-physicians and physicians for each indicator. After adjustment for potentially confounding patient and provider characteristics, the quality of pharmacologic care delivered by non-physician providers was similar to the care delivered by physicians for ten of the thirteen indicators evaluated, and there was no consistent directional association between provider type and indicator fulfillment for the remaining measures.

CONCLUSIONS: While there were significant shortfalls in the quality of ambulatory pharmacologic care among these visits, the quality of care delivered by non-physicians and physicians was generally comparable.

QUANTIFYING THE PHYSICALLY ENHANCING EFFECTS OF ANABOLIC-ANDROGENIC STEROIDS IN ATHLETES: A SYSTEMATIC REVIEW AND META-ANALYSIS Mary A. Andrews[1]; Charles D. Magee[1]; Travis Combest[2]; Rhonda Allard[1]; Kevin M. Douglas[1]. [1]Uniformed Services University of the Health Sciences, Bethesda, MD; [2]Walter Reed National Military Medical Center, Bethesda, MD. (Control ID #2690021)

BACKGROUND: Athletes and others who routinely exercise may use anabolic androgenic steroids (AAS) for physical enhancement. While the physiology underlying the physically enhancing properties of AAS is well-described, the magnitude of such effects is not. The purpose of this study is to synthesize the available literature to quantify the physically enhancing effects of AAS in healthy exercising adults.

METHODS: Primary outcomes were changes in muscle strength, cardiovascular endurance, power, lean mass, and fat mass. Secondary outcomes were adverse effects. A medical librarian comprehensively searched MEDLINE, EMBASE, Cochrane CENTRAL, SPORTDiscus, and PsychINFO for randomized controlled trials reporting the effect of AAS on athletic performance and body composition in healthy exercising adults. After confirming adequate interrater agreement, two authors screened titles and abstracts for eligibility. If screening suggested eligibility, full text articles were reviewed. If studies met inclusion criteria after full text review, data were extracted independently and in duplicate to minimize bias and error. If at least ten studies were available, data were pooled using random effects models according to the method of DerSimonian and Laird. Heterogeneity was assessed visually and with the I-squared statistic. Publication bias was assessed by Egger's method.

RESULTS: The search yielded 7179 studies, of which 25 met criteria for inclusion in the review. Muscle strength was assessed in 21 studies, cardiovascular endurance in six, power in five, lean mass in 14, and fat mass in 13. Compared with placebo, AAS increased both muscle strength [standardized mean difference (SMD) = 0.27; 95% CI, 0.07-0.47, I-squared = 12.7%, 21 studies] and lean body mass (SMD = 0.39; 95% CI, 0.17-0.61, I-squared = 26%, 14 studies) while decreasing fat mass (SMD = −0.29; 95% CI, −0.63 to 0.05, I- squared = 50.7%, 12 studies), although the latter was not statistically significant. The pooled increase in strength in the AAS group was 52% greater than in the placebo group. Egger's tests for publication bias were not significant for any outcomes. Seven studies reported adverse effects, most commonly decreased HDL, muscle cramps, acne, and mood changes.

CONCLUSIONS: In our review, AAS increased both muscle strength and lean mass in healthy exercising adults with small absolute effects and large relative effects when compared to placebo. Adverse outcomes were reported infrequently. Our review indicates that AAS may provide benefits to exercising adults in terms of increased strength and lean mass; however, we were limited by short duration of the studies and inconsistent methods of monitoring for adverse effects. Nevertheless, this study offers important information for physicians, public health professionals, athletic governing bodies, and others who counsel patients and shape policy regarding the use of AAS.

RACE AND OPIOID DOSE ARE ASSOCIATED WITH TAPERING AMONG PATIENTS ON CHRONIC OPIOID THERAPY Michele J. Buonora[1]; Joanna L. Starrels[1]; Yuming Ning[2]; Hector R. Perez[1]. [1]Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY; [2]Montefiore Medical Cneter, New York, NY. (Control ID #2706504)

BACKGROUND: To address the epidemic of opioid overdose, guidelines recommend that prescribers taper chronic opioid therapy (COT) when the risks of continued COT exceed the benefits. However, little is known about the likelihood and predictors of opioid tapering, and there is potential for provider bias in which patients get tapered, for example, by race. We sought to identify patient factors associated with tapering in a cohort of patients prescribed COT for chronic non-cancer pain.

METHODS: Using electronic medical record data from January 2009 to June 2015, we conducted a retrospective cohort study of COT patients in an urban academic medical healthcare system in Bronx, New York. To be eligible, patients had: 1) COT, defined as ≥ 3 opioid prescriptions in 2 consecutive 6-month periods from July 2009 to July 2010; 2) a stable opiate dose, defined by <20% change in average morphine equivalent daily dose (MEDD) between 2009 and 2010; and 3) no ICD code for cancer. To identify tapering, an average MEDD for each of the eleven 6-month periods was calculated and compared to

a baseline period [January-June 2010]. Patients were categorized into 3 groups: (1) "tapered" patients had a 30-90% dose-reduction in 2 consecutive 6-month periods from 2010 to 2015; (2) "discontinued or lost" patients received no opioids in 2014 and 2015; and (3) "continued" patients were neither tapered nor discontinued or lost. Bivariate analyses were used to compare characteristics between groups using chi-square tests for categorical variables (race/ethnicity, sex, language) and ANOVA or Kruskal-Wallis tests for continuous variables (age, baseline dose).

RESULTS: Of the 702 COT patients who met eligibility criteria, 202 (28.8%) were tapered, 226 (32.2%) were discontinued or lost, and 274 (39.0%) were continued. Compared to black and Hispanic patients, white non-Hispanic patients were less likely to be tapered (OR 0.90), but more likely to be discontinued or lost (OR 2.27) ($p < 0.001$). Patients who were continued had a higher median baseline dose (81.0 MEDD) than patients who were tapered (49.2 MEDD) or discontinued or lost (60.0 MEDD) ($p = 0.02$). Patients with high baseline dose (≥100 MEDD) were less likely to be tapered than those with baseline dose <100 MEDD (OR 0.69, $p = 0.058$), although this was not statistically significant. No significant differences between groups were observed in age, sex, or language spoken.

CONCLUSIONS: In this cohort, white non-Hispanic COT patients were less likely than black or Hispanic patients to be tapered, but more likely to have an abrupt discontinuation and/or be lost to follow-up. These findings may reflect provider bias in deciding to taper or racial differences in continuity of care; more research is needed. The finding that patients with higher dose COT were less likely to be tapered is contrary to current recommendations and requires further study.

RACE, VIGILANT COPING STRATEGY, AND HYPERTENSION IN AN INTEGRATED COMMUNITY Anika L. Hines[1]; Craig E. Pollack[2]; Thomas A. LaVeist[3]; Roland J. Thorpe[4]. [1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]George Washington University, Washington, DC; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. (Control ID #2707750)

BACKGROUND: Vigilant coping refers to individuals who, potentially as a result of experiencing discrimination in the past, proactively prepare for the possibility that they will be discriminated against or mistreated because of their race. The extent to which vigilant coping is linked with hypertension, a highly prevalent condition with well-documented racial/ethnic disparities, remains largely unknown. We sought to examine the association between race, vigilant coping strategy, and hypertension in a racially *integrated* community, which allows us to hold constant a number of physical and social attributes of neighborhoods that may confound these relationships.

METHODS: We performed a cross-sectional analysis of data from the EHDIC (Exploring Health Disparities in Integrated Communities) study. EDHIC is a multisite study of race disparities within communities where African-Americans and non-Hispanic whites live in integrated communities without racial differences in socioeconomic status (SES) as measured by median income. Hypertension was defined as: having an average SBP ≥140 mm/Hg and DBP ≥ 90 mm/Hg as measured at three points of the survey via a trained observer using a standardized protocol; reporting taking hypertension medication; or reporting being told by a doctor that they had high blood pressure in the past 5 years. Experiences with vigilant coping were measured using a modified 1995 Detroit Area Study vigilance anticipatory coping scale. We used a series of multivariable logistic regression models to evaluate vigilance as a potential mediator or, separately, moderator of the association of race with hypertension.

RESULTS: We included 715 EDHIC respondents—440 African-Americans and 275 whites. Although high for both groups, there was no difference in prevalence of hypertension between African-Americans and whites in this sample (68.6 versus 68.7; $p = 0.98$). Overall, a higher proportion of African-Americans reported experiences with discrimination (41.1 versus 22.9; $p < .0001$) and vigilance (67.3 versus 46.9; $p < .0001$) compared to whites. In this racially integrated community, neither vigilance (OR: 1.00, 95% CI: 0.91, 1.10) nor discrimination (OR: 1.22, 95% CI: 0.60, 2.46) was associated with hypertension. Vigilance served as neither a mediator nor a moderator in the association between race and hypertension.

CONCLUSIONS: African-Americans experienced more vigilance and discrimination compared to whites; however, within the context of this integrated community, these measures were not associated with hypertension. More research is needed to understand how structural inequalities impact the health of African-Americans and whites in integrated communities.

RACIAL AND ETHNIC DISPARITIES IN CHRONIC ILLNESS DIAGNOSIS AND ROUTINE HEALTH CARE Eun Ji Kim[1, 3]; Taekyu Kim[4]; Jane M. Liebschutz[2]; Michael Paasche-Orlow[1]; Amresh D. Hanchate[2]. [1]Boston University, Boston, MA; [2]Boston University School of Medicine, Boston, MA; [3]Bedford VA, Bedford, MA; [4]Massachusetts General Hospital, Boston, MA. (Control ID #2701435)

BACKGROUND: Asian Americans (AA) have higher rates of risk-adjusted inpatient mortality following acute myocardial infarction and stroke compared to Hispanics, non-Hispanic Whites, and non-Hispanic Blacks. A plausible explanation is higher prevalence of undiagnosed disease burden among AA. Using national data we estimated adjusted rates of prevalence of undiagnosed hypertension (HTN) and diabetes (DM) by race/ethnicity.

METHODS: From the 2011–2014 National Health and Nutrition Examination Surveys (NHANES) we obtained data on self-reported provider-diagnosed conditions and results of laboratory tests and physical examination. We included survey respondents 18 years or older with complete covariate data. The outcomes were undiagnosed HTN (SBP ≥ 140 or DBP ≥ 90 on physical examination with report of no prior diagnosis of HTN) and undiagnosed DM (Hgba1c ≥ 6.5 with report of no prior diagnosis). Using logistic regression, we obtained prevalence of undiagnosed HTN or DM by race/ethnicity, and among subgroups based on self-reported receipt of routine healthcare. We also estimated rates adjusted for socioeconomic status (education, income, insurance) and acculturation (limited English proficiency, not US citizen, and born outside of the US) to examine potential mediators.

RESULTS: The study sample of 10,488 included 40.1% Whites, 23.1% Blacks, 21.5% Hispanics, 12.4% Asians, and 3.0% Others. Significantly lower proportions of Hispanics (71.8%) and Asians (79.0%) reported receipt of routine healthcare compared to Whites (87.2%), Blacks (87.0%), and Others (85.8%) ($p < 0.01$). Among those who reported routine healthcare, more Hispanics (27.1%) and Asians (20.1%) reported having no healthcare visits in the prior year. The prevalence of undiagnosed HTN and DM were the highest among Asians ($p < 0.01$) (Table 1), including among those with routine healthcare ($p < 0.01$). After adjusting for age and gender, the odds ratio of having undiagnosed hypertension or diabetes was the highest for Asians (OR = 1.91, $p < 0.01$) compared to non-Hispanic Whites. This finding

persisted even after adjusting for socio-demographic, health care utilization, and acculturation-related covariates (OR = 2.14, $p < 0.01$).

CONCLUSIONS: Compared to other groups, Asian Americans had the highest rates of undiagnosed HTN and DM. This finding was evident among those who received routine healthcare and was independent of socio-demographic and acculturation-related covariates. Future studies should examine the potential sources of these disparities, including lack of patient-provider communications or perceptions that Asians are less likely to have HTN and DM.

Prevalence (weighted %) of undiagnosed HTN and DM

	White, non-Hispanic	Black, non-Hispanic	Hispanic	Asian	Other
Survey participants ($n = 10{,}488$)					
Undiagnosed HTN	5.0	5.9	4.0	6.0	5.8
Undiagnosed DM	1.4	3.4	2.5	4.1	3.1
Survey participants with routine care ($n = 8{,}769$)					
Undiagnosed HTN	5.2	8.2	6.0	9.6	6.0
Undiagnosed DM	1.4	3.4	2.7	3.6	3.2

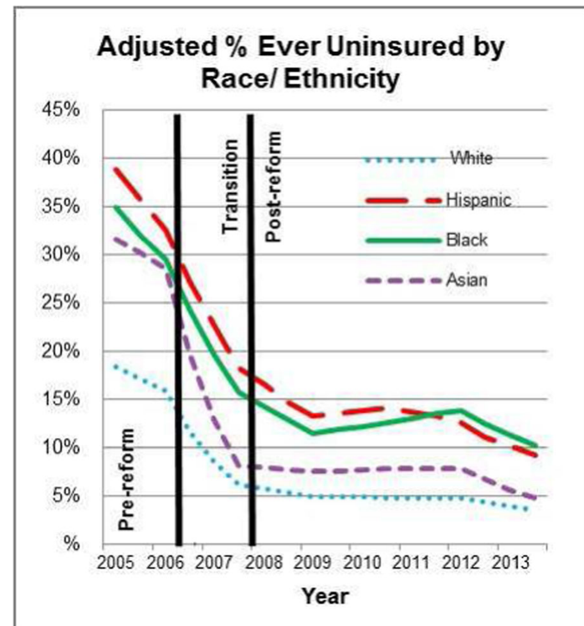
RACIAL DIFFERENCES IN INSURANCE STABILITY AFTER HEALTH INSURANCE REFORM Karen M. Freund[4]; Amy LeClair[3]; Norma Terrin[3]; Alejandro Moreno-Koehler[3]; Amresh D. Hanchate[1]; Jillian Suzukida[3]; Sucharita R. Kher[3]; Elena Byhoff[3]; Nancy R. Kressin[2]. [1]Boston University School of Medicine, Boston, MA; [2]Dept of Veterans Affairs and Boston University, West Roxbury, MA; [3]Tufts Medical Center, Boston, MA; [4]Tufts University School of Medicine, Boston, MA. (Control ID #2704997)

BACKGROUND: A potential benefit of insurance reform and broader access to health insurance is reduced disparities in insurance coverage and stability. We examined trends in insurance stability by racial/ethnic group across 2 health care systems, after state and national reform was implemented.

METHODS: We abstracted medical and billing records from 1/2005-12/2013, encompassing implementation of Massachusetts (MA) insurance reform, from 2 academic health centers and 5 community health centers that disproportionately care for underserved populations in MA. We included patients aged 21–64 who required regular care for hypertension, thus providing visit-level data on insurance coverage. We calculated insurance stability per person in 6-month intervals, defined as continuously insured vs some loss of insurance. We compared trends in stability by racial/ethnic group adjusting for age, sex, Charlson co-morbidity score, and census tract median income and high school graduation rates.

RESULTS: 41,859 unique patients and 272,289 6-month intervals were included: 54% were women, 28% non-Hispanic White, 7% Hispanic, 58% Black, and 6% Asian. In 2005 Whites had the lowest rates of being uninsured of all groups. For all groups, insurance coverage was greater in the transition and post-reform compared with the pre-reform period (all p <0.001). By 2013 adjusted rates of ever uninsured dropped to 4% for Whites, 9% for Hispanics, 10% for Blacks, and 5% for Asians. Adjusted incident rate ratios (IRRs) of insurance switches were higher for each group comparing post- to pre-reform (IRRs 1.3 (95% CI 1.2, 1.4) for Whites, 1.3 (1.1, 1.6) for Blacks, 1.3 (1.2, 1.3) for Hispanics, 2.1 (1.6, 2.7) for Asians, with a significant interaction by time period and race/ethnicity ($p = 0.002$).

CONCLUSIONS: Insurance reform improved rates of insurance coverage for all racial/ethnic groups. With higher rates of insurance coverage through reform also came higher rates of insurance switches.



RACIAL DISPARITIES IN THE REFERRAL TO CARDIOTHORACIC SURGERY FOR AORTIC STENOSIS Jose B. Cruz Rodriguez; Christopher Salazar-Fields; Priyanka Achayra; Aaron Horne. Methodist Dallas Medical Center, Dallas, TX. (Control ID #2675380)

BACKGROUND: Access to transcatheter aortic valve replacement (TAVR) in minority populations has been limited by lower rates of inclusion in trials and relatively short time since commercial approval of TAVR. It has been suggested that this underrepresentation might reflect racial differences in the prevalence of severe aortic valve stenosis or in the intervention rate of those with severe aortic stenosis. TAVR is growing in availability, but not all community-based centers have access to it. Therefore, our objective was to evaluate health disparities in the referral to cardiothoracic surgery (CTS) for aortic stenosis in African Americans (AA) and Hispanics compared to Caucasians in our community.

METHODS: Using a retrospective cohort design, we identified all patients >40 years old, who had been captured in the inpatient electronic medical record of Methodist Health System with AS from January 2011 to June 2016. Clinical and echocardiographic data were collected manually. We excluded Asian and Native American patients. Data was analyzed with an available case approach. Exposure was race/ethnicity; outcome was referral to CTS. Multivariable logistic regression analysis was conducted with variables that had significance to $p < 0.20$ in univariate model.

RESULTS: A total of 952 patients were included in the final analysis (423 Caucasian, 376 AA and 153 Hispanic). Compared to Caucasians, AA subjects were significantly younger, had more advanced degrees of kidney disease, were more likely to have Medicaid as payer, diabetes, hypertension, active smoking, obesity, systolic and diastolic heart failure. There was no statistical difference by race in sex, use of beta-blockers, hyperlipidemia and bicuspid aortic valves. AA patients had significantly higher aortic valve area indexed for body surface area, more aortic insufficiency, lower peak velocities, lower transvalvular gradients, less calcified valves and fewer patients in aortic stenosis stage D. After adjusting for the aforementioned variables, the odds ratio of

getting CTS referral was 0.48 for AAs ($p < 0.001$, 95% CI 0.33–0.70) and 0.92 for Hispanics ($p = 0.73$, 95% CI 0.60–1.44) compared to Caucasians.
CONCLUSIONS: Holding clinical and echocardiographic variables constant, AA patients were less likely to be referred to CTS for treatment of severe aortic stenosis. In our sample, AA patients had less severe hemodynamics of aortic stenosis; nonetheless, this was considered in the regression model. We found no difference in the referral pattern of Hispanics compared to Caucasians. Further research is needed in this topic to identify the reasons of this racial disparity in order to develop strategies to reach health equity across minorities.

RACIAL VARIATIONS IN MEDICAL CARE SPENDING PATTERNS AMONG HIGH-RISK PRIMARY CARE PATIENTS: RESULTS FROM THE STOP-DKD STUDY Leah Machen; Clementina Davenport; Megan Oakes; Uptal Patel; Clarissa J. Diamantidis. Duke, Durham, NC. (Control ID #2706607)

BACKGROUND: Individuals with chronic disease incur greater medical care expenditure than those without significant co-morbidity. Little is known about how socioeconomic status (SES) relates to prioritization of medical care spending over personal expenditures in multi-morbid individuals, and whether this relation differs between African Americans (AA) and non-AAs.
METHODS: The STOP-DKD study is an ongoing randomized controlled trial of active Duke Primary Care patient with diabetes, hypertension, and chronic kidney disease designed to examine the effect of a multi-factorial telehealth intervention on health outcomes. At the baseline exam (2014–2015), STOP-DKD participants underwent survey assessments inclusive of measures of socio-demographics and medication adherence. Measures of SES included annual household income (<\$30 K versus ≥ \$30 K), highest educational level (high school [HS] diploma vs. other), and employment status (full-time vs. other). The primary outcomes were based on 4 questions related to spending: "Have you reduced spending on basics like food or clothing in order to pay for your medical care or prescription drugs?", "Have you reduced spending on leisure activities like vacations, eating out, or movies in order to pay for your medical care or prescription drugs?", "Have you used all or a portion of your savings to pay for your medical care or prescription drugs?", and "Have you ever skipped any medication doses or taken less medicine than prescribed to make a medicine last longer?" Multifactorial logistic regression stratified by race and adjusted for age, sex, health insurance status, and household chaos, was used to determine the independent effect of SES on spending.
RESULTS: Of 281 baseline STOP-DKD participants 156 (55%) were AA. Compared with non-AA's, AA's had similar levels of income, education and employment, but were more likely to reduce spending on basic needs (28.2% vs. 13.6%) and leisure activities (34.6% vs. 19%), and to skip medications (25.5% vs. 15.2%), all $p < 0.05$. After multivariate adjustment, AA race (vs. non-AA) was associated with increased odds of reduced basic spending (OR 2.49 [95% CI 1.28,4.82]), reduced leisure spending (OR 2.27 [1.25,4.12]), and skipping medications (OR 2.07 [1.1,3.89]). Among AAs, full-time employment was associated with lower odds of reduced basic spending (OR 0.28 [0.09, 0.85]); HS diploma was associated with lower odds of reduced leisure spending (OR 0.34 [0.16,0.72]); income was not associated with any outcome. Non-AA's with higher income had lower odds of reduced basic spending, leisure spending, or use of savings (OR 0.24 [0.06,0.89]; OR 0.20 [0.06,0.65]; OR 0.24 [0.06,0.89], respectively). Non-AAs with HS education had lower odds of reduced basic spending (OR 0.23 [0.07,0.77]).
CONCLUSIONS: High-risk AAs in primary care are more likely to reduce spending on basics and leisure activities to afford their medical care than non-AAs of equivalent SES. Reasons behind these differential patterns warrant further study.

RATES AND COSTS OF GUIDELINE-CONCORDANT PREOPERATIVE STRESS TESTING Matt Pappas[2, 2]; Preethi Patel[2]; Michael B. Rothberg[1, 2]. [1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic, Medicine Institute, Cleveland, OH. (Control ID #2706259)

BACKGROUND: Operative interventions have long been recognized as associated with elevated risk of adverse cardiac events. The American College of Cardiology/American Heart Association (ACC/AHA) guidelines recommend cardiac stress testing for patients whose risk of a perioperative cardiac event is 1% or greater and who are unable to perform 4 metabolic equivalents (METs) of activity. However, those thresholds are arbitrary, and multiple risk stratification tools exist. Moreover, while value-based care initiatives have focused on overuse of cardiac stress testing among low-risk patients, little is known about the rates of guideline-concordant stress testing, or resultant costs. Different risk stratification tools may result in discordant recommendations, and the inclusion of patients at 1% risk or greater may result in large numbers of patients referred for preoperative stress testing. We set out to estimate the rates of preoperative stress testing recommended by current ACC/AHA guidelines, to investigate how the recommendation for or against stress testing varies between recommended risk stratification tools, and to estimate costs of guideline-concordant testing in the United States.
METHODS: The American College of Surgeons-National Surgical Quality Improvement Program (ACS-NSQIP) samples data from surgical patients at participating hospitals. Using ACS-NSQIP public use data, we first estimated Revised Cardiac Risk Index (RCRI) scores and complication rates predicted by the Gupta Myocardial Infarction/Cardiac Arrest (MICA) equation. We then calculated the agreement between those two prediction tools. To estimate costs of testing, we used previously-published data on relative frequency of different cardiac stress-testing strategies and the costs of each modality. We then extrapolated costs to the US adult population.
RESULTS: Using MICA, approximately 5% of surgical patients would be referred for preoperative stress testing. Using RCRI, between 5% (including an estimate of METs achieved) and 14.6% (RCRI alone) of patients would be referred for preoperative cardiac stress testing. Agreement between the two stratification tools was poor (kappa 0.24). An estimated 8.4% (and potentially up to 16.8%, depending on availability of peak MET data) of patients could be referred for preoperative cardiac stress testing under current guidelines. Current guidelines likely result in between \$2.6 and \$2.9 billion dollars spent on preoperative stress testing annually in the United States, not including downstream interventions such as coronary angiography or revascularization.
CONCLUSIONS: Current guidelines recommend considerable spending on preoperative stress testing, using a risk threshold without empiric support. Considering downstream procedures, such as revascularization, would further increase estimated expenditures. Because revascularization has not been shown to reduce perioperative complications, the value of this large source of medical expenditures remains unclear.

REAL-TIME FEEDBACK IN PAY-FOR-PERFORMANCE: DOES MORE INFORMATION LEAD TO IMPROVEMENT? Amelia Bond; Amanda Hodlofski; Kristen Caldarella; Jingsan Zhu; Andrea B. Troxel; Kevin G. Volpp; Ezekiel J. Emanuel; Amol S. Navathe. University of Pennsylvania, Philadelphia, PA. (Control ID #2706662)

BACKGROUND: Pay for performance (P4P) has thus far had mixed results influencing quality of care despite substantial investment. P4P may work in two ways - first by providing information to physicians on quality; and second by providing monetary incentives. This study investigates how the presentation of quality measure information to providers affects their response when monetary incentives remain unchanged. On January 1, 2014 Advocate Physician Partners, a clinically integrated hospital network with an existing P4P program, implemented a Cerner registry allowing physicians real-time access to their quality scores. We explore whether this information shock - from lagged and infrequent to real-time - increased physician performance.
METHODS: We used detailed physician and quality measure level registry data from four years prior to the registry implementation (2010–2013) and two years after implementation (2014–2015). We also linked physician-level data including age, gender and board certification; group-level data including EHR implementation date and registry click rates; and patient panel data including chronic conditions. Our final population included all consistently Advocate affiliated physicians between 2010 and 2015 representing 673 physicians and 270 million patient-measures. We used a predictive piecewise model to examine whether the registry introduction was associated with a change in the underlying trend in performance along specified quality metrics. This approach relies on historic trends to predict what scores would have been without the registry system introduction and compares predicted to actual scores. To address potential confounding from secular trends, we utilized out of sample HEDIS data to restrict to measures in which Advocate's trend is parallel to that of HEDIS Illinois and national scores.
RESULTS: We found no average performance increase associated with the introduction of the registry ($P > 0.18$ for all measures), which physician groups used on average five times per week. However, top quartile performers used the registry 26% more frequently ($P = 0.05$) and saw twice as many chronic disease patients ($P = 0.001$) and almost 170% more Medicare patients ($P < 0.001$) than bottom quartile performers, but did not experience significant improvements as their performance was already at the top of the distribution (average score for top/bottom performers was 95/68%). Physicians who improved most did not use the registry significantly more ($P = 0.32$) or have significantly different types of patients (Medicare $P = 0.53$, chronic disease $P = 0.15$) than those physicians who improved least (average score of most/least improved was 76/84%).
CONCLUSIONS: Information provision, even in real-time, is insufficient to improve performance. Change in performance is not well correlated with registry use as consistently high performers tended to use the registry more frequently than low performers. Future work should consider how to pair information provision with financial incentives.

REDUCING PRESCRIPTION DRUG SPENDING: A REVIEW OF POLICY OPTIONS G. Caleb Alexander[1]; Jeromie Ballreich[1]; Mariana Socal[1]; Taruja Karmarkar[1]; Antonio Trujillo[1]; Jeremy Greene[2]; Joshua Sharfstein[1]; Gerard F. Anderson[1, 1]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Johns Hopkins School of Medicine, Baltimore, MD. (Control ID #2705688)

BACKGROUND: High prices for pharmaceuticals have restricted access to branded drugs because some public programs are rationing care and many private insurers, including Medicare drug plans, are placing specialty drugs on high cost sharing tiers. Ongoing concerns over high prices and limited access to pharmaceuticals have generated a wide range of proposed solutions.
METHODS: We convened a small group of experts in the field and had them identify policy options that are available to reduce either branded drug costs or spending. Their discussion identified seminal articles. Based on these seminal articles, we constructed a preliminary list of policy options and key words that served as a format for conducting a structured literature review to identify additional policy options.
RESULTS: We identified forty-one solutions in the peer reviewed literature that can be classified into five broad categories: revising the patent system; encouraging research to increase development of new drugs; altering pharmaceutical regulation; decreasing market demand; and developing innovative pricing strategies. We discuss the rationale for these five approaches and summarize the proposed solutions. We also discuss four unresolved empirical issues are particularly important in any discussion of policy options.
CONCLUSIONS: Many have argued that the high levels of spending for branded prescription drugs are unsustainable. Others are more concerned about the problems many people have accessing the drugs they need or the impact on the health status of the population. Given the interest in the topic, it is likely that one or more of the policy proposals will be implemented in the coming months and years. However, it is likely that no single policy alternative will be a clear "winner". Resolution of specific empirical issues that we identify may assist policymakers to select policies that are most likely to achieve their stated aims while minimizing the likelihood of unintended consequences.

REFERRING COMPLEX PATIENTS FOR CARE MANAGEMENT: WHICH PATIENTS? Maria E. Garcia[2]; Richard W. Grant[1]; Connie S. Uratsu[1]. [1]Kaiser Permanente Northern California, Oakland, CA; [2]University of California, San Francisco, San Francisco, CA. (Control ID #2706158)

BACKGROUND: A large and increasing proportion of health care costs are spent caring for a small segment of medically and socially complex patients. To date, it has been difficult to identify which patients are best served by intensive care management. The objective of this study was to characterize factors that identify which complex patients are most suited for intensive care management.
METHODS: We conducted a mixed-methods study involving 35 care managers (CMs; 10 licensed social workers and 25 registered nurses) working in intensive care management programs within Kaiser Permanente Northern California (KPNC) outpatient medical centers. CMs reviewed a randomly selected list of ≤ 50 patients referred to them in the prior year and categorized patients as, 1) "good candidates" for care management, 2) patients "not needing" intensive care management, and 3) patients "needing more" than current care management could provide. After categorizing patients, researchers conducted semi-structured interviews to understand how CMs separated patients into the 3 groups.
RESULTS: Of the 1178 patients reviewed by CMs, less than two-thirds (62%) of referred patients were considered "good candidates", with 18% were categorized as "not needing" care management, and 19% "needs more." Patients considered "Good Candidates" for referral were older (76.2 years vs. 73.2 for "Not Needing" and 69.8 for "Needs More", $p < 0.001$); and these patients ($n = 736$) tended to be intermediate between "Not Needing" ($n = 216$) and "Needs More" ($n = 226$) in prior year utilization, costs, and admissions ($p < 0.001$). In qualitative analyses,

CMs discussed 346 unique, representative patients (176 “Good Candidates”, 76 “Not Needing”, and “94 “Needs More”). Four major themes emerged regarding appropriate referral: 1) Availability of social support, 2) Trajectory of medical condition, 3) Patient motivation, and 4) Psychiatric or Substance Use issues.

CONCLUSIONS: Current electronic medical records and intakes may not be capturing characteristics that indicate appropriateness for care management. To improve referral processes, measures of patient agency, motivation and availability of adequate social support need to be developed.

RELATIONSHIP BETWEEN ANXIETY AND SELF-MANAGEMENT BEHAVIORS OF PATIENTS WITH CHRONIC OBSTRUCTIVE LUNG DISEASE Esperanza Morales-Raveendran[1]; Ayerim Pichardo[1]; Kimberly A. Muellers[1]; Li Chen[1]; Rachel O'Conor[2]; Michael S. Wolf[2]; Alex Federman[1]; Juan Wisnivesky[1]. [1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Northwestern University, Chicago, IL. (Control ID #2705577)

BACKGROUND: Chronic obstructive pulmonary disease (COPD) is a debilitating respiratory disease that requires adherence to self-management tasks, like routine visits, consistent medication use, and acceptance of influenza vaccines, to maintain disease stability. Comorbid conditions may complicate a person's ability to manage their COPD. Comorbid anxiety has a detrimental impact on self-management among patients with some chronic diseases, however, there is limited knowledge regarding the impact of this mental health condition on COPD self-management behaviors.

METHODS: Our study enrolled current or prior smokers with a physician diagnosis of COPD. Participants were recruited from outpatient and inpatient settings of the Mount Sinai Hospital (New York, NY) and Northwestern University Hospital (Chicago, IL). Research assistants administered a survey in English or Spanish. Routine care was assessed by self-report and included questions regarding routine checkups for COPD and whether a healthcare provider was in charge of their COPD care. The Medication Adherence Rating Scale (MARS) was used to assess medication adherence (a score ≥4.5 was considered good adherence). Influenza vaccination was collected via self-report using validated items. Participants were administered the PROMIS Emotional Distress/Anxiety scale to ascertain for symptoms of anxiety. PROMIS measure responses were summed to form raw scores and converted into T-scores (standardized score); clinically significant anxiety was defined as a T-score 1 SD above the population mean (i.e., >60). We conducted chi-square analyses to assess the relationship between anxiety and COPD self-management outcomes.

RESULTS: The study included 140 COPD participants (mean age 68 ± 8.6 years, 60% female, 36% Black, 20% Hispanic); 14% had anxiety. COPD patients with anxiety were less likely than those without anxiety to have routine checkups for COPD (53% vs. 83%, $p = 0.002$) and less likely to have a healthcare provider in charge of their disease (63% vs. 88%, $p = 0.004$). There were no significant relationships between anxiety and COPD medication adherence (58% vs. 42%, $p = 0.19$) or routine influenza vaccination in the past 12 months (79% vs. 87%, $p = 0.37$).

CONCLUSIONS: In this sample of patients with COPD, those with above average symptoms of anxiety were significantly less likely to have routine care for COPD. However, medication adherence or influenza vaccinations were not related to level of anxiety. Further research is needed to assess if anxiety symptoms are related to other self-management behaviors among COPD patients and explore whether targeting anxiety symptoms can help improve COPD outcomes.

RELATIONSHIP BETWEEN PSYCHOLOGICAL WELL-BEING AND PATIENT SATISFACTION WITH PHYSICIANS DURING HOSPITALIZATION. Muhammad Mubbashir Sheikh[3]; Mukta Panda[1]; Rehan Qayyum[2, 4]. [1]University of Tennessee, Chattanooga, TN; [2]University of Tennessee College of Medicine, Chattanooga, TN; [3]University of Tennessee College of Medicine, Chattanooga, Chattanooga, TN; [4]Virginia Commonwealth University, Richmond, VA. (Control ID #2687882)

BACKGROUND: While studies in the ambulatory care setting have found that patients with high level of psychological well-being have high satisfaction with their physicians, no study has evaluated the relationship between psychological well-being and satisfaction with physicians in hospitalized patients. Therefore, we examined the relationship between a patient's psychological well-being and patient's satisfaction with physicians during hospitalization.

METHODS: Hospitalized patients older than 18 years and who provided consent were asked to complete a questionnaire. The questionnaire collected information on patient's age, gender, and race and included the following two validated tools: Brief Inventory of Thriving (BIT) for psychological well-being and TAISCH for measuring satisfaction with physicians in hospitalized patients (TAISCH). Patient satisfaction was further assessed using an internally developed 5-question satisfaction tool. The scores on three tools were rescaled such that the change in satisfaction scores represented the percentage change in in BIT score. The effect of psychological well-being on patient satisfaction was examined using mixed linear models to account for correlation in observations due to patients seen by the same physician. All analyses were performed in R 3.1.1 using 'lme4' package.

RESULTS: Of the 357 patients, 199 (55%) were females and 47 (13.1%) were African Americans. Mean (SD) age of the patients was 54.5 (19) years. These patients were seen by 122 physicians (range = 1 to 13 patients per physician). In unadjusted analysis, we found a robust and positive association of patient satisfaction with BIT score. A high BIT score correlates with high psychological well-being. After adjusting for patient's age, sex, and race mean BIT score remained significantly associated with patient satisfaction on both questionnaires. Each one percent increase in BIT score was associated with 0.26% (95% CI = 0.17 to 0.35%; $P < 0.001$) increase in TAISCH score and 0.31% (95% CI = 0.19 to 0.42%; $P < 0.001$) increase in internally developed 5-question satisfaction tool.

CONCLUSIONS: We found a statistically significant direct association between psychological well-being as measured by BIT score and patient satisfaction with physicians during hospitalization. Our findings suggest that methods to improve patients' psychological well-being may also improve patient satisfaction with their physicians.

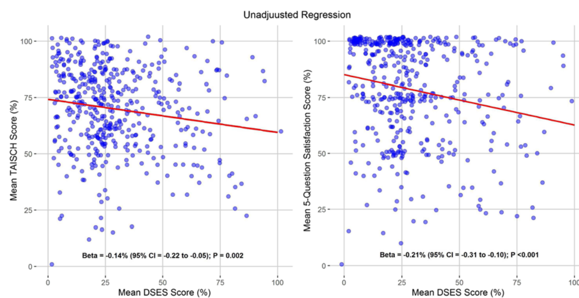
RELATIONSHIP BETWEEN SPIRITUALITY AND PATIENT SATISFACTION WITH PHYSICIANS DURING HOSPITALIZATION: RESULTS FROM THE SPIRITUALITY AND HOSPITALIZATION EXPERIENCE OF PATIENTS STUDY (SHEPS) Anna-Carson R. Uhelski[2]; Mukta Panda[1]; Rehan Qayyum[2]; Muhammad Mubbashir Sheikh[1]. [1]University of Tennessee, Chattanooga, TN; [2]University of Tennessee College of Medicine, Memphis, TN. (Control ID #2671538)

BACKGROUND: Studies have shown a direct relationship between patient satisfaction and patient adherence with favorable patient outcomes. While several physician and patient characteristics show an association with patient satisfaction, the effect of patient's spirituality on patient satisfaction has not been examined.

METHODS: Hospitalized patients older than 18 years, who provided consent, were asked to complete a questionnaire. The questionnaire collected patient age, gender, and race and included two validated tools: Daily Spiritual Experience Survey (DSES) and a validated patient satisfaction tool for hospitalized patients (TAISCH). Patient satisfaction was further assessed using an internally developed 5-question satisfaction tool. The scores on three tools were rescaled such that the change in satisfaction scores represented percentage change in scores for one percentage change in DSES score. Mixed linear regression models were created to examine the effect of spirituality on patient satisfaction to account for correlation in observation due to groups of patients seen by the same physician. All analyses were performed in R 3.1.1 using 'lme4' package.

RESULTS: We surveyed 469 patients: 260 (55%) females, 55 (11.7%) African Americans. Mean age of the patients was 52.3 years. Patients were seen by 170 physicians (range = 1 to 16 patients per physician). In unadjusted analysis, we found a strong, negative association of patient satisfaction with DSES score. A low DSES score correlates with high spirituality. After adjusting for patient's age, sex, and race, mean DSES score remained significantly associated with patient satisfaction on both questionnaires. Each one percent increase in DSES score was associated with −0.13% (95% CI = −0.22 to −0.04%; $P = 0.005$) decrease in TAISCH score and −0.20% (95% CI = −0.31 to −0.10%; $P < 0.001$) decrease in internally developed 5-question satisfaction tool.

CONCLUSIONS: We found a statistically significant inverse association between DSES score and patient satisfaction with physicians during hospitalization. These findings will add to current research developing methods of training physicians in confronting spiritualty. Our results suggest that addressing spiritual needs of patients during hospitalization may improve satisfaction with their physicians.



Scatter plots showing relationship between mean DSES scores and Patient satisfaction using TAISCH questionnaire (A) and five-domain questionnaire (B) with superimposed regression lines.

RELATIONSHIP OF PROCESS MEASURES TO SYSTEM OUTCOMES AND SAVINGS IN ACCOUNTABLE CARE ORGANIZATIONS

Alexander Bain[1]; Joshua M. Liao[1, 1]; Carrie H. Colla[2]; Valerie Lewis[2]; Amol S. Navathe[1, 1]. [1]University of Pennsylvania, Philadelphia, PA; [2]Dartmouth University, Hanover, NH. (Control ID #2705928)

BACKGROUND: Medicare started the Accountable Care Organizations (ACOs) program to control healthcare spending and improve quality through the incentive of shared savings. Early results have demonstrated modest cost savings and quality improvements from ACOs thus far. While process-oriented quality measures are more actionable targets than outcome measures and spending and count equally toward overall quality and shared savings eligibility, it is unclear if better performance on process measures is associated with system level quality outcomes and overall cost.

METHODS: Our objective was to evaluate how performance on ACO process measures relates to other measures of performance using a national sample of ACOs that have completed their third performance year (PY3) in the Medicare Shared Savings Program (MSSP). We used latent class analysis-based clustering (LCA) on the thirteen PY3 process-oriented measures to derive groups with high, intermediate, and low performance. We then analyzed the association between these groups and subsequent system outcome measures and spending.

RESULTS: 191 MSSP ACOs with 3,837,939 attributed beneficiaries had complete PY3 data for 2015 and were clustered by LCA into high ($n = 84$), intermediate ($n = 46$), and low ($n = 61$) performance groups that were significantly different across all 13 process measures (e.g., rate of pneumococcal vaccination 79.31 vs. 57.23 vs. 56.02, $P < 0.001$). Between the three clusters there were no significant differences in number of beneficiaries, sex, beneficiaries over 85 years old, or number of primary or specialist physicians per beneficiary, but ACOs in the high performing group had lower HCC risk scores (1.06 vs. 1.11 vs. 1.09, $P = 0.01$). Inclusion in the high performing group was associated with better performance in terms of system outcomes (risk adjusted all condition readmission 14.73 vs. 15.19 vs. 14.90 percent, $P = 0.002$; rate of unexpected COPD or asthma admissions 1.06 vs. 1.22 vs. 1.14 percent, $P = 0.03$; admissions for diabetic beneficiaries 51.98 vs. 56.38 vs. 56.51, $P = 0.002$). However, when evaluating changes in performance over the entire program period, the high performance process measure group did not have significantly improved system outcomes (e.g., change in all condition readmissions 0.09 vs. -0.03 vs. -0.12, $P = 0.17$). Moreover, the association between process measures and performance did not hold true for ACO spending in PY3 (percent spending above benchmark 1.47 vs. 1.78 vs. 1.28, $P = 0.93$) or across the program period (change in percent spending over benchmark 0.27 vs. 2.59 and 0.64, $P = 0.14$).

CONCLUSIONS: ACOs that performed highly on process measures also performed better on system level outcome measures. However, ACOs in the highest performing cluster did not experience significant changes in performance relative to their peers in system level quality metrics or spending over the program period.

RELATIONSHIP-AMONG PERCEPTIONS OF TEAM DYNAMICS SAFETY CULTURE AND CARE COORDINATION IN PRIMARY CARE

Karen J. Blumenthal[3, 1]; Alyna T. Chien[1, 1]; Sara Singer[2, 1]. [1]Harvard Medical School, Boston, MA; [2]Harvard School of Public Health, Boston, MA; [3]Massachusetts General Hospital, Boston, MA. (Control ID #2703675)

BACKGROUND: The safety of primary care needs improving, especially with increasing numbers of safety events and malpractice claims stemming from primary care. Studies have demonstrated that creating high-performing teams can improve patient safety and encourage a culture of safety within hospital settings, but few studies have examined this relationship in primary care. The objective of this study was to examine how team dynamics relate to perceptions of safety culture in primary care and whether care coordination, which in theory enables safer care through improved communication, plays an intervening role

METHODS: We conducted a cross sectional study using survey data from all patient-facing staff working at 19 Harvard Medical School affiliated primary care practices participating in the Harvard Academic Innovations Collaborative. The

survey included 3 domains: Team Dynamics (using a 33-item validated instrument), Care Coordination (5-items), and Perceptions of Safety Culture (4-items). All items were measured on a 5-point Likert scale (1 = strongly disagree, 5 = strongly agree). We used linear regression clustered by practice site to assess the relationship between team dynamics and perceptions of safety culture first without and then with care coordination in the model. We used a Sobel test to determine whether the reduction in the effect of team dynamics on perceptions of safety culture by care coordination was significant.

RESULTS: We received 1082 responses (63% response rate) from 256 attendings, 253 residents, and 573 other patient-facing providers. While mean (SD) ratings of team dynamics and of perceptions of safety culture were both moderately positive (3.79 [0.60] and 3.85 [0.72], respectively), care coordination ratings were more neutral and more varied (3.53 [0.89]). In regression models without care coordination, every one point increase in team dynamics was associated with a 0.75-point increase in positive perceptions of safety culture ($p < 0.001$). After adding care coordination to the base model, every one point increase in team dynamics was associated with a 0.73-point increase in perception of safety culture ($p < 0.001$). The decrement in the effect of team dynamics on perceptions of safety culture when care coordination was added to the model was significant (Sobel test $p < 0.001$), suggesting that the association between team dynamics and perceptions of safety culture is partially mediated by care coordination.

CONCLUSIONS: We found a significant and positive relationship between team dynamics and primary care staff perceptions of safety culture; this positive relationship was partially mediated by care coordination. These findings support the notion that investing in teamwork in the primary care setting can have a positive effect on safety culture. Future work should examine the relationship between team dynamics and patient safety outcomes in primary care and clarify the role of care coordination can play in achieving patient safety goals.

RELATIONSHIPS BETWEEN LUNG CANCER MORTALITY AND SMOKING, EDUCATION AND POVERTY IN A RURAL STATE

Kathleen Fairfield[1]; Adam Black[1]; Kimberly Murray[1]; Erika Ziller[2]; Leo B. Waterston[1]; F L. Lucas[1]; Paul Han[1]. [1]Maine Medical Center, Portland, ME; [2]University of Southern Maine, Portland, ME. (Control ID #2700056)

BACKGROUND: Lung cancer is the leading cause of cancer-related mortality. In rural states, services aimed at lung cancer prevention such as smoking cessation may not be available to the areas at highest risk. We sought to describe regional differences in lung cancer mortality and the relationship between lung cancer mortality, smoking, education and poverty across small geographic regions to inform local outreach for prevention and screening.

METHODS: We conducted a population-based cross-sectional analysis of: 1) lung cancer deaths in Maine from 2010–2014, ascertained by the state death registry; 2) smoking prevalence 3) education and (4) income, all ascertained by the Behavioral Risk Factor Surveillance System (BRFSS). Analyses examined small-area geographic variation in and association between all of these factors at the Hospital Service Area (HSA) Level, focusing on identifying predictors of lung cancer mortality. We defined low education as not having completed high school, and poverty as household income less than $15,000 annually.

RESULTS: Among 784,873 adults aged 35+ in Maine HSAs, 4635 died of lung cancer between 2010–2014. Lung cancer mortality rates (age and sex adjusted) varied markedly by HSA, ranging from 61.3 to 165.7 deaths per 100,000 person-years. There were marked differences across the 32 Maine HSAs in rates of smoking (range 12.4 to 28.6%), low education (4.7%-17.0%) and poverty (4.4 to 21.1%). We observed strong correlations between regional prevalence of smoking, poverty, low education, and lung cancer mortality (Table).

CONCLUSIONS: There is substantial small-area geographic variation in lung cancer mortality, smoking, and sociodemographic characteristics, which are all strongly correlated with one other. Efforts to improve prevention and screening for lung cancer should include targeting high risk areas with innovative engagement strategies that address social determinants of health.

Table: Correlation Matrix for Lung Cancer Mortality, Smoking, Poverty, and Education

Lung cancer mortality			
0.63	Smoking		
0.61	0.76	Poverty	
0.49	0.67	0.73	Low Education

RESIDENT EXPERIENCES WITH A PROGRAM TO SUPPORT ACADEMIC SCHOLARSHIP DURING INTERNAL MEDICINE RESIDENCY TRAINING

Andrea Carter[1]; Timothy Anderson[5]; Keri L. Rodriguez[2]; Kristina L. Hruska[2]; Shanta M. Zimmer[4]; Carla Spagnoletti[1]; Alison Morris[3]; Wishwa N. Kapoor[1]; Michael J. Fine[1, 2]. [1]University of Pittsburgh, Pittsburgh, PA; [2]VA Pittsburgh Healthcare System, Pittsburgh, PA; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA; [4]University of Colorado School of Medicine, Denver, CO; [5]University of California San Francisco School of Medicine, San Francisco, CA. (Control ID #2701959)

BACKGROUND: Scholarship is an essential component of residency training required by the Accreditation Council for Graduate Medical Education and identified by residents as influencing career choices and satisfaction. Leadership and Discovery (LEAD) is a program developed in 2012 as a component of the University of Pittsburgh Medical Center Internal Medicine (IM) Residency Program that requires all categorical residents to engage in mentored scholarship, generally carried out as a research project. The aims of this study were to compare the perceived value of LEAD among current and former participants and to identify facilitators and barriers to participation in the program.

METHODS: Our study sought information from the first 4 classes of IM residents participating in LEAD, including former graduates (started residency in 2012 & 2013) and current residents (started residency in 2014 & 2015). We surveyed all participants and conducted qualitative focus groups of purposeful samples from each class. The emailed survey contained 5-point Likert-scale questions (from 1 = very dissatisfied to 5 = very satisfied) regarding overall satisfaction with LEAD and its influence on future research plans. A qualitative methods expert led 6, 60-min focus groups (2 with graduates and 4 with current residents) to identify facilitators and barriers to participation and suggestions for improvement. Survey data were analyzed using Wilcoxon rank-sum and chi-square tests. Audiotaped focus groups were transcribed, then analyzed by 2 coders using the grounded theory approach of constant comparison.

RESULTS: Of 106 eligible residents, 78 (74%) completed the survey (40/52 graduates and 38/54 current residents). Graduates reported higher overall satisfaction with LEAD than current residents (median 3.5 vs 3.0, $p = 0.001$). Graduates agreed more frequently than current residents that participating in LEAD increased their likelihood of conducting future research (19/40 [48%] vs 7/38 [18%], $p = 0.008$). The 35 focus group participants (5–7 per group)

discussed common themes across groups ($n = \#$ of focus groups where we identified the theme). The most common facilitators were the desire for research experience to increase fellowship competitiveness ($n = 6$), using the residency advisor to identify a mentor ($n = 6$), and the aid of advice from an experienced mentor ($n = 6$). The most common barriers were time constraints from clinical duties ($n = 6$) and unclear expectations ($n = 5$). Suggestions for improvement were providing lists of available projects ($n = 5$) and mentors ($n = 5$) and clearly defining expectations ($n = 4$).

CONCLUSIONS: Compared to current residents, graduates reported higher overall satisfaction with LEAD and were more likely to agree that participating increased their likelihood of doing future research. Programs to support resident scholarship within IM residency should provide clear expectations and lists of "shovel-ready" projects and mentors for residents who face time constraints during clinical training.

RESIDENT OUTPATIENT INBOX MANAGEMENT IN A SINGLE ELECTRONIC HEALTH RECORD SYSTEM Anand D. Jagannath[4, 1]; Rosemarie Conigliaro[1]; William Southern[3]; Sheira Schlair[2]. [1]Albert Einstein College of Medicine, Bronx, NY; [2]Albert Einstein College of Medicine/ Montefiore Medical Center, Bronx, NY; [3]Montefiore, Bronx, NY; [4]Montefiore Medical Center, New York, NY. (Control ID #2702706)

BACKGROUND: Internal medicine residency training is weighted heavily towards inpatient care despite ACGME mandates for ambulatory exposure. Despite this imbalance, residents are expected to deliver effective primary care even when rotating on inpatient services. Electronic health records (EHR) brought hope of increased efficiency and quality of care; however its adoption has increased resident workload, duty hour violations, and led to decreased job satisfaction. It is unclear whether having separate EHR systems for inpatient and outpatient affects resident outpatient "inbox" management. This study aims to examine the impact of our institution's transition to a single EHR system on outpatient inbox management.

METHODS: 146 internal medicine residents at a large urban academic medical center were surveyed 6 months before and after transition to a single EHR system (previously separate EHRs). Residents self-reported their outpatient inbox practices (frequency of response to patient requests, mode of communication, note completion) and gave qualitative feedback as well. Student t-tests and Chi-squared tests were used to detect the statistical significance of observed differences. Logistic regression models were used to adjust for year in residency.

RESULTS: 66 (45.20%) and 77 (52.73%) of surveyed residents completed the pre-transition and post-transition surveys, respectively. PGY-1 residents accounted for the majority of responses (33.3 and 41.8%). Residents checked their outpatient inboxes and responded to patient needs more frequently while on inpatient rotations with a single EHR (25.6% vs 10.4%, $p = 0.019$). Outpatient note completion within two days of a patient visit increased (88.5% vs 70.2%, $p = 0.006$) as did the use of letters to communicate normal laboratory or imaging results to outpatients (67.9% vs 34.3%, $p < 0.001$). These tasks were completed during work hours more often (66.7% vs 38.81%, $p = 0.001$) with the single EHR. Adjustment by post-graduate year did not change any significant associations found. Residents who infrequently checked their inboxes on non-ambulatory rotations prior to the single EHR cited the need to open an extra EHR as a barrier; after transition, most residents stated that the barrier to inbox management was time constraints of inpatient rotations.

CONCLUSIONS: Outpatient inbox management improved with the use of a single EHR. Outpatient tasks were completed more often during work hours which may suggest an improvement in both duty hour compliance and quality of life. Further studies are needed to better characterize quality of life, job satisfaction, and a more optimal balance between inpatient and outpatient training.

RESIDENT PERCEPTIONS OF COST-EFFECTIVE CARE AFTER INTERNATIONAL HEALTH ELECTIVES: A QUALITATIVE STUDY. Hannah C. Nordhues; M. U. Bashir; Adam P. Sawatsky; Stephen P. Merry. Mayo Clinic, Rochester, MN. (Control ID #2703883)

BACKGROUND: The US spends more money per capita on health care than any other country. Most experts agree that the rising costs are unsustainable. One solution to this problem is teaching cost-effective care to physicians in training. Multiple studies have identified cost-effectiveness as an educational benefit of international health electives (IHE), but no study has analyzed residents' perspectives on cost-effective care after participation in IHEs. We aimed to explore residents' perceptions regarding cost-effective care after participation in an IHE.

METHODS: We conducted a thematic analysis of resident post-rotation reports to explore their perceptions of cost-effective care. The Mayo International Health Program provides residents an opportunity to participate in IHEs during training. Upon completion of their IHE, each participant is required to submit a reflective essay describing the experience and its personal and professional impact. We included all reflective reports between 2001 and 2014 ($n = 377$). We created a codebook *a priori* from the ACGME core competencies. Within the code of system-based practice, we identified a unique code of cost-effective care. Within this code, we analyzed the quotations to identify major themes.

RESULTS: We analyzed 377 reports by residents and fellows training in 40 medical and surgical specialties who visited 56 countries. The necessity of cost restraint in low-resource environments was a stimulus for reflection on cost-effectiveness. Within reflections, we identified 4 themes regarding residents' perceptions on cost-effective care: judicious use of resources; transparency of healthcare costs; step-wise approaches to treatment; and less fear of litigation. Residents experienced more judicious use of resources, and their decisions on testing and treatment were scrutinized. With this approach, they perceived less medical waste and residents relied more on clinical skills. Costs of tests were posted and discussed freely, and extra testing was seen as "food off the patient's table." They saw the lack transparency or "cost-awareness" in the US as a barrier to cost-effectiveness. Residents experienced more step-wise approaches to treatment, starting with empiric treatments for common diseases, with further testing only if the patient did not improve. Residents felt this approach was possible due to less fear of litigation driving "just in case" testing.

CONCLUSIONS: IHEs provide an opportunity for residents to reflect upon cost-effective care. While limited resources can lead to inadequate health care, residents identified benefits from the necessity of cost restraint. Given the unsustainable health care costs in the US, physicians need to adopt a similar urgency in using and teaching cost-restraint. Emphasizing judicious use of resources, ensuring transparency of costs, encouraging step-wise, empiric approaches to treatment, and reducing fear of litigation may help frame future education on cost-effective care.

RESIDENT PERSPECTIVES OF FIRM ROUNDS: A QUALITATIVE STUDY OF A NOVEL APPROACH TO THE TRANSITION OF PATIENT CARE FROM NIGHT TEAMS TO DAY TEAMS Jeremy I. Schwartz[1]; Allen Shih[1]; Nicola Hawley[2]; Andre N. Sofair[1]. [1]Yale School of Medicine, New Haven, CT; [2]Yale School of Public Health, New Haven, CT. (Control ID #2671291)

BACKGROUND: Transitioning the care of patients admitted to the hospital overnight between teams of medical residents often takes place without patient involvement. Attention to quality and safety as well as resident education is also highly variable during such handoffs. We introduced a new method of rounds to transition patients admitted by the night teams to the day teams. 'Firm Rounds' includes the members of one night team and two day teams and embodies three pillars: a patient-centered presentation of the history and physical at the bedside, a 'warm handoff' which includes introductions of the accepting day team by name and role, and the discussion of teaching points presented by one of the night team house officers. After implementing Firm Rounds for a year, we conducted the present study to assess its perceived impact on patient care, education, and quality and safety.
METHODS: We invited all residents in the Yale Primary Care Program to participate in this cross sectional, qualitative study. Twenty residents and recent graduates completed a semi-structured interview that was conducted by one of two student research assistants. Interviews were audio recorded and transcribed. Initial codes for the analysis were developed after an initial reading of all transcripts and were based on the interview guide questions and emergent themes from the data. Three reviewers each independently reviewed multiple transcripts, refining and discussing the codes until a final codebook was agreed upon and consensus reached on coding. A thematic analysis was conducted to identify salient themes in the data.
RESULTS: Residents felt that Firm Rounds improved the doctor-patient relationship since patients witness and participate in the transition of their care and have the opportunity to ask questions and make corrections. However, residents did express concerns about the large number of providers at the bedside, patient privacy in double rooms, and patients' ability to refuse having these rounds at the bedside. Residents felt that Firm Rounds enhanced their learning, given the frequent sharing of multiple clinical perspectives and the discussion of teaching points, though factors such as the night resident's dedication to teaching, quality of attending input, and clinical distractions led to variability of their learning. Finally, residents perceived distinct positive impacts from Firm Rounds on quality of care and patient safety, specifically in the domains of improved continuity of care, warm handoffs, and greater number of providers aware of each patient's clinical status.
CONCLUSIONS: This study identified perceived strengths and limitations of Firm Rounds by residents in our teaching program. Firm Rounds is generally appreciated by trainees and is seen as positively impacting education and patient care. Our findings will be further informed by a concomitant study of patient perspectives of Firm Rounds. Firm Rounds serves as a model that can be adopted and implemented by other residency programs.

RESIDENT PHYSICIANS' PERSONAL HEALTH CARE BEHAVIORS AND RESIDENT-IDENTIFIED BARRIERS TO HEALTH CARE ACCESS Ashley H. Snyder[2]; Katelin Mirkin[2]; Melissa B. Linskey[2]; Jennifer McCall-Hosenfeld[1]. [1]Penn State College of Medicine, Hershey, PA; [2]Penn State Milton S. Hershey Medical Center, Hershey, PA. (Control ID #2706891)

BACKGROUND: Resident physicians face demanding work schedules, financial constraints, and relationships of power imbalance with colleagues which may present barriers to accessing health care and affect well-being. The Accreditation Council for Graduate Medical Education emphasizes the importance of resident well-being, including psychological, emotional and physical health, and specifies that residents must be given the opportunity to attend to their health, even during scheduled work hours. However, little is known about resident health care behaviors and perceived barriers to health care access. We aim to address the knowledge gap in this area.
METHODS: A survey was distributed to 486 residents at a single, tertiary-care, academic medical center. Residents were asked to rate how high they prioritize caring for their own health. Barriers to care were based on prior publications and were measured in three ways: residents were asked (1) to rate how difficult it is to find time to access preventive and acute health care, (2) if there was a time in the past year when they needed to see a physician but could not, (3) rate a list of barriers to accessing care. We report frequencies for demographics and binary items and mean rating for scale-based items. Differences between specialties were compared using Chi-square test.
RESULTS: There were 110 survey responses (response rate 23%) of whom 64% were married 77% white, and 52% female. Residents placed low priority on caring for their own health (mean 4, scale: 1 = low, 10 = high). Residents reported difficulty accessing care for preventive health (mean 7.5) and acute illness (mean 7.1, scale: 1 = easy, 10 = very difficult). Nearly half of residents (46%) reported a time in the past 12 months when they needed to see a doctor but were unable. Residents often used self-diagnosis/treatment due to barriers accessing care (mean 7.3, scale: 1 = never, 10 = very often). Residents perceived "finding time" (mean 9.3) and "cost of lost work time" (mean 6.7, scale: 1 = minor, 10 = major) to be the largest barriers to accessing routine care for all specialty types. Medicine/other residents were significantly more likely to consider "I may have to see someone I know from work" (mean 5.3, $p = .03$) a barrier compared to surgery and anesthesia residents. Residents rated that rapid referral access (mean 8.6) and rapid/walk-in access to preventive care (mean 8.3, scale: 1 = not useful, 10 = very useful) would be most helpful in eliminating perceived barriers.
CONCLUSIONS: Resident physicians find it difficult to access health care when needed. Our findings demonstrate that residents place low priority on their personal health needs. This may be due to a misaligned culture in residency training in which resilience is perceived as prioritizing patient care and work obligations over personal well-being. Future studies further exploring the culture of residency training will be important in order to reduce barriers to health care access for residents.

RESIDENTIAL SOCIOECONOMIC, FOOD AND BUILT ENVIRONMENTAL CHARACTERISTICS ARE ASSOCIATED WITH GLYCEMIC CONTROL AMONG ADULTS WITH DIABETES IN NEW YORK CITY Bahman Tabaei[4]; Andrew Rundle[2]; Winfred Y. Wu[4]; Carol R. Horowitz[3]; Victoria L. Mayer[1]; Daniel Sheehan[2]; Shadi Chamany[4]. [1]Icahn School of Medicine at Mount Sinai, Brooklyn, NY; [2]Mailman School of Public Health, New York, NY; [3]Mount Sinai School of Medicine, New York, NY; [4]New York City Department of Health and Mental Hygeine, NYC, NY. (Control ID #2703104)

BACKGROUND: Residential environment may be related to diabetes incidence and prevalence, but it is unclear whether it directly contributes to diabetes control. There is little, if any prospective evaluation of whether cumulative

exposures to specific residential features are associated with glycemic control in persons with diabetes in a large multiracial, multiethnic cohort. We aimed to determine whether residential environment factors are associated with glycemic control in individuals with diabetes, and whether residential resources supporting high quality environments are associated with better glycemic control.

METHODS: The team conducted a longitudinal analysis of data from 182,756 adult residents of New York City with diabetes (at least two hemoglobin A1c tests ≥6.5%), and defined glycemic control as hemoglobin A1c (A1C) <7%. We utilized 7 years of data from the NYC Department of Health and Mental Hygiene's A1c registry, which contains the A1C test results from all NYC residents, These are reported to the Department under the local health code. After constructing measures of NYC residential environments, we performed factor analysis to formulate a residential composite score that divided residential areas into quintiles with the lowest and highest quintile areas reflecting the least advantaged and most advantaged environments respectively.

RESULTS: Several residential-level environment characteristics were positively associated with glycemic control. These included more advantaged socioeconomic conditions (lowest poverty rates, homicides and linguistic isolation, highest median income, education levels and % White), greater ratio of healthy and neutral food outlets to unhealthy food outlets, and greater residential walkability. Individuals who lived continuously in the most advantaged residential areas had significantly higher odds of glycemic control (OR = 2.59) and shorter time to achieve glycemic control (HR = 1.14) compared to the individuals who lived continuously in the least advantaged residential areas. Moving from less advantaged residential areas to more advantaged residential areas was related to improved diabetes control (0.38% decrease in A1C), while moving from more advantaged residential areas to less advantaged residential areas was related to worsening diabetes control (0.34% increase in A1C).

CONCLUSIONS: This analysis found an association between socioeconomic, food and built environments, and glycemic control, after controlling for environmental and individual level covariates. These results are consistent with the hypothesis that residential areas with greater resources to support healthy food, residential walkability and high socioeconomic environments are associated with glycemic control in persons with diabetes. Further research is needed to increase the confidence of the associations observed in the current study, as such findings have important implications for urban policy and population health improvement efforts.

RESILIENCE AMONG LGBT HEALTHCARE PROFESSIONALS

Carl G. Streed[1]; Michele Eliason[2]. [1]Brigham & Women's Hospital, Boston, MA; [2]San Francisco State University, San Francisco, CA. (Control ID #2670822)

BACKGROUND: Much has been written about the challenges of adopting a minority sexual or gender identity, from the stresses of disclosing to parents and family, to dealing with bullying in schools, and to coming out in the workplace. One area that has been neglected to date is how individuals deal with the stress of being lesbian, gay, bisexual or transgender as a healthcare professional. This pilot study was the first to study stress and resilience among lesbian, gay, bisexual, and transgender (LGBT) healthcare professionals, who must learn and work in environments that are often unfriendly or ignorant about LGBT issues.

METHODS: An online survey was distributed among professional networks of LGBT healthcare professionals.

RESULTS: Among 277 healthcare providers from diverse disciplines, fewer negative events are occurring in the workplace than previously reported. However, most settings still lack any training on LGBT issues and their nondiscrimination policies do not include gender identity. Approximately a quarter respondents had low levels of resilience; they reported more stress, greater frequency of consequences of stress on mental health, physical health, job satisfaction, and burnout. However, their work environments were similar to resilient respondents in terms of welcoming and inclusive policies. Despite similar overall levels of support to manage stress, low resilient respondents reported less support from coworkers and bosses/supervisors than resilient respondents.

CONCLUSIONS: Positive events, such as pro-LGBT comments and appropriate treatment of LGBT patients and families were much more common than negative events. However, we found that there are still unacceptably high levels of discriminatory policies and workplace harassment and differential treatment that can adversely affect LGBT healthcare professionals. This study identifies opportunities for increasing the joy in medicine and well-being of LGBT healthcare providers, including support from supervisors, updating institutional policies to include sexual orientation and gender identity, and providing support to attend LGBT organizations.

RESILIENCE AND GRIT IN THE MICROBIAL WORLD: STREPTOCOCCUS PYOGENES BACTEREMIA IN ADULTS IN THE 21ST CENTURY. REVIEW OF 68 EPISODES OVER A 10-YEAR PERIOD IN A LARGE COMMUNITY TEACHING HOSPITAL.

Jacob Hupp[2]; Joseph P. Myers[1]. [1]Summa Health System, Barberton, OH; [2]Summa Health System, Ravenna, OH. (Control ID #2694618)

BACKGROUND: *Streptococcus pyogenes* causes pharyngitis, tonsillitis, cellulitis and less frequently other clinical syndromes. It is infrequently included in the differential diagnosis of other infectious illnesses. *S. pyogenes* is also an organism without a vaccine. As physicians encounter fewer illnesses caused by vaccine-preventable organisms such as *Streptococcus pneumoniae* and *Haemophilus influenzae*, the void may be filled by *S. pyogenes*.

METHODS: To determine the frequency of bacteremic *S. pyogenes* infection at our teaching hospital, we reviewed the medical records of all adult patients (16 years of age and older) with *S. pyogenes* bacteremia (SPB) admitted to our institution during the almost 10-year period from January 1, 2007 to November 30, 2016. We report the epidemiology, source of infection, comorbid conditions, treatment and mortality for these patients.

RESULTS: There were 68 cases of SPB during the study period with a bimodal distribution of cases with peaks in spring and early winter. There were 26 episodes (38.2%) in the first five years and 42 episodes (61.8%) in the final five years of the study, suggesting an increasing incidence of the disease. There were 27 episodes in men (39.7%) and 41 episodes in women (60.3%). The patients' ages ranged from 17 to 91 years with a mean of 58.1 years and a median of 59.5 years. The seventh decade had the highest occurrence of SPB (13 cases, 19.1%). Skin and soft tissue infections with or without necrotizing fasciitis were the most common presentation (29 cases. 42.6%), followed by primary bacteremia (10 cases, 14.7%), pneumonia (7 cases, 10.3%), septic bursitis/arthritis (7 cases, 10.3%), obstetric/gynecologic (5 cases, 7.3%) and head/neck infections (5 cases, 7.3%). Many patients presented to the hospital in septic shock. All patients received appropriate initial

antimicrobial therapy because of the exquisite sensitivity of *S. pyogenes* to various empiric antimicrobial regimens. All strains of *S. pyognes* tested during the study period maintained sensitivity to penicillin G. Diabetes mellitus was the most common comorbid condition. Despite rapid initiation of appropriate antimicrobial and surgical therapy, seven of 68 patients died for a mortality rate of 10.3%.

CONCLUSIONS: Bacteremic *S. pyogenes* infections appear to be increasing in frequency. Adult hospitalists should be keenly aware of this information and understand the potential consequences of unrecognized, rapidly progressive group A streptococcal infection including necrotizing fasciitis, meningitis, septic arthritis, pneumonia and puerperal/ gynecologic infection. Emergent surgical intervention remains essential to the survival of many of these patients.

RESILIENCE AND TOLERANCE OF UNCERTAINTY AMONG DEPRESSED AND BURNT OUT RESIDENTS: CROSS-SECTIONAL STUDY Arabella L. Simpkin[1, 2]; Alisa Khan[3]; Daniel West[4, 5]; Briana Garcia[3]; Theodore Sectish[3, 2]; Nancy D. Spector[6]; Christopher Landrigan[3, 2]. [1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Boston Children's Hospital, Boston, MA; [4]University of California, San Francisco, San Francisco, CA; [5]Benioff Children's Hospital, San Francisco, CA; [6]Drexel University College of Medicine, Philadelphia, PA. (Control ID #2706109)

BACKGROUND: Depression and burnout are highly prevalent among residents, but little is known about modifiable personality traits—such as resilience and tolerance of uncertainty—that may predispose to these conditions which have profoundly negative implications for physicians, patients, and the healthcare system. How to stem the rise of burnout in healthcare professionals is an important unanswered question with a growing need for targeted interventions in medical education. This study aims to determine how tolerance of uncertainty is related to resilience among residents and whether these attributes are associated with depression and burnout.

METHODS: The authors surveyed 86 residents from four urban freestanding children's hospitals in North America in 2015. Tolerance of uncertainty was measured using the Physicians' Reaction to Uncertainty Scale, resilience using the 14-item Resilience Scale, depression using the Harvard national depression screening scale, and burnout using single item measures of emotional exhaustion and depersonalization from the Maslach Burnout Inventory.

RESULTS: 50/86 residents responded to the survey (58.1%). Higher levels of stress from uncertainty were correlated with lower resilience ($r = -.60$; $p < 0.001$) (FIgure 1). 5 residents (10%) met depression criteria and 15 residents (31%) met criteria for burnout. Depressed residents had higher mean levels of stress due to uncertainty (51.6[9.1] vs. 38.7[6.7]; $p < 0.001$) and lower mean levels of resilience (56.6[10.7] vs. 85.4[8.0]; $p < 0.001$) compared to residents who were not depressed. Burnt out residents also had higher mean levels of stress due to uncertainty (44.0[8.5] vs. 38.3[7.1]; $p = 0.02$) and lower mean levels of resilience (76.7[14.8] vs. 85.0[9.77]; $p = 0.02$) compared to residents who were not burnt out.

CONCLUSIONS: We found strong correlations between tolerance of uncertainty, resilience, depression, and burnout. Evidence suggests that these attributes are states, not traits, and thus are amenable to change through educational and experiential processes. Efforts to enhance tolerance of uncertainty and resilience may provide opportunities to mitigate resident depression and burnout.

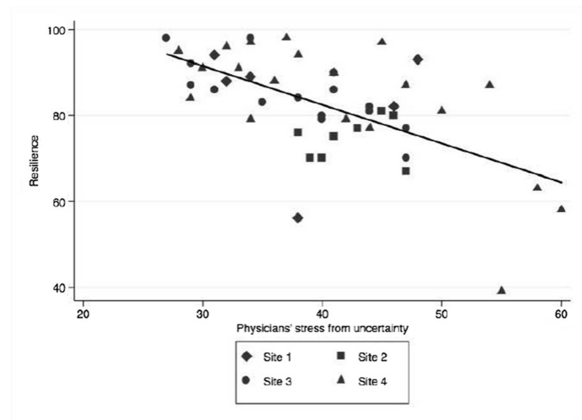


Figure 1 | **Correlation between resilience and physicians' stress from uncertainty.**

RESPONDING TO A NATIONAL READMISSIONS REDUCTION PENALTY PROGRAM FOR CHRONIC OBSTRUCTIVE PULMONARY DISEASE Valerie G. Press[1]; Tina Shah[1]; Ashley M. Snyder[1]; John Kim[1]; Michael Miller[1]; Edward Kim[1]; Samira Qadir[2]; Matthew M. Churpek[1]; Michael Howell[1, 2]; Steven R. White[1]. [1]University of Chicago, Chicago, IL; [2]University of Chicago Medicine, Chicago, IL. (Control ID #2702096)

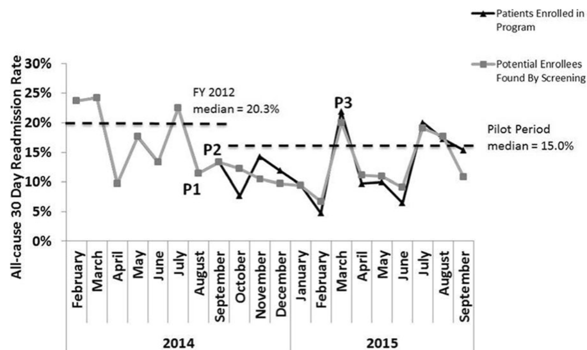
BACKGROUND: Hospitals now face penalties for excess readmissions for acute exacerbations of Chronic Obstructive Pulmonary Disease (AECOPD) under the Medicare Hospital Readmissions Reduction Program (HRRP) policy. To address this new policy, hospitals were required to implement programs despite limited evidence for guidance on effective interventions. We tested the feasibility of a hospital-based, comprehensive COPD integrated disease management program (IDMP) to reduce readmissions at our urban, academic hospital.

METHODS: Thirty-day readmissions were analyzed with run charts to study the program-level analysis among patients receiving the IDMP and with interrupted time series for the policy-level analysis for all COPD discharged patients. Participants were prospectively identified as likely hospitalized for COPD using a novel screening algorithm (program-level analysis) and retrospectively identified by administrative discharge codes for COPD (policy-level analysis). The inter-professional IDMP was delivered with components including: an inpatient COPD care pathway implemented by high-level providers, patient education that included self-management and inhaler technique, follow-up within 7 days of discharge, and a 24-hour access line for patients and emergency department providers post-discharge.

RESULTS: Of 592 patients identified for enrollment into the IDMP, 397 received the program. A run chart analysis demonstrated a decrease in the readmission rate with a seven-month shift below the median. When comparing all enrolled patients to a historical control population, there was no significant effect immediately or over time (OR 0.99, $p = 0.91$; OR 1.00, $p = 0.58$, respectively) on reduction of 30-day all-cause readmissions.

CONCLUSIONS: Our IDMP intervention targeting reduced readmissions among COPD patients demonstrates promise in evaluating the QI methods that show program effectiveness. Significant reductions in readmissions could

be demonstrated by QI measures (run chart analysis) but not when using adjusted analyses. Further, from a policy standpoint, a significant reduction could not be demonstrated using the IDMP. These results illustrate the potential danger of the Medicare HRRP penalty on national hospital readmissions policy, as moving the bar on readmissions will be effective only if these readmissions are preventable.



RETAINING RESIDENTS IN PRIMARY CARE FOR THE UNDERSERVED: PRIMARY CARING, RIGOR, AND COMMUNITY

Jasmine A. Ross[1]; Natasha Rastogi[2]; Lisa Altshuler[2]; Jennifer Adams[2]; Kathleen Hanley[4]; Richard E. Greene[2]; Les Chuang[2]; Sondra Zabar[2]; Mack Lipkin[3]. [1]NYU, Brooklyn, NY; [2]NYU School of Medicine, New York, NY; [3]New York University School of Medicine, New York, NY; [4]NYU, New York, NY. (Control ID #2705635)

BACKGROUND: As healthcare increases demands, primary care physicians need evidenced-based, patient-centered care coordination, effective use of information technology, interdisciplinary team functioning and shared decision-making skills more so in underserved areas. In 2008, we documented 20 years of the NYU/Bellevue Primary Care Internal Medicine Residency Program (NYUBPC) on readiness for practice[1]. In light of the recent primary care changes we assessed our recent training of Primary Care Residents in high quality, person-centered, systems-savvy, team-based care for the underserved. Specifically we aimed to: 1. Assess the NYUBPCP impact on graduate career choices, values and style 2. Elicit reflections that illustrate complexities in educating primary care physicians

METHODS: We surveyed 56 graduates of the NYUBPCP from 2007–2014. The 44 question survey included 12 open-ended questions about career path, current practice, preparedness for practice and specifics about how aspects of training provided necessary skills and knowledge. Responses were unidentified. We received 37 responses, (66%).

RESULTS: 36 respondents currently provide clinical care, with about 40% of their time spent in a primary care setting (S.D. 32%). On a 4-point scale 85% either agreed or strongly agreed with Primary Care as a career choice. 74% felt prepared for the challenges of a primary care practice, rating clinical experiences with underserved communities, and the psychosocial, clinical epidemiology and health policy focus as essential aspects of training. All but 4 provide care to medically underserved populations. They valued the community of peers and colleagues that the NYUBPCP provided. While 53% rated their clinical site as hectic/chaotic (4 or 5 on a 5 point scale), only 6% reported persistently feeling burnout. 19% reported at least one symptom of burnout. Qualitative analyses revealed overlapping themes in alumni perceptions of how residency influenced current practice, aspects of training that were difficult to implement and expectations for the future directions of primary care. Responses demonstrated a mismatch between the "purity" of primary care practice graduates strove to achieve after residency and the actuality of a practice influenced by external factors (e.g. time pressures, reimbursement issues and metric achievements). Some found it difficult to be involved with research or advocacy while in full-time clinical practice. Graduates believed the future of primary care lies in a team-based approach.

CONCLUSIONS: A training program emphasizing rigorous curriculum, committed role modeling, care of the underserved, and strong residency community for support continues to document high rates of retention in primary care. They are well adapted entering physicians with the skills and attitudes necessary to succeed in primary care and become educators of the next generation.

RETHINKING CERVICAL CANCER SCREENING QUALITY MEASURES: INCORPORATING FLEXIBILITY AND EFFICIENCY

Natasha Parekh; Julie M. Donohue; Jennifer Corbelli; Aiju Men; Marian Jarlenski. University of Pittsburgh, Pittsburgh, PA. (Control ID #2706240)

BACKGROUND: Monitoring cervical cancer screening quality measures is a priority for state Medicaid programs given that low-income women face increased risk for cervical cancer. The Healthcare Effectiveness Data and Information Set (HEDIS®) cervical cancer screening quality measure is defined as at least one cytology screen in 3 years among women 24–64 years or at least one cytology screen and HPV test in 5 years among women 35–64 years. There are potential flaws with current measures. First, they lack flexibility to allow for brief delays in screening. Second, they fail to recognize over-screening, which can lead to unnecessary procedures and treatment. Our objectives were to assess how adherence to 2009 cervical cancer screening guidelines changed based on a) adding window periods to intervals that define appropriate screening, and b) differentiating between appropriate and over-screening.

METHODS: Using Pennsylvania Medicaid claims data from 2007–2013 for women ages 18–64, we analyzed data stratified by age (<30 and ≥30 years) due to age-specific screening guidelines. We evaluated women who had pap exams (paps) between 11/1/09-4/30/10 and defined adherence by comparing time intervals between paps with guideline-based intervals. We defined adherence to current measures as under-screening and appropriate screening if the interval between paps was longer than and within guideline-based intervals, respectively, and adherence to alternative measures as under-screening, appropriate screening, and over-screening if the interval between paps was longer, within, or shorter than guideline-based intervals that included ±0, ±3, and ±6-month windows, respectively.

RESULTS: Our sample included 27,076 paps performed in 14,786 women. Based on current measures that do not include windows and that do not distinguish between over-screening and appropriate screening, 71% of women <30 and 65% of women ≥30 were appropriately screened and 29% of women <30 and 35% of women ≥30 were under-screened. With alternative measures that incorporate 0, 3 and 6-month windows and that differentiate between appropriate and over-screening, appropriate screening changed from 71 to 0

to 6 to 11% in <30-year-olds, and from 65 to 0 to 3 to 7% in ≥30-year-olds. Over-screening represented the majority (61-71%) of screening.

CONCLUSIONS: We observed up to an 11% increase in appropriate cervical cancer screening when including windows in performance measure definitions and up to a 71% decrease in appropriate screening when it was distinguished from over-screening. Because performance measures currently classify both appropriate screening and over-screening as measure compliance and are based on strict cutoffs without flexibility, they can incentivize providers to over-screen. A more comprehensive cervical cancer screening performance measure is needed to align with clinical guidelines, reduce unnecessary procedures, and reflect quality of women's health care.

REVISITING THE RESIDENT PRIMARY CARE PHYSICIAN PANEL: AN IMPORTANT CONSIDERATION IN PREVENTING BURNOUT IN GIM Utibe R. Essien; Jonathan R. Abraham; Kerri Palamara; Wei He; Steven J. Atlas. Massachusetts General Hospital, Boston, MA. (Control ID #2702639)

BACKGROUND: Ambulatory education for internal medicine (IM) residents is vital to training. Despite changes in continuity clinic models and increased time by residents in outpatient settings concern remains that their clinic experiences and panels do not reflect that of staff primary care physicians, creating additional stressors, burnout and negative attitudes toward primary care. We compared the characteristics of patients followed by resident and staff primary care physicians (PCPs) to determine if differences may identify potential targets for preventing burnout in residency.

METHODS: We used retrospective data from patients receiving care from IM residents and staff PCPs at 16 outpatient clinics affiliated with Massachusetts General Hospital from 2005–2015. A validated algorithm was used to attribute patients to resident and staff PCPs in 2015. Patient sociodemographic characteristics and comorbid conditions including age, gender, race/ethnicity, language, insurance status, health center status, area-based median household income and poverty level, education, practice site, physician complexity score and Charlson Index score were assessed.

RESULTS: Among all primary care patients, 10,538 (7.5%) were attributed to resident and 130,706 to staff PCPs. Compared to staff patients, resident patients were more likely to be male, African-American or Hispanic, receive Medicaid or be uninsured. Resident patients were more likely to live in low-income/poverty areas, less likely to speak English and less likely to have a college education. Resident patients also had higher comorbidity scores (*p*-values all < .0001) (Table 1).

CONCLUSIONS: Major differences in sociodemographic factors and comorbid conditions exist between resident and staff PCP patients, consistent with previous data. Compared to staff patients, resident patients were more ethnically diverse, medically complex and have a lower socioeconomic status. The impact of these sociodemographic factors along with the systematic limitations of caring for medically complex patients in the outpatient setting during residency may increase physician stress and burnout and ultimately result in poor patient outcomes. Further research is needed to explore the disparities in the characteristics of resident and staff PCP panels and the impact this may have on resident physician burnout.

Characteristics of Resident and Staff PCP Patients

Demographic Characteristics	Resident PCP Pateints *n* = 10,538	Staff PCP Patients *n* = 130,706	*p*-value

RIDESHARE-BASED MEDICAL TRANSPORTATION IMPROVES PRIMARY CARE SHOW RATES: A DIFFERENCE-IN-DIFFERENCE ANALYSIS OF A PILOT PROGRAM Krisda H. Chaiyachati[2]; Rebecca Hubbard[3]; Alyssa Yeager[4]; Brian M. Mugo[4]; Judy A. Shea[4]; Roy Rosin[1]; David Grande[4]. [1]Penn Medicine, Wayne, PA; [2]The University of Pennsylvania, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA; [4]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA. (Control ID #2705269)

BACKGROUND: Transportation to primary care is a major barrier for Medicaid patients despite access to non-emergency medical transportation (NEMT) insurance benefits. Rideshare services provided by Uber and Lyft have been proposed as potential NEMT alternatives because they are convenient and low cost. As part of a pilot-program, we designed a rideshare-based transportation intervention for Medicaid patients and tested whether primary care show rates improved.

METHODS: Our study population included adults living in West Philadelphia, and were Medicaid patients at one of two Penn internal medicine practices—an intervention and control clinic—within the same building. Intervention clinic patients with a scheduled appointment received a telephone reminder 2 days before and were offered free transportation to-and-from clinic using Lyft. Up to 3 attempts were made to contact the patient. For those who accepted, staff pre-scheduled a Lyft ride using a web-based dispatch tool, circumventing the need for patients to have a smartphone or app. To return home, patients called staff to dispatch a Lyft ride after their clinic visits. Control clinic patients received an appointment reminder 2 days before appointments as part of usual care. For both clinics, we collected appointment attendance data from a period before (Aug 4 - Sep 16, 2016) and during (Oct 12–21, 2016) the intervention. The primary outcome was appointment show rate—the proportion who attended among those called. We employed a difference-in-difference analytic approach using logistic regression with robust standard

errors to compare show rate changes at the two clinics between the two data collection periods. We adjusted for patient demographics, zip code, and provider types (resident, attending, or mid-level). Our approach accounts for the influence of secular trends in the intervention clinic and time-invariant differences between clinics.

RESULTS: The 60 individuals called in the intervention group had a median age of 52 years (IQR 41–58), and were female (70%), non-Hispanic (98%), and black (92%). Out of 45 who answered, 18 (40%) had a ride scheduled, among those 13 (72%) used the service. At the control clinic, the show rate declined from 60% (143/240) to 51% (34/67). At the intervention clinic, the show rate improved from 55% (72/132) to 68% (41/60). In the adjusted model, those called to receive the intervention had a 2.51 (95% CI: 1.08-5.81, $p = 0.032$) higher odds ratio of attending clinic. The average cost of per ride was $8.10.

CONCLUSIONS: Results of this pilot program suggest that a ride-share service can increase show rates to primary care appointments for Medicaid patients. These findings are not generalizable to non-urban environments and pre-appointment reminders with multiple follow-up attempts may explain these results, but patients received at least one reminder in both arms. Our findings have implications for payers and providers hoping to improve primary care show rates for low-income populations.

RISK FACTORS ASSOCIATED WITH 30 DAY READMISSION IN PATIENTS WITH DIABETIC FOOT INFECTIONS Marshall Miller; Heather Young; Bryan Knepper. Denver Health Medical Center, Denver, CO. (Control ID #2690262)

BACKGROUND: Diabetic foot infections (DFI) are the most common cause of hospitalization for patients with diabetes and the leading cause of amputations in developed countries. Previous studies have shown that diabetic patients have higher readmission rates than non-diabetics. It is important to identify variables that may be contributing to readmission. Our study aims to investigate which clinical variables are associated with 30 day hospital readmission in patients with DFI; this information could improve the practice of hospitalists.

METHODS: We conducted a retrospective cohort study of adult patients admitted to an academic safety net hospital in Denver, Colorado for diabetic foot infections between July 1, 2012 to July 1, 2015. We identified patients by ICD9 codes and randomly selected 35% of charts for review. Patients were excluded if they did not have a DFI by chart review, were pregnant, or incarcerated. The primary outcome was 30 day readmission. Data collected included baseline demographics, medical comorbidities, active substance abuse, homelessness, tobacco use, laboratory data, and surgical pathology data. Additional variables are the presence of gangrene, length of stay, time to surgery (day of admission to day of surgery), lack of a primary care provider, and type of surgery. Univariate and multivariable logistic regression models utilizing backwards selection were used to identify independent predictors.

RESULTS: A total of 140 patients were included in the study. The majority was male ($n = 106$, 76%). Median age was 55 years (IQR 49–61) and length of stay was 7 days (IQR 4–10). Thirty-one patients (22%) were readmitted in the 30 days following index hospitalization. Factors associated with readmission included treatment failure, elevated C-reactive protein, and hospital length of stay ($p < 0.05$). In multivariate analyses, length of stay and treatment failure were independent factors that predicted readmission; and homelessness showed a nonsignificant trend.

CONCLUSIONS: The 30-day readmission rate for patients with DFI is high. Factors such as treatment failure, C-reactive protein, and length of stay are independently associated with readmission. It is unclear if treatment failure is the cause of readmission or it is the result of readmission. More work is needed to determine the reason for readmission so that appropriate measures can be taken prior to discharge.

Multivariate model of risk factors for readmission within 30 days.

Risk Factor	Odds Ratio	95% confidence Interval	P-value
Length of Stay	1.08	1.01-1.16	0.03
Treatment Failure	2.67	1.15-6.21	0.02
Homelessness	2.01	0.76-5.33	0.16

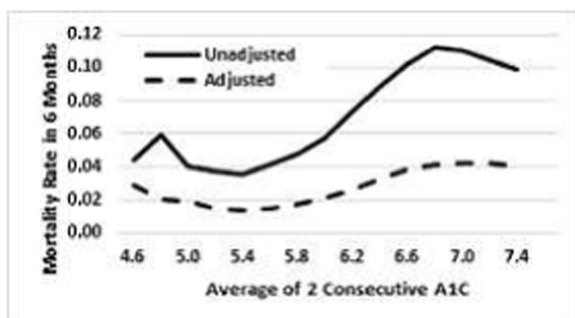
RISK OF MORTALITY AMONG VETERANS DEPENDS MORE ON COMORBIDITIES THAN ON GLYCOSYLATED HEMOGLOBIN LEVELS Sanja Avramovic[2]; Farrokh Alemi[2]; Richard B. Hayes[1]; Esther Levy[1]; Jordan Davis[1]; Mark D. Schwartz[1]. [1]NYU School of Medicine, New York, NY; [2]George Mason University, Fairfax, VA. (Control ID #2703999)

BACKGROUND: Prior studies of the mortality risk associated with glycosylated hemoglobin (A1c) have systematically excluded patients with key comorbidities, and thus may not reflect the true association of A1C with mortality. The objective of the study is to determine mortality risk after accounting for all comorbidities. Design: Retrospective, secondary data analysis from all 168 VA Medical Centers and 1,053 VA Community Based Outpatient Clinics; All patients who from 1/2008 to 12/2015 had >2 primary care visits, not more than 2 years apart, to a VA facility, who had no prevalent diabetes diagnosis before 1/2008, and who had at least 2 A1c measurements

METHODS: The A1c level for each patient was defined as the max of the average of two consecutive A1c test results during the study period. The primary outcome was mortality within 6 months of the date of the latter of two consecutive A1c tests. Stratified covariate balancing was used to measure unconfounded impact of A1c on mortality rate, adjusting for the impact of comorbidities.

RESULTS: 2,672,558 patients met the entry criteria. Average age was 62 (standard deviation$n = 14.6$), 93% were male, and 71% White. 48% had 1 comorbidity; 19% had 2; 11% had 3; 7% had 4; and 15% had 5 or more. 0.7% had low A1c (<5.0%), 69.7% had normal A1c (5.0 to 5.7%); 26.7% had prediabetic A1C (5.7 to 6.4%), and 2.9% had A1c levels in diabetic range (A1c > 6.5%). The solid line in the Figure shows the 6-month mortality risk associated with unadjusted A1c levels; note that the Figure has deleted A1c levels with less than 1,000 unique patients. All diseases (e.g. cancer) affected both A1c levels and mortality rates. After stratification removed the impact of comorbidities (dashed line), risk of mortality associated with A1c levels dropped. The comorbidity-adjusted risk (e.g. risk at A1c of 4.6%) was lower than unadjusted normal levels (e.g. risk at A1c levels of 5.4%). Prior to adjustment, a change from normal (A1c = 5.4%) to diabetic (A1c = 7%) was associated with 8% higher mortality, while afterwards the same A1C was associated with only 3% higher mortality.

CONCLUSIONS: A1c level is associated with mortality across the full range, with risk greatest for those with A1c >6.5% but most of the increase is accounted for by patients' comorbidities, so clinicians should focus on the progression of the underlying diseases and not simply on A1c test results among their patients at risk for diabetes.



ROLE OF MAGNESIUM IN THE TREATMENT OF DEPRESSION

Emily Tarleton; Benjamin Littenberg; Charles D. MacLean; Amanda G. Kennedy; Christopher Daley. University of Vermont, Burlington, VT. (Control ID #2703129)

BACKGROUND: Depression affects 350 million people worldwide and is predicted to be the leading cause of disease burden by 2030. Current treatment options are limited by cost, availability, side effects, and acceptability to patients. Several studies have looked at the association between magnesium and depression, yet its role in symptom management is unclear. The objective of this trial was to test whether supplementation with over-the-counter magnesium chloride improves symptoms of depression.

METHODS: A randomized cross-over trial was conducted in outpatient Primary Care Clinics and included 126 adults (mean age 52; 38% male) diagnosed with depression by their primary care provider and currently experiencing mild-to-moderate symptoms with Patient Health Questionnaire-9 (PHQ-9) scores of 5–19. The intervention consisted of six weeks of active treatment (magnesium chloride supplementation) compared to six weeks of control (no treatment). The main outcomes and measures included assessments of depression and anxiety symptoms at bi-weekly phone calls during both the 6-week treatment period and 6-week control period. The primary outcome was the difference in the change in depression symptoms during baseline and the end of each treatment period. Secondary outcomes included changes in anxiety symptoms as well as adherence to the supplement regimen, appearance of adverse effects, and intention to use magnesium supplements in the future.

RESULTS: Consumption of 248 mg elemental magnesium chloride for 6 weeks resulted in a clinically significant net improvement in PHQ-9 scores of −6.1 points (CI −7.92, −4.21; $P < 0.001$) and net improvement in Generalized Anxiety Disorders-7 scores of −4.5 points (CI −6.57, −2.34; $P < 0.001$). Average adherence was 83% by pill count. The supplements were well tolerated and 61% of participants reported they would use magnesium in the future. Similar effects were observed regardless of age, gender, baseline severity of depression, baseline magnesium level, or use of antidepressant medications. Treatment effects were observed within two weeks.

CONCLUSIONS: Magnesium is effective for mild-to-moderate depression in adults. It works quickly and is well tolerated without the need for close monitoring for toxicity. Magnesium supplements may be a safe and easily accessible alternative, or adjunct, to starting or increasing the dose of antidepressant medications.

RURAL RESIDENCE STATUS IS ASSOCIATED WITH PREVENTABLE HOSPITALIZATIONS AMONG ELDERLY DUAL VHA/MEDICARE USERS WITH TYPE II DIABETES MELLITUS

Drew Helmer[1, 2]; Mazhgan Rowneki[1]; Dennis Fried[1]; Chin-lin Tseng[1]; Danielle Rose[3]; Orysya Soroka[1]; Usha Sambamoorthi[4]. [1]VA-NJHCS, East Orange, NJ; [2]Rutgers University-New Jersey Medical School, Newark, NJ; [3]VA GLA Healthcare System, Sepulveda, CA; [4]University of West Virginia, Morgantown, WV. (Control ID #2706788)

BACKGROUND: Rural residence has been associated with poorer health outcomes. Preventable hospitalizations are inpatient stays potentially avoidable with timely access to high quality ambulatory care. We explored the association between rural residence and preventable hospitalizations for veterans with diabetes, given the complex and chronic nature of the disease and its prevalence among veterans (25%).

METHODS: We used a retrospective cohort (baseline years 2008–2009, outcome year 2010) of Veterans with type II diabetes mellitus, aged >65 years, dually enrolled in VHA and Medicare part A and B, and with no use of hospice or long term care facilities using inpatient and outpatient data derived from a VHA and Medicare. We classified Veterans' residence as urban, rural, or highly rural using ZIP code-based Rural Urban Commuting Area codes according to the VHA Office of Rural Health. We applied the Prevention Quality Indicators (PQI) definition of preventable hospitalizations to inpatient care experienced in 2010. We measured the association between preventable hospitalizations and rural residence using a multivariate logistic regression model controlling for age, sex, race, marital status, Medicaid enrollment status, Diabetes Complications Severity index, HbA1c levels, lipid levels, mental health conditions, cancer, chronic obstructive pulmonary disease, asthma, arthritis, Body Mass Index, anti-diabetes drug use, insulin use, tobacco/alcohol/drug use, VHA priority status, and census divisions.

RESULTS: Our cohort was 572,360 Veterans with mean age 76 years, who were 86.84% white and 98.36% male. Most (62.31%) of our cohort resided in urban areas, 35.92% in rural areas, and 1.77% in highly rural areas. Approximately 8% experienced a PQI during 2010. In bivariate analysis, there were differences by rurality of residence in obesity (urban 25.56%, rural 29.17%, highly rural 31.14%), presence of diabetes-related complications (urban 85.14%, rural 82.77%, highly rural 81.67%), poverty (urban 3.83%, rural 5.66%, highly rural 7.99%), and moderate or severe disability (urban veterans 30.05%, rural 26.27%, highly rural veterans 24.02%). Compared to urban veterans, rural veterans (OR = 1.087; CI = 1.063–1.110) and highly rural veterans (OR = 1.186; CI = 1.102–1.277) had a greater odds of experiencing a PQI.

CONCLUSIONS: Veterans with diabetes who resided in rural or highly rural areas were more likely than urban residents to experience a preventable hospitalization controlling for disease severity, comorbid illness, and sociodemographic status. Our analysis, utilizing data from both VHA and Medicare, captures the totality of preventable hospitalizations and demonstrates a disparity in access to and/or quality of ambulatory care based on rural residence. Further analysis might identify potential source(s) of this disparity including geographic barriers to accessing care, care coordination differences, unmeasured residual disease severity, or patient preference.

SATISFACTION, CHANGE IN KNOWLEDGE AND ADHERENCE TO DIABETES PREVENTION AFTER A PHARMACIST LED PREDIABETES SHARED DECISION MAKING VISIT: THE PREDIABETES INFORMED DECISION AND EDUCATION (PRIDE) STUDY. O. Kenrik Duru[2, 1]; Jacqueline Martin[1, 2]; Jonathan Grotts[1, 2]; Tannaz Moin[3]; Jeffery Y. Fu[1, 2]; Chi-Hong Tseng[1, 2]; Richard Maranon[1, 2]; Gerardo Moreno[2, 1]; Keith Norris[1, 2]; Susan Ettner[1, 2]; Carol Mangione[1, 2]. [1]David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]UCLA, Los Angeles, CA; [3]UCLA/VA Greater Los Angeles, Los Angeles, CA. (Control ID #2707085)

BACKGROUND: Approximately 1 in 3 Americans have prediabetes (pre-DM) and 11% are predicted to develop diabetes over a 3-year period. Our goals are to describe patients' satisfaction with a pharmacist led pre-DM Shared Decision Making (SDM) visit; change in knowledge about pre-DM; and to assess whether participant characteristics are associated with adherence to the Diabetes Prevention Program (DPP) 4 months after the SDM visit.

METHODS: All subjects are from the intervention arm of a primary care practice level cluster-randomized trial of SDM designed to evaluate uptake of diabetes prevention. We included 236 of 356 subjects who had reached the 4 month follow interview by 11/30/16. Eligible participants were between 18 and 65 years of age with a body mass index (BMI) > 24 m/kg^2 (>22 m/kg^2 if Asian) and an A1c between 5.7-6.4%. During the SDM visit, subjects selected 1 of 4 treatments: DPP, Metformin (MF), DPP + MF, or no treatment. In a follow-up interview, we asked: "Did the appointment with the pharmacist meet your expectations?" and "Do you have a better understanding of prediabetes as a result of meeting with the pharmacist?" Also, at 4 months follow-up, we assessed DPP adherence defined as attending 9 or more sessions based on records from the DPP sites and self-reported adherence to MF. We assessed variation in DPP adherence by age, race/ethnicity, gender, BMI and A1c with a multivariate logistic regression model.

RESULTS: Among the 236 SDM participants who had completed the 4-month interview, the mean (SD) age was 56.3 years (11.2), BMI was 30.3 kg/m2 (5.1), and A1c was 6.0%. The sample included 43.6% White, 20.3% Asian, 18.2% Hispanic, and 12.7% African American participants, as well as 58.9% women. At 4 months follow-up, 93.1% reported that the visit met their expectations and 90.2% reported that they had a better understanding of pre-DM. Additionally, at 4 months follow-up, 41% who chose the DPP attended at least one class. For the 27% subjects who chose the DPP and completed 9 or more classes, significant correlates of adherence included age, with those between ages 50–59 (OR = 2.64) and > to 60 years (OR = 2.47) more likely to be adherent than those less than 50 years of age ($p = .04$), and female (OR = 1.89) as compared to male gender ($p = .04$). Seventy percent of those who selected metformin reported that they were currently using the medication at 4 months follow-up.

CONCLUSIONS: Persons with pre-DM who participate in a pharmacist led SDM visit overwhelmingly report that the visit met their expectations and that participation increased their preDM knowledge. However, for those who selected the DPP, participation in 9 or more visits was low at 27%, whereas those who chose metformin reported higher rates of adherence. These findings support the importance of providing patients with the needed information to select one or both prevention treatments to stem the increasing incidence of diabetes.

SCHEDULED OUTPATIENT APPOINTMENTS AT HOSPITAL DISCHARGE ARE NOT ASSOCIATED WITH READMISSION Sachin J. Shah[3]; Alexander Grunfeld[4]; Daniel E. Lage[2]; Roger B. Davis[1]; Joshua Metlay[3]. [1]Beth Israel Deaconess Medical Center, Brookline, MA; [2]Harvard Medical School, Cambridge, MA; [3]Massachusetts General Hospital, Boston, MA; [4]University of Manitoba, Winnipeg, MB, Canada. (Control ID #2705323)

BACKGROUND: Scheduled outpatient follow up at the time of hospital discharge is a quality measure. There are few data to support this; studies that have examined this question are mixed. We examined if those who have and complete an appointment are less likely to be readmitted.

METHODS: We conducted a retrospective cohort study at the Massachusetts General Hospital (MGH). Eligible patients were adults (age > = 50 years) linked to an MGH primary care physician, admitted to the hospital with a medical diagnosis and discharged alive between August 2014 and September 2015. Sociodemographic, ADL impairment, clinical, discharge, and appointment data were extracted from the electronic medical record. Education and income data were obtained from zip code linked Census data. We measured the effect of two exposures: (1) the presence of a primary care follow-up appointment within 30 days at the time of discharge and (2) the completion of an appointment within 30 days of discharge. The outcome was measured as all-cause readmission to MGH within 30 days of discharge. We utilized a multivariable, extended Cox proportional hazard model to determine if having or completing an appointment were each associated with the risk of readmission. Completing an appointment was modeled as a time-varying covariate.

RESULTS: Of the 3024 eligible patients, 35.5% had an appointment to be seen within 30 days of discharge. Patients with an appointment scheduled at discharge were more likely to be eligible for Medicare and Medicaid (18.4% vs. 15.5%, $p < 0.01$), have 1 or more impairments in activities of daily living (28.8% vs. 24.1%, $p < 0.01$), be sicker (Elixhauser score 3.8 vs 3.6, $p < 0.01$), and have a longer length of stay (5.0 vs. 4.6, $p < 0.01$). Patients who had an appointment scheduled at discharge completed an appointment sooner (median days to first completed appointment, 7 vs 12, $p < 0.01$). Patients with an appointment scheduled at the time of discharge were no more likely to be readmitted compared to patients without scheduled appointments (15.3% vs. 14.0%, $p = 0.35$). After adjusting for age, sex, race, functional status, admission diagnosis, comorbidities and length of stay, patients who had an appointment at the time of discharge were no more likely to be readmitted (hazard ratio 1.06, 95% CI 0.87–1.29, $p = 0.56$). After the same multivariable adjustment, completing an appointment was not associated with subsequent risk of readmission (HR 0.90, 95%CI 0.72–1.13, $p = 0.34$).

CONCLUSIONS: There is no apparent association with scheduled or completed appointments and subsequent readmission. Patients with an appointment at discharge appeared sicker at baseline and were seen sooner. The fact that high risk patients were more likely to be scheduled and seen sooner may have masked the true risk reduction attributable to follow up appointments. Future work will determine which patients and clinical conditions may benefit from a primary care appointment following hospital discharge.

SCREENING FOR HOMELESSNESS: VA PROVIDER REFLECTIONS ON ADDRESSING A SOCIAL DETERMINANT OF HEALTH

Manik Chhabra[1]; Meagan Cusack[3]; Melissa Dichter[2]; Ann E. Montgomery[3]; Gala True[3]. [1]Veterans Affairs Medical Center, Philadelphia, PA; [2]Center for Health Equity Research and Promotion, Philadelphia, PA; [3]U.S. Department of Veterans Affairs, Phildelphia, PA. (Control ID #2705724)

BACKGROUND: As health systems begin to address social determinants of health as a routine component of care, they face implementation challenges for screening and referring patients to meet these needs. The U.S. Department of Veterans Affairs (VA) has a long history of addressing social determinants, including housing. To end homelessness among Veterans, the VA has allocated significant resources towards prevention and housing initiatives. This includes the integration of a two-question homelessness screening clinical reminder (HSCR) into the electronic medical record (EMR). The HSCR is administered to patients in outpatient clinics in order to identify Veterans experiencing homelessness or risk, and ensure referral to appropriate services. This study explores perspectives of VA clinical providers on administering the HSCR and addressing Veteran's responses.

METHODS: We conducted semi-structured qualitative interviews at the Philadelphia VA Medical Center with physicians and nurse practitioners who had administered the HSCR and documented at least 5 positive screens in the past two years. The study employed a modified grounded theory approach and constant comparative method for analyzing qualitative data. Interviews concluded once thematic saturation was reached.

RESULTS: Twenty-two providers were interviewed (20 physicians and two nurse practitioners). Overall, providers found the HSCR easy to administer, though most adapted the language from its original form. The HSCR served to prompt the providers to incorporate patient housing situation into routine assessment, which they typically did not do prior to this implementation. Providers felt that housing insecurity affected patients' overall health, and knowing housing status affected clinical decision-making. Patients typically responded positively to screening, and providers found the referral process easy. However, unlike with other consults, providers often didn't know what happened to patients after referral. While providers viewed the health-system as having an important role in addressing housing concerns, there were mixed opinions on whether it was the role of physicians to directly administer the screening reminder.

CONCLUSIONS: Previous literature highlights challenges providers face in asking about housing status and addressing housing insecurity. Our study finds that incorporation of a HSCR into the EMR increased awareness of housing insecurity as a risk factor for patients, and altered plans of care. Provider views on addressing housing were likely impacted by the availability of resources on site at the VA. The implementation of screening tools and services for housing insecurity remain a challenge for health systems with limited resources. Lessons from the VA will be important to inform and refine the current set of policies and practices that identify, refer, and intervene on patients experiencing homelessness, and serve as a model for addressing other social determinants of health.

SCREENING FOR MILITARY SEXUAL TRAUMA IS ASSOCIATED WITH IMPROVED HIV SCREENING IN WOMEN VETERANS

Shivani Reddy[1, 2]; Harini Bathulapalli[3]; Cynthia Brandt[3, 4]. [1]VA Boston Healthcare System, Boston, MA; [2]RTI International, Waltham, MA; [3]VA Connecticut Healthcare System, West Haven, CT; [4]Yale School of Medicine, New Haven, CT. (Control ID #2707403)

BACKGROUND: The Veterans Health Administration (VHA) has adopted a policy of routine HIV screening for all adults. In a 2014 nationwide VHA study, women veterans were more likely to be screened for HIV than male veterans (30% versus 20%, respectively). In this study, we examine factors associated with HIV screening in women veterans, specifically examining the association of military sexual trauma (MST) screening and positive MST history with testing for HIV. MST screening is another mandatory screen in the VA and may promote other required screenings. Additionally, a history of MST is associated with high risk behaviors and sexually transmitted infections, which are also risk factors for HIV infection. We hypothesize that women who have been screened for MST or have a positive history of MST are more likely to undergo HIV testing.

METHODS: This is a cross-sectional study using data from the Women Veteran's Cohort Study, a population of veterans of obtained from the OEF/OIF/OND roster merged with VHA Corporate Data Warehouse (electronic health record data). The outcome of HIV testing is defined as a laboratory test having been performed at least once over this time frame. The predictor MST screening is defined as a completed decision support reminder, while MST history was defined by answer to the screening question. Covariates include demographic characteristics, risk factors for HIV (sexually transmitted infections, hepatitis B, hepatitis C, substance abuse, and homelessness), mental health diagnoses (depression, post-traumatic stress disorder, bipolar disorder, and schizophrenia), and any receipt of care in a women's health clinic (WHC). Descriptive and bivariate statistics were performed comparing predictor values for patients with and without an HIV lab test. T-tests were performed for continuous variables and chi-squared tests for categorical variables.

RESULTS: We identified 129,469 women veterans within the VHA system between September 2001 and September 2014. Nearly 12% of women veterans had a lab test indicating HIV screening. In our bivariate analysis, women veterans screened for HIV were more likely to be younger, unmarried, Black or Hispanic, have a risk factor for HIV, or carry a mental health diagnosis. ($p < 0.001$ for all). Among women who were screened for HIV, 97.6% were screened for MST, compared with 73.7% for women without an HIV screen ($p < 0.001$). MST screening occurred before or concurrently with HIV screening approximately 90% of the time. Women veterans with any visit to a WHC were more likely to receive HIV screening (82.8% vs. 44.8%; $X^2 = 7815$, $p < 0.001$). Women veterans screened for HIV were more likely to have a history of MST compared with unscreened women, though the absolute difference was small (17.4% vs. 16.3%, $X^2 = 9.71$, $p < 0.001$).

CONCLUSIONS: Screening for MST—mandatory in the VA—is associated with improved testing for HIV, which is also required. Comprehensive screening for military sexual trauma may promote guideline recommended screening for HIV.

SCREENING FOR SEXUALLY TRANSMITTED INFECTIONS AFTER MEDICAID ELIGIBLITY AND CERVICAL CANCER SCREENING GUIDELINE CHANGES

Natasha Parekh[1]; Julie M. Donohue[2]; Jennifer Corbelli[1]; Aiju Men[2]; Marian Jarlenski[2]. [1]University of Pittsburgh, PIttsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA. (Control ID #2705806)

BACKGROUND: Chlamydia and gonorrhea are the most commonly reported sexually transmitted infections (STIs) in the United States. STI screening is important to prevent complications like pelvic inflammatory disease and infertility, and is cost-effective. Therefore, major organizations recommend

annual screening in sexually active women <25 years old and older women at increased risk. From 2007–2013, Pennsylvania (PA) Medicaid began a family planning waiver which covered women's health services (including STI testing) for uninsured women with an income ≤185% of federal poverty level. Expectations were for STI screening to increase due to the program. However, national cervical cancer (CC) screening guideline changes in 2009 and 2012 recommended less frequent CC screening, causing concern that STI testing rates would decrease because the two screenings were typically performed concurrently. It is unclear how rates of STI testing changed in PA Medicaid in response to these countervailing forces. We therefore assessed STI testing rates among PA Medicaid-enrolled women from 2007 to 2013.

METHODS: We performed an observational study evaluating medical claims for PA Medicaid-enrolled women 16–30 years of age from 2007–2013. We divided our population into 3 cohorts: 2007 (reflecting 2003 CC screening guidelines and start of the waiver program), 2010 (reflecting 2009 CC screening guidelines), and 2013 (reflecting 2012 CC screening guidelines). We required women to be continuously enrolled in Medicaid during their respective 1-year study periods. Women were excluded if they were dually enrolled in Medicare and/or had HIV/AIDS (warrants alternate screening). Our primary outcome was receipt of at least one STI test in the 1-year study period. We performed logistic regression to assess covariates associated with annual STI testing.

RESULTS: Among 506,520 women, 58% were White, 29% were Black, 12% were Hispanic, and 90% were urban. Mean age was 22 years. Between 2007–2010, STI testing increased from 31 to 45%, and stabilized at 45% in 2013. In multivariable analyses, odds for annual STI testing were significantly higher among Blacks compared with Whites (AOR 1.42, 95% CI 1.39–1.46); Hispanics compared with non-Hispanics (AOR 2.56, 95% CI 2.56–2.56); and urban compared with rural residents (AOR 1.06, 95% CI 1.04–1.08).

CONCLUSIONS: We observed a dramatic increase in STI testing between 2007–2010. Potential reasons are the waiver program (15% of our cohort was enrolled by 2013), increased use of urine and vaginal (rather than cervical) STI testing, and improvements in laboratory reporting. It is reassuring that despite clinician concerns, changes in cervical cancer screening guidelines did not affect STI testing rates. Between 2010–2013, testing rates stabilized at only 45%, and disparities existed overall, suggesting opportunities for improvement.

SCREENING RATES FOR GENETIC COUNSELING REFERRAL ARE LOW AMONG A NATIONAL SAMPLE OF WOMEN AT RISK FOR A BRCA MUTATION

Leland Hull[2]; Jennifer Haas[1]; Steven R. Simon[2]. [1]Brigham and Women's Hospital, Boston, MA; [2]VA Boston Healthcare System, Boston, MA. (Control ID #2699685)

BACKGROUND: The US Preventive Services Task Force recommends that primary care providers screen women at risk for a *BRCA* mutation for referral to genetic counseling services. Our study objectives are to determine the national rates of screening for genetic counseling referral, genetic counseling, and genetic testing among women at increased risk for a *BRCA* mutation and to identify the characteristics associated with screening.

METHODS: This is a cross-sectional analysis of the 2015 National Health Interview Survey. The FHS-7, a validated screening tool, was used to identify women *at risk* for hereditary breast cancer syndromes, including women with a 1st-degree relative with breast or ovarian cancer, at least two 1st- or 2nd-degree relatives with breast cancer and ovarian or colorectal cancer, or a relative with breast cancer diagnosed at age <50. We also created a *higher risk* subgroup including women with a 1st-degree relative with male breast cancer, 1st-degree relative with breast cancer diagnosed at age <50, or two 1st-degree relatives with breast or ovarian cancer. The primary outcome was *screening* for genetic counseling referral, defined as a positive response to: "Have you ever discussed the possibility of getting a genetic test with a doctor or other health professional?" Secondary outcomes were use of genetic counseling or testing for increased cancer risk. Unadjusted associations between family history or covariates and the outcomes were assessed using chi-squared tests; multivariable regression was used to determine associations adjusted for possible confounders (odds ratios [OR] with 95% confidence intervals [CI]). SAS 9.4 was used for all analyses incorporating sample weights.

RESULTS: Of 18,601 women, a minority ($n = 4{,}261$; weighted population estimate of 28 million; 22.3%) were *at risk* for hereditary breast cancer; 20% of this group ($n = 855$) met *higher risk* criteria. Screening rates were low in both the *at risk* group (11.2%) and *higher risk* (19.7%) subgroup. Family history was positively associated with the outcomes; *at risk* women were about 5 times more likely and *higher risk* women were about 11 times more likely to report screening than women without a family history. A positive family history was also associated with increased odds of counseling and testing (data not shown). *At risk* women age ≥60 were less likely to be screened than women age 18–39 (OR 0.54, 95% CI 0.39–0.76). Screening was also more likely among *at risk* black women compared to white women (OR 1.42, 95% CI 1.03–1.95) and women with annual family income ≥ $75,000 compared to income of < $35,000 (OR 1.62, 95% CI 1.24–2.11). A personal history of breast or ovarian cancer was associated with all outcomes in both the *at risk* and *higher risk* groups (data not shown).

CONCLUSIONS: Despite a recommendation in place for over a decade, fewer than 20% of women at risk for the *BRCA* mutation reported being screened. Further research is needed to develop strategies to close this gap, with emphasis on those with lower incomes.

SELF-REPORTED PHYSICIAN NON-ENGLISH LANGUAGE ABILITY BY SPECIALTY AND REGION IN CALIFORNIA

Maria E. Garcia[2]; Andrew B. Bindman[1]; Margaret Fix[3]; Denis Hulett[3]; Janet Coffman[3]. [1]University of California San Francisco, San Francisco, CA; [2]University of California, San Francisco, San Francisco, CA; [3]Philip R. Lee Institute for Health Policy Studies, San Francisco, CA. (Control ID #2706098)

BACKGROUND: In 2011, 44% of the population in California spoke a language at home other than English and 25% reported speaking English 'not well' or 'not at all.' The number of Californians with limited English proficiency is expected to grow in coming years. Few studies have assessed physician fluency in non-English languages. We examined physician self-reported fluency in four languages by medical specialty.

METHODS: We performed cross-sectional analyses of data from a survey the California Medical Board Survey administered to physicians whose licenses were due for renewal between September 2013 and August 2015. Measures examined were physician demographics, practice characteristics (including ZIP code), specialty, and self-reported physician language proficiency in the four most commonly spoken languages in California other than English (Spanish, Cantonese, Mandarin, and Tagalog).

RESULTS: Of the 66,496 physicians included in the survey, 25% reported proficiency in Spanish; compared to 2%, 6 and 3% for Cantonese, Mandarin, and Tagalog, respectively. Younger physicians were more likely to report

speaking Spanish and Mandarin (with 40 and 42% of physicians who report proficiency being <46 years old, respectively). In contrast, Cantonese and Tagalog-speaking physicians tended to be older (33 and 42%, respectively, were >60 years old). While most Cantonese, Mandarin and Tagalog-speaking physicians self-identified as Asian Pacific Islander (94, 93, and 94%, respectively), physicians of many ethnic/racial backgrounds reported Spanish proficiency. 37% of Spanish-speaking physicians self-identified as non-Hispanic white, 23% as Asian Pacific Islander, and 21% as Latino. 10% of respondents declined to state race/ethnicity. A large proportion of physicians reporting proficiency in a target language practiced in primary care specialties; 36, 37, 31 and 56% of physicians reporting Spanish, Cantonese, Mandarin or Tagalog ability. In contrast, among physicians working in hospital settings, higher percentages of physicians in specialties with low patient contact (such as radiology, anesthesiology and pathology) spoke a target language compared to those in specialties with high patient contact (such as emergency medicine). The lowest percentages of physicians reporting proficiency in a target language were psychiatrists (4, 3, 3 and 9% respectively among Spanish, Cantonese, Mandarin, and Tagalog speakers).

CONCLUSIONS: One quarter of California physicians report that they speak Spanish and smaller percentages speak Cantonese, Mandarin, or Tagalog. Large proportions of physicians who speak these languages provide primary care. The age differences in languages spoken may reflect changes in medical school curricula and admissions criteria, hiring preferences, as well as changing immigration policies over the past few decades. An important limitation of our study is the reliance on self-reported physician language ability. No objective measure of language fluency is available.

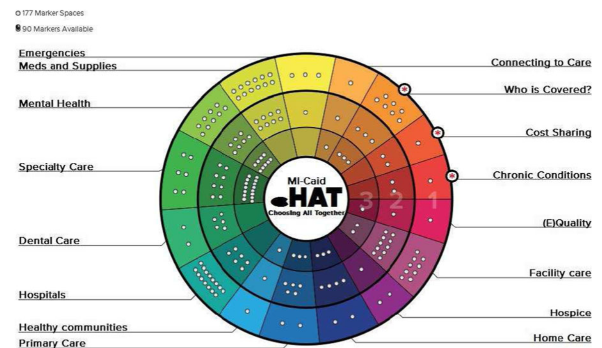
SETTING PRIORITIES FOR MEDICAID: THE VIEWS OF MINORITY AND UNDERSERVED COMMUNITIES Susan D. Goold[2]; Lisa Szymecko[2]; Hyungjin M. Kim[2]; Cengiz Salman[2]; A. M. Fendrick[2]; Edith C. Kieffer[2]; Marion Danis[1]; Zachary Rowe[3]. [1]National Institutes of Health, Bethesda, MD; [2]University of Michigan, Ann Arbor, MI; [3]Friends of Parkside, Detroit, MI. (Control ID #2705844)

BACKGROUND: Decisions about who should be eligible and what benefits covered by state Medicaid programs challenges policy makers. Engaging those most affected by such tradeoffs could make allocations more just, and more sensitive to their needs and values.

METHODS: Academic-community partnerships in Michigan adapted the simulation exercise CHAT (CHoosing All Together) to engage community members in deliberations about Medicaid priorities. After an informational video about Medicaid, individuals and deliberating groups choose from a menu of spending options constrained by limited resources (Fig. 1). We randomly assigned low-income participants to participate in CHAT with ($n = 209$) or without group deliberations ($n = 181$) in English, Spanish or Arabic. Data collection included pre- and post-CHAT individual priorities and deliberating groups' priorities. Within-participant changes in priorities from pre- to post-deliberation used a mixed-effect logistic regression model accounting for within-participant repeated assessment nested within groups.

RESULTS: Participants ranged from 18 to 81 years old (Mea$n = 48$); 62% were women. Over half (57%) self-identified as white, 31% African-American, 17% Hispanic, 9% Native American, and 12% Arab/Arab-American/Chaldean. Most (78%) had incomes < $35,000/year, 30% reported poor or fair health status and 66% had at least one chronic condition. Both deliberating and control participants prioritized eligibility consistent with Medicaid expansion. They also prioritized coverage for a broad range of services, including dental care (93.5% deliberators and 91.7% control participants) and enhanced coverage for chronic conditions (69.7% deliberators and 65.7% of control participants). Most accepted daily copays for elective hospitalization (71.6% deliberators and 67.9% of control participants) and more restricted access to specialists (60.2% of deliberators and 57.4% of control participants). Deliberators were more likely than controls to increase what they allocated to mental health care (between arm difference in allocatio$n = 0.22$, $p = .03$) and eligibility (between arm difference in allocatio$n = 0.18$, $p = .04$) after deliberations.

CONCLUSIONS: Low-income community members in Michigan put a high priority on Medicaid expansion and broad coverage. When given the opportunity to deliberate about priorities, individuals increase allocations to mental health and eligibility.



SEVERELY ELEVATED BLOOD PRESSURE IN THE EMERGENCY DEPARTMENT IS AN INDEPENDENT PREDICTOR OF 6 AND 12 MONTH CARDIOVASCULAR EVENTS Patrick Brown; Ahmed AbdulHamid; Anita Eapen; Ahmed Elbanna; Bradley J. Greib; Amit Vahia; Joseph Miller. Henry Ford Health System, Detroit, MI. (Control ID #2702876)

BACKGROUND: Severely elevated blood pressure (BP) absent acute target organ damage is common in emergency department (ED) patients but the 6 and 12-month risk for such patients is not well described. We tested the hypothesis that severely elevated BP, independent of known cardiovascular risk factors, is associated with 6 and 12 month cardiovascular events.

METHODS: We performed a retrospective cohort study using a registry at 8 affiliated hospitals and free-standing EDs. We included all unique adult encounters with recorded BP. We excluded patients that required hospital admission or had an ED systolic BP (SBP) < 110 mmHg. Data extraction included the first recorded ED BP and clinical information with a focus on cardiovascular risk factors. Composite outcomes were obtained from diagnostic coding over a 1-year period following the index visit and included death, myocardial infarction (MI), stroke and acute heart failure (AHF). Logistic and Cox proportional hazards modeling analyzed the association between composite outcomes and increments of HTN above a reference SBP 110–140 mmHg. The model adjusted for age, sex, race, a history of HTN, insurance, and 7 core cardiovascular comorbidities.

RESULTS: Analysis included 196,244 unique patients over a one year period. The mean age was 46.5 (±19) years, and 56.9% were female. There were 14,887 patients with ED SBP ≥180 mmHg, including 4,379 with a SBP ≥ 200 mmHg.

Adjusting for age, sex, race, HTN, insurance and multiple cardiovascular comorbidities, SBP 180–200 mmHg remained an independent predictor of cardiovascular events (OR 1.15, 95% CI 1.1–1.2), as did SBP 200–220 mmHg (OR 1.3, 95% CI 1.2–1.4) and SBP > 220 mmHg (OR 1.7, 95% CI 1.5–2.0).

CONCLUSIONS: Among patients discharged from the ED, severely elevated BP is an independent predictor of 6 and 12 month cardiovascular events, and the magnitude of association increases with higher BP. Further study is needed to evaluate population health strategies that address cardiovascular risks among patients with recent ED visits with extremes of BP elevation.

SHOPPING AT HEALTH OR ORGANIC SPECIALTY STORES IS ASSOCIATED WITH FRUIT AND VEGETABLE CONSUMPTION IN A BI-ETHNIC AND UNDER-RESOURCED COMMUNITY IN SOUTH LOS ANGELES Peter Capone-Newton[4]; Sitaram Vangala[3]; Ibrahima Sankare[1]; Rachelle Bross[2]; Felica U. Jones[5]; Stefanie D. Vassar[1]; Arleen F. Brown[1]. [1]UCLA, Los Angeles, CA; [2]UCLA Clinical and Translational Science Institute, Harbor-UCLA Medical Center and Los Angeles Biomedical Research Institute, Torrance, CA; [3]University of California, Los Angeles, Los Angeles, CA; [4]Veterans Affairs West Los Angeles Medical Center, Los Angeles, CA; [5]Healthy African American Families, Los Angeles, CA. (Control ID #2706315)

BACKGROUND: Obesity and other adverse health outcomes are influenced by individual and community-level risk factors, including the food environment. This neighborhood-based study examined the association between food store types and fruit and vegetable consumption.

METHODS: The Healthy Community Neighborhood Initiative is a community partnered participatory study to understand and reduce health care disparities in a bi-ethnic, under-resourced community in South Los Angeles. The main outcome was daily fruit and vegetable (f/v) frequency. Participants ($n = 192$) were asked to list information on the stores where they shopped most frequently, including store type defined as specialty stores (with emphasis on healthy and organic foods), versus other store types (discount, convenience, full service supermarkets), and travel mode to the store (car, public transit, rideshare). A linear regression model of daily f/v frequency was adjusted for age, sex, race/ethnicity, education, store preferences, mode of transport, store distance, and store type. Effects are summarized in terms of estimated differences, standard errors and p-values.

RESULTS: In adjusted models, specialty store shopping (0.75 (0.31), $p = 0.015$) and college graduation (0.55 (0.29), $p = 0.056$) were associated with higher daily f/v frequency. Age group 18–29 (−1.01 (0.38), $p = 0.009$) was associated with less frequent daily consumption compared with the >65 group. A total of 30 participants (16%) ever shopped at a specialty food store. Most participants (89%) reported shopping at a full-service supermarket at least once. The next most frequented store types were Spanish-language (28%) and discount (16%). Specialty store shoppers travelled the farthest, an average of 4.2 miles (SD 2.3), followed by full-service, 2.2 miles (SD 1.7) and discount 2.0 miles (SD 1.3).

CONCLUSIONS: Residents who shopped at specialty stores had a healthier diet than those who shopped at any other store type. In this community, only specialty store shopping was associated with improved diet, yet most participants shopped in stores likely to sell fruits and vegetables. This regression analysis can be interpreted as a mediation model. In this causal framework, bivariate associations (not shown) between college graduation and specialty store shopping show a weak association, education is more strongly associated with f/v consumption, and specialty store shopping is associated with f/v consumption. In the multivariate analysis, the association between college graduation becomes statistically insignificant, and the coefficient is decreased. Thus, specialty store shopping only partially mediates the association between college graduation and f/v consumption. If food stores are partial or not mediators at all, then factors like education, income, and others may be more important for dietary change than access to food stores. To improve dietary quality in this community approaches beyond availability of healthy food options are needed.

SMOKEFREETXT FOR HOMELESS SMOKERS: A PILOT RCT WITH A MIXED-METHODS ANALYSIS Claire McGlave[2]; Gina R. Kruse[2]; Awesta Yaqubi[2]; Yuchiao Chang[1, 2]; Nancy A. Rigotti[2]; Travis P. Baggett[2]. [1]Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital, Boston, MA. (Control ID #2707515)

BACKGROUND: Homeless smokers want to quit smoking but face numerous barriers to doing so, including a lack of social support and pervasive smoking in the setting of homelessness. Mobile phone possession is common among homeless people, and a short message service (SMS) could address challenges to smoking cessation in this population by providing homeless smokers with virtual support to manage ubiquitous social triggers to smoke. Our objective was to evaluate the effect of a freely available but underused stop-smoking SMS program on smoking abstinence among homeless smokers.

METHODS: In 10/2015-06/2016, we conducted a pilot randomized controlled trial (RCT) with a sequential mixed-methods design that used qualitative interviews to explain the quantitative results. Eligibility criteria included age ≥18 years, current homelessness, current smoking (≥5 cigarettes/day), and desire to quit smoking in the next month. Control arm ($N = 25$) and SMS arm ($N = 25$) participants were offered nicotine patches, weekly in-person counseling, and a mobile phone. SMS arm participants additionally received help with enrolling in SmokefreeTXT, a free service administered by the National Cancer Institute (NCI) that sends 1–5 SMS messages daily and offers on-demand tips for managing cravings, mood symptoms, and slips. The primary outcome was smoking abstinence, defined as an exhaled carbon monoxide <8 parts per million, assessed 14 times over 8 weeks of follow-up and analyzed using repeated-measures logistic regression with generalized estimating equations. The secondary outcomes were use of SmokefreeTXT, assessed by data obtained from NCI; satisfaction with and appropriateness of SmokefreeTXT, assessed by surveys and in-depth interviews; and mobile phone retention, assessed by self-report.

RESULTS: 67% of eligible individuals agreed to participate. Smoking abstinence did not differ significantly between arms at the end of treatment (SMS 16% vs. control 8%; $p = 0.67$) or averaged across all time points (SMS vs. control OR 0.92, 95% CI 0.30–2.84). 88% of SMS arm participants enrolled in SmokefreeTXT; of these, 32% responded to ≥1 interactive prompts sent by the program. Among SmokefreeTXT enrollees who completed exit surveys ($N = 15$), 67% were very or extremely satisfied with the program. However, qualitative interviews revealed that some participants felt the messages were “impersonal, like a robot.” Several found the number of messages “overwhelming” and wanted “less texts a day.” Others noted practical barriers to

receiving the SMS messages, including limited phone battery life and lost or stolen phones. 40% of SMS arm participants retained their study-supplied mobile phone for the 8-week duration of the trial.

CONCLUSIONS: SmokefreeTXT, when added to nicotine patch therapy and in-person counseling, did not improve smoking abstinence in this RCT of homeless smokers. SMS interventions for homeless smokers may need to be better tailored to their unique needs and combined with efforts to promote mobile phone retention.

SMOKING CESSATION BEHAVIORS AMONG ADULT SMOKERS WITH CHRONIC MEDICAL CONDITIONS IN THE UNITED STATES

Sara Kalkhoran[1, 2]; Gina R. Kruse[1, 2]; Nancy A. Rigotti[1, 2]. [1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA. (Control ID #2699191)

BACKGROUND: General internists care for many patients with chronic diseases whose symptoms or progression is worsened by tobacco use, including COPD, asthma, cardiovascular disease, and cancer. Little is known about how their efforts to stop smoking and use of resources differ from smokers without comorbidities. Using data from the nationally-representative Population Assessment of Tobacco and Health (PATH) Study, we compared US smokers with medical comorbidities to smokers without comorbidities in their quit attempts and use of cessation aids.

METHODS: We used data from 32,320 adults aged 18+ from Wave 1 of the PATH study (Sept 2013 to Dec 2014). We included past-year cigarette smokers and excluded adults using other tobacco products in the past 12 months. Participants self-reported medical comorbidities. We calculated the population-weighted prevalence of smoking cessation behaviors and e-cigarette use by medical comorbidity and used logistic regression to assess the association between each comorbidity and cessation behaviors, controlling for demographic characteristics, insurance, education, region, having seen a medical doctor in the past 12 months and cigarettes per day.

RESULTS: Past-12 month cigarette smoking prevalence ranged from 12% in cancer to 30% in COPD. Smokers with 1 or more comorbidity had higher odds of a quit attempt in the past 12 months compared those with no comorbidity (aOR 1.37, 95% CI 1.20-1.56), as were all individual comorbidities. Among smokers who tried to quit, those with hypertension, high cholesterol, COPD, asthma, and diabetes had increased odds of using evidence-based smoking cessation methods compared to those with no comorbidities (Table). No comorbidity was associated with using e-cigarettes to quit in the past year. Smokers with COPD and asthma who tried to quit cigarettes had decreased odds of successfully quitting compared to those without comorbidities.

CONCLUSIONS: Adult smokers with medical comorbidities, compared to those without, try to quit cigarettes at higher rates and use more evidence-based treatments but not more e-cigarettes to quit. Despite this, those with comorbidities were not more likely to quit successfully, and COPD and asthma were associated with less quitting. This highlights the importance of addressing tobacco use among adults with comorbidities at every visit, as these individuals may require additional assistance to reduce their risk of further harm for tobacco use.

Past-12 month cessation behaviors in smokers who attempted to quit by medical comorbidity

	Used evidence-based medication or counseling aOR (95% CI)	Used e-cigarettes to quit aOR (95% CI)	Successfully quit smoking aOR (95% CI)

SOCIAL DYNAMICS OF A PRODUCE PRESCRIPTION PROGRAM FOR HYPERTENSION AT SAFETY NET CLINICS

Allison V. Schlosser[1]; Samantha Smith[2]; Kakul Joshi[1]; Anna B. Thornton[4]; Erika Trapl[1]; Shari Bolen[3]. [1]Case Western Reserve University, Cleveland, OH; [2]Cuyahoga County Board of Health, Parma, OH; [3]MetroHealth/Case Western Reserve University, Cleveland, OH; [4]Prevention Research Center for Healthy Neighborhoods at CWRU, Shaker Heights, OH. (Control ID #2706567)

BACKGROUND: Several studies have shown improvements in fruit and vegetable (FV) intake with produce prescription programs, yet little is known regarding participant experiences with these interventions. We conducted a qualitative study to explore social dynamics of providers and patients in a produce prescription program for hypertension (PRx HTN). PRx HTN was offered at 3 safety net clinics in partnership with 20 local Farmers Markets (FMs) in 2015.

METHODS: We conducted in-person, semi-structured interviews with 5 providers (at least one from each clinic) and 23 patients (6–8 patients from each clinic). Project staff recruited interviewees via a mail-in response card sent to all program participants and e-mail to program providers. Patient interviews focused on three areas: 1) beliefs about food, healthy eating, and farmer's markets; 2) experiences of clinic-based program activities; and 3) experiences at farmer's markets. Provider interviews focused on their experience providing the program. All interviews were audio-recorded, transcribed, and analyzed using NVIVO qualitative data analysis software. We conducted analyses of *a priori* themes related to program processes and emergent themes related to participant experiences. Two investigators independently coded 10% of the interviews, achieving 80% inter-coder reliability.

RESULTS: Patients interviewed were mainly middle-aged (mean age 62 years), African American (100%) women (78%) with a mean hypertension duration of 12 years (similar to the overall participant population). Providers were mainly middle-aged men and women of diverse race/ethnicities. Several themes emerged related to social dynamics.

First, both providers and patients reported increased positive social interaction through program activities. Patients reported the belief that providers "care" for them when they discuss nutrition, and providers viewed nutritional education as a positive tool to use beyond medications. Second, patients described FMs as positive spaces in which to engage with others. This experience was particularly common among older adults with limited venues for social interaction. Third, patient families provided social support by engaging with the program formally (e.g., as husband and wife participants) or informally (e.g., attending FMs with the participant). Finally, patients frequently understood program education, such as healthy eating patterns, in relation to their personal histories growing their own FVs within their families or communities.

CONCLUSIONS: Social aspects increased patient enthusiasm for the program and should be leveraged in future efforts by incorporating family and friends when available. Positive social interactions could enhance resilience among program providers by reducing burnout, and among their food insecure patients by providing additional support for them to better manage their diet.

SOCIOECONOMIC DETERMINANTS OF DELAYED SYMPTOM-ONSET-TO-PRESENTATION TIME IN ASCENDING AORTIC DISSECTION PATIENTS Tanya Doctorian. Kaiser Permanente Fontana Medical Center, Fontana, CA. (Control ID #2705747)

BACKGROUND: Ascending aortic dissection (AoD) is the most lethal condition involving the aorta. Despite increasing awareness of AoD among clinicians and improvements in diagnostic imaging, the mortality and morbidity rates of this condition remain high. In an effort to further optimize outcomes, symptom onset and its impact on presentation is needed. The onset of symptoms to hospital presentation, or pre-hospital delay, is a known cause for increased morbidity and mortality. Historically, ethnicity and insurance status were considered to be factors associated with delayed presentation to the emergency department in patients with ascending AoD. The objective of this study was to determine whether ethnicity, insurance status, marital status and gender function as barriers to presentation in patients with ascending AoD.

METHODS: 235 patients presenting with ascending AoD from 2007 to 2016 to a tertiary hospital with a diverse patient population were retrospectively studied. 145 patients with complete data were included in this analysis. Patients without complete data were excluded. Symptom-onset-to-hospital-arrival time was analyzed for the following factors: gender, ethnicity (White, Black, Hispanic/Latino, Asian, other), type of insurance (private insurance, uninsured, Medicare/Medicaid), and marital status. Symptom onset time was identified by review of medical records and emergency services data. Non-parametric univariate and multivariate analyses were carried out to compare differences in time to presentation between groups.

RESULTS: See table

CONCLUSIONS: In this cohort, ethnicity, insurance status, gender, and marital status were associated with significant barriers to presentation in patients with ascending AoD. In particular, ascending AoD patients who were female, Hispanic/Latino, uninsured, and widowed presented significantly later than the other patient groups. Enhanced public awareness and targeted education to these vulnerable patient groups are necessary to decrease pre-hospital delays, reduce barriers to presentation, and further improve clinical outcomes in ascending AoD patients.

	Percentage of Population	Symptom onset to Presentation time {median (min – max)} in hours	P-value
Gender			
Male	82%	2 (0.5 – 168)	Reference
Female	28%	4 (0.5 – 168)	0.004
Ethnicity			
White/Caucasian	34%	2 (0.5 – 48)	Reference
Black	35%	4 (0.5 – 168)	0.026
Hispanic/Latino	19.80%	8 (0.5 – 168)	0.004
Asian	12.6%	6 (0.5 – 168)	0.054
Other	3.60%	2 (0.5 – 5)	0.305
Insurance Status			
Private insurance	53%	2 (0.5 – 168)	Reference
Uninsured	4.5%	8 (4 – 168)	0.001
Medicare/Medicaid	38.7%	3 (1 – 44)	0.413
Marital status			
Married	59.46%	2 (0.05 – 168)	Reference
Divorced	9.90%	3 (0.05 – 24)	0.219
Widowed	8.11%	24 (1 – 168)	<0.001
Single/Never Married	22.53%	4 (0.5 – 168)	0.029

SPECIALTY REFERRALS: BLAME IT ON THE SCHEDULING? Andrew Schreiner[2]; William P. Moran[2]; Jingwen Zhang[1]; Justin Marsden[2]; Patrick D. Mauldin[2]. [1]MUSC, Charleston, SC; [2]Medical University of South Carolina, Charleston, SC. (Control ID #2707637)

BACKGROUND: Referrals from primary care practitioners to specialty providers occur with great frequency in the U.S. and are rapidly increasing. In 2009, 105 million ambulatory office visits resulted in referral, with the proportion of ambulatory visits resulting in specialty referral nearly doubling (4.8 to 9.3%) over the previous decade (1999 to 2009). Estimated costs for these specialty visits approach $98 billion annually. Specialty referrals contribute to clinical volume, the cost of services, and the fragmentation of care. While many factors may contribute to the decision to refer, this study looks at the execution of specialty referrals from the perspective of scheduling.

METHODS: We searched the electronic health record of an academic, internal medicine, patient-centered medical home (PCMH) at the Medical University of South Carolina (MUSC) for ambulatory referral orders to specialty providers during a six month period between July and December 2014. These referrals were then randomly selected and reviewed with a data abstraction tool. Data abstraction elements included the referral specialty, the date of the scheduled specialty appointment, the date of the attended specialty visit, the number of times scheduled, and the ordering provider. With this data, we compared the rates of scheduling and attendance of specialty visits based upon the number of times an initial specialty encounter was scheduled. Univariate analysis (Chi squared test) was used for proportions.

RESULTS: Primary care providers ordered 2,757 referrals for specialty consultation. After random selection, 1,080 charts underwent review with the exclusion of 33 podiatry referrals (due to an inability to confirm scheduling or attendance). Forty-one different specialties appeared in the referral order destinations with referrals to gastroenterology (151, 14.0%), ophthalmology (107, 9.9%), and dermatology (86, 8.0%) occurring most frequently. Of the 1,047 specialty referrals, 851 (81.3%) were scheduled, and 684 (80.4%) of those scheduled were attended. In total, patients attended 65.3% of specialty referrals ordered by general internists. With regards to scheduling, 196 referrals were never scheduled, 628 were scheduled once, and 223 were scheduled on more than one occasion. There was a statistically significant difference in the proportion referral visits attended between those scheduled once (83.0%) and those scheduled more than once (74%, $p = 0.004$).

CONCLUSIONS: Many patients receiving orders for specialty referral never get an appointment scheduled with the intended specialty provider. Further, patients with multiple scheduled visits to a specialty provider attended less often than those patients with only one scheduled visit. Both of these observations identify opportunities for clinics and health systems to improve the tracking and completion of specialty referrals. Future questions need to address any potential impact on this referral scheduling in relation to clinically relevant outcomes.

SPILLOVER EFFECTS OF ADULT MEDICAID EXPANSIONS ON CHILDREN'S USE OF PREVENTIVE VISITS Maya S. Venkataramani[1]; Craig E. Pollack[1]; Eric Roberts[2]. [1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Harvard Medical School, Boston, MA. (Control ID #2703084)

BACKGROUND: With the implementation of the Affordable Care Act, 32 states have expanded Medicaid eligibility for adults. While research has demonstrated substantial benefits for the adults who gain Medicaid eligibility, the potential spillover effects on other groups have been less well evaluated. One potentially important, but little studied, consequence of expanding health insurance access for parents is its impact on well child visit (WCV) utilization. We leverage a national experiment, specifically state-level policy variation in adult Medicaid eligibility, to estimate the relationship between parents' Medicaid coverage and children's receipt of annual WCVs.

METHODS: We analyzed data from the Medical Expenditure Panel Survey (MEPS) from 2001–2013, linked to state Medicaid eligibility criteria and county-level characteristics. Our primary analytic sample consisted of children ages 2 through 17 linked to their parent or guardian (ages 20 to 64 years) living in households with incomes <200% of the Federal Poverty Level. The main outcome was whether a child received at least one WCV in the year. We controlled for relevant parental, family, child and county-level characteristics as well as state and year fixed effects. We first conducted an intention-to-treat (ITT) analysis to examine the relationship between within-state changes in adult Medicaid eligibility and WCVs, modeling the probability of WCV receipt with parental Medicaid eligibility as the main independent variable. We then performed an instrumental variable (IV) analysis to model the relationship between parental Medicaid enrollment and WCV utilization, using within-state Medicaid eligibility changes as an instrument for parental Medicaid enrollment.

RESULTS: Our primary analytic sample consisted of 50,622 parent–child dyads (representing 266,557,804 weighted pairs) across the 13 study years. The percentage of children receiving an annual WCV increased from 32.7% in 2001 to 47.9% in 2013. In the ITT analysis, a 10 point increase in a state's adult Medicaid eligibility (measured relative to the FPL) was associated with a 0.28% increase in the probability that a low-income child received an annual WCV (95% confidence interval (CI): 0.11 to 0.44%, $p < 0.001$). Our IV analysis revealed that parents' Medicaid enrollment was associated with a 29% increase in the probability of having a WCV (95% CI: 12 to 47%, $p =$ 0.001). We observed similar results in sensitivity analyses that controlled for child Medicaid enrollment.

CONCLUSIONS: Our study highlights that Medicaid eligibility expansions targeted at low-income adults can result in beneficial effects for their children by increasing their receipt of recommended pediatric care. We illustrate an important spillover effect of adult insurance coverage that should be considered in future policy decisions.

SPONSORSHIP AS A PATH TO LEADERSHIP: VIEWS OF SPONSORS AND PROTéGéS AT ONE ACADEMIC HEALTH CENTER Rachel Levine[2]; Manasa Ayyala[2]; Joann Bodurtha[1]; Kimberly Skarupski[1]; Marlis Gonzalez Fernandez[1]; Lisa Ishii[1]; Barbara Fivush[1]. [1]JHUSOM, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #2694212)

BACKGROUND: Lack of diversity in top leadership positions remains an ongoing problem in academic medicine (AM), despite initiatives to address this. In business, the focus has shifted from mentorship to sponsorship and structured sponsorship programs have been used to successfully propel women and minorities into leadership. Sponsorship increases the visibility of talented individuals (protégés) by providing access to career- advancing opportunities and influential networks. In this study, we used qualitative methods to explore the relationship between sponsorship and advancement in AM.

METHODS: In 2016, we conducted semi-structured, one on one interviews with 23 Johns Hopkins School of Medicine (SOM) faculty. We used purposeful sampling to recruit study informants including 12 sponsors and 11 protégés. Faculty in positions of influence and power who are able to promote the careers of other faculty were considered sponsors. Thus, we targeted all SOM clinical department chairs to participate as sponsors. We defined a protégé as a faculty who had been recognized for leadership potential. To identify protégés, we contacted faculty who participated in the Johns Hopkins Medicine Leadership Development Program from 2009 to 2014. Interviews were audiotaped and transcribed. Data analysis was iterative, and an editing analysis style was used to identify themes related to sponsorship.

RESULTS: We identified the following themes: 1) Faster and further: sponsorship is critical for advancement; 2) Opening doors: sponsorship activities provide opportunities but credibility is key; 3) Benefits of sponsorship go beyond the advancement of a particular protégé; 4) Risks for sponsors and protégés are real; 5) Sponsorship may undermine transparency and perceptions of meritocracy in AM. Informants describe sponsorship as critical for rapid, high level advancement especially for "nontraditional" leadership candidates such as women and UIM faculty. Some sponsorship activities include nominating protégés for local and national committees, high profile speaking opportunities, prestigious awards, and leadership roles. Credibility (explicit backing from the sponsor) is viewed as fundamental for successful sponsorship. Sponsorship increases the overall talent and success of an organization. Sponsors risk their reputation when promoting a protégé. Protégés risk being pushed toward opportunities for which they may be under-prepared and/or being seen simply as an extension of their sponsor. Informants describe a tension between sponsorship and a belief that advancement in AM is transparent and solely merit- based. They also acknowledge that unconscious bias may influence who gets selected for sponsorship.

CONCLUSIONS: Informants view sponsorship as key to achieving high level leadership. It remains unclear if structured sponsorship programs can help to address the lack of diversity in leadership in AM. However, increased awareness of how sponsorship works may encourage women and UIM faculty to seek out and benefit from it.

STEPPING UP OR SCALING BACK? AN EXAMINATION OF (DE)INTENSIFICATION RECOMMENDATIONS IN CLINICAL PRACTICE GUIDELINES. Adam A. Markovitz[2, 1]; TImothy Hofer[2, 1]; Whit Froehlich[2, 1]; Shannon E. Lohman[1]; Tanner Caverly[2, 1]; Jeremy Sussman[2, 1]; Eve A. Kerr[2, 1]. [1]VA Center for Clinical Management Research, Ann Arbor, MI; [2]University of Michigan Medical School, Ann Arbor, MI. (Control ID #2705017)

BACKGROUND: While initiatives like the Choosing Wisely campaign have focused on reducing one-time, discrete services (e.g., avoid antibiotics for upper respiratory infections), clinical guidelines rarely seem to address when to reduce long-term use of routine services for ongoing or chronic conditions. We quantified how frequently guidelines recommend *deintensification* - stopping or scaling back the intensity or frequency of routine services currently part of a patient's ongoing care.

METHODS: We identified all current guidelines for diabetes and cardiovascular disease across 7 major professional and federal organizations between January 1 2012 and April 30 2016. Recommendations were included if they pertained to services performed in the ambulatory setting, for the same patient over time, and under a primary care physician's discretion. Recommendations were categorized as intensification or deintensification and tabulated across: (1) societies; (2) testing or treatment; and (3) suggestive (e.g., "is reasonable," "should be considered") or prescriptive (e.g., "is indicated," "should be given").

RESULTS: We identified 372 recommendations across 22 guidelines that met inclusion criteria. We categorized 105 (28%) recommendations as deintensification and 267 (72%) as intensification. We found that only two organizations had more than 25% of recommendations categorized as deintensification (Figure). Only 25% of treatment recommendations were categorized as deintensification, while 36% of testing recommendations were deintensification. Among deintensification recommendations, 34% were suggestive and 66% were prescriptive; among intensification recommendations, 38% were suggestive, and 63% prescriptive.

CONCLUSIONS: Current guidelines make substantially more recommendations for intensification of routine services for cardiovascular disease and diabetes than deintensification. There is considerable inconsistency in how often organizations develop and publish deintensification recommendations. If we are to decrease overtreatment and overtesting, guideline developers need to pay more consistent attention to recommending when clinicians should stop or scale back routine services.

STORIES FOR CHANGE: PILOT FEASIBILITY PROJECT OF A DIABETES DIGITAL STORYTELLING INTERVENTION FOR REFUGEE AND IMMIGRANT ADULTS WITH TYPE 2 DIABETES Mark L. Wieland[1]; Jane W. Njeru[1]; Marcelo M. Hanza[1]; Deborah Boehm[7]; Davinder Singh[2]; Barbara Yawn[3]; Christi A. Patten[1]; Matthew M. Clark[1]; Jennifer A. Weis[1]; Ahmed Osman[4]; Miriam Goodson[5]; Graciella Porraz-Capetillo[1]; Abdulla Hared[4]; Rachel Hasley[6]; Laura M. Guzman-Corrales[7]; Rachel Sandler[7]; Valentina Hernadez[2]; Paul J. Novotny[1]; Jeff A. Sloan[1]; Irene G. Sia[1]. [1]Mayo Clinic, Rochester, MN; [2]Mountain Park Health Center, Phoenix, AZ; [3]Olmsted Medical Center, Rochester, MN; [4]Somali Community Resettlement Services, Rochester, MN; [5]Alliance of Chicanos, Hispanics, and Latin Americans, Rochester, MN; [6]Community Health Services, Inc, Rochester, MN; [7]Minneapolis Medical Research Foundation, Minneapolis, MN. (Control ID #2704272)

BACKGROUND: There exists a need for the development of effective type 2 diabetes (T2DM) interventions for underserved adults that can be widely disseminated. One promising type of intervention are culturally tailored interventions that incorporate health technology to help reduce T2DM-related health disparities that affect immigrant groups to the US. Digital storytelling interventions are narrative based videos elicited through a community based participatory research (CBPR) approach that highlights the authentic voices of participants overcoming obstacles to healthy behaviors. The purpose of this pilot project was to examine the potential effectiveness of a digital storytelling intervention designed through a CBPR approach for Latino and Somali immigrants with T2DM.

METHODS: *Study design*: A pilot feasibility cohort study of a 12-min culturally and linguistically tailored digital storytelling intervention consisting of an introduction, 4 stories of managing T2DM, and a concluding educational message. *Setting*: Five primary care clinics in Minnesota and Arizona. *Population*: 25 Somali and Latino patients with T2DM received the digital storytelling intervention. Control patients with T2DM ($n = 25$) were matched to the intervention arm by site, race/ethnicity and baseline hemoglobin A1C (HbA1C). *Measures*: Acceptability of the intervention, confidence and motivation about managing diabetes as a result of watching the video were assessed by structured interviews. HbA1C was assessed at baseline and up to six months follow-up. *Data analysis*: Interview and HbA1C data were reported using descriptive statistics. A paired samples t-test was used to assess changes in HbA1C among intervention participants from baseline to the first follow-u *P* value. An independent samples t-test was used to compare the change in HbA1C between intervention participants and controls.

RESULTS: All participants in the intervention arm reported that the digital story telling intervention got their attention, was interesting, and useful; 96% reported more confidence about managing their T2DM after watching the video; 92% felt the video motivated them to change a specific behavior related to T2DM self-management. Mean baseline HbA1C for the intervention participants was 9.3%; change from baseline to first follow-up was −0.8% ($p = 0$ .02). Baseline characteristics were similar between the two arms. This effect size was attenuated when comparing intervention participants with controls (−0.8% vs. -0.4%, $p = 0.31$).

CONCLUSIONS: Implementation of a digital storytelling intervention for T2DM among immigrant populations in primary care settings is feasible and

resulted in self-rated improvement in psychosocial constructs that are associated with healthy T2DM self-management behaviors, and there was some evidence of improvement in glycemic control. A large scale efficacy trial of the intervention is warranted.

STRESS MANAGEMENT AND RESILIENCY TRAINING FOR HEALTHCARE PROVIDERS Michelle L. Dossett[1, 2]; Darshan Mehta[1, 2]. [1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA. (Control ID #2705610)

BACKGROUND: Burnout is epidemic among healthcare providers. Prior studies have suggested that resiliency training programs incorporating mind-body skills may reduce provider burnout. We examined the effects of a stress management and resiliency training (SMART) program developed for clinical populations and adapted it to healthcare providers.

METHODS: Seventeen physicians and nurse practitioners participated in our 8-session SMART Program. Fifteen clinicians completed pre- and post-program measures which included the perceived stress scale-10 (PSS-10), global physical and mental health and job satisfaction questionnaires, and previously validated single item measures of emotional exhaustion and depersonalization (burnout). We also asked participants to rate the relevancy of the program to their life and work, the helpfulness of the skills taught, and to comment on how the program affected them personally and professionally.

RESULTS: Participants attended an average of 6 of 8 sessions. We observed a trend toward improvement in all factors examined (Table 1). All participants agreed that the program was relevant to their life and work (81% strongly agreed) and the skills taught were found to be helpful (88% strongly agreed). Qualitative analysis of free text responses revealed that participants developed greater awareness, presence with patients and loved ones, appreciation for life, and empowerment to make positive life changes.

CONCLUSIONS: Our results suggest that delivering the SMART Program to healthcare providers is feasible and may serve as a useful tool for increasing provider resilience and reducing burnout. A second cohort is currently underway.

Table 1: Pre-Post Changes in Stress, Health, Job Satisfaction and Burnout

	Pre Mean (SD) or %	Post Mean (SD) or %	p	Cohen's d
Perceived Stress Scale	15.7 (5.5)	13.3 (3.9)	0.105	0.45
Global Physical Health	16.7 (1.4)	17.3 (1.4)	0.072	0.50
Global Mental Health	14.2 (3.3)	15.3 (3.1)	0.084	0.48

STUDENT-RUN FREE CLINIC VOLUNTEER PERSPECTIVES ON INTERPROFESSIONAL CARE AND LEARNING Madhurima Baliga[3]; Tuong Phan[3]; Jacqueline To[3]; Samuel Gordon[3]; Andrew Stahly[2]; Daniel Hecht[2]; Caitlin Felder-Heim[2]; Kari Mader[1]; Joseph Johnson[4]; Lynn Vanderweilen[3]. [1]University of Colorado, Denver, CO; [2]University of Colorado School of Public Health, Denver, CO; [3]University of Colorado School of Medicine, Denver, CO; [4]The DAWN Clinic, Aurora, CO. (Control ID #2706353)

BACKGROUND: Student run free clinics (SRFCs) offer health services to underserved communities and unique education opportunities to students. While the literature suggests that SRFCs are a good setting for interprofessional and clinical learning, more reseach is needed to fully understand the impact of volunteering at an SRFC on student attitudes. We aimed to evaluate student volunteers' attitudes towards interprofessionalism, underserved healthcare, and primary care at our local SRFC, the DAWN (Dedicated to Aurora's Wellness and Needs) Clinic in Aurora, CO. This clinic operates two evenings per week, staffed by graduate and undergraduate students of various health professions, and supervised by practicing preceptors. Students work together in mixed-profession teams to serve patients that are typically uninsured (93%) and of minority racial or ethnic background (86.2%).

METHODS: Student volunteers were surveyed before volunteering at DAWN and surveyed again after having volunteered for 1 year, from March 2015 to August 2016. Participation in the study was voluntary. In order to maintain privacy, subjects created their own unique identifier and responses were collected via RedCap, an online survey management database. Survey questions were adapted from the Readiness for Interprofessional Learning Scale (RIPLS), Student Perceptions of Interprofessional Clinical Education Revised (SPICE-R), and Medical Student Attitudes Toward the Underserved (MSATU) surveys. Survey data was analyzed using paired t-tests to detect changes in attitudes after volunteering at the DAWN Clinic.

RESULTS: A total of 26 volunteers participated in both the pre- and post-survey. Due to low retention rate in the post-survey, while most attitudes tended to be more positive following a year of service at DAWN, only a few questions demonstrated statistically significant improvement. Volunteers agreed or strongly agreed that learning with other students and professionals would make them a more effective member of a health and social care team ($p = 0.04$). Volunteers also agreed or strongly agreed that trust and respect are required for successful small-group learning ($p = 0.02$).

CONCLUSIONS: SRFCs positively impact student attitudes towards other professions and towards interprofessional care. Attitudes towards underserved healthcare and primary care are more difficult to elucidate, a limitation being that these participants have self-selected to volunteer at a free clinic. Future work includes assessing the attitudes of all volunteers who have volunteered at DAWN, controlling for number of times they have volunteered, and also assess their attitudes on underserved care and primary care.

SUBSISTENCE DIFFICULTIES PREDICT WORSE ABSTINENCE OUTCOMES AMONG HOMELESS SMOKERS: SECONDARY ANALYSIS OF A RANDOMIZED SMOKING CESSATION TRIAL Awesta Yaqubi[2]; Yuchiao Chang[2, 1]; Seth A. Berkowitz[2, 1]; Claire McGlave[2]; Nancy A. Rigotti[2, 1]; Travis P. Baggett[2, 1]. [1]Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital, Boston, MA. (Control ID #2698807)

BACKGROUND: Three-quarters of homeless adults smoke cigarettes. Although most homeless smokers want to stop smoking, cessation rates in this population are generally low. Competing priorities for shelter, food, clothing, and other subsistence needs may be one explanation for this. We assessed the impact of subsistence difficulties on smoking abstinence among participants in a randomized controlled trial (RCT) for homeless smokers.

METHODS: We conducted a secondary analysis of data from a 3-arm smoking cessation pilot RCT of nicotine patch therapy and behavioral counseling alone or in combination with financial incentives or text messaging. All study activities occurred at Boston Health Care for the Homeless Program from 10/2015 to 6/2016. Participants were homeless adult smokers (≥5 cigarettes/day) who were ready to quit smoking within the next month. We assessed past-month subsistence difficulties at baseline using a 5-item scale originally developed for the RAND Course of Homelessness Study and subsequently shown to have good internal consistency ($\alpha = 0.80$) in homeless smokers. Scale items assessed the frequency (0 = never, 3 = usually) of difficulty finding shelter, food, clothing, a place to wash, and a place to use the bathroom. The primary outcome was a repeated measure of smoking abstinence, defined as an exhaled carbon monoxide <8 parts per million and assessed 14 times over 8 weeks of follow-up. Secondary outcomes included attendance of weekly counseling and days of nicotine patch use in the past week, each assessed 8 times over 8 weeks of follow-up. We examined the associations between baseline subsistence difficulties and each outcome using repeated-measures logistic or linear regression with generalized estimating equations, adjusting for age, gender, race, drug and alcohol use severity, psychiatric symptom severity, nicotine dependence, and treatment assignment.

RESULTS: Among randomized participants ($N = 75$), considerable proportions reported any past-month difficulty finding shelter (56%), food (33%), clothing (51%), somewhere to wash (29%), and somewhere to use the bathroom (33%). In the multivariable model, greater baseline subsistence difficulties predicted lower odds of smoking abstinence during follow-up (OR 0.90, 95% CI 0.82–0.99, per 1 point increase in subsistence difficulty score). Compared with participants in the lowest tertile of subsistence difficulties, those in the highest tertile had one-third the odds of being abstinent during follow-up (OR 0.33, 95% CI 0.11–0.93). Subsistence difficulty score was not significantly associated with counseling attendance (OR 1.04, 95% CI 0.95–1.15) or days of nicotine patch use (0 days difference, 95% CI −0.13, 0.13).

CONCLUSIONS: Homeless smokers with greater subsistence difficulties were less likely to be abstinent of smoking during follow-up despite similar use of counseling and nicotine patch therapy. Interventions for homeless smokers should assist with identifying resources to help address competing subsistence priorities.

SUBSTANCE USE DISORDER INITIATIVE IMPACT ON INTERNIST PREPAREDNESS, ATTITUDE, AND PRACTICE

Sarah E. Wakeman[2]; Genevieve Pham-Kanter[1]; Karen Donelan[3]. [1]Drexel University, Philadelphia, PA; [2]Massachusetts General Hospital, Charlestown, MA; [3]Massachusetts General Hospital, Boston, MA. (Control ID #2705835)

BACKGROUND: Alcohol and drug use disorders are frequently seen within general medical settings. Despite the prevalence, our previous research found that the majority of general internists do not feel very prepared to care for patients with SUD and few frequently provide treatment themselves.

METHODS: Pre- post- intervention web-based survey assessing general internists' attitudes, clinical practice, and preparedness to care for patients with SUD before and after the rollout of a hospital wide SUD initiative. The initiative included an inpatient addiction consult team, a post-discharge addiction clinic, recovery coaches, and integrated SUD treatment within primary care with bimonthly case conferences with addiction specialists.

RESULTS: The sampling frame consisted of all general internal medicine physicians at Massachusetts General Hospital in Boston Massachusetts in September 2014 ($n = 290$) and 2015 ($n = 296$). There were 149 respondents for the baseline and 143 respondents for the follow-up survey, response rates of 51 and 48%. There were no significant differences between groups with respect to gender, time spent providing clinical care, years since medical school graduation, having a family member with SUD, practice setting, or frequency seeing patients with SUD. Physicians who had a patient receive care from the consult team, discharge clinic, recovery coaches, or the integrated health center teams were significantly more likely to find caring for patients with SUD as satisfying as other clinical activities (44% vs 9%) and to disagree with the statement "using medications like methadone and buprenorphine for opioid use disorder is simply replacing one addiction with another" (91% vs 72%). These physicians were also significantly more likely to feel very prepared to screen for SUD (27% vs 9%), diagnose SUD (23% vs 9%), deliver a brief intervention (16% vs 5%), refer a patient to treatment (36% vs 14%), discuss medication treatments (22% vs 5%), discuss overdose prevention and naloxone (33% vs 5%), and discuss harm reduction with a patient (22% vs 7%). Physicians who had a patient receive care were also significantly more likely to frequently refer a patient to treatment (28% vs 2%), prescribe naloxone (11% vs 0%), prescribe addiction pharmacotherapy (15% vs 2%), and provide addiction treatment directly rather than referring to another caregiver (18% vs 5%).

CONCLUSIONS: Access to clinical care for SUD across a hospital system including an inpatient addiction consult team, integrated SUD treatment in primary care with addiction specialist support, recovery coaches, and a post discharge clinic significantly improved general internists' attitudes, preparedness, and clinical practice related to SUD.

SUBSTANCE USE SCREENING AND BRIEF INTERVENTION PATIENT CHARACTERISTICS AND SCREENING RESULTS: DIFFERENCES BETWEEN PRIMARY CARE AND EMERGENCY DEPARTMENTS

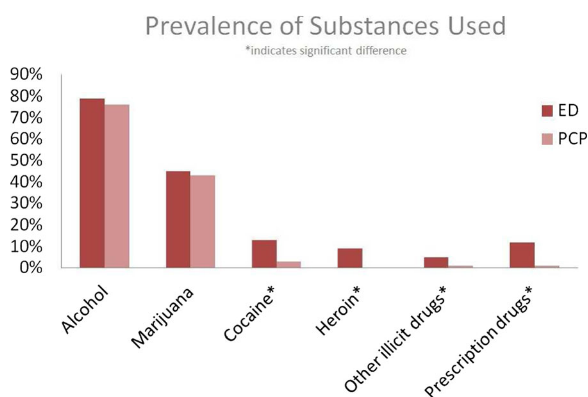
Jeanne Morley[1, 3]; Sandeep Kapoor[2, 3]; Kristen Pappacena[4]; Cherine Akkari[4]; Camila Bernal[4]; Charles Neighbors[4, 5]; Mark Auerbach[2, 3]; Nancy Kwon[2, 3]; Jonathan Morgenstern[1, 3]; Joseph Conigliaro[1, 3]; Megan O'Grady[4, 5]. [1]Northwell Health, Great Neck, NY; [2]Northwell Health, New Hyde Park, NY; [3]Hofstra Northwell School of Medicine, Hempstead, NY; [4]The National Center on Addiction and Substance Abuse, New York, NY; [5]Yale University, New Haven, CT. (Control ID #2704884)

BACKGROUND: Screening, Brief Intervention, and Referral to Treatment (SBIRT) for substance use has been cited as potentially valuable in current efforts to integrate care. However, it has not been widely implemented due to well-documented barriers. Two popular SBIRT settings are primary care practices (PCPs) and emergency departments (ED); however little research has examined their differences in terms of implementation needs. In order to better understand PCP and ED settings as part of SBIRT implementation, we examined whether patient characteristics and SBIRT screening results differed between them.

METHODS: Patients presenting to a PCP or ED were screened for risky substance use (SU) utilizing the AUDIT and DAST screening tools (n = 41,567) as part of an interdisciplinary SBIRT program and, if positive, were further assessed for psychosocial, health, and substance use problems (n = 1604). Demographic information was collected on all patients screened and data was analyzed using descriptive statistics, chi-square, t-test, and multilevel logistic regression analyses.

RESULTS: As compared to PCP patients, ED patients were 1) more severe in terms of substance use patterns and screening scores (Mean AUDIT scores ED 11.62; PCP 7.73; X2 = 8.66; $p < 0.05$); 2) more likely to use a variety of illicit drugs (cocaine (ED 13%; PCP 3% X2 = 34.51; $p < 0.05$), heroin (ED 9%; PC$P < 1$%; X2 = 40.8; $p < 0.05$); other illicit drugs (ED 5%; PCP 1%; X2 = 13.42; $p < 0.05$); prescription drugs (ED 12%; PCP 1%; X2 = 50.67; $p < 0.05$); 3) more likely to report psychosocial issues: unstable housing (ED 16%; PCP 1%, X2 = 16.37; $p < 0.05$), depression (ED 61%; PCP 39%; X2 = 18.48; $p < 0.05$), anxiety (ED 60%; PCP 49%; X2 = 4.34; $p < 0.05$); and 4) were more likely to screen into a higher risk category (Odds ratio = 2.64; 95% CI = 1.06, 6.55).

CONCLUSIONS: This study found important differences in patient characteristics and screening results between PCP and ED patients, with ED patients demonstrating more advanced levels of impairment, higher prevalence of multi-substance misuse, and more psychosocial comorbidities. To address this disparity, EDs implementing SBIRT may need to prepare for these more complex patients by providing additional resources and enhanced coordination with Primary Care.



Prevalence of Substances Used

SUBSTANTIAL VARIATION IN THE PRICES OF DRUGS USED IN COST-EFFECTIVENESS ANALYSES OF NOVEL ORAL ANTI-COAGULANTS Chana A. Sacks; Aaron Kesselheim; Michael Fralick. Brigham and Women's Hospital, Boston, MA. (Control ID #2705444)

BACKGROUND: Cost-effectiveness analyses (CEAs) are important tools to critically assess the value of medical interventions. However, in the US, the cost of a medication - a critical input to these analyses - is often difficult to determine. We conducted a systematic review of CEAs of novel oral anticoagulants (NOACs) to determine the sources of drug costs used in these assessments and to evaluate the variability in prices from these different sources.

METHODS: We identified CEAs for dabigatran, rivaroxaban, and apixaban using the Tufts Medical Center Cost-Effectiveness Analysis Registry, a database of more than 5,000 CEAs from 1976–2014. We searched MEDLINE and EMBASE from January 2014 - October 2016 to include CEAs published since the end of the registry. CEAs for the three drugs of interest based in the US health care system were included. We excluded review articles, editorials, and CEAs that did not use the US dollar. Two authors (CAS, MF) independently reviewed all identified CEAs and extracted the year, cost, and source of each cost for each NOAC and all comparator drugs. For the three NOACs, we then compared the cost trends in 1) wholesale acquisition cost, obtained from RedBook 2) average wholesale price, obtained from RedBook 3) and cash prices, obtained from GoodRx, which reports average prices from thousands of U.S. pharmacies from 2013–2015.

RESULTS: We identified 23 CEAs published between 2011–2016: 10 included dabigatran, 9 apixaban, and 10 rivaroxaban. Five studies analyzed multiple NOACs. Including both NOACs and comparators, a total of 58 medication costs were identified. Wholesale acquisition cost was used 13 times, more than any other measure. In 7 cases, the study cited Redbook, though did not specify whether the wholesale acquisition cost or the average wholesale price was used. Other sources included a previously published CEA (7), an estimate based on the cost of a related drug or the drug's European price (7), Analysource (7), Centers for Medicare and Medicaid (5), pharmacy cash prices (4), and "hospital costs" (4). In 4 cases, we could not determine the source of the price used. For all drugs, the average wholesale price was the highest, an average of $72.16/month more than the wholesale acquisition cost. In all but one case, the GoodRx price was between the two, an average of $17.80/month above the wholesale acquisition cost (range -$10.91 to $36.23). For all three drugs, all costs increased over time, with the wholesale acquisition cost increasing 44% for apixaban between 2013 and 2015, 44% for rivaroxaban between 2012 and 2015, and 53% for dabigatran between 2011 and 2015.

CONCLUSIONS: There is wide variation in the sources of prices used in CEAs, which leads to substantial differences in the cost inputs in these analyses. The costs of the three examined NOACs have also steadily increased since market entry. With greater attention to drug costs in upcoming years among payors and patients, a more consistent approach to the cost inputs of CEAs will be needed.

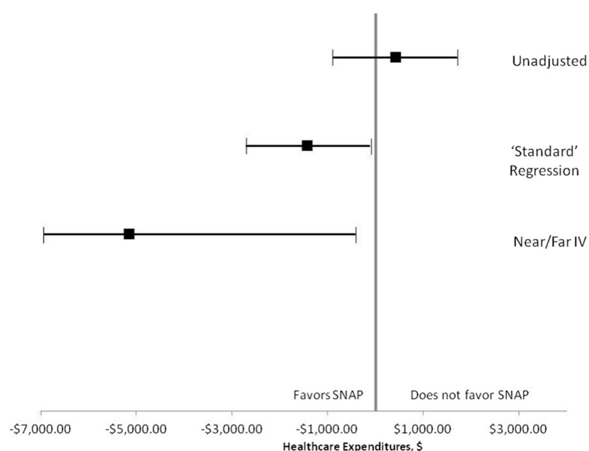
SUPPLEMENTAL NUTRITION ASSISTANCE PROGRAM (SNAP) PARTICIPATION AND HEALTHCARE EXPENDITURES AMONG LOW-INCOME ADULTS Seth A. Berkowitz[1]; Hilary Seligman[4]; James B. Meigs[2]; Sanjay Basu[3]. [1]MGH, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Stanford University, Stanford, CA; [4]University of California, San Francisco, San Francisco, CA. (Control ID #2698891)

BACKGROUND: Food insecurity is associated with high healthcare expenditures. It is unknown whether the Supplemental Nutrition Assistance Program (SNAP), which addresses food insecurity, can reduce expenditures.

METHODS: Using linked data from the 2011 National Health Interview Survey and the 2012–13 Medical Expenditures Panel Survey ($N = 4447$ adults with income <200% of the federal poverty threshold), we tested the hypothesis that self-reported SNAP receipt in 2011 is associated with lower total healthcare expenditures (all paid claims and out-of-pocket costs) in 2012–13. We first used 'standard' generalized linear modeling (gamma distribution, log link, with survey design information), adjusting for demographics (age, sex, race/ethnicity), socioeconomic factors (income, education, SSDI disability, urban/rural), census region, health insurance, and self-reported medical conditions. Next, to address unobserved selection bias into SNAP, we used near/far matching, a type of instrumental variable (IV) analysis. SNAP eligibility is set federally, but states vary in SNAP enrollment policies (e.g., online applications or fingerprinting requirements), thus subtly 'encouraging' or 'discouraging' enrollment. This variation formed our IV. Near/far matching compares people similar in observed characteristics ('near'), but who differ in how easy or hard it is to enroll in SNAP in their state ('far'). The IV strongly predicted SNAP enrollment (first-stage partial F statistic = 42.5) and passed IV validity tests (Sargan and Basmann tests of overidentifying restrictions).

RESULTS: Compared with other low-income adults, SNAP recipients were younger, more likely to be racial/ethnic minorities, and had lower income ($p < .001$ for all). In 'standard' regression with covariate adjustment, SNAP was associated with lower estimated annual healthcare expenditures (−$1,409.44; 95%CI -$2,693.73 to -$125.15)(*Figure*). In the near/far matching analysis, SNAP receipt was associated with even lower subsequent expenditures (−$5,160.16; 95%CI -$6,923.70 to -$437.85).

CONCLUSIONS: SNAP enrollment is associated with reduced healthcare spending among low-income U.S. adults.



Forest plot comparing difference in healthcare expenditures between those who did and did not receive SNAP

SUPPLY AND DEMAND: ASSOCIATION BETWEEN OF NON-ENGLISH LANGUAGE SPEAKING FIRST YEAR RESIDENT PHYSICIANS AND AREAS OF NEED IN THE UNITED STATES

Lisa C. Diamond[2]; Erik Vickstrom[3]; Mohammed Imran Mujawar[2]; Margaux C. Genoff[1]; Francesca Gany[2]. [1]Memorial Sloan Kettering Cancer Center, New York City, NY; [2]Memorial Sloan-Kettering Cancer Center, New York, NY; [3]U.S. Census Bureau, Washington, DC. (Control ID #2705798)

BACKGROUND: Over 25 million US inhabitants are limited English proficient (LEP). It is unknown whether physicians fluent in non-English languages are training in geographic areas with the highest proportion of LEP people. We sought to assess the spatial alignment of non-English language-speaking resident physicians and the geographic areas where language skills are needed.

METHODS: We conducted a cross-sectional study of 2013–2014 data from the Association of American Medical College's (AAMC) Electronic Residency Application Service (ERAS) database, Graduate Medical Education Track (GMETrack) database, and American Community Survey data from the US Census. All applicants for post-graduate medical training in 2013–2014 were included ($n = 50{,}766$). The ERAS application includes socio-demographic questions (e.g. racial/ethnic identity and languages spoken). Residency program locations were assigned to Core Based Statistical Areas. We measured LEP people's exposure to non-English language-speaking resident physicians. We then calculated the spatial alignment of non-English language-speaking resident physicians relative to the distribution of the LEP-speaking population.

RESULTS: Thirty-seven percent of resident physicians in 2013–2014 spoke at least one non-English language. LEP speakers' exposure to non-English language-speaking residents varied. The resident physician to LEP ratios were 13.6 for Spanish, 52.9 for Chinese, 22.7 for Vietnamese, 38.5 for Korean, and 20.2 for Tagalog, the five most common languages spoken by LEP people in the US. There were differences across metropolitan areas by language. For Spanish, the resident physician to Spanish LEP ratio was 5.1 in Los Angeles (33% of the national ratio) but 23.7 in New York (153% of the national ratio) (Figure). The differences were most drastic for Tagalog, where the ratio was 70.4 in New York (349% of the national ratio) compared to 2.9 in San Francisco (14% of the national ratio) and 0 in San Diego, San Jose, and Seattle. Spatial alignment of Spanish-speaking residents is greatest in the Northeast and lowest in the Mid-West, Southeast, and Northwest regions of the US. Among the top five LEP languages in the US, Chinese-speaking resident physicians (.33) were the least spatially mismatched, followed by Spanish (.36), Vietnamese (.42), Korean (.43), and Tagalog (.63).

CONCLUSIONS: Diversity of language ability in the physician workforce is an important complement to language assistance services for providing quality care to patients with LEP. Residency programs in areas of high need must consider whether resident physician non-English language fluency would improve the service to their communities.

SYMPTOM PREDICTORS OF DELAYED ASCENDING AORTIC DISSECTION PRESENTATION Tanya Doctorian. Kaiser Permanente Fontana Medical Center, Fontana, CA. (Control ID #2705790)

BACKGROUND: Ascending aortic dissection (AoD) is the most lethal condition involving the aorta. Despite increasing awareness of AoD among clinicians and improvements in diagnostic imaging, the mortality and morbidity rates of this condition remain high. In an effort to further optimize outcomes, symptom onset and its impact on presentation is needed. Symptom-onset-to-hospital-presentation time delay, or pre-hospital delay, is a known cause for increased morbidity and mortality. In an effort to further optimize outcomes, by decreasing pre-hospital delays, symptom onset and its impact on presentation is needed. The objective of this study was to determine whether the type and nature of specific symptoms are associated with delays in presentation of ascending AoD patients.

METHODS: 235 patients presenting with ascending AoD from 2007 to 2016 to a tertiary hospital with a diverse patient population were retrospectively studied. 145 patients with complete data were included in this analysis. Patients without complete data were excluded. Symptom-onset-to-hospital-arrival time was analyzed for the following factors: type of symptoms (chest pain, back pain, abdominal pain, syncope/dizziness, other) and nature of symptoms (constant, intermittent). Symptom-onset time was identified by review of medical records and emergency services data. Non-parametric univariate and multivariate analyses were carried out to compare differences in time-to-presentation between groups.

RESULTS: See table

CONCLUSIONS: As expected, ascending AoD patients presenting with chest pain presented the fastest from among the groups. Patients with abdominal pain had a significantly longer delay than patients with the other presenting symptoms. As expected, patients with intermittent symptoms presented significantly later than patients with constant symptoms. Interestingly, symptom-onset-to-presentation time remains long even with the classical symptom of chest pain, which is the most common presenting symptom of ascending AoD. Thus, continued and enhanced population education and awareness is necessary to reduce pre-hospital delays and improve outcomes in ascending AoD patients.

Symptoms	Percentage of Population	Symptom onset-to-Presentation {Median (min – max)} in hours	P-value
Chest pain	69.37%	2.5 (0.5 – 168)	Reference
Back pain	10.81%	6 (1 – 120)	<0.001
Abdominal pain	3.50%	26.5 (5 – 72)	0.004
Syncope/Dizziness	5.41%	14.5 (2 – 144)	0.002
Other	7.00%	7 (4 – 168)	0.002
Constant	62.16%	2 (0.5 – 24)	Reference
Intermittent	37.84%	12 (2 – 168)	<0.001

SYSTEMATIC REVIEW OF EFFECTS OF MARIJUANA USE ON CARDIOVASCULAR RISK FACTORS AND OUTCOMES Divya Ravi[2]; Mehrnaz Ghasemiesfe[2]; Salomeh Keyhani[1]. [1]University of California at San Francisco, San Francisco, CA; [2]Northern California Institute for Research and Education, San Francisco, CA. (Control ID #2700211)

BACKGROUND: Marijuana is one of the most widely used illicit substances worldwide. While the number of users of marijuana is increasing, the perceived associated health risk seems to be declining. With more states legalizing recreational marijuana, a better understanding of the long-term health implications associated with the use of marijuana is necessary. In particular, a better understanding of the effect of marijuana on cardiovascular health is needed as it remains the number one cause of morbidity and mortality in the US and worldwide. We conducted a systematic review to examine the known effects of marijuana use on cardiovascular risk factor control and cardiovascular outcomes.

METHODS: We searched PubMed, Medline (1975–2016) for studies published in English that examined the association of marijuana use with cardiovascular risk factor control and outcomes. MeSH terms for search are outlined in the table. All titles and abstracts were independently reviewed for inclusion by two authors (DR, MG). Included articles again were independently reviewed by the same two authors. Conflict over the inclusion of a publication was resolved by a third reviewer (SK). We extracted data on study design, cannabis make up, route of exposure, dosage, physiological changes, cardiovascular risk factors and outcomes.

RESULTS: We screened 1608 titles and abstracts, kappa for inclusion was excellent (86.55%). 142 abstracts met the inclusion criteria. Of these papers, 31 of these were excluded on full text review leaving 111 included papers. Among the final sample, we identified 14 prospective cohort studies, 9 retrospective cohort studies,11 case control studies, 63 interventional studies, 9 crossover and 5 cross-sectional studies. Smoking was the predominant form of marijuana use studied. The majority of studies ($n = 77$, 69.3%) were focused on the acute hemodynamic changes following exposure to marijuana while studies reporting on the effect of marijuana on cardiovascular risk factor control ($n = 24$, 21.6%) and cardiovascular disease outcomes such as acute myocardial infarction, stroke, arrhythmia and cardiac arrest was more limited ($n = 21$, 18.9%). Multiple interventional studies reported increases in heart rate ($n =$ 71,63.9%) and drops in blood pressure ($n = 14$,12.6%) associated with use. Three studies reported on an association between marijuana use and acute myocardial infarction and 5 studies reported on an association between marijuana use and stroke, although study quality was variable.

CONCLUSIONS: Smoking marijuana causes acute hemodynamic changes. There is some evidence that marijuana is associated with adverse health outcomes. However, most available research in this realm is of poor quality. In the light of increasing social acceptance, a substantial investment in understanding the health effects of marijuana is warranted.

TAILORING COMMUNICATION TO HEALTH NUMERACY IN THE BREAST CANCER TREATMENT CONSULTATION: FEASABILITY AND OUTCOMES OF A WEB BASED SCREENING TEST FOR USE IN THE CLINICAL SETTING Marilyn M. Schapira[4, 6]; Kathlyn Fletcher[2]; Pamela S. Ganschow[3]; Elizabeth Jacobs[5]; Cynthia Walker[7]; Alicia J. Smallwood[1]; Denisse Gil[3]; Arshia Faghri[4]; Joan Neuner[1]. [1]Medical College of Wisconsin, Milwaukee, WI; [2]Medical College of Wisconsin/ Milwaukee VAMC, Tbd, AL; [3]Stroger Hospital/Rush University Medical Center, Chicago, IL; [4]University of Pennsylvania, Philadelphia, PA; [5]University of Wisconsin School of Medicine and Public Health, Madison, WI; [6]CMC VA Medical Center, Philadelphia, PA; [7]Duquesne University, Pittsburgh, PA. (Control ID #2701548)

BACKGROUND: The breast cancer treatment consultation often includes complex numeric information on prognosis and treatment. Without objective measures of patient numeracy, clinicians may convey information that is too complex for a given patient. A screening test for health numeracy and numeracy specific communcation guidance for providers can guide the content and format of communication in the cancer consultation.

METHODS: A cohort study was conducted of English or Spanish speaking women with a diagnosis of stage 0 to 3 breast cancer. Prior to a consultation with a radiation oncologist, general surgeon, or medical oncologist, the subject completed the NUMiCAT, a computer adaptive test consisting of up to10 multiple choice questions, with scores categorized as low, medium, or hgh. A NUMiCAT report with communication guidance specific to numeracy levels (information on strategies to consider or avoid) was provided to the clinician prior to the visit. The consultation was audio-recorded, Spanish consultations translated, transcribed, and coded for complexity of numeric information and use of teach back techniques to confirm patient understanding. Post-consultation surveys assessed feasibility and usability of the intervention. Analysis of transcripts coded the use complex numeric constructs in the domain of statistics. The association of patient NUMiCAT scores with communication of statistics and the use of teach back technique were evaluated using chi-square tests.

RESULTS: We enrolled 46 subjects that were diverse in primary language (32 English and 14 Spanish), education, race/ethnicity, and numeracy (39% low, 33% medium, 28% high). Patients rated as excellent or very good the clarity of purpose of the NUMiCAT (75%), the computer experience and ease of navigation (71 and 80%, respectively), clarity of questions (59%) and the overall experience of taking the NUMiCAT (63%). Clinicians rated as excellent or very good the clarity of the NUMiCAT report (96%), helpfulness of the report (40%), and satisfaction integration into the visit (35%). Twenty-seven percent (27%) of clinicians modified their communication somewhat (22%) or quite a bit (5%) based on the NUMiCAT report. Qualitative analysis revealed that statistical concepts were conveyed in 35 and teach back technique used in 26% of consultations. A trend towards higher use of statistics with more numerate patients was found ($p < 0.09$) but no association between use of teach back technique and patient numeracy ($p = 0.11$).

CONCLUSIONS: The use of a web-based numeracy screening test in the clinical setting was acceptable to patients and clinicians. However, increased awareness of patient numeracy level had only a small to moderate impact on clinican communication. Future strategies for providing effective tailored communication may require more intensive clinician communication training to support numeracy specific communication salient to the clinical context.

TEACHING TO TEST? A COMPARISON OF LAB TESTING IN TEACHING VERSUS NON-TEACHING HOSPITALS FOR TWO COMMON MEDICAL CONDITIONS Victoria Valencia[1]; Vineet M. Arora[2]; Sumant Ranji[3]; Carlos Meza[4]; Christopher Moriates[1]. [1]Dell Medical School at The University of Texas at Austin, Austin, TX; [2]University of Chicago Medical Center, Chicago, IL; [3]Zuckerberg San Francisco General Hospital, San Francisco, CA; [4]University Medical Center Brackenridge, Austin, TX. (Control ID #2690134)

BACKGROUND: It is often assumed resident physicians at academic medical centers order more tests for inpatients due to different aspects of the clinical learning environment. Despite this prevailing notion, there is very little evidence to support this claim. We sought to quantify differences in ordering practices between teaching hospitals and non-teaching hospitals for two common medical conditions - bacterial pneumonia and cellulitis.

METHODS: We used the Texas Inpatient Public Use Data File, a billing level state-wide dataset, to analyze all inpatient encounters between January 2014-June 2015 with a principal diagnosis of bacterial pneumonia ($N = 31,948$) or cellulitis ($N = 24,303$), and calculated number of lab tests per hospital day by summing individual units billed for laboratory revenue codes and dividing by length of stay (LOS). Labs per day were adjusted individually by the illness severity of the encounter using DRG weight. We categorized hospitals with > 100 cases of each principal diagnosis into 3 types: major teaching (member of Council of Teaching Hospitals, $N = 14$), minor teaching ($N = 13$), and non-teaching ($N = 89$) and compared labs per day across hospital types. We excluded patients who were <18 years of age, had an ICU stay during the hospitalization, were transferred from another hospital, or had a LOS > =2SD of the condition's mean LOS. We used one-way ANOVA tests to determine if severity-adjusted labs per day varied by hospital type, and multilevel quasi Poisson regression models with hospital as a random effect to determine if hospital type was associated with the raw number of labs in an encounter.

RESULTS: Mean adjusted labs per day varied significantly by hospital type and was highest for major teaching hospitals for both pneumonia and cellulitis after adjusting for severity of illness (major/minor/non-teaching pneumonia: 6.23/4.86/4.26, $p < 0.001$; major/minor/non-teaching cellulitis: 6.12/4.84/4.21, $p < 0.001$). Variance in adjusted labs per day was highest for academic teaching hospitals. Correlation analysis indicated strong association of mean severity-adjusted labs per day at the hospital level with an $R^2 = 0.80$, indicating that hospitals that ordered more labs for one condition also ordered more labs for the other condition. Quasi Poisson regression analysis indicated an association between raw number of labs per encounter and major teaching hospital (relative risk (RR) cellulitis (95% CI) = 1.44 (1.27-1.62), $p < 0.001$; pneumonia RR = 1.48 (1.33-1.64), $p < 0.001$) when compared to non-teaching hospitals.

CONCLUSIONS: Patients admitted to hospitals with pneumonia or cellulitis in the state of Texas may receive 20-60% more laboratory tests if they go to a major teaching hospital versus a non-teaching hospital. This relationship holds for two common inpatient conditions and after multiple adjustments for illness severity, length of stay and patient demographics.

TEACHING TRAINEES HOW TO CARE: PROPOSING A NEW STANDARD FOR PATIENT CARE

David S. Burstein. George Washington University Hospital, Washington, DC. (Control ID #2670997)

BACKGROUND: Physicians must care for those who are sick and dying, yet expectations around this task are fundamentally missing in medical training. Written assessments predominantly test biomedical knowledge. Standardized patient exercises are criticized as superficial. The Institute of Medicine's *Dying in America* shows how there is little formal instruction in the skills physicians will need when dealing with complex chronic illness. Meanwhile, value-based medicine and patient experience measures are redefining quality in healthcare. For medical education to respond, the act of caring must be better characterized and assessed; however, trainees value patients' perspectives and emotions less as they move through training, and learned empathic behaviors have a risk of disingenuous use in practice. An approach to patient care that respects these caveats is needed to facilitate curricular initiatives, assessment, and authentic practice habits.

METHODS: A formative textual analysis of academic and popular literature was performed to identify the things physicians do that make patients feel cared for. 11 books were purposively sampled based on subject matter including relief of suffering, empathy and end-of-life care. PubMed was searched for descriptions and investigations of doctor-patient relationships in medical training and clinical practice. More than 140 articles met inclusion criteria. Various articles types were considered and non-reputable journals were excluded. Behaviors, traits and values associated with high quality, person-focused patient care were coded into meaning, referential and thematic units. Units were analyzed into categories of learnable "endpoints" intended to promote genuine practice behaviors. 39 novel units were identified before saturation was reached. Endpoints were checked for accuracy and completeness via thirty to 60 min discussions of findings during and after the study period with experienced colleagues across many disciplines.

RESULTS: Seven endpoints were identified: Find Meaning, Appreciate Suffering, Be Present, Facilitate Patient Ease, Take Care of Oneself, Understand Power, and Use the Team. Empathy and compassion are adjuncts.

CONCLUSIONS: Authentic patient care skills can be characterized. These findings honor the changes in empathy that occur during clinical training and discourage artificial interactions with patients. They may represent an alternative, and perhaps more specific, avenue for assessing interpersonal skills and professionalism. Further discussion is needed to ensure that they are not biased by single authorship. Such an approach to patient care offers common perspective on the artistic nature of clinical practice. Accountability to these tenants could have profound implications in professional development, patient and practitioner satisfaction, and end-of-life care. Acknowledgements: Thank you to Dr. Rudolf Kumapley, Division Chair of Hospital Medicine, Stroger Cook County Hospital of Chicago, IL for encouraging this endeavor.

TEAM-BASED PRIMARY CARE REDESIGN ON THE PRACTICE FRONTLINE: FIELD OBSERVATIONS OF PRIMARY CARE PRACTICES

Anita D. Misra-Hebert[2]; Jacqueline Fox[3]; Adam T. Perzynski[1]; David Aron[4]; William Miller[5]; Michael B. Rothberg[2]; Kurt C. Stange[6]. [1]Case Western Reserve University at MetroHealth, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH; [3]Cleveland clinic, Cleveland, OH; [4]Louis Stokes Cleveland Veterans Affairs Medical Center, Cleveland, OH; [5]Lehigh Valley Health Network, Allentown, PA; [6]Case Western Reserve University, Cleveland, OH. (Control ID #2704118)

BACKGROUND: Primary care practice redesign with a shift to team-based care models is being implemented nationally to improve care delivery through the provision of high quality, efficient, accessible, and coordinated care. We evaluated a practice redesign effort in our integrated health system with an enhanced role of medical assistants (MAs) on care teams in primary care outpatient practices and focused on physician and team experience.

METHODS: Practice observations and informal interviews were conducted at 9 outpatient primary care practices in our health system, including urban, rural, and suburban settings. Each observation was conducted for a 4-hour session and included at least 1 physician and team participating in the new model. Field notes were recorded independently by 1 physician and 1 research nurse. Themes were identified using an editing style qualitative analysis. Notes were coded using NVivo software. Initial themes observed were discussed with primary care stakeholder panel participants including 8 patients and 4 primary care employees for feedback for factors important to practice environment.

RESULTS: We identified that MAs serve varied roles across practices. MA responsibilities were adapted to incorporate flexibility to respond to unique practice needs and were adjusted to unpredictable demands for patient needs or urgent messages during a clinic session. Analysis of field notes indicated variability in MA involvement in check-in and discharge processes. MA roles included 1) functioning as a scribe to document progress notes in the electronic medical record (EMR) for a portion of or the entire encounter, 2) maintaining clinical workflow with check-in or discharge or performing point of care testing, and 3) pre-visit and after-visit work such as managing paperwork, phone messages or order entry. Challenges to care delivery identified by teams included staffing changes, time pressure for physicians and non-physicians, lack of control of physician schedules- specifically access provided by team care models vs. usual care, the EMR, and after-visit work. Positive relationships between MAs and patients, MAs and physicians, and physicians and patients were observed and identified as key factors in successful implementation of team-based models. Feedback from patient stakeholders confirmed importance of organized check-in and discharge processes, appreciating team members' involvement in discharge and follow-up, need for appropriate scheduling, and value of a physician knowing a patient's history.

CONCLUSIONS: Effective transitions to team-based models of primary care delivery incorporated flexibility for practices to adapt responsibilities of added team members to fit the needs of the clinicians and practice. Focusing not only on optimizing practice workflow, but on developing positive relationships among team members and between all team members and patients was identified as a key factor to successfully implemented team-based models.

TELEHEALTH TRAINING IN MEDICAL EDUCATION: A SYSTEMATIC REVIEW

Peggy Leung[2]; Caroline Siegel[3]; Drew Wright[2]; Pamela Charney[1]. [1]Weill Cornell Medical College, New York City, NY; [2]Weill Cornell/NewYork Presbyterian, New York City, NY; [3]University of California, Los Angeles, Los Angeles, CA. (Control ID #2702698)

BACKGROUND: Telehealth has transformed the way we care for millions of patients. Despite its increasing use, little is known about how we educate our medical students and residents in its use. Here we conduct a systematic review of the peer-reviewed literature to explore how telehealth training is provided and the attitudes/concerns that surround its use.

METHODS: We conducted systematic literature searches in Medline, Embase and Cochrane from their inception through November 2016. Major search

terms included telehealth, medical education, medical schools, and residency. In addition, reference and related article searches were conducted in Ovid and PubMed. We included English-language manuscripts that pertained to (1) medical students and residents in any year of training and from any specialty, and (2) telehealth modalities such as telephone medicine and video conferencing. Two researchers independently reviewed all retrieved articles to identify studies meeting eligibility criteria and abstract pertinent data. The kappa prior to reconciliation (0.82) suggests high interrater reliability. The Medical Education Research Study Quality Instrument (MERSQI), a validated tool on a scale of 6 to 18, was used to evaluate study quality for our quantitative studies. For our qualitative studies, we used Consolidated Criteria for Reporting Qualitative Research (COREQ), a 32-point scale, to assess study quality.

RESULTS: 25 out of 1873 studies met our inclusion criteria. The studies included were quantitative ($n = 21$; 18 observational and 3 pre-post intervention studies), qualitative ($n = 3$), or both ($n = 1$). Platforms studied included telephone consultations ($n = 13$), video-conferencing ($n = 3$), smart phone applications ($n = 1$), electronic asynchronous communication ($n = 2$), and multimodality approaches ($n = 6$). The mean MERSQI score was 9.3 (ranging from 6 to 15), while the mean COREQ score was 13.3 (ranging from 9 to 20). 9 (36%) articles evaluated telehealth training programs. The majority detailed methods that improved learners' technical skills and all noted device satisfaction. Another 5 (20%) articles discussed positive student attitudes towards the platforms' use and students' intent on future use. However, many felt unprepared to use them. Thirdly, 5 (20%) articles discussed international users' attitudes. Similar to their American counterparts, the majority recognized the utility of telehealth, however cited concerns about equity of the technology. Lastly, 6 (24%) articles focused on patient safety. Respondents largely saw improved access to providers, however there are mixed reviews about the quality of care provided.

CONCLUSIONS: Despite robust growth in telehealth, medical education in this area is lacking and there is no consensus on which method will yield the most favorable results. We believe that training is rare and in need. Moreover, there are still many questions about how these platforms will affect the quality of patient-physician relationship, patient safety, and equity in its use.

TELEPHONE VERSUS EMAIL TO IMPROVE COMMUNICATION BETWEEN INPATIENT AND PRIMARY CARE PROVIDERS

David Lawrence; Sara Keller; Sarah J. Conway; Elizabeth Lee; Mukund Ramkumar; William Queale; Elizabeth Biddison; Sanjay Desai; Daniel Brotman; Stephen Berry. Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #2698304)

BACKGROUND: Direct communication between inpatient and primary care providers (PCPs) during a hospitalization may improve patient outcomes, but is often hard to achieve. Email is asynchronous and may thus facilitate direct communication more effectively than telephone. This prospective, controlled trial compared the effects of telephone and email-based interventions on rates of direct communication.

METHODS: All patients discharged from four internal medicine teaching services at a large urban hospital between July 2015 and June 2016 were included. The primary outcome was direct communication with the PCP as reported by the discharging provider in a mandatory field of the electronic health record. The two services with the highest and lowest rates of direct communication during a nine-month pre-intervention period were assigned as controls. The remaining two services were randomly assigned to either the telephone or email intervention. At the start of the intervention period, medical residents were asked to communicate with every patient's PCP, either by telephone (phone arm) or encrypted email (email arm) if the PCP was outside the health system, or by the most convenient method if the PCP was within the system. Comparisons were made using a difference-in-differences analysis with repeated-measures multivariate logistic regression.

RESULTS: Of the 3,775 patients studied, 50% were female, 61% African-American, and 2% Hispanic, and the median age was 56 years [IQR 44–69]. Respective pre- and post-intervention rates of direct communication were 38 and 33% for the combined control services, 28 and 40% for the email arm, and 38 and 58% for the telephone arm (figure). After adjusting for demographics, length of stay and severity of illness score, both the telephone (AOR 3.09 [95% CI, 2.01–4.77]) and email arms (1.73 [1.13–2.67]) had increased communication rates relative to the combined control services, with the telephone arm experiencing a larger increase than the email arm (1.77 [1.07-2.94]).

CONCLUSIONS: Both telephone and email-based interventions increased rates of direct communication compared to controls, with telephone demonstrating a larger increase. Barriers to email may include unavailability of PCP email addresses and cumbersome encryption protocols necessary to protect patient information. Until new platforms for secure, asynchronous communication are readily available, telephone may remain the most effective method for direct communication between inpatient and primary care providers.

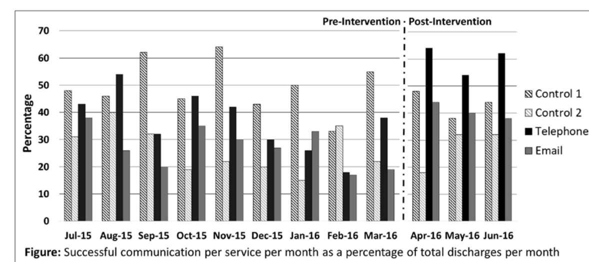

Figure: Successful communication per service per month as a percentage of total discharges per month

TEST RESULT MANAGEMENT APPROACHES AMONG CANADIAN INTERNAL MEDICINE ATTENDINGS AND TRAINEES

Thomas Bodley[2]; Janice L. Kwan[1]; Patrick Darragh[2]; Peter Cram[2]. [1]Mount Sinai Hospital, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada. (Control ID #2704176)

BACKGROUND: Little is known about current methods used by physicians to manage test results on hospitalized patients and virtually none of the existing research comes from Canada. We conducted a survey of Internal Medicine attending physicians and trainees at 3 large University of Toronto academic health centers. We hypothesized that problems identified in older US studies would persist in present-day Canada.

METHODS: We administered a paper-based survey to internal medicine attending physicians and trainees between November and December 2016. The survey consisted of 39 individual questions including: 1) demographics and clinical experience; 2) test ordering practices; 3) methods used for managing test results; and 4) formal education relating to these topics. This analysis focuses on section 3 of the survey regarding managing test results (18 questions). Respondents were asked if they kept a record of the tests they ordered and if they had a system to detect if a patient failed to receive a test. Respondents were asked the number of times in the past two months they identified a result they "wish they had known about sooner". A 5-point Likert scale was used to determine respondent satisfaction with current methods for managing test results and level

of concern that an ordered test may not be performed (1 being not at all satisfied/ concerned and 5 being extremely satisfied/concerned). Likert scale responses were dichotomized into favorable responses (4 or 5) versus less favorable responses (1–3) for statistical analysis. We compared responses of attendings versus trainees using a two sided Chi-Squared test.

RESULTS: During our first of three anticipated rounds of survey administration, we received responses from 55.8% of attendings (29 of 52) and 88.9% of trainees (32 of 36). The average age of attendings was 42.8 years, 58.6% were male, and 51.7% had more than 10 years of practice experience. 34.3% of trainees were medical students and 65.7% were residents; mean age for trainees was 26.8 years and 46.9% were male. 44.8% of attendings and 43.8% of trainees reported keeping a record of tests they order, and 55.2% versus 62.5% respectively report having a system to detect if a patient fails to receive an ordered test. 73.9% of attending physicians and 96.9% of trainees reported at least one test result they "wish they had known about sooner" in the past 2 months with 13.8 and 25% respectively reporting more than 5 such results. 37.9% of attendings and 15.6% of trainees were concerned or very concerned (Likert response 4 or 5) that an ordered test may not be performed ($p = 0.05$). Attendings were more often satisfied or very satisfied (Likert response 4 or 5) than trainees with their current methods for managing test results (44.8% versus 12.5%, $p = 0.01$).

CONCLUSIONS: Canadian attending physicians and trainees identified many problems in test result management, similar to prior, older US studies. Our results suggest that there is still considerable need for improvement.

TEXT MESSAGING TO IMPROVE OUTCOMES IN PATIENTS WITH PAINFUL DIABETIC PERIPHERAL NEUROPATHY (PDPN) Victoria Bauer[1]; Chi-hsiung Wang[1]; Nancy Goodman[1]; Terri L. Craig[2]; Scott Glosner[2]; Mark Juhn[2]; Joseph C. Cappelleri[2]; Alesia Sadosky[2]; Camille Cooley[3]; Brittany Lapin[4]; Christopher Masi[1]. [1]NorthShore University HealthSystem, Evanston, IL; [2]Pfizer Inc, New York, NY; [3]Northwestern University, Evanston, IL; [4]Cleveland Clinic, Cleveland, OH. (Control ID #2701161)

BACKGROUND: Painful diabetic peripheral neuropathy (pDPN) affects over 20% of diabetics and is associated with foot ulceration and amputation. Research suggests that text messages can improve medication adherence and health outcomes among diabetics. To date, no studies have examined text messaging among patients with pDPN. The goal of this study was to determine the impact of twice daily diabetes self-management text messages on health outcomes in this population.

METHODS: We queried the electronic data warehouse of an integrated health-system to identify patients likely to have pDPN. Prospective subjects were contacted after obtaining consent from their physician, and were screened in person by a research nurse to confirm eligibility. Subjects were randomized to receive usual care or usual care plus twice daily one-way text messages regarding glucose monitoring, nutrition, exercise, living with a chronic disease, and foot care. Patients were surveyed at baseline and at six months using the Pain Numerical Rating Scale, Diabetes Self-Management Questionnaire, EuroQol EQ-5D Health Related Qualify of Life Questionnaire, and Diabetes Health Beliefs Questionnaire. Descriptive statistics, t-tests, and chi-square tests were used to assess results.

RESULTS: Of the 69 patients enrolled, baseline and six month data are available for 51 (28 intervention and 23 usual care). Of these, 51% are female and the mean age is 60.3 years. 68% are non-Hispanic White, 23% are African-American, and 6% are Asian American. The mean number of years with diabetes is 14.3. By six months, self-reported pain had declined in the intervention group from 6.3 to 5.5 out of 10 ($p = 0.1$) and in the control group from 6.3 to 5.9 ($p = 0.34$). The between-group difference was not statistically significant ($p = 0.48$). Compared with usual care, the intervention group had higher scores for total self-care (45.6 vs 39.6 out of 70, $p = 0.04$) and foot care (9.8 vs 7.9 out of 14, $p = 0.02$) at six months. In addition, a significant increase in blood glucose testing occurred in the intervention group (+26%, $p = 0.04$) but not the usual care group (−1%, $p = 0.89$). At six months, the intervention group reported fewer problems with self-care (1.2 vs. 1.4 out of 5, $p = 0.04$) and fewer symptoms of anxiety or depression (1.6 vs. 2.2 out of 5, $p = 0.01$). Self-rated health was also higher in the intervention group compared to the control group at six months (65.4 vs 57.9 out of 100, $p = 0.03$). Compared to the control group, the intervention group reported greater perceived benefits of medication adherence ($p < 0.01$), fewer perceived barriers ($p = 0.04$), and greater perceived diabetes control ($p = 0.03$) at six months. Hemoglobin A1c declined in both groups but the between-group difference at six months was not statistically significant.

CONCLUSIONS: Preliminary results suggest that patients with pDPN who receive twice daily text messages regarding diabetes management report improved self-care activities, self-rated health, and diabetes control.

THE ASSOCIATION BETWEEN DEPRESSION SEVERITY AND STIGMATIZED BELIEFS IN EMIRATI STUDENTS: PRELIMINARY FINDINGS OF A CROSS-SECTIONAL STUDY Danny Lee[2]; Arif Pendi[1]; Hajra Hussain[3]; Jahanzeb Ashraf[4]; David Baron[5]. [1]University of California, Irvine, Orange, CA; [2]Virginia Commonwealth University School of Medicine, Yorba Linda, CA; [3]Amity University, Dubai, United Arab Emirates; [4]American University of the Caribbean, Cupecoy, Sint Maarten (Dutch part); [5]University of Southern California, Los Angeles, CA. (Control ID #2687305)

BACKGROUND: It has been reported that the prevalence of depression has increased globally. Unfortunately, the social stigma surrounding mental illness has been known to discourage attempts to seek help for mental disorders. Depression, one of the most common mental illnesses in students, has been associated with a depression-specific social stigma. Given the critical role that general internists fill by prescribing medications and referring patients to psychiatrists, it is necessary to inform general practitioners of the prevalence of depression in university students and how depression severity may be linked to stigmatized beliefs. Thus, this study had the following objectives: (1) clarify the prevalence of depression in Emirati university students, (2) study the link between stigma and depression severity, and (3) identify predictors of stigmatized beliefs.

METHODS: An anonymous survey link was emailed to all students at a university in the United Arab Emirates. The survey contained a socio-demographic section, the Patient Health Questionnaire-9 (PHQ-9), and the Depression Stigma Scale (DSS). Students over the age of 18 were included; those below 18 were excluded. Based on PHQ-9 scores, respondents were classified as either moderately to severely depressed or mildly to not depressed. The two groups of respondents were compared in terms of scores on personal and perceived subscales of DSS via a *t*-test. To study potential confounders or socio-demographic predictors, a series of linear regressions was applied. According to the literature, PHQ-9 and DSS standardized scales have been reported to be valid and reliable.

RESULTS: In the sample, 39.5% Emirati respondents ($n = 129$; 70.5% female; aged 18 years and older) exhibited moderate to severe depression severity; this group displayed less personal stigma (16.1 ± 6.5 versus 17.0 ± 6.3, $p = 0.438$) and perceived stigma (19.8 ± 6.5 versus 22.2 ± 6.8, $p = 0.048$)

compared to other respondents. Additionally, heterosexuality ($p = 0.004$) and non-Indian ethnicity ($p = 0.007$) were predictors of personal stigma. No socio-demographic predictors of perceived stigma were detected.

CONCLUSIONS: Preliminary results of this cross-sectional study indicate a large burden of high depression severity in Emirati university students. More depressed students were associated with less personal and perceived stigma, though only the latter association was statistically significant. Because nearly 4 of 10 respondents exhibited moderate to severe depression, on-campus efforts to manage depression must be prioritized. Although there was less perceived stigma among students with greater depression severity, heterosexual and non-Indian students may benefit from targeted stigma reduction. For general internists, preliminary findings suggest that it is imperative to screen for depression in this population.

THE ASSOCIATION BETWEEN DEPRESSION SEVERITY AND STIGMATIZED BELIEFS IN GRADUATE STUDENTS: PRELIMINARY FINDINGS OF A CROSS-SECTIONAL STUDY

Danny Lee[2]; Arif Pendi[1]; Jahanzeb Ashraf[3]; Kate Basia Wolitzky-Taylor[4]; Jeffrey Sugar[5]; Kasim Pendi[6]; Joshua Lee[4]; David Baron[5]. [1]University of California, Irvine, Orange, CA; [2]Virginia Commonwealth University School of Medicine, Yorba Linda, CA; [3]American University of the Caribbean, Cupecoy, Sint Maarten (Dutch part); [4]University of California Los Angeles, Los Angeles, CA; [5]University of Southern California, Los Angeles, CA; [6]University of California Riverside, Riverside, CA. (Control ID #2687292)

BACKGROUND: The burden of depression may be increasing in graduate students, a distinct group from undergraduates or those in the workforce. Unfortunately, the ill-effects of social stigma have been reported to discourage treatment-seeking behavior. Often, it falls on primary care physicians to prescribe medication or to provide referrals to psychiatrists, requiring awareness to combat the increasing burden of depression in this population. There were three objectives: (1) establish the prevalence of depression in graduate students, (2) investigate the relationship between depression severity and stigmatized beliefs, and (3) identify predictors of depression stigma.

METHODS: A cross-sectional study design was used: an anonymous survey with a socio-demographic section, Patient Health Quesitonnaire-9 (PHQ-9), and Depression Stigma Scale (DSS) was posted online at a metropolitan university in the USA. Convenience sampling required posts to social media, e-bulletins, and emails forwarded by student organizations. Full-time graduate students over the age of 18 were included; students that were undergraduates, part-time, and/or under the age of 18 were excluded. Responses were divided into moderately to severely depressed or mildly to not depressed and compared in terms of continuous scores on the DSS subscales for personal and perceived stigma via *t*-test. A series of linear regressions were applied for socio-demographic predictors and confounding factors. The PHQ-9 and DSS scales have been associated with adequate reliability and validity.

RESULTS: 35.7% graduate student respondents ($n = 199$; 67% female; aged 19–23 years and above) screened positive for moderate to severe depression according to the PHQ-9 summed-item scoring method. More depressed students expressed more stigmatized personal beliefs (11.1 ± 5.9 versus 9.7 ± 6.4, $p = 0.106$) and perceived beliefs (23.7 ± 5.8 versus 21.8 ± 6.0, $p = 0.004$) compared to their less severely depressed counterparts. A non-Christian affiliation was predictive of depression severity ($p < 0.05$). Furthermore, male gender, heterosexuality, and lower class (1st-2nd year students) were identified as predictors of greater personal stigma ($p < 0.05$).

CONCLUSIONS: These preliminary findings suggest a large burden of depression in graduate students and a positive association between perceived stigmatized beliefs and depression severity. For universities, it is imperative to allocate substantial resources for depression management, cultivate a positive campus culture to combat perceived stigma, and potentially target males, heterosexual students, and lowerclassmen with stigma reduction efforts. For general internists, it may be necessary to aggressively screen for depression in this population particularly because more perceived stigma was exhibited by graduate students with greater depression severity.

THE ASSOCIATION BETWEEN DEPRESSION SEVERITY AND STIGMATIZED BELIEFS IN TAIWANESE STUDENTS: PRELIMINARY FINDINGS OF A CROSS-SECTIONAL STUDY

Danny Lee[2]; Arif Pendi[1]; Jahanzeb Ashraf[3]; Jean Feng-Jen Tsai[4]; Ciny Liu[4]; David Baron[5]. [1]University of California, Irvine, Orange, CA; [2]Virginia Commonwealth University School of Medicine, Yorba Linda, CA; [3]American University of the Caribbean, Cupecoy, Sint Maarten (Dutch part); [4]Taipei Medical University, Taipei, Taiwan; [5]University of Southern California, Los Angeles, CA. (Control ID #2687304)

BACKGROUND: Among university students worldwide, the burden of depression has been increasing. Unfortunately, the pervasive stigma surrounding depression has been known to inhibit help-seeking among those with diagnosable mental illness. Because it is often general internists that refer patients to psychiatrists or prescribe medication, primary care physicians must be aware of the burden of depression in university students and the relationship of depression severity to stigmatized beliefs. Thus, this study had the following objectives: (1) determine the prevalence of depression in Taiwanese university students (2) study the association between depression stigma and depression severity, and (3) find predictors of stigmatized beliefs.

METHODS: A cross-sectional study was conducted at a university in Taiwan. An anonymous, online survey was sent out by the institution registrar that consisted of a socio-demographic questionnaire Patient Health Questionnaire-9 (PHQ-9), and Depression Stigma Scale (DSS). Both undergraduate and graduate students at the age of 18 and over were included; those under the age of 18 were excluded. Responses were scored according to the PHQ-9 summed item scoring method and divided into severely depressed or mildly to not depressed groups. The groups' personal and perceived stigmatized beliefs were then compared as continuous scores on the DSS subscales by applying the *t*-test. A series of linear regressions was conducted in order to identify factors and socio-demographic predictors. The PHQ-9 and DSS scales have demonstrated acceptable reliability and validity in the literature.

RESULTS: Approximately 21.3% of respondents ($n = 207$; 75% female; aged 18 years and above) exhibited moderate to severe depression severity. Moreover, moderately to severely depressed students displayed more personal stigmatized beliefs (12.7 ± 5.4 versus 10.2 ± 4.9, $p = 0.006$) and perceived stigmatized beliefs (21.8 ± 5.7 versus 19.0 ± 5.9, $p = 0.006$) compared to their less severely depressed counterparts. A non-heterosexual orientation and alcohol use were identified as predictors of perceived stigma and personal stigma, respectively ($p < 0.05$)

CONCLUSIONS: Preliminary results of the study suggest a significant burden of depression among Taiwanese university students and a robust association between depression severity and depression stigma, personal and perceived. As a result, on-campus resources must be allocated to meet the need of depression management and stigma reduction, particularly student populations that have been identified as predictors. General internists must be aware of the burden of depression and the stigmatized beliefs exhibited by more depressed students so as to more effectively prevent and screen for depressive disorders in this demographic group.

THE ASSOCIATION BETWEEN HEALTH LITERACY AND MEDICATION SELF-MANAGEMENT AMONG PATIENTS WITH UNCONTROLLED HYPERTENSION IN COMMUNITY HEALTH CENTERS. Kunal N. Karmali[1]; Michael S. Wolf[1]; Ji Young Lee[1]; Danielle Lazar[2]; Stephen Persell[1]. [1]Northwestern University, Chicago, IL; [2]Access Community Health Network, Chicago, IL. (Control ID #2701453)

BACKGROUND: Hypertension (HTN) is a chronic condition often requiring complex regimens. Patients with limited health literacy can have difficulty performing self-management needed for HTN control. We sought to determine the association between health literacy and medication self-management behaviors in hypertensive adults.

METHODS: We performed a cross-sectional analysis of adults with uncontrolled HTN recruited for a randomized trial from 12 community health centers in Chicago, IL. Participants were eligible if they were ≥18 years of age with ≥ 3 chronic medications and suboptimal blood pressure control (≥130/≥80 mmHg if diabetic and ≥135/≥85 mmHg if non-diabetic). Baseline health literacy was measured by the Newest Vital Sign. We determined medication reconciliation by blinded physician review of electronic health record-derived medication lists and patient-reported lists for all chronic medications and HTN medications. We measured medication understanding of drug indications by structured questionnaire and adherence by 4-day recall. We determined the association between health literacy and medication reconciliation, medication understanding, and medication adherence using multivariable generalized linear models with clinic-level random effects.

RESULTS: Of the 919 participants, 47% were classified as likely limited health literacy (low), 33% as possibly limited health literacy (moderate), and 19% as adequate health literacy. Compared with participants with adequate health literacy, those with low health literacy were less likely to have all chronic medications reconciled (18.6% vs. 30.6%, $p = 0.005$) and more likely to not know the indication for one or more chronic medication (28.0% vs. 14.9%, $p = 0.003$). There was no difference in 4-day recall of adherence (56.2% vs. 46.0%, $p = 0.077$). In adjusted models, there was a step-wise association between degree of health literacy and medication reconciliation and medication understanding (Table). There was an inverse association between degree of health literacy and adherence (Table). Similar findings were observed for HTN medications but results were imprecise.

CONCLUSIONS: Limited health literacy is highly prevalent among patients with uncontrolled HTN in these safety-net settings. Limited health literacy was associated in a graded manner with medication reconciliation discrepancies and medication understanding but not with medication adherence. These results suggest that medication self-management interventions should be tailored to level of health literacy.

Associations between health literacy and medication self-management

	Likely limited health literacy, OR (95% CI)	Possibly limited health literacy, OR (95% CI)
Chronic medications		
Medication reconciliation	0.50 (0.28, 0.89)	0.61 (0.47, 0.80)
Medication understanding	0.52 (0.32, 0.85)	0.61 (0.43, 0.84)
Medication adherence	1.40 (1.04, 1.88)	1.28 (0.84, 1.95)
Antihypertensive medications		
Medication reconciliation	0.55 (0.40, 0.77)	0.84 (0.65, 1.07)
Medication understanding	0.74 (0.37, 1.49)	0.70 (0.43, 1.13)

THE ASSOCIATION BETWEEN PATIENT REPORTED AVOIDANCE OF CARE AND HEALTHCARE UTILIZATION Janet J. Ho[2]; Long H. Ngo[2]; Christina C. Wee[1]. [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Beth Israel Deaconess Medical Center, Brookline, MA. (Control ID #2706096)

BACKGROUND: Delays and avoidance of care are commonly used metrics that are thought to be undesirable because they may produce adverse outcomes. Delays, generally assessed by patient self-report, have been shown to increase hospital length of stay or prognosis for certain specific conditions (e.g. heart attack or stroke). It is unclear, however, whether patient reported predilections to avoid care result in delays that may lead to fewer outpatient visits but greater risk of being hospitalized.

METHODS: We analyzed the association between patient reported predilection to avoid healthcare among participants in the Medicare Current Beneficiary Survey (MCBS), a nationally representative, 4-year longitudinal survey of beneficiary health and healthcare experiences, with linkages to Medicare claims. We included community-dwelling adults 65 years and older with at least 2 full years of consecutive enrollment. Survey responses from the first year were matched with utilization claims from the following year. Those who responded "True" to the question "I would do almost anything to avoid going to the doctor" were classified as having a predilection to avoid care. Outpatient visits (OPV) and Inpatient hospitalizations (IPV) were extracted from claims. We analyzed the number of OPV using a two-step hurdle negative binomial approach and analyzed IPV as a dichotomous event using logistic regression. All models were adjusted for relevant confounders, and the complex sampling design of MCBS and repeated measures were further adjusted by MCBS sample weights.

RESULTS: Of 76,529 paired survey-utilization observations, 26.78% reported a predilection to avoid care. After adjustment for demographics (age, sex, race, income, insurance, education, geographical/rural location, marital status), illness burden (26 chronic comorbidities, smoking status, body mass index), and functional limitations (ADL, IADL, physical/mental limitations, self-rated health), older adults reporting care avoidance were less likely to have OPV (OR 0.8, $p < 0.0001$), had fewer number of visits among those with OPV (RR = 0.9, $p < .0001$), but were not more likely to have greater IPV (OR 0.96, $p = 0.07$).

CONCLUSIONS: Older adults who self-reported a predilection to avoid medical care had significantly fewer outpatient visits, but were not more likely to be hospitalized. Future research should seek to understand which patients would benefit from targeted engagement with primary outpatient care to more effectively modify potential adverse ramifications on downstream healthcare outcomes and costs.

THE ASSOCIATION BETWEEN POOR PATIENT PERCEPTIONS OF THEIR PRIMARY CARE PROVIDERS AND OUTPATIENT HEALTHCARE UTILIZATION Janet J. Ho[3]; Long H. Ngo[2]; Christina C. Wee[1]. [1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Beth Israel Deaconess Medical Center, Brookline, MA; [3]Beth Israel Deaconess/Harvard Medical School, BROOKLINE, MA. (Control ID #2706542)

BACKGROUND: Patient experiences are increasingly incorporated as measures of healthcare access and quality, despite showing inconsistent associations with health outcomes. Prior work shows that patient perceptions of healthcare environments may affect the settings where patients choose to access healthcare. In this context, we explore whether poor patient perceptions of their individual primary care provider (PCP) are associated with reduced healthcare-seeking behavior and outpatient visits (OPV).

METHODS: We analyzed the association between patient perceptions of their PCP and annual utilization of OPV among participants in the Medicare Current Beneficiary Survey (MCBS), a nationally representative, 4-year longitudinal survey of beneficiary health and healthcare experiences, with linkages to Medicare claims. We included community-dwelling adults 65 years and older with an identified PCP and at least 2 full years of consecutive enrollment. Survey responses from the first year were matched with utilization claims from the following year. 12 MCBS survey items captured 3 domains: PCP's interpersonal manner (IM), Trust in PCP (TR), and PCP competence/knowledge (CK). We analyzed the association between respondents with overall negative (vs. neutral to positive) perceptions in each domain and annual OPV. We used a two-stage hurdle negative binomial model adjusted for relevant confounders, the complex sampling design, and repeated measures.

RESULTS: Of 76,529 paired survey-utilization observations, 9% reported poor perceptions in IM, 3% in TR, and 2% in CK. After adjustment for demographics (age, sex, race, income, insurance, education, geographical/rural location, marital status), illness burden (26 chronic comorbidities, smoking status, body mass index), and functional limitations (ADL, IADL, physical/mental limitations, self-rated health), poor perceptions did not decrease likelihood of OPV (see table). Among those with OPV, poor TR was significantly associated with a higher numbers of visits.

CONCLUSIONS: Among a nationally representative sample of older adults, poor patient perceptions of PCPs was not significantly associated with reduced outpatient utilization. Future research should seek to better understand other patient perceptions or patient-centered factors that may impact healthcare access or serve as metrics for downstream healthcare outcomes and costs.

Table. Poor Patient Perceptions of PCP and Outpatient Visits

Poor Perceptions of: (N=76, 529)	Annual Outpatient Visits Stage 1 Odds Ratio	Stage 2 Relative Risk
Interpersonal Manner (9%)		
1. adjusted for demographics, comorbidities	0.98	1.04
2. model 1 + functional status	0.95	1.02
Trust (3%)		
1. adjusted for demographics, comorbidities	1.09	**1.17****
2. model 1 + functional status	1.06	**1.13****
Competence/ Knowledge (2%)		
1. adjusted for demographics, comorbidities	1.05	**1.12***
2. model 1 + functional status	1.05	1.09

THE ASSOCIATION OF A COLORECTAL CANCER SCREENING PATIENT NAVIGATION PROGRAM WITH ADHERENCE TO RECOMMENDED FOLLOW-UP SURVEILLANCE COLONOSCOPY. Julian Mitton[4]; Janet J. Ho[1]; Wei He[3]; Imarhia Enogieru[5]; Sanja Percac-Lima[2]. [1]Beth Israel Deaconess/Harvard Medical School, BROOKLINE, MA; [2]Massachusetts General Hospital, Boston, MA; [3]MGH, Boston, MA; [4]Massachusetts General Hospital, Cambridge, MA; [5]Harvard Medical School, Boston, MA. (Control ID #2706583)

BACKGROUND: Colorectal cancer (CRC) can be prevented using colonoscopy to detect early invasive disease and remove precursor lesions. Patients who have had a polypectomy are at higher risk for developing CRC and often require follow-up surveillance colonoscopy (FSC). Disparities in CRC screening and outcomes exist in minority and non-English speaking populations. Patient navigation (PN) has been shown to increase CRC screening colonoscopy rates in these populations, however less is known about the impact of PN on adherence to FSC. Our objective is to evaluate the impact of PN at time of initial screening colonoscopy on adherence to FSC.

METHODS: We performed a retrospective matched-control cohort study in an urban academic primary care network. Patients 50–74 years old enrolled in a CRC screening PN program at a community health center who had an abnormal screening colonoscopy in 2010–2011 requiring FSC were matched by chart review in a 1:3 ratio by age, gender, race, language, and CRC risk category to patients at primary care practices without PN who also had abnormal screening colonoscopy requiring follow-up during the same time period. The main outcome is completion of FSC in the PN group compared to the matched controls. We conducted descriptive statistics and used a chi-square test for unadjusted comparison. We further analyzed FSC using multivariable logistic regression with adjustment for health insurance, education and prior number of annual clinic visits.

RESULTS: There were 62 patients enrolled in CRC screening PN with 157 matched controls. Mean age was 60 years (SD 7.27), 40% were women, 58% non-Latino white, 59% spoke English, 11% required FSC in one year, 42% in 3 years, and 46% in 5 years. 72% of patients with PN at initial screening underwent a timely FSC compared to 71% in the non-PN matched control group ($p = 0.850$). After full adjustment, patients with PN had similar odds of completing FSC (OR = 0.99, CI 0.49-2.00) compared to those without PN.

CONCLUSIONS: In our study, nearly 30% of patients with abnormal screening colonoscopies did not complete recommended FSC. PN at initial screening colonoscopy did not appear to improve the odds of FSC. Future research should seek to better understand if PN at the recommended time of FSC, rather than only at time of screening colonoscopy, would improve adherence to FSC and equity in CRC outcomes. These results have implications for primary care practices seeking to improve access and adherence to follow-up surveillance colonoscopy, especially those serving minority and non-English speaking patients.

THE ASSOCIATION OF A REGIONAL HEALTH IMPROVEMENT COLLABORATIVE WITH CHANGES IN AMBULATORY CARE SENSITIVE HOSPITALIZATIONS Joseph Tanenbaum[3]; Douglas Einstadter[4]; Mark E. Votruba[1]; Randall D. Cebul[2]. [1]Case Western Reserve University, Cleveland, OH; [2]Case Western Reserve University, Chagrin Falls, OH; [3]Metro Health Medical Center, Cleveland, OH; [4]MetroHealth Medical Center, Cleveland, OH. (Control ID #2704742)

BACKGROUND: Dramatic changes in healthcare financing and delivery have been motivated in part by the belief that improvements in primary care quality can reduce the incidence and costs of preventable hospitalizations. Primary care-centered regional health improvement collaboratives (RHIC) have emerged as a potentially transformational approach to improve primary care quality. However, the extent to which a RHIC can avert ambulatory care sensitive hospitalizations (ACSH) and associated costs is unknown.

METHODS: We conducted a difference-in-differences analysis of ACSH rates in Cuyahoga County, Ohio, before (2003–2008) and after (2009–2014) establishment of a RHIC. Two post periods were analyzed (2009–2011 and 2012–2014) to account for co-emerging healthcare delivery and payment innovations associated with the Affordable Care Act. Better Health Partnership (BHP) focused on improvements in quality for cardiovascular diseases (diabetes, hypertension, and heart failure). All adult residents in Ohio's six most populous counties hospitalized between 2003–2014 were included in this study. We used a population-based, all-payer database of all hospital discharges in Ohio to compare rates of ACSH in Cuyahoga County and the next five most populous Ohio counties. Secondary analyses to examine alternative explanations for our findings included differential changes in: 1) the use of hospital observations; 2) medical resources (hospital beds); 3) impact of the Great Recession, such as rates of uninsurance or unemployment; and 4) association of BHP on non-ambulatory care sensitive hospitalization rates. Cost savings were estimated by multiplying estimates of year-specific averted hospitalizations in Cuyahoga County by year-specific mean cost per hospitalization. All models used ordinary least squares linear regression and included county and year-specific fixed effects.

RESULTS: Trends in age-and sex-adjusted ACSH rates in Cuyahoga County were similar to Ohio's next five most populous counties during 2003–2008 but declined significantly more in 2009–2011 (106.0 fewer hospitalizations per 100,000 residents, $p < 0.01$) and 2012–2014 (90.8 fewer hospitalizations per 100,000 residents, $p < 0.05$). We estimated 5,748 averted ACSHs leading to cost savings of $39,669,432. Changes in hospitalization rates for non-ambulatory care conditions in Cuyahoga County were not significantly different ($p = 0.44$) than those in the comparator counties. Reductions in ACSH rates in Cuyahoga County likewise were not explained by differential observation rates, hospital bed supply, or impact of the Great Recession.

CONCLUSIONS: ACSH rates decreased more in Cuyahoga County than comparator Ohio counties following the establishment of a primary care-focused RHIC. This study supports increasing the prevalence of primary care-centered collaborative efforts. More widespread adoption of RHICs may lead to a reduction in ACSHs and associated costs.

THE ASSOCIATION OF BODY MASS INDEX AND HEALTH RELATED QUALITY OF LIFE

Rachel Apple[2]; Christianne Roumie[1]; Ken Wallston[1]; David Schlundt[1]; Shelagh Mulvaney[1]; Margaret Hargreaves[1]; Craig Bullington[1]; Russell L. Rothman[1]; William J. Heerman[2]. [1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN. (Control ID #2701165)

BACKGROUND: A patient-centered approach to improving weight-related outcomes requires an understanding of how overweight/obesity are related to both physical and mental aspects of quality of life (QOL) while accounting for comorbid chronic illness. Because these relationships are not well described, this study aimed to evaluate how body mass index (BMI) was associated with quality of life in a large, geographically diverse adult population.

METHODS: Participants were surveyed as part of a Patient-Centered Outcomes Research Institute (PCORI) funded evaluation of healthy weight across the Mid-South Common Data Research Network. We recruited participants from 12 medical clinics in 5 states. The primary exposure was BMI, calculated from self-reported height and weight. The primary outcome was self-reported quality of life, using the Patient-Reported Outcomes Measurement Information System (PROMIS) physical and mental QOL subscales. Each subscale contained 4 items with normalized scores ranging from 16.2-67.7 (Physical Health) and 21.2-67.6 (Mental Health). We conducted multivariable linear regressions between BMI and each QOL sub-scale, adjusting for age, gender, race/ethnicity, income, education, diabetes, hypertension, and hyperlipidemia. We hypothesized that the relationship between BMI and QOL may not be a linear, and tested this assumption using a smoothed polynomial regression.

RESULTS: The 11,776 respondents were predominantly female (71.7%) and White (83.6%), with a median age of 52.7 years (IQR 37.8–63.9). The median BMI was 27.9 (IQR 24.0–33.3). The median physical health score was 50.8 (IQR 42.3–54.1), and the median mental health score was 50.8 (IQR 45.8–56.0). Unadjusted polynomial regressions between BMI and QOL showed a non-linear relationship, whereby respondents who were underweight showed improved QOL scores as BMI increased to the normal range and then decreased. The average QOL score for underweight respondents was 50.4 (SD 9.5) for physical health and 50.5 (SD 9.3) for mental health, and the average QOL score for normal weight respondents was 52.2 (SD 8.2) for physical health and 52.0 (SD 8.2) for mental health. Excluding participants who were underweight due to the non-linear relationship, adjusted linear regression demonstrated that increased BMI was associated with decreases in both PROMIS physical health scores ($\beta = -0.30$, 95% CI −0.32, −0.27 $p < 0.001$) and PROMIS mental health scores ($\beta = -0.13$, 95% CI −0.16, −0.10 $p < 0.001$).

CONCLUSIONS: This evaluation demonstrates that there is an independent association between both underweight and overweight/obesity with worse mental health and physical health quality of life, even after controlling for comorbid chronic illness. This suggests that quality of life is an important metric for evaluation in obesity research, and further underscores the importance of addressing obesity at a population level to not only reduce long-term comorbidities, but also to improve quality of life.

THE ASSOCIATION OF HIGH PERFORMING MEDICAL HOMES WITH POPULATION HEALTH

Karin M. Nelson[3, 4]; Philip W. Sylling[1]; Leslie Taylor[1]; Danielle Rose[2]; Alaina M. Mori[1]; Stephan D. Fihn[1, 4]. [1]Department of Veterans Affairs, Seattle, WA; [2]VA GLA Healthcare System, Sepulveda, CA; [3]VA Puget Sound Health Care System, Seattle, WA; [4]University of Washington, Seattle, WA. (Control ID #2705465)

BACKGROUND: Despite widespread adoption of the patient centered medical home (PCMH), it is not clear which elements are essential to improving clinical quality and population health. We used national data from the Veterans Health Administration (VHA) Patient Aligned Care Team (PACT) program to assess this question.

METHODS: We conducted a patient-level, observational study to assess the association between the degree to which the PACT model had been implemented at 164 hospital-based clinics and 745 community-based VHA primary care clinics in 2012 and clinical quality measured during the period from 2012–2014. Patients were included if they received primary care from FY2012–2014 and had their chart abstracted by VA's External Peer Review Program (EPRP), a national performance evaluation program ($n = 422{,}125$). Clinical quality was measured using 48 preventive (e.g., receipt of guideline concordant vaccinations and screening tests) and chronic disease management indicators (e.g., annual retinal examinations in patients with diabetes). Clinic level PCMH implementation was measured by the PACT implementation Progress Index (PI^2), which provides a composite score for 8 core domains (access, continuity, care coordination, comprehensiveness, self-management support, patient-

centered care and communication, shared decision making and team-based care). Using logistic regression with multiple binary outcomes for each domain, we calculated the difference in predicted probability of meeting each quality indicator for clinics in the highest quartile domain scores compared to all other clinics. To estimate the projected overall effect on the entire VHA primary care population of over 5.4 million VHA primary care patients, we estimated the eligible cohort for each measure among all VHA primary care patients and calculated the number additional measures that would be expected to have met quality criteria had the lower performing clinics performed similarly to clinics in the highest quartile domain scores.

RESULTS: Clinics in the top quartile for care coordination, access, and continuity were significantly more likely to meet multiple quality indicators. Although clinic-level differences were relatively modest, when we projected the observed advantage of effectively implementing PACT to all clinics serving the entire population, 248,427 additional quality measures would have been met if all clinics had performance similar to the top quartile clinics in the access domain. We calculated similar broad potential effects on quality for the care coordination ($n = 305{,}929$) and continuity domains ($n = 259{,}078$).

CONCLUSIONS: Clinics with better care coordination, access, and continuity exhibited better performance on a broad range of clinical quality indicators. Although clinic-level differences in performance were modest, when extrapolated to the entire VA patient population, the accumulated, potential improvement in population health was sizable.

THE BENEFITS AND CHALLENGES OF CUSTOMISING A COMMERCIAL CPOE SYSTEM IN LARGE U.K. TEACHING HOSPITAL

Clare L. Brown[5, 6]; Neil W. Watson[4]; Andrew K. Husband[3]; David W. Bates[1]; Sarah P. Slight[2, 6]. [1]Brigham and Women, Boston, MA; [2]Durham University, Stockton on Tees, United Kingdom; [3]Durham University, Teesside, United Kingdom; [4]The Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; [5]University of Durham, Sunderland, United Kingdom; [6]Newcastle Upon Tyne NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom. (Control ID #2707415)

BACKGROUND: The Health Information Technology for Economic and Clinical Health (HITECH) Act in 2009 provided substantial financial incentives to organizations that could demonstrate 'meaningful use' of Electronic Health Records (EHRs) in the U.S. The National Health Service's (NHS) Integrated Digital Care Fund and the Safer Hospitals Safer Wards Fund in the U.K have also expanded the implementation of commercial Computerized Provider Order Entry systems (CPOE).[1] These systems are often customized according to the needs and expectations of the users and organization. The aim of this study was to explore how a commercial CPOE system had been customised after its implementation in a large UK teaching hospital, and what the benefits and challenges were.

METHODS: After obtaining the necessary ethical and institutional approvals, a range of ward staff (e.g., doctors, nurses, pharmacists) across four adult wards in a UK teaching hospital and members of the CPOE implementation team were recruited. One researcher conducted 32 semi-structured interviews between Mar 2015 and Aug 2016, lasting between 17–70 min and performed 35 hours of observations. All interviews were transcribed verbatim and the transcripts checked for accuracy. The data were analysed using the framework approach [2] with the aid of qualitative data analysis software NVivo version 10; a list of themes were developed inductively, and explanations for recurring patterns in these data were further refined and presented.

RESULTS: Participants highlighted a number of key benefits and challenges with CPOE customisation: 1) Some users described modifying the screen layout relatively easily in order to improve the visibility of important information (e.g., a medication's stop date). However, other users were unaware of how to do this, as the customisation button was 'not obvious'. 2) Users reported insufficient use of Clinical Decision Support (CDS) by the organization and actively requested more alerts e.g., drug-drug interactions to be switched on. 3) At an organizational level, order sentences and order sets were developed to improve the safety and efficiency of certain tasks. However, some users had difficulties remembering 'key trigger words' to identify them, which in turn limited their use. 4) The organization also modified the system to enable patient's blood glucose results to be reviewed and insulin to be prescribed electronically. However, if prescribing was performed remotely clinical decisions could be made in the absence of data not available on the system, e.g., whether the patient was fasting. 5) The organization developed a pharmacy task list, which helped users work more efficiently, but lacked the sensitivity to identify all 'high-risk' patients.

CONCLUSIONS: We identified five key areas in which users or the organisation had customised the system. We identified a range of barriers and facilitators to making such changes, which can be used to inform future development.

THE CHANGING MORTALITY AND COMPOSITION OF OPIOID-RELATED HOSPITALIZATIONS VERSUS OTHER HOSPITALIZATIONS IN THE UNITED STATES

Zirui Song. Massachusetts General Hospital, Boston, MA; Harvard Medical School, Boston, MA. (Control ID #2701314)

BACKGROUND: Amidst the opioid epidemic, hospitals often serve as the last resort for care. However, data are lacking on outcomes and composition of opioid hospitalizations in the U.S. Using nationally-representative data, this study offers initial evidence on the mortality and attributes of patients hospitalized with opioid primary diagnoses vs. for other conditions.

METHODS: Using 1993–2013 all-payer data from the National Inpatient Sample, 1,886,291 opioid hospitalizations were compared with 18,374,901 hospitalizations for other drugs and 759,941,269 hospitalizations for all other causes. Census data were used to standardize the volume of hospitalizations by the U.S. population. The key outcome variable was in-hospital mortality. Secondary outcomes were length of stay and hospital costs. Characteristics of opioid vs. other hospitalizations were examined using the t-test, Wilcoxon-Mann–Whitney test, and Chi-squared test. A linear multivariable difference-in-differences model assessed changes in mortality among opioid hospitalizations vs. those for other drugs. Covariates included age, sex, race, payer, income, comorbidities, attributes of the hospitalization, and time. Hospital fixed effects adjusted for time-invariant hospital factors to isolate within-hospital changes over time. The model included sample weights and standard errors clustered by hospital. Sensitivity analyses tested changes in the model and the covariates.

RESULTS: Mortality among opioid hospitalizations grew from 0.43% on average before 2000 to 1.83% by 2013, an average increase of 0.11%-points per year ($p < 0.001$) relative to that of hospitalizations due to other drugs, which was unchanged. The volume of opioid hospitalizations remained stable at 0.3 per 1,000 people over the study period and unchanged vs. those for other drugs, implying an increasing case fatality for opioid hospitalizations. Indeed, the

composition of opioid hospitalizations shifted from opioid dependence and abuse to opioid/heroin poisoning during the study period. Hospitalizations for poisonings grew by 0.01 per 1,000 people per year ($p < 0.001$) after 2000, replacing those for dependence or abuse, which declined by 0.01 per 1,000 people per year ($p < 0.001$). Mortality among hospitalizations for poisonings averaged 2.64% after 2000, over 10 times higher than those for dependence or abuse. Patients admitted for poisonings were more likely white, 50–64 years old, Medicare beneficiaries with disability, and residents of lower-income areas. There was no differential change in costs of opioid hospitalizations vs. those for other drugs. Length of stay also evolved similarly between opioid and comparison hospitalizations.

CONCLUSIONS: Mortality among opioid hospitalizations grew more than 3-fold in recent years, driven by a shift towards higher severity of opioid misuse concentrated in vulnerable and disabled populations. This emphasizes the need to strengthen community interventions and better prepare hospitals to care for a greater severity of opioid intoxication.

THE DATA TRIAL: A RANDOMIZED CONTROLLED TRIAL OF NEXT GENERATION AUDIT AND FEEDBACK Alvin Rajkomar[2]; Sajan Patel[2]; Victoria Valencia[1]; Sumant Ranji[3]; James D. Harrison[2]; Priya A. Prasad[2]; Michelle Mourad[2]. [1]Dell Medical School at The University of Texas at Austin, Austin, TX; [2]University of California San Francisco, San Francisco, CA; [3]Zuckerberg San Francisco General Hospital, San Francisco, CA, San Francisco, CA. (Control ID #2691527)

BACKGROUND: Audit and feedback improves clinical care by highlighting the gap between current and ideal practice. Electronic health record (EHR) data can provide contemporaneous data for quality improvement but has not yet been studied extensively. We conducted a randomized controlled trial (RCT) to determine whether audit and feedback leveraging EHR data with modern web-based dashboards could improve quality outcomes in an academic medical center compared to usual feedback.

METHODS: Eight medicine teams were randomly assigned to receive usual versus intensive feedback from February - April 2016. Usual feedback (ongoing for the 19 months prior to the intervention) consisted of a twice-monthly email with graphical feedback of each team's performance on QI metrics. The intensive feedback consisted of both access to a team-based, real-time online data dashboard and weekly in-person review of team data, which we referred to as "STAT rounds." STAT rounds were a 15-min session of facilitated discussion among intervention teams to review performance of metrics and identify roadblocks and solutions to meet them. The primary outcome was the team's performance on a composite measure of three discharge metrics: a completed medication reconciliation in the EHR prior to discharge, a high-quality after-visit-summary (AVS), and a discharge summary completed within 24 hours of discharge. We used generalized linear models to assess the adjusted effect of the intervention on the primary outcome.

RESULTS: A total of 24 medicine teams (12 intervention and 12 control) comprised of 84 housestaff and 48 attendings participated in the trial over 3 months. The dashboard was accessed an average of 56 times per month. STAT rounds were conducted 12 times with at least one physician representative from each team 98% of the time. The primary outcome, completion of all three metrics, was achieved 79.3% (426/537) in the intervention group compared to 63.2% (326/516) in the control group. Adjusted for possible confounders, composite performance of metrics was significantly increased in the intervention group (OR = 2.40, (95% CI 1.66–3.45). Out of the components, the lowest performing metric in the baseline period – the high-quality after visit summary, demonstrated the strongest improvement during the study period in the intervention group (74% vs 88%, $p < 0.0001$.

CONCLUSIONS: In this RCT, intensive audit and feedback with an electronic dashboard and STAT rounds significantly increased a composite measure of three quality improvement measures compared to usual feedback.

THE DEGREE TO WHICH PRACTICE CONFIGURATION, SIZE, AND COMPOSITION CHANGE WHILE PRACTICES ESTABLISH TEAMS Alyna T. Chien[1, 2]; Michael Anne Kyle[3, 4]; Antoinette S. Peters[1, 5]; Kevin Nguyen[3]; Meredith Rosenthal[3]; Shalini Tendulkar[6, 7]; Sara Singer[1, 3]. [1]Harvard Medical School, Boston, MA; [2]Boston Children's Hospital, Boston, MA; [3]Harvard T.H. Chan School of Public Health, Boston, MA; [4]Harvard Business School, Boston, MA; [5]Harvard Pilgrim Health Care, Boston, MA; [6]Tufts University, Medford, MA; [7]Institute for Community Health, Cambridge, MA. (Control ID #2698787)

BACKGROUND: Team-based care has been associated with greater quality healthcare and physician professional satisfaction. However, little is known about how practices reorganize themselves when transitioning from traditional arrangements to team-based care.

METHODS: Using a pre-post study design and detailed personnel lists (e.g., licensure, job titles and descriptions, and team rosters), we studied 18 hospital- and community-based academic primary care practices that participated in a two-year learning collaborative aimed at establishing team-based care. We measured changes in practice: 1. configuration (e.g., percent of practice staff assigned to "teams" versus serving as "floats" between teams or acting as system-wide supports), 2. size (e.g., total staff members, physician panel sizes), and 3. composition (e.g., ratios of non-physician staff per full-time equivalent [FTE] primary care physicians [PCP]) in the year prior to establishing team-based care (2012) to three subsequent years (2013–2015).

RESULTS: By the second year of the collaborative (2013), all 18 practices had created teams, and 5 further sub-divided their teams into "teamlets." On average, practices assigned 71% (SD 24%) of their staff to "teams" and 29% (SD 24%) to "floats." Teams included a mean of 14 (SD 10) staff members with 51% of teams including ≥1 PCP with either ≥1 registered nurse or ≥1 medical assistant while 33% included ≥1 PCP, ≥1 registered nurse, ≥1 medical assistant, and ≥1 administrative staff member. Teamlets had an average of 6 (SD 6) staff on them; 36% of all teamlets consisted of ≥1 PCP and ≥1 medical assistant. Neither the number of staff members nor physician panel size increased significantly over time, but practices had significantly changed their composition by the fourth year of the collaborative (2015). The ratio of nurse practitioners/physician assistants per 10 FTE PCP increased from 0.4 (SD 0.8) in 2012 to 2.6 (SD 3.3) in 2015 (2015 vs 2012 $p = 0.01$), and the ratio of administrative staff per 10 FTE PCP increased from 13.7 (SD 5.5) in 2012 to 18.5 (SD 7.1) in 2015 (2015 vs 2012 $p = 0.03$).

CONCLUSIONS: When establishing team-based care, practices can change configurations and composition without significantly increasing number of staff or physician panel size.

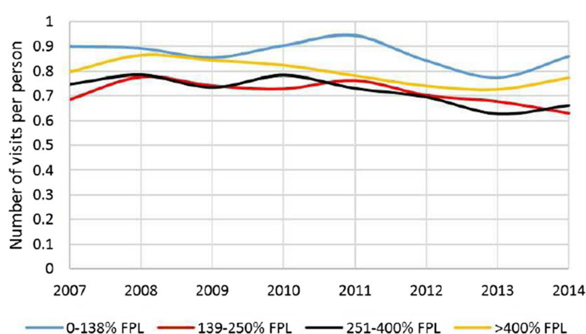
THE DEMAND FOR PRIMARY CARE UNDER THE AFFORDABLE CARE ACT MEDICAID EXPANSIONS Phuc H. Le[1]; Ha T. Tran[2]; Chi R. Nguyen[2]; Michael B. Rothberg[1]; David R. Lairson[2]. [1]Cleveland Clinic, Cleveland, OH; [2]University of Texas Health Science Center School of Public Health, Houston, TX. (Control ID #2705921)

BACKGROUND: Previous studies found that the Affordable Care Act Medicaid Expansions increased insurance coverage, access to care and utilization in low-income persons. Little is known about the demand for primary care on a national scale which is useful for health policy decision making. We aimed to estimate the current demand for primary care and examine trends over time.

METHODS: We used a cross-sectional design and two-part model to estimate the demand for care in US adults aged 18–64. The two-part model estimated the probability of having a visit in the first stage using logistic regression, and number of visits in the second stage using negative binomial regression. The dependent variables were visit (yes/no) and counts of total visits, visits to physicians, and visits to primary care doctors. Based on the Grossman's models of demand for health and healthcare and Andersen-Aday's behavioral model, we identified explanatory variables including demographics, socioeconomic status, health insurance, usual source of care, health status, and cost. The Medical Expenditure Panel Survey 2007–2014 data were used to estimate the mean demand by year and by poverty level (0–138% Federal Poverty Level (FPL); 139–250% FPL; 251–400% FPL; and >400% FPL). We used trend analysis to examine the change in demand overtime. All analyses were conducted in Stata 12.0 and SAS 9.4. A 2-sided p-value <0.05 was statistical significance.

RESULTS: From 2007–2014, the demand for total visits increased from 4.7-5.5 visits/person ($p < 0.05$). Half of the visits were to physicians and <1 visit was made to a primary care doctor. In 2014, mean demand for total visits and physician visits was significantly higher than in earlier years, while the mean demand for primary care was lower ($p < 0.05$). For the lowest income (0–138% FPL) group, demand for total visits was significantly higher in 2014 than before but demand for primary care remained stable.

CONCLUSIONS: Although demand for care increased in 2014, most of the increase was attributed to the low-income group which sought to providers other than primary care doctors. Our study suggests that Medicaid Expansions initially increased the demand for visits in the low-income group but more time is required to determine if the increase was sustained and access to primary care doctors was affected.



THE DIABETIC EYE: DIABETIC RETINOPATHY SCREENING IN A RESIDENT OPERATED CLINIC SHRINA Parekh; Anu Saini; prerna sharma. UPMC, Pittsburgh, PA. (Control ID #2707512)

BACKGROUND: Diabetic Retinopathy is one of the leading causes of blindness in the United States. While many new treatment strategies have been developed in the past decades, we falter at the most significant yet basic step towards treatment; referral and eye exams. At UPMC, EMR tracked data indicates that Mercy Health Center (a resident operated primary health center) has a low rate of documented diabetic eye exams of roughly 27%. This poor rate of screening was concerning and raised many interesting questions in regards to the patient population and individual screening rates. Our objective was to perform a retrospective chart review of diabetic patients at the Mercy Health Center Clinic and study the factors affecting non-compliance and lack of referral. We hope to raise awareness to many resident-operated health centers who could benefit in understanding the complexity of factors that govern referring diabetic patients for retinopathy screening.

METHODS: We compared age, sex, gender ang HgbA1c in two groups-patients screened and not screened versus patients referred and not referred by the PCP. A two sample Student's t test was used to compare the mean HbA1c and age levels in the two screening groups as well as the two referral groups. A Chi-squared test was used to test of an association of gender and HbA1c > 7 with referral and screening. There were no patients with HbA1c greater than 8 in the referral group data set.

RESULTS: The results from the analysis of the data revealed the HgbA1c value of greater than 7 was significantly associated with whether or not the patient was screened. Patients were clearly more likely to be screened for diabetic retinopathy if their HgbA1C value was higher than 7. Those patients who had HgbA1c value of greater than 7 were screened for diabetic retinopathy 87.5% of the time. While the age and gender association in both groups were not clinically significant with their P value greater than 0.05. The association of HgbA1c value was also not found to be clinically significant in the group for PCP referral.

CONCLUSIONS: In conclusion, this data helps us understand whether there maybe a patient driven factor involved in increasing the rates of retinopathy screening. It maybe that patients who are aware of their higher HgbA1c are more likely to follow up with an ophthalmologist and do regular eye exams. Another factor affecting this screening rate maybe that those patients with uncontrolled diabetes are more likely to be counselled and provided emphasis of the screening for retinopathy by their healthcare provider. In either scenario, this study helps us better understand the dynamics of physician referral and patient follow-up especially in high risk populations where screening for a particular disease greatly affects morbidity in a patient. Furthermore, this can help the primary care physicians taking care of the patient understand the motivational factors that affect the screening rates and follow up in patient population.

THE DIFFERENTIAL EFFECTS OF GENDER ON MOOD SYMPTOMS, HEALTH-RELATED QUALITY OF LIFE, SOCIAL SUPPORT, AND DISEASE SEVERITY AMONG PATIENTS WITH SYSTOLIC HEART FAILURE Anam A. Waheed[1]; Emily Guhl[3]; Kaleab Abebe[2]; Yan Huang[2]; Amy Anderson[2]; Bea Herbeck Belnap[2]; Bruce L. Rollman[2]. [1]UPMC, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA; [3]University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #2706927)

BACKGROUND: Heart failure (HF) affects nearly 6 million Americans and is among the most prevalent cardiovascular disorders. Although gender moderates the course of many medical disorders, little is known about the differential effects of gender on patients with systolic HF. We explore its effects among patients enrolled in the NIH-funded Hopeful Heart Trial, which is currently examining the impact of treating depression in patients with systolic HF.

METHODS: We screened patients with systolic HF (EF <45%) and NYHA class II-IV symptoms at 8 Pittsburgh-area hospitals, for depression with the Patient Health Questionnaire (PHQ-2) just prior to discharge home and telephoned them 2 weeks later to administer the PHQ-9. Protocol-eligible patients with a positive PHQ-2 depression screen and 10 on the PHQ-9 were

randomized to either our depression intervention or usual care ("depressed"); while a randomly selected cohort of patients with a negative PHQ-2 depression screen and <5 on the follow-up PHQ-9 were assigned to our control group ("non-depressed"). We collected sociodemographic and clinical information by patient self-report and chart review at baseline, and assessed mental and physical health-related quality of life (HRQoL) using the SF-12 MCS and PCS, respectively; and social support using the ENRICHD Social Support Index (ESSI) at 2 week follow-up. We then used student's t-test or chi-square test to evaluate for significant differences in patients' characteristics by gender.

RESULTS: From 3/14-11/16 we enrolled 545 patients with systolic HF, 44% female(F) and 56% male(M). The distribution of demographic variables followed identical patterns for both gender groups, with overall mean age of 63.5 years, and about 70% of both genders being Caucasian. The prevalence of comorbid conditions in both genders was also similar, specifically hypertension (F:81%, M:85%, p:0.205), diabetes (F:49%, M:51%, p:0.528), depression (F:33%, M:32%, p:0.645), anxiety (F:7%, M:5%, p:0.645), both depression and anxiety (F:31%, M:29%, p:0.645). Mean levels of social support assessed by the ESSI scale (F:27.3, M:27.1, p:0.778) and HRQoL assessed by mean SF score (M:44, F:43.9, p:0.942) were also similar in both genders. Cardiac function measured by TTE revealed a mean EF of 28.2 in females (range 19.8–36.6) and 27.1 in males (17.5–36.7), demonstrating similar distributions. In spite of having similar degrees of objectively measured HF, women reported higher levels of HF symptoms as assessed by the NYHA categories. 58% of women reported NYHA Class III symptoms and 12% reported Class IV symptoms, compared to 45 and 8% of men respectively ($P < 0.001$).

CONCLUSIONS: Female participants in the Hopeful Heart Trial reported worse subjective severity of HF by NYHA class compared to male participants, despite no significant baseline differences in age, race, EF, mood symptoms, HRQoL, or disease burden. Future reports from our ongoing Trial will examine the differential impact of gender on long-term HF treatment outcomes.

THE DURATION OF ABDOMINAL PAIN APPRISED BY A PATIENT ON THE OFFICE VISIT CAN BE A PREDICTOR OF THE NECESSITY OF ADMISSION. Naoko E. Furukawa; Masaki Tago; Shun Yamashita; Masaki Hyakutake; Shu-ichi Yamashita. Saga University Hospital, Saga, Japan. (Control ID #2689016)

BACKGROUND: There are a few studies of relationship between the duration of abdominal pain and the seriousness of the underlying diseases. The aim of this study is to elucidate the relationship between the duration of pain and the seriousness of the disease by researching the difference of admission rate among patients with various duration of abdominal pain.

METHODS: We retrospectively analyzed the new patients who visited the outpatient clinic or emergency room of the department of General Medicine, Saga university, Japan, for abdominal pain from April 2014 to July 2015. We researched the duration of pain and the necessity of admission on the first visit by chart review. First, the patients were divided into 4 groups according to the duration of pain (shorter than 1 day: group 1; G1, 1 to 2 days: G2, 3 to 14 days: G3, more than 15 days: G4). Second, we analyzed the patients in G1. The patients were divided into 4 groups according to the hours of pain (for 1 hours: G1-1, 2 to 3 hours: G1-2, 4 to 9 hours: G1-3, 10 to 24 hours: G1-4). The admission rate of each group was determined. Third, we analyzed the patients in G4. The patients were divided into 4 groups according to the days of pain (for 15 to 30 days: G4-1, 31 to 90 days: G4-2, 91 to 365 days: G4-3, longer than 366 days: G4-4). Chi-squared test was used to determine the presence of significant differences among each group.

RESULTS: There were 471 patients (13%) visiting with abdominal pain of 3698 new patients during the research period. Of all the patients with abdominal pain, the mean age was 50 ± 20 years, 191 patients (41%) were male and 59 patients (13%) were admitted. The number of patients belonging to G1 was 150, G2 69, G3 98, and G4 103, and their admission rate was 16, 17, 12 and 6% respectively. G4 had significant lower rate of admission than G1 ($p = 0.017$) and G2 ($p = 0.021$) by Chi-squared test. The number of patients belonging to G1-1 was 19, G1-2 39, G1-3 52, and G1-4 40, and their admission rate was 5%, 10, 27 and 13% respectively. There was no significant difference among 4 groups by Chi-squared test ($p = 0.056$); however, G1-3 had the highest rate of admission. The number of patients of belonging to G4-1 was 11, G4-2 34, G4-3 29 and G4-4 29 and the admission rate was 27, 9, 0 and 0% respectively. There was significant difference among 4 groups by Chi-squared test ($p = 0.004$).

CONCLUSIONS: The patients with abdominal pain shorter than 14 days have higher rate of admission than those with pain longer than 14 days, which suggests that acute and sub-acute pain should be treated more cautiously than chronic ones. Still, small but definite part of patients with chronic abdominal pain longer than 14 days and shorter than 90 days have possibilities of admission, so it might be dangerous to take lightly of them. Among the patients with abdominal pain shorter than 24 hours, we should treat the patients with pain for 4 to 9 hours, who had the highest rate of admission, with extreme caution.

THE ED HOSPITALIST TEAM - A COORDINATED STRATEGY FOR CARING FOR ADMITTED PATIENTS WHO ARE STILL IN THE EMERGENCY DEPARTMENT Katherine A. Hochman[1]; Brian Bosworth[1]; Nicole Adler[2]; joshua smith[1]. [1]NYU Langone Medical Center, New York, NY; [2]NYULMC, New York, NY. (Control ID #2701212)

BACKGROUND: Patients admitted to the Medicine Service from the Emergency Department (ED) at times when no beds are available pose a particular challenge to workflow, staffing and patient care. Due to the expansion of our clinically integrated network and recruitment of high-volume surgical teams, the hospital daily census surged, causing an increase in the average number of patients admitted to the hospital but physically located in the ED. The Hospitalist program was charged with developing a coordinated strategy to manage these patients

METHODS: In 2015, we created an ED Hospitalist Team composed of a hospitalist and a nurse practitioner to care for patients admitted to the Medicine Service but awaiting beds on the floor. We purposely created this model so that the medicine teams could focus on caring for patients on their own units and not disrupt their workflow by traveling to the ED. We created a Checklist (Figure 1) for this ED Hospitalist Team to ensure that protocols and pathways were followed, just as they would be on the medical floor. We partnered with ED leadership to identify workspace and standardize handoffs, as well as with leadership from Social Work to proactively identify complex situations starting on hospital day 0. Patients requiring ICU level care were excluded (as intensivists were involved immediately). All patients admitted to the medicine service (i.e. patients who would ultimately be cared for on the general medicine, cardiac, oncologic or hepatobiliary teams), were cared for by the ED Hospitalist team until a bed became available on the appropriate unit.

RESULTS: The average number of patients admitted to the hospital, but physically located in the ED increased from 2.1/day in April 2015 to 14.5/day in October 2016. At least 70% of these patients were admitted to the

Medicine Service. Even with this increase, the observed to expected length of stay (O:E LOS) for Medicine patients remained at 0.92. The discharge before noon rate increased from 39 to 43% during this same period.

CONCLUSIONS: We have demonstrated a strategic and sustainable approach for managing a growing number of patients who are admitted to the Medicine Service but physically located in the ED. By consolidating our resources in creating an ED Hospitalist team, we are able to maintain our workflow efficiencies on the floor, as demonstrated by the O:E LOS and our improved discharge before noon rate.

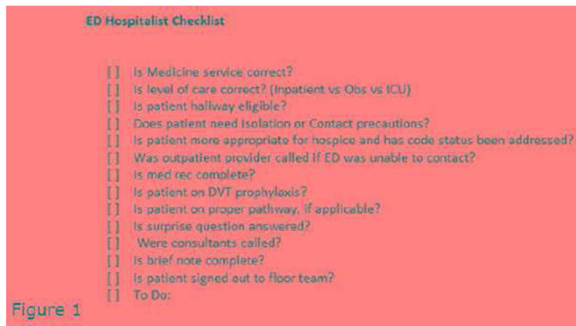


Figure 1

THE EFFECT OF A MOBILE HEALTH INTERVENTION (MPATH-CRC) ON COLORECTAL CANCER SCREENING IN A DIVERSE PATIENT POPULATION David P. Miller[1]; Nancy M. Denizard-Thompson[1]; Larry D. Case[1]; Kathryn Weaver[1]; Michael P. Pignone[4]; Donna Kronner[1]; Jennifer L. Troyer[2]; John G. Spangler[3]. [1]Wake Forest School of Medicine, Winston-Salem, NC; [2]University of North Carolina at Charlotte, Charlotte, NC; [3]Wake Forest School of Medicine, Winston Salem, NC; [4]University of Texas at Austin, Austin, TX. (Control ID #2705792)

BACKGROUND: Although national guidelines encourage routine screening for colorectal cancer (CRC), less than two-thirds of Americans are screened. Screening rates are even lower among low socioeconomic status (SES) individuals, but the rise of mobile device ownership offers new opportunities to reach broadly across populations. Therefore, we developed a mobile health (mHealth) intervention to promote CRC screening. The intervention, called mobile Patient Technology for Health (mPATH-CRC), is a user-friendly iPad app that includes a CRC screening decision aid, the ability for patients to "self-order" a screening test, and follow-up text messages to help patients complete screening. We tested the ability of mPATH-CRC to increase CRC screening in a multi-site randomized controlled trial conducted in a diverse patient population.

METHODS: We conducted the study in 6 community-based primary care practices located in 5 counties in North Carolina. We queried the clinics' shared electronic health record to identify English-speaking individuals aged 50 to 74 years who were scheduled to see a primary care provider (PCP) and were due for CRC screening. A research assistant then called these patients to confirm eligibility and invite them to participate. We randomized participants, stratified by site, to view either mPATH-CRC or a control program about healthy lifestyles immediately before they saw their PCP. The primary outcome was completion of CRC screening within 24 weeks of study entry as defined by blinded chart review and confirmed by a follow-up phone survey. All analyses were based on intention to treat.

RESULTS: Among the 450 participants, 223 were randomized to mPATH-CRC and 227 to the control program. Patient demographics were similar in both groups. The median age was 57 (range 50–74), 57% were white, 38% were black, 53% had annual incomes < $20,000, and 37% had limited health literacy. On surveys administered immediately after participants used the programs, more patients in the mPATH-CRC group than control group were able to state a screening preference (97% vs. 71%, $p < 0.0001$) and increased their intention to receive screening (27% vs. 15%, $p < 0.001$). Completion of CRC screening was higher in the mPATH-CRC group than control group (30.0% vs 13.7%, $p < 0.001$). Additionally, mPATH-CRC doubled screening within specific low SES strata: limited health literacy (26% vs 13%, $p = 0.05$), income < $20,000 (25% vs 12%, $p = 0.02$), and non-white race (35% vs. 17%, $p = 0.01$). In a multivariable logistic regression model adjusted for site, mPATH-CRC almost tripled the odds of completing screening (OR 2.80, 95% CI 1.72–4.53).

CONCLUSIONS: The mPATH-CRC program more than doubled receipt of CRC screening, with similar effects seen across SES strata. These results indicate mHealth programs can reach broadly across populations, potentially decreasing health disparities. Future research should examine how mHealth programs like mPATH-CRC can be implemented in routine practice to improve health outcomes.

THE EFFECT OF PATIENT-CENTERED PRESCRIBING ON MEDICATION ADHERENCE: A NATIONAL ANALYSIS Michael S. Wolf[1]; Ruth Parker[4]; Jenny Jiang[3]; Guisselle del Salto[1]; Deesha Patel[1]; Michael S. Taitel[2]. [1]Northwestern University, Chicago, IL; [2]Walgreens, Deerfield, IL; [3]Walgreens Co, Deerfield, IL; [4]Emory University, Atlanta, GA. (Control ID #2707594)

BACKGROUND: Over the past decade, evidence has emerged supporting the use of a Universal Medication Schedule (UMS) to simplify medication instructions to support patients' prescription (Rx) use. The UMS standardizes the prescribing and dispensing of medicine by more explicitly stating when to take medicine (morning, noon, evening, bedtime). Despite widespread support for this concept, the UMS has not been widely adopted by health systems. Partnering with a large national pharmacy chain (Walgreens), we examined the prevalence of the UMS in current real-world prescribing practices, and sought to evaluate its effectiveness to promote adherence in a national sample of diabetic adults.

METHODS: A cohort of diabetic patients 18 and older affiliated with Walgreens stores nationally and new to a therapy between January and June of 2014 was created ($N = 676{,}739$). The primary independent variable of interest was whether or not prescription instructions dispensed with a medication were written in the manner of the UMS standard ('take in morning, at noon, in evening, at bedtime'). The outcome under study was adherence to medications as determined by pharmacy fill data over the 12 months following the new prescription. The proportion of days covered (PDC) was calculated per each prescription. Proper adherence was considered as having taken > 80% of a medication. Relevant patient and regimen characteristics were derived either from the pharmacy record or imputed using U.S. census tract data. We assessed patient-level characteristics by sig-classification, while census tracts for each patient were linked to aggregate level socio-demographic data. Generalized estimating equations (GEEs) were utilized to compare UMS vs non-UMS prescriptions in predicting PDC. Interaction terms were included to assess effect modification by multi-daily dosing, age, and education.

RESULTS: The cohort of patients was prescribed 722,492 medications that were included in analyses. In GEE models, medications prescribed using the UMS demonstrated slightly better adherence over 1 year compared to non-UMS form prescriptions (Relative Risk (RR) 1.013, 95% Confidence Interval (CI) 1.00-1.023, $p = 0.02$). Yet significant independent associations and interactions with the UMS study arm were noted for the following covariates: 1) multi-daily dosing (> once

daily dosing); 2) age (>65); and 3) education (<9th grade). Specifically, among less educated, diabetic patients over 65 contending with multi-daily regimens (N = 115,285; 14.5% of the overall sample), those whose prescriptions were written with the UMS had greater adherence compared to their more educated counterparts with non-UMS prescriptions. The effect was much larger than what was observed in the general sample (RR 1.11, 95% CI 1.04-1.19, $p = 0.001$).

CONCLUSIONS: The UMS is a minimal, highly scalable intervention that can support adherence among vulnerable groups; by age, education, and regimen complexity. Physicians and health systems might consider it as a new prescribing standard.

THE EFFECT OF RED BLOOD CELL TRANSFUSION ON PHYSICAL AND FUNCTIONAL WELL-BEING QUALITY OF LIFE IN HOSPITALIZED PATIENTS WITH ANEMIA Micah T. Prochaska; David Meltzer. University of Chicago, Chicago, IL. (Control ID #2694242)

BACKGROUND: Anemia is common in hospitalized patients and is associated with decreased health-related quality of life (QOL). Transfusion of red blood cells is the primary treatment for anemia in hospitalized patients, and evidence suggests that receipt of a transfusion while hospitalized can improve patient fatigue, an important QOL symptom of anemia. This raises the question of whether transfusion during hospitalization may also improve other important QOL domains in patients with anemia, such as physical and functional well-being. However, there are no data describing how transfusion during hospitalization affects these QOL domains. Therefore, we sought to measure the effect of transfusion from hospitalization to 30 days post-discharge on the QOL changes in patients' physical and functional well-being.

METHODS: From April 2014 through June 2015, hospitalized general medicine patients with a Hb < 9 g/dL were approached for an interview while hospitalized and a 30-day post-discharge phone interview. At both time points physical and functional well-being were measured using the Trial Outcome Index Anemia (TOI-An) sections that are part of the larger Functional Assessment of Chronic Illness Therapy Anemia questionnaire. TOI-An scores range from 0–136. Changes physical and functional well-being were calculated by subtracting responses on the TOI-An while hospitalized from responses at the 30-day post discharge interview. Patients' hemoglobin (Hb) values while hospitalized, transfusions received and demographic data were abstracted from hospital administrative data. Linear regression was used to test for the effect of transfusion on changes in physical and functional well-being, controlling for age, sex, length of stay, comorbidities, and units transfused.

RESULTS: 513 participants completed both the inpatient and follow-up interview. There were no significant differences between those who were transfused versus those who were not transfused in demographics [(age 57 vs. 55; $p = 0.07$), (female 58% vs. 63%; $p = 0.24$), (African American 64% vs. 59%; $p = 0.54$)], comorbidities (Charlson Comorbidity Index, $p = 0.9$), or baseline (inpatient) physical and functional well-being score (TOI-An 57 vs 59; $p = 0.44$). In linear regression models, the interaction between transfusion, minimum Hb while hospitalized, and baseline physical and functional well-being predicted improvements in physical and functional well-being for patients under the age of 50 ($\beta = -0.35$, $p = 0.04$). A similar effect was seen when analyzing patients of all ages, but the result did not reach statistical significance ($\beta = -0.15$, $p = 0.1$).

CONCLUSIONS: Our results demonstrate that transfusion of hospitalized patients with anemia may improve the physical and functional well-being QOL 30 days after discharge, specifically patients less than 50 years old. Practitioners may be able to combine self-reported QOL measures in patients with a Hb < 9 g/dL to target patients likely to benefit with improved QOL from a transfusion.

THE EFFECT OF STATE MEDICAID EXPANSIONS ON PRESCRIPTION DRUG USE Ausmita Ghosh[2]; Kosali Simon[2]; Benjamin D. Sommers[1, 3]. [1]Harvard School of Public Health, Brookline, MA; [2]Indiana University, Bloomington, IN; [3]Brigham & Women's Hospital, Boston, MA. (Control ID #2704652)

BACKGROUND: The Affordable Care Act (ACA) expanded Medicaid eligibility in participating states to millions of low-income adults. Multiple studies using surveys have demonstrated improved access to care and increased use of services. However, more detailed information on changes in utilization after the expansion can help paint a clearer picture of the law's impact. Given the prominent role of prescription medications in the management of chronic conditions, as well as the high prevalence of unmet health care needs in the population newly eligible for Medicaid, the use of prescription drugs represents an important measure of the ACA's policy impact.

METHODS: We obtained 2013–2015 data from a large, nationally representative, all-payer pharmacy transactions database to examine effects on prescription medication utilization. We used a differences-in-differences regression framework to compare the number of prescriptions filled in expansion vs. non-expansion states, before and after the ACA expansion took effect in January 2014. We compared the source of insurance payment for each prescription, and we also assessed utilization rates within specific drug classes, using Uniform System of Classification product codes. Our models adjusted for the racial and ethnic composition of each state as well as annual state-specific unemployment rates. We also compared utilization changes within states based on the pre-ACA uninsured rate in each area.

RESULTS: Over the first nearly 1.5 years of the ACA's Medicaid expansion, prescriptions paid for by Medicaid increased by 19 percent in expansion states relative to states that did not expand ($p < 0.01$). The greatest increases in Medicaid prescriptions associated with the ACA expansion occurred among diabetes medications, which increased by 24 percent; other classes of medication that experienced large increases include contraceptives (22%), cardiovascular drugs (21%), and mental health drugs (19%) (all p-values <0.01). We did not observe reductions in uninsured or privately insured prescriptions, suggesting that increased utilization under Medicaid did not substitute for other forms of payment. Within expansion states, increases in prescription drug utilization were larger in geographical areas with higher uninsured rates prior to the ACA. Finally, we find suggestive evidence that increases in prescription drug utilization were greater in areas with larger Hispanic and black populations, indicating that Medicaid expansion may be reducing ethnic/racial disparities in access to medications.

CONCLUSIONS: As federal policymakers debate the future of the ACA, we find that the 2014 Medicaid expansion was associated with significantly increased utilization of prescription drugs by patients in Medicaid. In particular, we find large increases in medications that treat chronic disease, suggesting a potential pathway to improved quality of care and health. Future research is needed to assess the long-term health impacts of these changes.

THE EFFECT OF TRIAGE DIAGNOSIS ON CLINICAL REASONING Raj Sehgal[1, 2]; Kevin Ozment[1]; Temple Ratcliffe[1, 2]; Joshua T. Hanson[1, 2]; Jane E. O'Rorke[1, 2]. [1]UTHSCSA, San Antonio, TX; [2]South Texas Veterans Health Care System, San Antonio, TX. (Control ID #2696980)

BACKGROUND: Cognitive errors are common in medicine and can lead to negative patient outcomes. A common error is "anchoring", or the overreliance on a single piece of information in making a diagnosis. With work hour restrictions increasing, trainees frequently assume the care of patients admitted by other providers. There is little in the literature about the effect these initial diagnoses have on the subsequent reasoning by trainees. At our institution, the decision to admit a patient is made by a faculty Triage Physician (TP). The TP admits the patient to a housestaff team, and provides a reason for admission which might be general (ex. "fever") or specific (ex. "pneumonia"). Our aim was to examine the effect that this triage diagnosis has on subsequent diagnostic reasoning by Resident Physicians (RP).
METHODS: We retrospectively reviewed admissions for 100 randomly selected weekdays over a four year period. Patients admitted on weekends and nights were excluded due to differences in the admission process during these times. Data was collected on patients admitted on these dates, including triage diagnosis, the RP's admission diagnosis, and the Attending Physician's (AP) admission diagnosis. Admission notes were also reviewed for evidence of documentation in these diagnostic categories: determination of the most likely diagnosis, consideration of alternative diagnoses, identification of precipitants, and selection of further diagnostic investigations.
RESULTS: 255 patient charts were reviewed, with 145 patients having a specific triage diagnosis and 110 having a general triage diagnosis. 65.5% of RP admission notes documented consideration of alternative diagnoses for general diagnoses versus only 41.4% for specific diagnoses (p-value < 0.0001). RPs also documented the selection of diagnostic tests more frequently when given a general diagnosis (81.8% vs. 61.4%, P value < 0.0001). There were no significant differences between the general and specific groups when it came to documenting the most likely diagnosis or identifying precipitants. Findings for APs were similar to those of RPs.
CONCLUSIONS: RPs and APs showed decreased documentation of diagnostic reasoning when given a specific triage diagnosis, even though documentation of the most likely diagnosis did not significantly change. This suggests that giving trainees a more general, symptom-based initial diagnosis might improve the documentation of diagnostic reasoning.

THE EFFECTIVENESS OF COMPUTERIZED SERVICES AND PEER COACHES TO IMPROVE WEIGHT IN PATIENTS WITH SERIOUS MENTAL ILLNESS Alexander S. Young[3]; Amy N. Cohen[1]; Noosha Niv[4]; Julie Kreyenbuhl[2]; Richard Goldberg[5]. [1]UCLA, Los Angeles, CA; [2]University of Maryland School of Medicine, Baltimore, MD; [3]VA & UCLA, Los Angeles, CA; [4]VA Long Beach Healthcare System, Long Beach, CA; [5]VA Maryland Healthcare System, Baltimore, MD. (Control ID #2698021)

BACKGROUND: People with serious mental illness have high rates of obesity and related medical problems, and die years prematurely, most commonly from cardiovascular disease. Specialized, in-person weight interventions result in weight loss in efficacy trials with highly select, motivated patients who are often paid to participate. In usual care, patient enrollment and retention are low, and effectiveness has been limited. Barriers to use of interventions include limited availability of clinical staff, patients who avoid groups and frequent visits to clinics, and limited patient motivation for ongoing services. The goal of this study was to examine, in patients with serious mental illness, whether internet-based provision of weight management with peer coaching is feasible, acceptable, increases patient engagement, and has greater effectiveness than in-person delivery or usual care.
METHODS: Randomized, controlled, comparative effectiveness study with overweight patients with serious mental illness. 276 patients were randomly assigned to 1) computerized weight management with peer coaching (WebMOVE), 2) in-person clinician-led weight services, or 3) usual care. The computerized system could be accessed from clinic kiosks or anywhere with internet access. It provided audio and text-based education, video, pedometer tracking, goal setting, homework, diet plans, and quizzes. Coaching was delivered by individuals with lived experience with mental illness, was phone-based, and utilized motivational interviewing principles. In-person weight management had the same curriculum as the online program. Patient outcomes were studied at 6 months using mixed methods.
RESULTS: In obese patients, 52/200 (26%) lost 5% or more weight at 6 months. The probability of losing 5% or more weight was significantly different among the three treatment conditions ($\chi^2 = 6.4$; $p = .04$). 22/59 (37%) of the WebMOVE group lost 5% or more weight, while 12/68 (18%) of the in-person group, and 18/73 (25%) in usual care lost 5% of weight at 6 months. Patients were significantly more likely to lose 5% or more of body weight in the WebMOVE group compared to the MOVE SMI group ($\chi^2 = 6.2$; $p = .01$). Average weight change in WebMOVE was 0.5 BMI units (2.8 kg, $t = 3.2$, $p = .001$). No significant change in BMI was seen with in-person services ($t = .10$, $p = .92$), or usual care ($t = -.25$, $p = .80$). When non-obese patients were included in analyses, the condition by visit effect was no longer significant ($F = 2.8$, $p = .06$). WebMOVE was well received, while the acceptability of in-person services was mixed.
CONCLUSIONS: In obese patients with serious mental illness, computerized weight management with peer supports results in lower weight, and can have greater effectiveness than clinician-led in-person services. This intervention is well received, and should be feasible to disseminate.

THE EVOLVING ROLE OF NURSES IN A PATIENT CENTERED MEDICAL HOME: NURSING STAFF TIME ALLOCATION AND JOB SATISFACTION Karen Abernathy[2]; Jingwen Zhang[1]; Kimberly S. Davis[2]; Patty Hutto[1]; Patrick D. Mauldin[2]; William P. Moran[2]. [1]MUSC, Charleston, SC; [2]Medical University of South Carolina, Charleston, SC. (Control ID #2704768)

BACKGROUND: The patient-centered medical home (PCMH) supported by the Electronic Health Record (EHR) has requirements and clinical tasks which go well beyond the traditional primary care model. The remodeling required for PCMH to be successful has resulted in a shifting of roles for clinical staff, leading to changes in workflow and assigned duties. We sought to assess the distribution of tasks and time spent performing these tasks among nursing staff in a PCMH certified academic internal medicine clinic and to evaluate nursing job satisfaction.
METHODS: This study was conducted at a NCQA certified level 3 PCMH academic internal medicine clinic from May - August 2016. Clinic registered nurses (RNs) and licensed practical nurses (LPNs) developed a comprehensive list of 74 activities they performed in clinic. Activities were programmed into a tablet which automatically date/time stamped activity duration. A research assistant followed RNs and LPNs for 38 half-day sessions and documented the activities as they were completed. Nurse job satisfaction was assessed by a validated survey with 28 questions using a 5-point Likert scale.
RESULTS: The 74 activities were aggregated into 10 discrete and mutually exclusive task groups: care coordination, clinic operations, interruptions, EHR/

in-basket, paperwork, rooming, patient/family communication, searching, team communication and training. EHR use and in-basket management accounted for a large proportion of both LPNs and RNs time, ranging from 23-43 to 37-48%, respectively. Care coordination and patient/family communication accounted for 16-26% of the workday for RNs. LPNs spent 25-34% of their time rooming patients. Sixteen nurses completed the job satisfaction survey in September 2016, with a response rate of 88%. The survey was measured on a Likert scale with one (strongly disagree) to five (strongly agree), revealing a mean score of 3.1 for LPNs (SD = 1.2) and 3.0 for RNs (SD = 1.2).
CONCLUSIONS: As primary care clinics continue to adapt to the EHR and ever-increasing administrative duties and outcome measures, we must acknowledge the impact these changes are having on nurses. This study analyzed the day-to-day tasks and responsibilities of nursing staff and has established that nurses are spending the majority of their time on the EHR and other tasks that do not involve direct patient care. Finding ways to increase nurses' interactions with patients, such as re-assessing staffing models to allow for more support and limiting the non-face-to-face and EHR tasks may be a way to improve job satisfaction and retention among nurses. This study was limited to a single academic internal medicine clinic and the results may not be generalizable to other practices. We only observed nursing staff and do not have time data for other providers within the clinic. The Hawthorne effect could have been a factor as nurses may have changed their behavior due to being observed. The survey may suffer from respondent bias and the total number of respondents is low.

THE HOSPITAL SCORE TO PREDICT 30 DAY READMISSIONS AMONG PATIENTS ADMITTED FOR ACUTE VENOUS THROMBOEMBOLISM: PRELIMINARY FINDINGS Julie M. Pearson; Sally Weinstein; Dana Sperber; Eric Goodman; Andrew Dunn; Beth G. Raucher. Mount Sinai Hospital, New York, NY. (Control ID #2699319)

BACKGROUND: The HOSPITAL score is an internationally validated risk assessment to identify patients at risk of 30 day readmission for adults discharged from an inpatient medical department.[1] The HOSPITAL score is validated for all hospital admissions - acute and chronic. The purpose of this study was to assess the use of the HOSPITAL score to predict readmissions among patients with an acute condition, specifically for patients with acute venous thromboembolism (VTE).
METHODS: A random stratified sample of hospital discharges with principal diagnosis codes of VTE were extracted from administrative data to conduct a case–control comparison (9/2014 - 8/2016). The seven predictor variables from the HOSPITAL score were extracted via electronic chart review, and included the following: hemoglobin, discharge from oncology service, sodium level, procedure during the index admission, index type of admission (urgent), number of admissions during the last 12 months, and length of stay. The range of the HOSPITAL score is 0–15 with a greater score indicating a higher risk for readmission. Risk for readmission is categorized into three groups, low risk (0–4 points), intermediate risk (5–6 points) and high risk (≥7 points).
RESULTS: 194 hospital discharges were reviewed; of these, 76 were readmitted within 30 days of hospitalization. VTE patients who were readmitted had similar demographics when compared to the VTE patients who were not readmitted with the exception of race (Table 1). The average HOSPITAL score for patients who were readmitted (5.38) was significantly higher than the average score among patients who were not readmitted (4.27, $p < 0.01$).
CONCLUSIONS: The HOSPITAL score identified patients who were at risk for 30 day readmissions after hospital admission for acute VTE. The HOSPITAL risk score is unique in that it predicts readmissions among patients admitted for acute and chronic conditions whereas most scores predict readmissions for chronic conditions. These findings suggest that the score may help to identify patients with acute VTE at high risk for readmission to allocate transitions of care resources more efficiently. Additional analysis with the complete VTE population during the time period is warranted to assess the readmission rate for each risk category. 1. Donzé, Jacques D., Mark V. Williams, Edmondo J. Robinson, Eyal Zimlichman, Drahomir Aujesky, Eduard E. Vasilevskis, Sunil Kripalani et al. "International Validity of the HOSPITAL Score to Predict 30-Day Potentially Avoidable Hospital Readmissions." JAMA internal medicine 176, no. 4 (2016): 496–502.

Table 1. Demographic information for patients with VTE

Variable	Patients Readmitted within 30 Days (n = 76, cases)	Patients Not Readmitted within 30 Days (n = 118, controls)	p - value
Age (mean)	60.1 years (SD=16.1)	63.7 years (SD=17.6)	0.141
Gender			
Female	43 (56.6%)	70 (59.3%)	0.705
Male	33 (43.4%)	48 (40.7%)	
Race*			
Black	43	43	0.015
White	17	41	
Other	14	33	

*3 patients were removed to conduct the Chi-Square analysis: 1 American Indian (control), 2 Asians (cases)

THE IMPACT OF ACCOUNTABLE CARE ORGANIZATION PARTICIPATION ON POST-ACUTE CARE UTILIZATION AMONG MEDICARE BENEFICIARIES Amol S. Navathe[1, 3]; Alex Bain[1]; Ning Chen[1]; Rachel M. Werner[2]. [1]University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania and Philadelphia VA, Philadelphia, PA; [3]CMC Philadelphia VAMC, Philadelphia, PA. (Control ID #2705732)

BACKGROUND: Medicare payments for post-acute care (PAC) have grown faster than most other categories of spending and a 2013 IOM Report indicated that PAC utilization is the largest driver of overall spending variation. While Medicare shared-savings accountable care organizations (ACOs) have incentives to reduce PAC utilization, the impact of admission to an ACO hospital on post-acute care utilization is unknown.
METHODS: Our objective was to evaluate changes in PAC utilization, measured by the proportion of discharges to each of inpatient rehabilitation facilities (IRF), skilled nursing facilities (SNF), and home health agency services (HHA), among hospitals participating in the Medicare Shared Savings ACO program. Using a national sample of 11,683,573 Medicare patients who experienced 26,503,086 admissions from 2010–2013 and a linear probability model, we implemented a difference-in-differences design to evaluate changes in PAC utilization among patients admitted to 235 ACO-participating hospitals before and after the start of the ACO contracts, compared to patients admitted to 3,241 non-ACO hospitals (comparison group). We adjust for hospital fixed effects, market and beneficiary characteristics including comorbidities, a primary diagnosis-specific fixed effect, and secular trends in all analyses.
RESULTS: Admission to an ACO hospital did not result in a change in PAC utilization compared to admission to a non-ACO hospital. For example, the differential change (i.e., comparing admission to ACO vs. non-ACO hospital in the pre- vs. post-ACO period) in the probability of discharge to any PAC was 0.0022 ($P = 0.16$), SNF was −0.0003 ($P = 0.85$), IRF was 0.0006 ($P = 0.40$), and HHA was 0.0018 ($P = 0.11$). These results were robust to analysis of PAC utilization conditional on

discharge to any PAC and restriction to conditions with high PAC use nationally such as major joint replacement of the lower extremity (change in probability of IRF 0.0026, $P = 0.46$, and SNF −0.0110, $P = 0.07$ respectively), coronary artery bypass graft surgery (IRF 0.0085, $P = 0.25$ and SNF −0.0047, $P = 0.66$), and congestive heart failure (IRF 0.000, $P = 0.49$ and SNF −0.0011, $P = 0.75$). Further, the results were similar among ACO-participating hospitals that also had a PAC participant and for utilization measured by length of stay for SNF and IRF and number of visits for HHA.

CONCLUSIONS: Admission to an ACO hospital does not result in changes in PAC utilization, even when considering high PAC-use conditions and ACO hospitals that also have an ACO-participating PAC. This suggests that ACOs may not be an effective policy lever in reducing unwarranted PAC variation.

THE IMPACT OF AGE ON 30-DAY UNSCHEDULED READMISSIONS FOR DIABETES MELLITUS PATIENTS Guat Kheng Goh[4]; Soo Lee[2, 3]; Phillip Phan[3, 1]; Paul A. Tambyah[5, 4]. [1]Johns Hopkins Medicine, Baltimore, MD; [2]Old Dominion University, Norfolk, VA; [3]Johns Hopkins University, Baltimore, MD; [4]National University Health System, Singapore, Singapore; [5]National University of Singapore, Singapore, Singapore. (Control ID #2699510)

BACKGROUND: Global healthcare costs on diabetes mellitus (DM) increased 12% from $548 billion to $612 billion in 2014. In patients over 40 years old, readmissions accounted for most of the hospitalization costs. To improve case management of this population, we study the impact of age and other risk factors on unscheduled readmissions among DM patients.

METHODS: 1,242 patients diagnosed with DM or DM-related conditions from an acute care tertiary hospital in Singapore were analyzed for two outcomes: 30-day unscheduled readmissions and two or more readmissions in 2014. Predictor variables included patients' pre-existing conditions, hospital care, and post-discharge care. Differences between DM readmission and non-readmission groups were analyzed using Student's t- and χ^2-tests for continuous (mean ± standard deviation) and dichotomous variables respectively. The predictive model was analyzed using logistics regression.

RESULTS: 215 patients (17.3%) were readmitted, of which 73 were readmitted two or more times (5.9%). Patients with comorbidities (9.66 ± 3.62 vs 8.47 ± 4.08, $p < .01$), visited the specialist outpatient clinic (SOC) before admission (5.62 ± 4.89 vs 4.68 ± 4.82, $p = .03$), and stayed at subsidized wards (OR = 1.46 [95%CI = 1.07–1.98], $p = 0.02$) were at higher risk of readmission. Patients discharged in the morning were at lower risk of readmission (OR = 0.39 [95%CI = 0.24–0.63], $p < .01$). Younger patients (60.21 ± 14.80 vs 64.10 ± 15.23, $p = .03$), those with more comorbidities (10.39 ± 4.13 vs 8.57 ± 4, $p < .01$), SOC visits (7.85 ± 7.699 vs 4.62 ± 4.37, $p < .01$), and male (OR = 1.97 [95%CI = 1.18–3.26, $p = .01$) were at greater risk of multiple readmissions.

CONCLUSIONS: Identifying drivers of DM readmissions helps policymakers develop interventions to improve clinical care and improve patient outcomes. Contrary to current understanding, older DM patients were *not* at higher risk of readmission. Instead, illness severity and economic status were more important predictors. To the extent that morning discharges indicate efficient organization processes, improving processes can lower readmissions. Future research is needed to explore if better primary care would significantly reduce readmission risk.

THE IMPACT OF CANCER SURVIVORSHIP CARE PLANS ON PRIMARY CARE PROVIDERS' CLINICAL DECISION MAKING AT THE POINT-OF-CARE SarahMaria Donohue[3]; James E. Haine[4]; Elizabeth (Betsy) Trowbridge[1]; Sandra Kamnetz[4]; David Feldstein[4]; James M. Sosman[4]; Zhanhai Li[2]; Lee G. Wilke[3]; Mary Sesto[3]; Amye J. Tevaarwerk[3]. [1]UW SMPH, Madison, WI; [2]UW-Madison, Madison, WI; [3]University of Wisconsin, Madison, WI; [4]University of Wisconsin School of Medicine and Public Health, Madison, WI. (Control ID #2705595)

BACKGROUND: It is recommended that every cancer survivor and their primary care provider (PCP) receive an individualized survivorship care plan (SCP) at the end of active cancer treatment which summarizes cancer diagnosis, treatment and follow up. While the SCP has the potential to improve patient care, whether they are used by PCPs has not been studied. We assessed the use of SCPs in primary care visits and explored the barriers and facilitators to use.

METHODS: We identified breast cancer survivors who (1) were seen by a PCP associated with the UW Health system and (2) had an UW EHR-generated SCP. PCPs identified as the PCP for multiple survivors, had a single survivor with the most recent clinic visit selected in order to identify unique PCP-survivor dyads. A 15-question survey, and PDFs of (1) the survivor's individualized SCP and (2) the clinic note for the survivor's most recent visit were sent to PCPs of eligible patients via email in November 2016 with reminders at 7 and 14 days to nonrespondents.. The survey was designed to determine if the survivor's SCP (a) was utilized by the PCP for the visit and (b) influenced clinical decision-making at the point-of-care.

RESULTS: 88 unique PCP-survivor dyads were identified. The survey response rate was 45.5% ($n = 40/88$). Most PCPs ($n = 24/40$, 60%) identified that cancer or a related issue was discussed at the visit. Cancer information needed in the context of the visit included treatment ($n = 16/24$, 67%), followup visits the cancer team is responsible for ($n = 14/24$, 58%) and followup visits the PCP is responsible for ($n = 14/24$, 58%). PCPs reported acquiring this information by asking the patient or family ($n = 20/24$, 83%), checking oncology notes in the EHR ($n = 18/24$, 75%), checking the SCP ($n = 4/24$, 17%) and checking an online resource ($n = 2/24$, 8%). Most PCPs ($n = 29/40$, 73%) reported being unaware prior to survey that the patient had an SCP. Eleven ($n = 11/40$, 28%) of PCPs reported knowing that the patient had an SCP prior to the survey. Among them, most ($n = 7/11$, 64%) reported previously using the SCP. PCPs who utilized the SCP at the visit ($n = 4$) used the SCP to obtain: cancer treatment, followup visits and plan/monitoring that were PCP responsiblities. PCPs identified barriers to use as (1) unaware of SCP existence ($n = 11/21$, 52.38%), (2) difficulty locating the SCP in the EHR even when aware ($n = 7/21$, 33.33%), and (3) identifying the needed information faster via another mechanism ($n = 3/21$, 14.29%). Most PCPs ($n = 22/40$, 55%) reported that an SCP would be quite or very helpful in future visits with their patient.

CONCLUSIONS: The majority of survivor followup visits addressed cancer or cancer-related issues. PCPs felt that SCPs would be helpful for patient care, but multiple barriers including lack of awareness and inability to find the SCPs prevented them from being useful. Further efforts are needed to educate PCPs about SCPs and overcome access issues while determing how to best tailor SCPs for PCP use.

THE IMPACT OF COMPETING COMMUNITY HEALTH CENTER PROVIDER RESPONSIBILITIES ON AN EHR-BASED INTERVENTION. Guisselle del Salto[2]; Elizabeth Adetoro[4]; Sarah S. Rittner[4]; Andrew Hamilton[4]; Pankaja Desai[4]; Fred Rachman[4]; Laura M. Curtis[2]; Michael S.

Taitel[3]; Ruth Parker[5]; Tim Long[6]; David R. Buchanan[1]; Michael S. Wolf[2]. [1]Erie Family Health Center, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]Walgreens, Deerfield, IL; [4]Alliance of Chicago Community Health Services, Chicago, IL; [5]Emory University, Atlanta, GA; [6]Near North Health Service Coorporation, Chicago, IL. (Control ID #2705856)

BACKGROUND: The Office of the National Coordinator's 'Meaningful Use' initiative and other national calls require bolstering Electronic Health Record System (EHRS) to improve healthcare. From promoting and tracking the use of preventive services to better care management, new EHR tools are constantly being introduced to providers. Yet, challenges providers experience due to complex patient populations and EHR modifications are unclear. We offer a local perspective of challenges encountered when leveraging EHRS to improve patient-centered medication prescribing and education materials about point-of-care delivery in two, large federally qualified health centers.

METHODS: We conducted a root cause analysis evaluating a multi-site ($N=11$) intervention that alters EHR medication instructions to follow an evidence-based approach regarding when to take their medicine (morning, noon, evening, bedtime), the delivery of low literacy, 1-page medication summaries at the time of prescribing, and a complete list of patients' current medications each corresponding to a set of instructions and a checkbox (for morning, noon, evening, bedtime) to help patients visualize when to take their medicine. We were able to track prescriber usage of these new EHR functions and interviews were conducted with a convenience sample of prescribers to better understand any reasons why the functions were not utilized.

RESULTS: Ten months after implementing new prescribing tools - including provider orientations via email, webinar, written instructional guide, and in-person review - 23% of providers used any of the functions at least once. Provider interviews ($N=14$) revealed that many remained unfamiliar with the tools. Providers that were aware of these functions often did not use them due to complicated patient care management needs, competing educational programs (specifically the launch of new diabetes general education materials with the after-visit summary as part of a Meaningful Use initiative), or other significant EHR modifications. For instance, during the initial roll-out of our EHR tools, 42 other EHR upgrades and functions were imparted to providers. None were research related or addressing the medication prescribing specifically, but these did cause distractions as with each new onboarding of a new function, webinars and YouTube links were provided to prescribers to orient them to the update.

CONCLUSIONS: While EHRS may hold promise for improving patient care, our findings suggest that implementation and sustainability over time may be significantly hindered given competing initiatives. Despite intensive efforts to onboard providers to changes, even subtle impacts on workflow can undermine efforts.

THE IMPACT OF HAVING A TRUSTED ADVISOR ON PHYSICIAN BURNOUT, PRODUCTIVITY, AND CAREER SATISFACTION: EVIDENCE FROM A LARGE MULTISPECIALTY PHYSICIAN SURVEY

Michael K. Hidrue[3]; Sandhya K. Rao[2]; Sara Lehrhoff[3]; Timothy G. Ferris[1]; Alexa Kimball[4]. [1]MGH, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Mass General Physicians Organization, Boston, MA; [4]Beth Isreal Medical Center, Boston, MA. (Control ID #2705795)

BACKGROUND: The value of having a trusted mentor, especially during the early years after training, in academic medicine is well recognized. However, there is limited empirical work that analyzes the impact of advising on a physician's personal and career development. This study examines the impact of having trusted advisor on physician burnout, work engagement, and career satisfaction in the first ten years after training.

METHODS: We used data from a 2014 Massachusetts General Physician Organization (MGPO) survey. The MGPO survey was administered to all clinically active physicians at the institution. Having a trusted advisor and career satisfaction were assessed using a five-point Likert scale, burnout was assessed with the Maslach Burnout Inventory-General Service (MBI-GS), and work engagement was assessed with the Utrecht Engagement Scale (UWES). The MBI-GS and the UWES have three subscales that reflect the underlying dimensions of burnout and engagement.

RESULTS: The sample included 768 physicians who are clinically active and have less than 10 years of experience and a response rate of 96%. Of the 768 physicians, 467 (60.8%) either agreed or strongly agreed with having trusted advisor, 180 (23.4%) either disagreed or strongly disagreed with having a trusted advisor, and the remaining 121 (15.8%) indicated neither. We found those with a trusted advisor had lower burnout scores, higher engagement scores, and higher job satisfaction. In a multivariate regression analysis controlling for age, gender, specialty, and number of years at Massachusetts General Hospital, we found physicians with a trusted advisor are less exhausted (16% lower, $p<0.001$), less cynical (28% lower, $p<0.001$), more efficient (9% higher, $p<0.001$), more dedicated (22% higher, $p<0.001$), and have more vigor (28% higher, $p<0.001$) than those without trusted advisor. We also found physicians who have a trusted advisor are more likely to be satisfied with their career than those without trusted advisor (OR = 3.2, 95% CI = 2.0, 5.2).

CONCLUSIONS: These findings imply health organizations can mitigate burnout, improve career satisfaction, and increase productivity of junior physicians by designing robust mentorship programs.

THE IMPACT OF MEDICAL SCRIBES, PROVIDER WORK-LIFE AND SATISFACTION IN A MULTI-SPECIALTY CLINIC

Marc L. Martel; Brian H. Imdieke; Sara Poplau; Mark Linzer. Hennepin County Medical Center, Minneapolis, MN. (Control ID #2707708)

BACKGROUND: Medical Scribes are being integrated with increasing frequency in various clinical settings. Studies have shown improved provider efficiency and productivity with scribe support. Our objective was to assess the relationship between medical scribe use and important indicators of provider wellness in the ambulatory clinic setting.

METHODS: We performed a prospective, quasi-experimental study of providers in our hospital-based clinic system. We evaluated the effect of incorporating trained medical scribes in the clinics; before and 3 months after scribe integration, on key measures of provider satisfaction and wellness. The primary outcome measure was provider job satisfaction.

RESULTS: Fifty-one providers were surveyed from nine outpatient clinics before and after the introduction of medical scribes. The pre-scribe response rate was 86.3%, three-months post was 80.4%. Provider satisfaction their clinic role improved from 66.7 to 90.2% satisfied ($p=0.008$). Provider's perception of time pressure for documentation was reduced by >50% ($p<0.0001$). Medical scribes also significantly improved the perception of time spent documenting from home ($p=0.003$), the ability to listen to patients ($p=0.043$), and the ability to provide high quality care ($p=0.022$).

CONCLUSIONS: Medical scribes positively impacted provider work-life, with improvements in provider perceptions of adequate time with patients, overall documentation time, and home documentation burden.

Table 1. Mini Z survey results before and after the introduction of medical scribes.

	Pre-Scribe $n = 44$	Post-Scribe $n = 41$	*P* value
Satisfied with role in clinic (Agree, Agree Strongly)	30 (66.7%)	37 (90.2%)	0.008
Great deal of stress because of my job (Agree, Agree Strongly)	29 (64.4%)	21 (51.2%)	0.215
Control over workload (Poor, Marginal)	25 (55.6%)	15 (36.6%)	0.078
Time for documentation (Poor, Marginal)	33 (75.0%)	10 (24.4%)	<0.0001
Work atmosphere description (Very busy, Hectic, Chaotic)	26 (57.8%)	17 (41.5%)	0.131
Ability to listen to patients (Agree, Agree Strongly)	30 (66.7%)	35 (85.4%)	0.043
Ability to provide high quality care (Agree, Agree Strongly)	31 (70.5%)	37 (90.2%)	0.022
Ability to spend necessary time with patients (Agree, Agree Strongly)	20 (44.4%)	24 (58.5%)	0.191
Amount of time spent on EMR at home (Excessive, Moderately High)	28 (63.6%)	13 (31.4%)	0.003
Value Scribe (Agree, Agree Strongly)		37 (90.2%)	

THE IMPACT OF MICHIGAN'S MEDICAID EXPANSION ON DENTAL CARE ACCESS, UTILIZATION AND HEALTH

Edith C. Kieffer[2, 2]; Susan D. Goold[2, 2]; Renuka Tipirneni[2, 2]; Ann-Marie Rosland[2, 1]; Adrianne N. Haggins[2, 2]; Jeff Kullgren[2, 1]; Sarah J. Clark[2, 2]; Tammy Chang[2, 3]; Erin Beathard[2]; Christina Mrukowicz[2]; Erica Solway[2]; Zachary Rowe[2, 4]; Erin Sears[2]; Lisa Szymecko[2]; Sunghee Lee[2, 2]; John Z. Ayanian[2]. [1]Ann Arbor VA Healthcare System and University of Michigan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Institute for Healthcare Policy and Innovation, Ann Arbor, MI; [4]Friends of Parkside, Detroit, MI. (Control ID #2705443)

BACKGROUND: Dental disease is prevalent among low-income adults. However, adult dental care remains an optional service in Medicaid expansion under the ACA. Among 32 Medicaid expansion states/DC, Michigan's Healthy Michigan Plan (HMP) is among 27 with at least limited dental coverage. Beneficiaries enroll in Medicaid managed care plans, which are responsible for administering the dental benefit. This mixed-methods study examines the perspectives of HMP beneficiaries about their dental coverage, care, and impact on health.

METHODS: We conducted 67 semi-structured interviews with beneficiaries enrolled in HMP for ≥6 months in April-August 2015. Interviews were analyzed using standard qualitative analysis techniques. From January-October 2016, we conducted a telephone survey in English, Arabic or Spanish with 4,099 non-elderly beneficiaries with ≥12 months of coverage and ≥10 months in a health plan. Sampling was stratified by income and region of the state. Weights adjust for sample design and nonresponse (RR = 54.3%). Outcomes included knowledge of dental coverage, perceived access to and affordability of dental care, and impact of dental care on health and employability.

RESULTS: 22% of survey respondents didn't know about HMP's dental benefit. 47% reported better ability to obtain dental care since HMP enrollment; 18% were unsure; 29% reported no change; and 6% reported worse ability. Among 628 respondents who reported foregoing needed care due to cost in the past 12 months, 68% reported foregoing dental care. Among all respondents, those who were aware that HMP covered dental care were likelier to report better dental care availability with HMP than those who were unaware (93% vs 7%), and less likely to forego dental care due to cost (33% vs 67%). In interviews, many beneficiaries who hadn't obtained dental care were unaware of the covered benefit or had difficulty locating a dentist who accepted their Medicaid coverage. 40% of survey respondents reported improved health of their teeth and gums. In interviews, beneficiaries described how cleanings, fillings and dentures improved their appearance, daily functioning and employability. Some described living with serious oral health problems prior to HMP coverage and receiving life-changing dental procedures after HMP enrollment. "The infection got so bad that it virtually threatened my life. I tell people to take care of their teeth, and now people can." (Male, 58, rural)

CONCLUSIONS: More than a fifth of beneficiaries were unaware of HMP dental coverage, likely decreasing their perceptions of dental care affordability and access, use of dental services, and impact on oral health. Provider availability was sometimes a barrier. Nonetheless, HMP beneficiaries reported increased access to and use of dental care for serious dental problems and routine care. As policymakers consider ways to constrain Medicaid spending and enhance its value, they should recognize the impact of dental care on functioning and health of low income populations.

THE IMPACT OF MICHIGAN'S MEDICAID EXPANSION ON LOW-INCOME ENROLLEES' FUNCTIONAL STATUS, ABILITY TO WORK, AND EMPLOYMENT: A MIXED METHODS STUDY

Renuka Tipirneni[2, 2]; Edith C. Kieffer[2, 2]; Ann-Marie Rosland[2, 2]; Jeff Kullgren[1, 2]; Adrianne N. Haggins[2, 2]; Tammy Chang[2, 2]; Sarah J. Clark[2, 2]; Sunghee Lee[2]; Erica Solway[2]; Christina Mrukowicz[2]; Erin Beathard[2]; John Z. Ayanian[2, 2]; Susan D. Goold[2, 2]. [1]Ann Arbor VA Healthcare System and University of Michigan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI. (Control ID #2703593)

BACKGROUND: Michigan is one of 31 states to have expanded Medicaid under the Affordable Care Act. Known as the Healthy Michigan Plan (HMP), the program was launched to improve not only the health and well-being of low-income residents but also the state's business climate and economy. The objective of this study was to understand the impact of HMP on enrollees' functional status, ability to work, and employment.

METHODS: To inform survey development, we conducted 67 semi-structured interviews with HMP enrollees during April-August 2015, which were transcribed and analyzed using standard qualitative analysis techniques. A survey instrument assessing functional/health status, ability to work, and employment was subsequently developed. Between January-October 2016 we conducted a computer-assisted telephone survey of 4,108 non-elderly HMP enrollees with ≥12 months of HMP coverage and ≥10 months in a Medicaid health plan (response rate = 54%). Sampling was stratified by income and region of Michigan. Surveys were conducted in English, Arabic and Spanish. Weights adjusting for sample design and nonresponse were incorporated in the analysis.

RESULTS: Most (80%) respondents had incomes below 100% of the federal poverty level, 68% reported they had excellent/very good/good health, and

66% had ≥1 chronic health condition. One-quarter (25%) reported they had a significant physical functional limitation and 22% had a mental functional limitation. However, 49% of respondents reported better physical health, 40% better mental health, and 43% better dental health since HMP enrollment. Nearly half (47%) reported they were employed/self-employed, 28% were out of work, 13% were unable to work, and 3% were retired. HMP enrollees were more likely to be employed if they had good or better health status or if they had no chronic conditions. Employed respondents missed a mean of 7.7 work days (SD 0.6) in the past year due to illness. Over two-thirds (71%) of employed respondents reported that getting HMP insurance helped them to do a better job at work. For those who changed or sought a job, 60% strongly agreed/agreed that it made them better able to look for a job and 38% strongly agreed/agreed that having HMP insurance helped them get a better job. In interviews, several HMP enrollees attributed their ability to get or maintain employment to improved physical, mental and dental health because of services covered by HMP. Remaining barriers to work cited by enrollees included older age, disability, illness, and caregiving responsibilities.

CONCLUSIONS: Low-income HMP enrollees reported improved functioning, ability to work, and job seeking after obtaining health insurance through Medicaid expansion. While many attributed improvements in employment and ability to work to improved physical, mental and dental health due to covered services, others had ongoing barriers to employment.

THE IMPACT OF MICHIGAN'S MEDICAID EXPANSION ON THE DIAGNOSIS AND ABILITY TO CARE FOR CHRONIC ILLNESSES

Ann-Marie Rosland[2, 3]; Edith C. Kieffer[1]; Renuka Tipirneni[3]; Jeff Kullgren[2, 3]; Adrianne N. Haggins[1]; Tammy Chang[1]; Sarah J. Clark[1]; Sunghee Lee[1]; Erica Solway[1]; Christina Mrukowicz[1]; Erin Beathard[1]; John Z. Ayanian[1]; Susan D. Goold[3, 1]. [1]University of Michigan, Ann Arbor, MI; [2]VA Ann Arbor Healthcare System, Ann Arbor, MI; [3]University of Michigan Medical School, Ann Arbor, MI. (Control ID #2703770)

BACKGROUND: As the prevalence of chronic health conditions increases among U.S. adults, expanded access to Medicaid may mitigate the impact of these conditions on poor health and disability. We evaluated the impact of enrollment in Michigan's expansion of Medicaid, the Healthy Michigan Plan (HMP), on diagnosis of chronic conditions and on access to care and health status among low-income enrollees with a chronic condition.

METHODS: We surveyed HMP Enrollees with ≥12 months of HMP coverage by telephone in English, Arabic, or Spanish from January-October 2016. Sampling was stratified on income and region of the state. Validated survey items assessing chronic condition diagnoses and health status from previous national health surveys were used. Analyses incorporated weights adjusting for sample design and nonresponse.

RESULTS: 4108 HMP enrollees were surveyed (response rate 54%). 57% were women, and 35% were 18–34 years old, 34% 35–50 years, and 31% 51–64 years old. 51% reported income < =35% Federal Poverty Level, 45% at 36-100%, and 20% at 101-133%. Overall, 54% of HMP enrollees reported at least one chronic physical condition (ranging from 11% for heart conditions to 35% for hypertension), 31% reported a chronic mental health condition (e.g. depression, anxiety, or bipolar disorder), and 20% had both a physical and mental health chronic condition. About a third (32-36%) of those with common physical health conditions (hypertension, heart disease, diabetes, COPD), 44% of those with stroke, and 28% of those with a mood disorder reported being newly diagnosed with the condition after enrolling in HMP. Among those with a chronic physical or mental health condition ('chronically ill'), in the year prior to HMP enrollment 60% had lacked insurance, 57% had not seen a primary care provider, and 54% had problems paying medical bills. Since HMP enrollment, 66% of chronically ill enrollees reported their ability to fill prescription medications improved and 87% reported their ability to pay medical bills had improved. 53 and 44% of chronically ill enrollees reported overall improvements in their physical and mental health status, respectively, after enrolling in HMP, while only 8 and 6% reported their physical and mental health status had worsened.

CONCLUSIONS: Chronic health conditions, including comorbid physical and mental health conditions, were common among enrollees in Michigan's Medicaid expansion enrollees, even though most enrollees were under 50 years old. A large proportion of these conditions were newly diagnosed after enrolling in HMP. Prior to HMP enrollment, a majority of enrollees with chronic illness lacked health insurance and could not access needed care. Since enrollment, over half of these individuals reported improved physical health and most were better able to access medications that are crucial to managing chronic conditions and avoiding future complications.

THE IMPACT OF THE 2013 NATIONAL CHOLESTEROL TREATMENT GUIDELINE IN THE VA: AN INTERRUPTED TIME SERIES ANALYSIS

Adam A. Markovitz[3, 2]; Rob Holleman[2]; Mandi L. Klamerus[2]; TImothy Hofer[1, 2]; Eve A. Kerr[1, 2]; Jeremy Sussman[1, 2]. [1]University of MIchigan, Ann Arbor, MI; [2]VA Center for Clinical Management Research, Ann Arbor, MI; [3]University of Michigan Medical School, Ann Arbor, MI. (Control ID #2704781)

BACKGROUND: The 2013 national cardiology cholesterol treatment guideline fundamentally shifted focus away from the "treat-to-target" cholesterol levels approach of the 2004 guideline and to prescribing moderate and high intensity cholesterol-lowering statin drugs based on patient cardiovascular risk (Table). Despite being widely publicized, we know very little about how this new guideline affected patient care. We examined prescribing data before and after the guideline release to estimate whether new guideline increased the use of moderate or high intensity statins, particularly among patients with increased cardiovascular risk.

METHODS: We performed an interrupted time series analysis of active patients ages 40 to 75 who sought care in the Veterans Health Administration from July 1 2011 to June 30 2016 and were exempt from drug copayments ($n = 791{,}525$). Our main study outcome was whether a patient met the 2013 guideline in a given quarter (Table). Secondary outcomes included use of statin drugs, nonstatin lipid-lowering drugs, and lipid testing. Our exposure was introduction of the new guideline in the fourth quarter of 2013. To address pre-existing statin trends, we performed an interrupted time series analysis and estimated marginal effects (ME) by comparing predicted and observed statin use at the study's end. Finally, we examined whether guideline responses varied across pre-specified guideline "risk groups."

RESULTS: The release of the new guideline was associated with a 7 percentage-point increase in the probability of meeting the 2013 guideline (ME, 0.070, Standard Error [SE], 0.002), after adjusting for underlying time trends. This reflected a shift away from low (ME, −0.032, SE, 0.001) or moderate intensity statins (ME, −0.024, SE, 0.002) and toward high intensity statins (ME, 0.086, SE, 0.001). There was a slight decrease in nonstatin lipid-lowering drugs (ME, −0.009, SE, 0.001) and a small increase in lipid testing

(ME, 0.016, SE, 0.001). Gains in meeting the guideline were large among patients with ASCVD, diabetes, and high ASCVD risk but not hyperlipidemia. **CONCLUSIONS**: The 2013 guideline was associated with immediate and sustained changes in statin prescribing that were predominantly concordant with the guideline. Our findings highlight the potential for guidelines to influence patient care when given wide media exposure. Professional societies must work to publicize new guidelines more effectively if we are to ensure the adoption of guideline changes.

Guideline recommendations

New 2013 ACC/AHA guidelines	
Atherosclerotic cardiovascular disease (ASCVD)	On moderate or high intensity statin
Hyperlipidemia (LDL ≥ 190 mg/dL), non-ASCVD	" "
Diabetes, non-ASCVD	" "
High risk (≥7.5%10-year ASCVD risk)	" "
Low risk (<7.5%10-year ASCVD risk)	N/A
Old 2004 ATP III guidelines	
High risk (ASCVD, diabetes)	LDL < 100 mg/dL
Moderate risk (≥2 risk factors)	LDL < 130 mg/dL
Low risk (<2 risk factors)	LDL < 160 mg/dL

THE INSULIN TITRATION PROGRAM: MEDICAL STUDENTS HELPING PATIENTS IMPROVE DIABETES CONTROL Ryan Johnson[2]; Lani Kroese[2]; Kelsey Savery[2]; Mohan Nadkarni[1]; Ira Helenius[2]. [1]UVAHS, Charlottesville, VA; [2]University of Virginia, Charlottesville, VA. (Control ID #2704168)

BACKGROUND: Type 2 Diabetes Mellitus (T2DM) is a major cause of early illness and death worldwide. Fortunately, many complications of T2DM can be prevented with adequate glycemic control, often achieved through pharmacologic therapies and lifestyle intervention. Many patients need support controlling their disease, and medical students can help provide this support between clinic visits. The purpose of this study was to assess the effectiveness of a medical student-led Insulin Titration Program (ITP) in helping patients better manage their diabetes. A previous assessment of this program in 2015 showed benefit but did not use a control group, and included no patient self-assessment survey.
METHODS: The ITP program was implemented in 2014 in a large outpatient internal medicine teaching clinic associated with the University of Virginia. This study is a non-randomized trial comparing outcomes in a convenience sample of referred patients with uncontrolled T2DM who receive the intervention to a control group of randomly chosen patients with uncontrolled T2DM in the same clinic who were not referred to the ITP. The ITP intervention involved weekly phone calls from trained medical student volunteers who provided lifestyle counseling and adjusted the patient's long-acting insulin dose per the program protocol. The primary outcome for the study was the change in HbA1C values after a study period of 3 months of enrollment. The study group was also administered a telephone-based version of the Summary of Diabetes Self-Care Assessment (SDSCA) before and after the intervention. The SDSCA is a previously validated self-report questionnaire which assesses various aspects of DM self-management.
RESULTS: Results of this study indicate that participation in the ITP was associated with larger improvement in glycemic control when compared to controls. The study group consisted of 31 patients with a mean age of 56.4 (+/− 11.6). The control group consisted of 32 patients with a mean age of 51.5 (+/− 13.2). Enrollment HbA1C values for the study and control group were 10.6% (+/− 1.8) and 9.9% (+/− 1.8) respectively. HbA1C values after an average of 17.0 weeks (+/− 5.2) for the study and control group were 9.2% (+/−2.0) and 9.5% (+/− 2.2) respectively. We found that the decrease in HbA1C values after the study period were significantly lower in the study group with a mean decrease in HbA1C of 1.4% (+/− 2.0) when compared with the control group decrease of 0.4% (+/− 2.0); $p = 0.05$. There was no difference found between the pre- and post-intervention dose of insulin in the study group. The answers to the SDSCA questionnaire also showed no statistical difference after the intervention.
CONCLUSIONS: The results indicate that a medical student-led telephone-based intervention can play an important role in managing chronic illnesses such as T2DM. Further investigation is needed to determine which, if any, specific behavioral changes are positively impacted by such a telephone-based intervention.

THE INTERACTIVE INFLUENCE OF GENDER, ACCULTURATION, AND EDUCATION ON CURRENT SMOKING AMONG LATINOS OF DIFFERENT NATIONAL BACKGROUNDS Erik J. Rodriquez[3]; Alicia Fernandez[1]; Jennifer Livaudais-Toman[2]; Eliseo J. Perez-Stable[3]. [1]UCSF, San Francisco, CA; [2]University of California, San Francisco, Greenwich, CT; [3]National Institutes of Health, Bethesda, MD. (Control ID #2705897)

BACKGROUND: Acculturation and educational levels influence smoking behavior among Latinos. More acculturated women are more likely to smoke, but findings among Latino men have been mixed. Among Latinos, in contrast to Whites, a higher level of education does not always decrease the risk of current smoking. We hypothesized that a) greater acculturation level would increase the likelihood of current smoking, especially among women; b) educational attainment of high school or greater would decrease the likelihood of current smoking; and c) the relationship between acculturation level, educational attainment, and current smoking would differ by national background.
METHODS: The National Health Interview Survey (NHIS) is a nationally representative survey which uses a complex, multistage sampling methodology to assess health behaviors. Data from Latinos in the 2009–2012 NHIS were analyzed and included gender, national background, acculturation, educational attainment, and current smoking. Latino national background groups included participants identifying as Cuban, Dominican, Mexican, Puerto Rican, and Central and South American. Categorical levels of acculturation were defined: 1) Less acculturated (foreign born and preferred Spanish), 2) Bicultural (U.S. born and preferred Spanish or foreign born and preferred English), and 3) More acculturated (U.S. born and preferred English. Multivariable logistic regression models were stratified by gender and national background.
RESULTS: 20,993 participants self-identified as Latino (55% women; 45% men). Mean age was 40.2 years and more men than women were married or living with a partner (63% vs. 60%; $p < 0.001$). For both genders, over 60% of participants had a high school level of education or less. While the majority of Latinos were interviewed only in English (62%), less than half (39%) were born in the U.S. Mexicans were the largest national background (65%), group followed by Central and South Americans (17%) and Puerto Ricans (10%). Overall, 17.8% of men and 9.6% of women reported current smoking. Among women, current smoking was more prevalent among those with more than a 9th grade education (10% vs. 5%). Smoking prevalence was greatest among men with a 9th to 11th grade (22%) or high school (21%) education, compared to those with less than a 9th grade (15%) and lowest for men with a bachelor's degree (9%). For Latinos in aggregate, an interactive effect between greater acculturation and education reduced the odds of smoking among men (adjusted

odds ratio [aOR] = 0.71; 95% confidence interval [CI] = 0.56, 0.89). More acculturated and educated Mexican men had a lower odds of smoking (aOR = 0.66; 95% CI = 0.48, 0.92).

CONCLUSIONS: Increased acculturation and educational level was associated with less cigarette smoking among Latinos in aggregate. The effect of acculturation on health behaviors among Latinos is influenced by education and is not linear. These factors must be considered when developing tobacco control strategies.

THE NEED FOR POINT OF CARE ULTRASOUND TRAINING FOR INTERNAL MEDICINE RESIDENTS WHO ROTATE TO RESOURCE-POOR CLINICAL SITES Stephanie Maximous; Phillip Lamberty; Carla Spagnoletti. University of Pittsburgh, Pittsburgh, PA. (Control ID #2703672)

BACKGROUND: Interest in provision of health care in resource-poor settings is prevalent among US physicians. As such, many internal medicine (IM) training programs offer formal experiences to support this interest. The WHO estimates 2/3 of the world's population have inadequate access to diagnostic imaging, though ultrasound machines are more likely to be available than other imaging modalities. However a training gap for their use exists for both local clinicians and rotating residents. In anticipation of developing a mastery-learning point of care (POC) ultrasound curriculum for IM residents who rotate to resource-poor sites, we conducted a needs assessment to determine current practices among IM residents with POC ultrasound in resource-poor settings.

METHODS: The cross sectional survey was administered to the 12 GH track residents within the IM residency program at the University of Pittsburgh Medical Center (UPMC) in 2016, chosen because of their structured clinical experiences in sites of varying resources. Respondents were asked to indicate the conditions for which they have utilized POC ultrasound, how frequently their use of ultrasound impacts their management, and how confident they are acquiring and interpreting ultrasound images. They were also asked to identify the major barriers to using POC ultrasound. Data were analyzed using frequencies and summary statistics.

RESULTS: All (100%) completed the needs assessment. They reported diverse conditions amenable to POC ultrasound diagnostics at their clinical sites abroad, including heart failure, pleural effusions, soft tissue abscesses, and hepatobiliary pathologies. A total of 70% indicated lack of access to ideal imaging tests on a daily basis at their resource-poor clinical sites. They indicated that use of POC ultrasound at these sites impacted their clinical judgment or changed patient outcomes 75% of the time. The mean self-rating for confidence with image acquisition and interpretation was 3.13 (scale 1–5 where 1 = not confident, 5 = extremely). All (100%) indicated desire for further training. The top 3 barriers to use of POC ultrasound included lack of available equipment (66%), lack of confidence in skills (71%), and lack of preceptors to provide feedback on their technique (80%).

CONCLUSIONS: The data presented supports the need for additional POC ultrasound training for a group of internal medicine residents with clinical experiences in both resource-rich and resource-poor settings. The GH track residents are a pilot group selected to examine feasibility and shape the development of a POC ultrasound curriculum for internal medicine trainees. Future plans to ensure sustainability include a teach-the-teacher curriculum for GH track residents who become proficient in ultrasound and application of this curriculum to full-time clinicians at resource-poor sites. The curriculum can then be expanded to other institutions interested in better preparing trainees to practice medicine in resource-poor settings.

THE NEXT GENERATION OF GENERALISTS: WHAT KNOWLEDGE AND SKILLS DO PRIMARY CARE PHYSICIANS AND LEADERS NEED? Anna Volerman; Michael T. Quinn; Julie Grutzmacher; Deborah L. Burnet. University of Chicago, Chicago, IL. (Control ID #2706746)

BACKGROUND: Primary care faces immense challenges in today's health care system and transformation is required to effectively deliver high-quality, high-value, patient-centered care. A diverse, well-prepared workforce is needed, and primary care leaders are necessary to guide clinics and systems in the transformation toward population health and team-based care. Our objective is to understand key factors in residency training that led to a subsequent career in primary care to inform a new program for resident and faculty physicians in urban communities.

METHODS: We conducted a survey of primary care physicians (PCPs) in internal medicine, pediatrics, and family medicine in the Chicago area. The survey was distributed electronically to PCPs at one major academic medical center and its affiliated community health centers. Questions focused on identifying important factors in residency training for a career in primary care as well as knowledge and skills necessary for primary care physicians and leaders in today's healthcare system. Responses were obtained with a five-point Likert scale for level of importance and also ranking and open-ended questions. Demographic, residency, and practice information was collected. The study was IRB exempt.

RESULTS: The survey was completed by 82 primary care physicians, with 48.8% Internal Medicine, 31.3% Family Medicine, 12.5% Pediatrics, and 7.5% Medicine-Pediatrics. The majority practice in an academic medical center (56.3%), followed by community health center (37.5%). Years in practice varied from 0–5 years (30%) to more than 25 years (20%). Physicians worked on average 20 clinic hours per week, including direct patient care and precepting trainees. One-third completed residency training in a formally designated primary care track (32.4%), and the majority did not complete fellowship (64.9%). Respondents indicated the most important training components for a subsequent career as a PCP were being exposed to a PCP role model and learning in a variety of primary care settings. For physicians to transform primary care, the most important knowledge and skills were: interprofessional collaboration (30%), leadership skills (28%), effective communication (27%), care coordination (25%), and integrated behavioral health (23%).

CONCLUSIONS: Primary care programs would benefit from incorporating experiences in a variety of ambulatory settings and providing strong role models for trainees in primary care. In addition, primary care leaders need strong training in team-based care, population health, leadership, and communication; these topics should be emphasized in primary care curricula. The results are affected by selection bias, with disproportionate representation from academic medical centers and within one community of practice. Further studies examining key knowledge and skills for primary care physicians and leaders can inform training programs that aim to prepare physicians to practice in and guide primary care practice transformation.

THE PATIENT EXPERIENCE WITH INTEGRATION OF COMPLEMENTARY AND INTEGRATIVE HEALTH INTO CONVENTIONAL CHRONIC PAIN CARE Caitlin Felder-Heim[1]; Danielle M. Kline[4]; Ingrid Binswanger[5]; Stacy Fischer[5]; Regina Fink[2]; Lisa Corbin[4]; Joseph W. Frank[3]. [1]University of Colorado, Denver, CO; [2]University of Colorado Anschutz Medical Campus, Aurora, CO; [3]University of Colorado School of Medicine, Aurora, CO; [4]University of Colorado Denver School of Medicine, Aurora, CO; [5]University of Colorado School of Medicine, Denver, CO. (Control ID #2706134)

BACKGROUND: There is an urgent need for novel strategies to manage chronic pain. Expert guidelines recommend multimodal pain care, which may include Complementary and Integrative Health (CIH) modalities such as acupuncture or yoga. However, little is known about the patient experience of initiation and integration of CIH into conventional pain care.

METHODS: We conducted a qualitative study of patients experiencing chronic pain and accessing CIH ($N = 11$). We recruited patients from Internal Medicine and Integrative Medicine clinics at an academic medical center through the use of flyers posted in waiting areas. Inclusion criteria were chronic pain (pain ≥ 3 months duration), experience with CIH, age ≥ 18 years, and English fluency. We conducted semi-structured, audio-recorded interviews about participants' experiences with chronic pain care and CIH followed by a brief survey to collect demographics, brief pain inventory, and CIH use patterns. Using a team-based, mixed inductive and deductive analytic approach, we iteratively refined emerging themes within the study team and based on feedback from Integrative Medicine experts.

RESULTS: Participants were older ($\mu = 52$ years, SD = 14), female (80%), and white (70%). Mean pain duration was 12.8 years. Average daily pain scores for the participants ranged from 3 to 6.5 on a 0–10 numeric rating scale. Among participants, 60% reported current opioid medication use; 80% used non-opioid analgesics. We organized emergent themes into 3 domains: 1) CIH initiation, 2) CIH effectiveness, and 3) barriers to accessing CIH. Participants described three key factors involved in CIH initiation: provider or acquaintance recommendation, disillusionment with conventional care, and desperation for pain relief. One participant initiated CIH after "experiencing that level of frustration with the typical mainstream medical system." The effectiveness of CIH treatments was perceived as unique to each participant and influenced by the CAM provider's affect and capabilities. Participants also felt that CIH modalities worked synergistically to provide pain relief. One participant noted, "I'm only getting improvement because I'm doing so many [different treatments] and because I'm hitting so many different aspects." Most participants spent years developing an effective pain regimen, and experience substantial barriers to accessing CIH included logistical barriers, cost, and difficulty reliably accessing CIH providers.

CONCLUSIONS: Patients' experiences with CIH for chronic pain reveal important facilitators of CIH treatment initiation and barriers to its integration into conventional care. Patients view CIH as a key part of their pain care, working synergistically with conventional treatments, and yet experience significant barriers to accessing CIH. Future studies should evaluate the effectiveness of interventions such as patient navigators or referral networks to improve the integration of CIH into conventional pain care.

THE PHYSICIAN EXPERIENCE IN AN INTERVENTION TO IMPROVE ADHERENCE TO OPIOID PRESCRIBING GUIDELINES

Phoebe A. Cushman[1, 2]; Payel J. Roy[1, 2]; Jane M. Liebschutz[1, 2]; Karen E. Lasser[1, 2]; Julia Keosaian[1, 2]; Victoria A. Parker[3]. [1]Boston Medical Center, Boston, MA; [2]Boston University School of Medicine, Boston, MA; [3]Boston University School of Public Health, Boston, MA. (Control ID #2703752)

BACKGROUND: Efforts to curb the opioid crisis have generated multiple guidelines to increase safety of opioid prescribing for chronic nonmalignant pain (CNMP). We analyzed implementation of an intervention (TOPCARE, "Transforming Opioid Prescribing in Primary Care") to improve primary care physician (PCP) adherence to opioid guidelines. We explored how TOPCARE influences PCPs' *knowledge*, *attitudes*, and *behavior* regarding opioid guidelines and how PCPs' *clinical contexts* affect TOPCARE implementation.

METHODS: We conducted semi-structured qualitative interviews with 22 of 24 intervention PCPs from TOPCARE, a cluster RCT at 4 safety-net primary care clinics. The intervention consists of a patient registry, population management by nurse care managers (NCMs), education by academic detailers (ADs), and electronic decision support tools. We conducted thematic analysis of the transcribed interviews, tracking with Nvivo.© Our conceptual model merged two existing frameworks and guided *a priori* codes: Cabana et. al's "Why don't physicians follow clinical practice guidelines?" and Rycroft-Malone's "Promoting Action on Research Implementation in Health Services" (PARiHS). We double-coded every third interview and met weekly to reconcile codes.

RESULTS: Key themes included *increased knowledge*, *unexpected feedback*, *increased outcome expectancy*, *transfer of tasks to NCMs*, *guidelines becoming routine*, *reduced isolation*, *and reduced variability in opioid prescribing*. PCPs gained *knowledge* of guidelines via expertise of NCMs, ADs, and support tools. PCPs also received unexpected feedback about patients by applying guidelines: "TOPCARE came around and [the NCM] said, 'You've never checked urine on this person,' [so we did]. It's been a shock—I'd considered [the patient] one of my stars!" PCP *attitudes* toward CNMP did not change under TOPCARE. However, PCP outcome expectancy increased; PCPs voiced expectations that applying guidelines would yield useful results: "[Under TOPCARE], I've become more systematic about doing the PEG scale [for pain] and seeing opioids as a trial." PCP *behavior* change occurred by way of NCMs taking on guideline-recommended tasks. TOPCARE also helped PCPs make guidelines part of their routine. In examining PCPs' *clinical contexts*, we found that TOPCARE helped reduce PCP isolation in their opioid prescribing decisions, particularly through partnerships they formed with NCMs: "It gives me a second opinion, somebody else's eyes." We also found that variability among prescribing styles within a practice hindered guideline implementation; PCPs felt that TOPCARE reduced that variability: "We'd had some prescribers in the past who were 'cowboys,' prescribing a lot. [Under TOPCARE], we are more together about how we prescribe."

CONCLUSIONS: An intervention to improve adherence to opioid guidelines increased PCPs' knowledge and outcome expectancy. PCPs experienced tangible and emotional support to help reduce variability and carry out guideline-concordant care.

THE PREVALENCE AND IMPACT OF UNHEALTHY ALCOHOL USE AMONG MEN WHO HAVE SEX WITH MEN INITIATING PRE-EXPOSURE PROPHYLAXIS FOR HIV INFECTION: A PILOT STUDY

E. J. Edelman[1]; Onyema Ogbuagu[1]; Emily Williams[2]; Lydia A. Barakat[1]; Adedotun Ogunbajo[3]; Perry J. Tiberio[4]; Philip Chan[3]; Brandon D. Marshall[3]. [1]Yale University School of Medicine, New Haven, CT; [2]University of Washington/VA Puget Sound, Seattle, WA; [3]Brown University, Providence, RI; [4]Yale New Haven Hospital, New Haven, CT. (Control ID #2706910)

BACKGROUND: Unhealthy alcohol use is common among men who have sex with men (MSM) and may influence HIV risk prevention. Among MSM initiating pre-exposure prophylaxis (PrEP) for HIV infection, we sought to determine the prevalence of unhealthy alcohol use and examine its impact on PrEP adherence and retention in care.

METHODS: MSM who initiated PrEP between 2015 to 2016 at one of two PrEP clinics in Providence, RI or New Haven, CT were enrolled into an

observational cohort study. Data were collected as part of routine clinical care using structured encounter forms. The prevalence of unhealthy alcohol use (by Alcohol Use Disorders Identification Test [AUDIT]-C score >4) was described at baseline and compared across those with and without low PrEP adherence (self-report of missing seven or more pills in the last 30 days at the 3-month visit). We additionally examined the association between level of alcohol use (AUDIT-C scores, categorized based on the distribution, as 0, 1–6 and 7–12) and low PrEP adherence using the Mantel-Haenszel test for linear trend. We then examined the prevalence of unhealthy alcohol use across those with and without retention in care (follow-up visit within three months of the baseline clinic visit). Significance was defined as $p <= 0.05$.

RESULTS: Among 131 MSM, 40% were between 25–34 years old and the sample was racially (65% white, 13% black, 25% multiracial/other/unknown) and ethnically (22% Hispanic) diverse. At baseline, 71 (54%) of MSM met criteria for unhealthy alcohol use. Among MSM retained in care at three months ($n = 93$), 12% of those with unhealthy alcohol use had low PrEP adherence compared to 7% without unhealthy alcohol use (odds ratio [95% confidence interval] = 1.76 [0.4, 9.1], $p = 0.47$). However, increasing levels of alcohol use were associated with a greater proportion reporting low PrEP adherence: among those with an AUDIT-C of 0, 1–6 and 7–12, the proportion reporting non-adherence was 0%, 8 and 38%, respectively ($p = 0.03$ for trend). Three-month retention in care was similar among those with (72%) and without unhealthy alcohol use (70%, $p > 0.05$).

CONCLUSIONS: Unhealthy alcohol use is very common among MSM initiating PrEP and may negatively impact adherence to PrEP. Interventions to address unhealthy alcohol in PrEP care settings are needed.

THE PROMISES AND PERILS OF A PRODUCE PRESCRIPTION PROGRAM: A QUALITATIVE EXPLORATION Allison V. Schlosser[1]; Kakul Joshi[1]; Samantha Smith[2]; Anna B. Thornton[4]; Erika Trapl[1]; Shari Bolen[3]. [1]Case Western Reserve University, Cleveland, OH; [2]Cuyahoga County Board of Health, Parma, OH; [3]MetroHealth/Case Western Reserve University, Cleveland, OH; [4]Prevention Research Center for Healthy Neighborhoods at CWRU, Shaker Heights, OH. (Control ID #2702609)

BACKGROUND: Although produce prescription programs have shown improvements in healthy eating behaviors, little is known about how participants experience them.

METHODS: We conducted in-person, semi-structured interviews with participants in a unique produce prescription program for hypertensive adults (PRx HTN) at 3 safety net clinics in partnership with 20 farmer's markets (FMs). We interviewed 5 providers (at least 1 from each clinic), 23 patients (6–8 from each clinic), and 2 FM managers. Project staff recruited interviewees via a mail-in response card sent to all program participants and e-mail to program providers. Patient interviews focused on: 1) beliefs about food, healthy eating and FMs; 2) clinic-based program experiences; and 3) FM experiences. Provider and market manager interviews focused on their experiences providing the program. All interviews were audio-taped, transcribed, and analyzed using NVIVO software. We conducted analyses of *a priori* themes related to program processes and emergent themes of program experiences. Two investigators independently coded 10% of the interviews, achieving 80% inter-coder reliability.

RESULTS: Patients were mainly middle-aged (mean age 62 years), African American (100%), and female (78%). Providers and market managers were mainly middle-aged men and women of diverse race/ethnicities. We identified six overarching themes related to program experience (program enthusiasm, increased fruit and vegetable (FV) intake, economic hardship, co-morbidity, social interactions, and beliefs about patient agency). First, program providers, patients, and market managers expressed confidence in and enthusiasm for the program. Although providers faced some challenges integrating the program into clinics, they improvised solutions such as simplifying scheduling and providing education in group settings. Second, patients reported greater access to and consumption of fresh produce, exposure to novel FV, and knowledge of food preparation. Third, patients often described economic hardships influencing their FV shopping and eating patterns pre and post program. Fourth, patient co-morbidity (e.g., diabetes) shaped their program experience via parallel healthcare and prior nutrition interventions bolstering PRx education. Fifth, positive social interactions between patients and providers enhanced participants' sense that providers "care" for them. Sixth, patient, provider, and market manager beliefs about patient agency shaped their views of program goals and implementation.

CONCLUSIONS: Our findings highlight the promises and challenges of produce prescription programs for disadvantaged patients with complex health and economic needs. To sustain improvements in healthy eating and better integrate the program into clinics, future efforts should consider patient economic constraints, the influence of co-morbidity, and participant beliefs regarding patient agency.

THE RELATIONSHIP BETWEEN HEALTH LITERACY AND PATIENT-PHYSICIAN COMMUNICATION ON RECEIPT AND QUALITY OF DISCHARGE INSTRUCTIONS PRIOR TO HOSPITAL DISCHARGE: A PILOT STUDY Meredith Park[2]; Margot Hedlin[3]; Darren A. DeWalt[4]; Amy Weil[3]; Jamie A. Jarmul[1]. [1]UNC-Chapel Hill, Durham, NC; [2]UNC-Chapel Hill, Greensboro, NC; [3]UNC Chapel Hill School of Medicine, Chapel Hill NC, NC; [4]Center for Medicare and Medicaid Innovation, Baltimore, MD. (Control ID #2703618)

BACKGROUND: Low health literacy and poor patient-physician communication during hospitalization is associated with increased adverse events after hospital discharge as well as increased risk of hospital readmission (Kripalani 2007; Hersh 2015). However, it is unclear whether health literacy directly impacts patients' experiences of physician communication at hospital discharge, as well as patients' ability to recall important instructions after discharge. The objective of this pilot study was to collect preliminary data on screening for health literacy in an inpatient setting, as well as patient-reported data on physician communication, scheduling of follow-up appointments and quality of discharge instructions.

METHODS: Study design: Mixed methods pilot study Setting: Large, academic medical center serving a safety net population Population: Convenience sample of admitted medical patients categorized as either moderate or high risk of readmission (using an EMR-based algorithm) Measures: Health literacy was assessed using the Newest Vital Sign (NVS); quality of patient-provider communication was assessed using the Health Communication Assessment Tool (HCAT) (20 questions; scale of 1 (poor) to 5 (excellent)). We collected qualitative data on quality of discharge instructions and scheduling of follow-up appointments through in-person and phone interviews. Analytic procedures: This study was approved by the IRB at UNC Hospitals. Eligible patients were approached and informed consent was obtained when chart review indicated that they were within 24 hours of discharge. We first administered the NVS and HCAT and then conducted the in-person interview; follow-up phone interviews were conducted within 7–14 days of discharge.

RESULTS: We enrolled a total of 10 patients in this pilot study; 8 out of 10 patients had limited literacy. The mean of all HCAT questions was ≥ 4.4, indicating that patients generally felt communication with their physicians during hospitalization was excellent. While the majority of patients (8 of 10) felt prepared for discharge, several (4 out of 10) had not discussed follow-up plans with their physicians and most (8 of 10) did not have a follow-up appointment scheduled when interviewed less than 24 h before hospital discharge. We were able to contact 6 of 10 patients for the follow-up phone interview; 4 out of 6 were able to recall the primary diagnosis from their hospitalization and 3 of 6 had received written information about "red flag" symptoms for their conditions.
CONCLUSIONS: In this small study, the majority of patients had limited health literacy, but most were satisfied with communication with their physicians. Patients felt prepared at discharge, but few actually knew the reason they were hospitalized and had follow up appointments scheduled.

THE ROLE OF SUBJECTIVE SOCIAL STATUS IN SMOKERS' RESPONSE TO A PROACTIVE SMOKING CESSATION INTERVENTION Elisheva Danan[1]; Steven Fu[1]; Rachel Widome[4]; Barbara Clothier[2]; Siamak Noorbaloochi[1]; Patrick Hammett[4]; Diana Burgess[3]. [1]Minneapolis VA Health Care System, Minneapolis, MN; [2]Mpls VAHCS, Minneapolis, MN; [3]University of Minnesota and Minneapolis Veterans Affairs Health Care System, Minneapolis, MN; [4]University of Minnesota, Minneapolis, MN. (Control ID #2705723)

BACKGROUND: While the overall prevalence of smoking in the US has declined over the past several decades, disparities in smoking prevalence and quit rates by socioeconomic status have increased. Underlying this are likely "fundamental causes" as defined by Phelan and Link (2005), in which those with lesser social and material resources are less likely to reap benefits from traditional health-promotion interventions. Our objective was to test whether a proactive, population-based tobacco cessation intervention would confer greater benefit to higher social status individuals.
METHODS: This was a secondary analysis of a randomized clinical trial involving a population-based registry of current smokers, identified using the Department of Veterans Affairs (VA) electronic medical record. Current smokers were randomized to usual care or proactive care, which combined proactive outreach and the offer of free smoking cessation services. Social status was assessed by the 10-level MacArthur Scale of Subjective Social Status (SSS), which captures perception of one's position in the social hierarchy. The primary outcome was 6-month prolonged smoking abstinence at 1 year and was assessed by a follow-up survey sent to all participants who had enrolled in the trial at baseline ($N = 2249$).
RESULTS: There was an interaction between treatment group and SSS ($p = .0047$), after taking into account the stratification by site study design and demographics, such that higher SSS smokers were more likely than lower SSS smokers to benefit from the intervention. The OR for proactive versus usual care was 2.36 (95% CI = (1.43,3.88)) for the higher SSS group (highest 4 levels) and OR = 0.92 (95% CI = (0.58, 1.46)) for the lower group (lowest 4 levels). Estimated quit rates for the proactive and usual care arms were 24.2 and 12.0%, respectively for the higher SSS group and 13.5 and 14.6% for the lower group.
CONCLUSIONS: Fundamental causes are likely important drivers of smoking disparities and are not necessarily overcome by offering traditional smoking interventions. While proactive cessation outreach is an important and effective tool for connecting with hard-to-reach smokers, disadvantaged smokers could likely benefit from interventions that go even further to enhance their access to resources.

THE ROLE OF THIRD YEAR CLERKSHIP STUDENTS AND THE POTENTIAL FOR CHANGE Catherine Burke; Dylan E. Masters; Patricia O'Sullivan; Leslie Sheu. University of California, San Francisco, San Francisco, CA. (Control ID #2689096)

BACKGROUND: Preclerkship medical education has undergone extensive reform and the clinical years are growing targets for curricular innovation. Perceptions of the third year medical student (MS3) role and responsibilities vary and are not standardized across clerkships or clinical sites. As institutions implement new and innovative preclerkship programs, the perspective of clerkship leadership regarding the current role of MS3s will facilitate targeting and redefining these roles within novel curricula. This research sought to answer the following questions: What is the current role of the MS3? What factors influence this role? What is the potential for MS3 roles to change, particularly in the context of preclinical curricular change?
METHODS: In this qualitative exploratory study, we interviewed current clerkship directors and site directors for eight core clerkships using semi-structured questions regarding the current MS3 role, factors contributing to the role, and the potential for changing the role in the context of curricular reform. Through an iterative consensus building process, researchers identified themes relevant to the three research questions.
RESULTS: Twenty-three clerkship directors and site directors participated. Results reveal that the MS3 role is determined by intrinsic student-specific factors, supervisor-specific factors, and system constraints. The MS3 role is considered unique, adding value to teams through team-patient communication and inquiry tasks. The role is considered authentic and workplace learning is enhanced when the student is able to function as a "mini-resident," assisting with patient care tasks. Directors' positive perceptions of a novel curriculum are associated with identification of new and expanded MS3 roles, such as engagement in interdisciplinary collaboration and care transitions, or formalizing sharing of learning topics with the team; neutral or negative perceptions are associated with concerns about further systems constraints or deviation from traditional clinical skills and knowledge acquisition.
CONCLUSIONS: A paradox exists wherein MS3s are considered unbound by defined physician roles allowing them freedom to engage in unique tasks, but are simultaneously expected to mirror more advanced team members in an apprenticeship model. The contradictory nature of the role makes it difficult for directors to describe and consider change. While system constraints understandably limit the MS3 role, the role is largely determined by individual students and supervisors. Directors' historical perspectives and reliance on tradition may hinder them from expanding the MS3 role to capitalize on new skills developed within a reformed preclerkship curriculum. Thoughtful and deliberate engagement of directors is required to assist in envisioning innovative changes to MS3 roles that utilize novel skills in training 21st century physicians.

THE TRANSITION TO RESIDENCY BLOCK SCHEDULING: A SYSTEMATIC REVIEW Ami DeWaters; Hilda Loria; Helen Mayo. UT Southwestern, Dallas, TX. (Control ID #2701148)

BACKGROUND: In an effort to improve resident satisfaction with ambulatory training, many Internal Medicine residencies have redesigned traditional ambulatory schedules (a half day of clinic/week) into a block schedule (e.g. the 4 + 1). However, the impact of block scheduling is poorly understood. We conducted a systematic review to examine the impact of transitioning from a

traditional to a block schedule on resident and patient satisfaction with ambulatory care, as well as continuity of patient care.

METHODS: We searched Ovid MEDLINE, Ovid MEDLINE InProcess, EBSCO CINAHL, EBSCO ERIC and the Cochrane Library from date of inception to June 2016. Reference lists of included articles were reviewed to identify additional studies. We included studies a) if the ambulatory schedule transitioned from the traditional one half day of clinic/week to a block schedule (clinic scheduled in blocks lasting anywhere from 1 week to 1 year), b) that were either a RCT or observational study with a comparison group, including a historical comparison group, c) set in Internal Medicine residencies within the US, and d) which had patient and/or resident satisfaction, or continuity of patient care as a primary outcome. 7,741 studies were identified. Two authors independently reviewed titles and abstracts to identify 37 studies for full text review, of which 9 studies met inclusion criteria. Data were extracted on methods, settings, scheduling, and outcomes.

RESULTS: The definition of block scheduling was heterogeneous including: a 4 weeks inpatient + 1 week ambulatory schedule (3 studies), a 3 weeks inpatient + 1 week ambulatory schedule (1 study), a 1 month inpatient + 1 month ambulatory schedule (1 study), a "long block" of ambulatory training lasting 1 year in the 17th-28th months of residency (1 study), and 3 multisite studies which combined all of the above into their definition of block scheduling. Patient satisfaction was a primary outcome in 3 studies, each of which found it unchanged after implementing block scheduling. Five of six studies that examined resident satisfaction as a primary outcome showed significant increases in resident satisfaction with ambulatory training after transitioning to block scheduling. Provider continuity of care, defined by the percentage of time that providers saw their own patients, was examined by 3 studies, all of which showed a decline in continuity (10.2–15% less time seeing their own patients) with block scheduling.

CONCLUSIONS: The transition from traditional to block scheduling in Internal Medicine residencies increased resident satisfaction with ambulatory training and had no impact on patient satisfaction. However, provider continuity of care declined in the block system. Further research is necessary to determine whether changes in continuity of care associated with block scheduling have affected patient care outcomes.

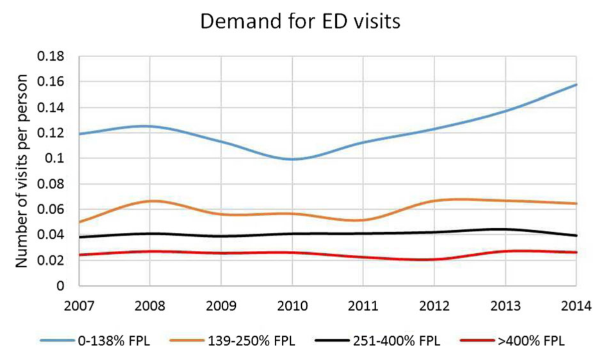
THE TREND IN THE DEMAND FOR EMERGENCY DEPARTMENT VISITS BEFORE AND AFTER THE AFFORDABLE CARE ACT MEDICAID EXPANSIONS Phuc H. Le[1]; Chi R. Nguyen[2]; Ha T. Tran[2]; Michael B. Rothberg[1]; David R. Lairson[2]. [1]Cleveland Clinic, Cleveland, OH; [2]University of Texas Health Science Center School of Public Health, Houston, TX. (Control ID #2705829)

BACKGROUND: The Affordable Care Act Medicaid Expansions aimed to improve insurance coverage so as to increase access to primary care and reduce unnecessary emergency department (ED) use in low-income persons. Previous studies on the association of improved coverage and ED use were mixed. There is no national estimate of the demand for ED visits to inform decision making in the rapidly changing US healthcare environment. We aimed to estimate the demand for ED visits and examine the trend over time.

METHODS: A pooled cross-sectional design and two-part model were used to estimate the demand for ED visits in US adults aged 18–64 years. The first stage of the model, the probability of having an ED visit, was estimated with logistic regression. In the second stage, the number of ED visits conditional on making ≥1 visit was predicted using negative binomial regression. The demand was the product of the predicted probability and number of visits. Grossman's models of demand for health and healthcare and Andersen-Aday's behavioral model informed selection of independent variables which included demographics, socioeconomic status, insurance, usual source of care, health status, and cost. Using 2007–2014 Medical Expenditure Panel Survey (MEPS) data, we estimated the mean demand by year and by poverty level (0–138% Federal Poverty Level (FPL); 139–250% FPL; 251–400% FPL; and >400% FPL). Finally, we performed trend analysis to examine the change in demand overtime. We used Stata 12.0 and SAS 9.4 to analyze data. A two-sided p-value of <0.05 was considered statistical significance.

RESULTS: The demand for ED visits increased from 0.047 visits/person in 2007 to 0.061 visits/person in 2014 (p for trend <0.05. However, persons ≤250%FPL saw a statistically significant increase in use. Comparing 2014 to earlier years, the average demand was significantly higher for the population (0.061 vs. 0.051 visits/person), and for the lowest income (0–138% FPL) group (0.158 vs. 0.117 visits/person) (p-values < 0.05).

CONCLUSIONS: The demand for ED visits increased following the full enactment of Medicaid Expansions, especially for low income individuals. The increase in demand was highest among the poorest persons. Our study suggest that low-income persons still rely on expensive EDs despite the insurance coverage. Other measures may be necessary to ensure access to primary care for the underserved.



THE TYPES AND CAUSES OF MEDICATION ERRORS WHEN USING COMPUTERIZED PROVIDER ORDER ENTRY SYSTEMS IN PEDIATRICS: A SYSTEMATIC REVIEW Clare L. Brown[4]; Niamh Forde[3]; Katherine Coffey[3]; Andrew K. Husband[2]; David W. Bates[1]; Sarah P. Slight[3]. [1]Brigham and Women, Boston, MA; [2]Durham University, Teesside, United Kingdom; [3]Durham University, Stockton on Tees, United Kingdom; [4]University of Durham, Sunderland, United Kingdom. (Control ID #2707448)

BACKGROUND: Pediatric patients are particularly vulnerable to medication errors. It has been estimated that up to a quarter of pediatric medication orders may contain an error.[1] Computerized Provider Order Entry (CPOE) with Clinical Decision Support (CDS) has been associated with a reduction in pediatric medication errors[2]. However, some new types of error have also emerged with the use of these systems. We performed a systematic literature review to identify and understand the types and causes of medication errors associated with the use of CPOE systems in pediatrics, and provide recommendations on how these systems could be improved.

METHODS: Our review was conducted according to the PRISMA guidelines. We included primary research studies that discussed the occurrence and underlying causes of errors that were generated using CPOE systems. The search

included English language articles and the timeframe was not restricted. Non-peer-reviewed publications, editorials and commentaries were excluded. Three large databases, the Cumulative Index Nursing and Allied Health Literature (CINAHL), Embase and Medline were searched using broad search terms related to 'CPOE', 'Errors' and 'Pediatrics'. Three authors independently reviewed the titles; abstracts and full texts were then reviewed independently by two authors, with one acting as a constant across all publications. Data were extracted using a customised data extraction sheet and a narrative synthesis of all eligible studies was undertaken. This review was registered with PROSPERO.

RESULTS: We identified 414 papers of which 47 articles (44 full texts and 3 conference abstracts) met our inclusion criteria. We highlighted four key types of errors: 1) Drug selection errors, where the wrong dose and/or route was accidently selected from alphabetical drop-down menus; 2) Drug calculation errors–when prescribing oral liquids, due to a lack of standardised concentrations on the system (e.g., mg/5 ml and mg/1 ml); failure to update the child's weight on the system also contributed to the occurrence of these errors; 3) Discrepancies between the medication order placed and the free-text administration instructions provided, due to a lack of available dosing options on some systems (e.g. '1 drop daily' while the 'additional instructions' field read '1 dropper (full) daily'); and 4) Erroneous alerts such as an under-dose alert for erythromycin when it was prescribed as an anti-motility agent (rather than as an antibiotic), were presented resulting in high alert override rates.

CONCLUSIONS: This review outlines four key types of errors that occurred during the use of CPOE in the paediatric population. The existence of safeguards within CPOE systems used in pediatrics is critically important across all these four areas in order to avoid these errors occurring in the future. Further research is needed to prevent future errors.

THERE'S JUST NO CRYSTAL BALL: A QUALITATIVE STUDY OF PHYSICIANS' PERSPECTIVES ON DECISION MAKING ABOUT DIALYSIS INITIATION IN OLDER ADULTS Melissa W. Wachterman[4, 5]; Tarikwa Leveille[4, 5]; Nancy L. Keating[3, 5]; Steven R. Simon[2]; Barbara G. Bokhour[1]. [1]ENRM Veterans Affairs Medical Center, Bedford, MA; [2]VA Boston Healthcare System, Boston, MA; [3]Harvard Medical School, Boston, MA; [4]VA Boston Healthcare System, Jamaica Plain, MA; [5]Brigham and Women's Hospital, Boston, MA. (Control ID #2702364)

BACKGROUND: Older adults are the fastest growing group of patients with end-stage renal disease (ESRD). The 1-year mortality rate for those over age 80 initiating dialysis is about 50%. Dialysis may increase longevity, but decrease quality of life and increase the medicalization of the last phase of life. Over half of dialysis patients regret having initiated dialysis, and many report 'no choice' but to start. Conservative non-dialytic management is uncommon in the United States. Little is known about clinicians' perspectives on decision-making about dialysis initiation. We explored nephrologists' perspectives about the decision-making process around dialysis initiation in older adults with ESRD.

METHODS: We conducted semi-structured in-person interviews with 17 nephrologists who care for older adults with advanced chronic kidney disease in different clinical settings (outpatient clinic, hospital, dialysis unit) in both academic and community practices. Interviews were audiorecorded and transcribed. We analyzed the data using grounded thematic analysis, a systematic approach to deriving qualitative themes from textual data.

RESULTS: We identified six interrelated themes that affect decisions about dialysis versus non-dialytic management of ESRD, including 4 barriers and two facilitators of real choice. Barriers included: 1) "No crystal ball"-nephrologists talked about how difficult it can be to predict who will do well versus poorly on dialysis and told stories about older adults who, unexpectedly, did well on dialysis. This weighed on them and gave them pause about not recommending dialysis initiation even when they thought patients would do poorly on dialysis; 2) "Alternative to dialysis is death"-doctors characterized the dialysis decision as a binary choice between life and death; 3) "You can always stop dialysis"-doctors noted that the decision is reversible, which some said they emphasize when patients voice ambivalence or lean towards not initiating dialysis; 4) Confronting death is difficult -nephrologists stated that it was hard to face death and to discuss it with patients and families. Facilitators of real choice included: 5) Consideration of quality of life-taking into account the downsides of dialysis; 6) Communication about patient and family preferences and goals-rarely done.

CONCLUSIONS: Elements of the dialysis initiation decision such as perception of "life or death" stakes, reversibility, and the emotional burden on nephrologists of not initiating dialysis combine to make initiation the default. Future interventions may include communication training for providers that attempts to mitigate the barriers we identified and facilitate conversations that incorporate information about quality of life and elicit patient and family preferences and personal goals, a critical component of providing patient-centered care. Future research should assess primary care providers' views about how they can collaborate with nephrologists in engaging patients in these difficult decisions.

THREE HABITS OF HIGHLY EFFECTIVE RESIDENTS IN OUTPATIENT CLINIC Karthik J. Kota[1]; Amar Kohli[1]; Gary Fischer[2]. [1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA. (Control ID #2701422)

BACKGROUND: With throughput and complexity increasing in primary care, the ability to provide efficient care in outpatient practice is a crucial skill for residents to master. Current research focuses on clinic flow and office staff management, rarely addressing physician efficiency. The few studies on residents and efficiency (none in Internal Medicine) focus on precepting before starting the day, documentation in forms, preparatory primary care "boot camps," and motion studies. In order to discover methods by which residents become efficient, this study conducted one-on-one interviews to elicit trends and themes on efficiency and inefficiency

METHODS: Internal medicine residents with primary care clinic at the University of Pittsburgh Physicians - General Internal Medicine (Oakland) Clinic were invited (by email and study coordinators) to one-on-one, semi-structured interviews conducted by phone and recorded for later transcription. The semi-structured format included questions on practice style, office visit mechanics, 2 vignettes (1 urgent care, 1 complex primary patient), and thoughts on efficiency. Interviews were transcribed by one author and verified by another. Respondents' names were not included in transcriptions. Coding was done separately by two authors and compared prior to final analysis

RESULTS: 8 of 9 recorded interviews have been transcribed, with further interviews planned; averaging 25 min, interviews ranged from 13 to 37 min. Of the ones transcribed, 4 were graduated (Post Graduate Year (PGY)-4), 2 were PGY-3, and 2 were PGY-2; 2 self-described as inefficient, 6 as efficient. Several themes emerged. Inefficient residents looked up patients prior to the clinic day; efficient ones did so the day of clinic. Inefficient residents *did not*

write notes while in the room (finding it difficult to empathize and pay attention while using the computer), while efficient ones (with one exception) at least started a note in the room (of note, nearly all efficient residents stressed starting notes early). Efficient residents lumped activities before precepting (e.g., pelvic exams, pending orders), while inefficient residents tended to defer activities until approved by attendings. Of note, no resident was ever asked to change or addend their note

CONCLUSIONS: The preliminary analysis of this qualitative study shows clear differences between residents who self-identify as efficient and inefficient. Though of roughly equal quality (as determined by the lack of needing to change or addend notes), self-identified efficient residents are more independent, spend less time preparing (e.g., pre-reading, planning notes as opposed to starting them), and tend to be more focused (e.g., urgent care is for urgent care, not health maintenance). Further research will elucidate other themes, but initial efforts to improve resident efficiency may focus on encouraging independent action, focusing visits, and facilitating starting notes in the room (e.g., templated common outpatient presentations)

TIME TO FILLING OF NEW PRESCRIPTIONS FOR CHRONIC DISEASE MEDICATIONS AMONG THE ELDERLY Jessica M. Franklin[1]; Alexis Krumme[1]; Mufaddal Mahesri[1]; Gregory Brill[1]; Heather Black[3]; Caroline McKay[3]; Newell McElwee[3]; Niteesh K. Choudhry[2]. [1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Merck & Co, Inc., Kenilworth, NJ. (Control ID #2697852)

BACKGROUND: Data on primary nonadherence remains sparse. In addition, previous work on primary nonadherence has used a wide range of follow-up periods from 30 days to 18 months, making results difficult to compare. We sought to evaluate primary nonadherence by measuring time until filling in a cohort of elderly patients.

METHODS: Data comes from a linked database of electronic health records (EHR) and claims for patients aged 65 years enrolled in Medicare A/B/D. From these data, we identified patients receiving a new prescription for a chronic disease medication. Patients were required to have continuous Medicare enrollment for 180 days prior to the index prescription order and no fills or orders for the medication during this period. We then followed patients for a fill of the index prescription for one year. Patients were censored when medication filling could not be assessed due to end of data availability, disenrollment from Medicare Part D, a hospitalization or other institutional stay lasting at least one week, or death. Cox models were used to assess differences in time until filling across patient and therapeutic characteristics.

RESULTS: In 28,770 new medication orders, the majority (58%) were filled within 1 day, 73% were filled within 7 days, 81% were filled within 30 days, and 93% were filled by the end of one year. The rate and timing of filling was similar across therapeutic areas except for insulin, where filling rates were much lower (Table). Within therapeutic areas, time until filling was generally similar across medication classes. Prescriptions with supply > 30 days had a 13% (11–15%) lower rate of filling than prescriptions with supply < 30 days. Men were less likely to fill than women (hazard ratio [HR]: 0.93 [0.90–0.95]), and patients greater than 74 years old were more likely to fill (HR: 1.05 [1.03–1.08]). Patients with increasing numbers of current medications were much more likely to fill their new prescription. Patients with 3–4 medications had a 71% (65–77%) higher rate of filling than patients with 2 or fewer medications. Patients with 5–7 medications had twice the rate of filling (HR: 2.06 [1.99–2.14]), and patients with more than 7 current medications had 2.4 (2.3–2.5) times the rate of filling.

CONCLUSIONS: With the exception of insulin, the rates of primary nonadherence were relatively low, and the vast majority of prescriptions were filled quickly. Focusing interventions on patients with few current medications or those initiating specific medications, such as insulin, may be a promising approach to improve medication adherence.

Time until filling across therapeutic areas

Therapeutic area	% Filling by day 30	% Filling by day 365	50th percentile filling time	Hazard ratio (95% CI)
Antihypertensive	83%	93%	0	[REF]
Antidiabetic	82%	93%	0	0.976 (0.924, 1.031)
Antihyperlipidemic	80%	94%	0	0.916 (0.884, 0.948)
Antiplatelet	84%	93%	0	0.979 (0.865, 1.107)
Anticoagulant	83%	95%	0	0.991 (0.922, 1.064)
Antiosteoporosis	77%	89%	0	0.823 (0.774, 0.876)
Insulin	55%	81%	11	0.420 (0.376, 0.469)
Asthma/COPD	81%	93%	0	0.967 (0.937, 0.948)

TIME TO GET WITH THE USPSTF HYPERTENSION GUIDELINES? LOW PREVALENCE OF HOME AND AMBULATORY BLOOD PRESSURE MONITORING IN PATIENTS WITH ELEVATED SCREENING OFFICE BLOOD PRESSURE Christina Eckhardt; Nathalie Moise; Daichi Shimbo; Alexandra Sullivan; Ian M. Kronish. Columbia University Medical Center, New York, NY. (Control ID #2705419)

BACKGROUND: In 2015, the US Preventive Services Task Force (USPSTF) updated their screening recommendations to advise that patients with elevated office blood pressure (BP) undergo ambulatory (ABPM) or home blood pressure monitoring (HBPM) to rule out white coat hypertension before receiving a new diagnosis of hypertension. Despite growing support for out-of-office BP testing, little is known about how often this recommendation is followed. This study aimed to determine prevalence of out-of-office BP testing prior to the release of 2015 USPSTF guidelines in order to elucidate baseline rates of use and identify potential barriers.

METHODS: We performed a retrospective chart review of patients scheduled for primary care visits in 2014 at 5 clinics affiliated with an academic medical center in New York City (New York-Presbyterian Hospital). Patients were considered eligible for ABPM or HBPM if they satisfied USPSTF criteria: 1) office BP ≥140/90 mmHg during a scheduled visit and 2) no prior diagnosis of hypertension per review of primary care notes. Patients were excluded if BP was ≥180/110 mmHg or if there was evidence of hypertension-induced end-organ damage (i.e., coronary artery disease, chronic kidney disease, heart failure, peripheral vascular disease) based on review of problem lists, labs, and EKGs. Patients were categorized as receiving ABPM or HBPM by

reviewing provider notes and orders. Fisher exact test was used to compare provider type in those who ordered out-of-office BP monitoring.

RESULTS: In 2014, there were 521 unique patients who met criteria to undergo out-of-office BP testing. Mean patient age was 44 ± 15 years. The majority (61%) were women. Race/ethnicity was not documented for 56% of eligible patients, 36% identified as Hispanic, 6% as black, and 2% as white.. Out-of-office BP testing was ordered for 6 (1.2%) patients (0 ABPM, 6 HBPM). A higher percentage of attendings ordered out-of-office BP testing as compared to residents and nurse practitioners (2.1% vs. 0.7% vs. 0.0%, $p = 0.3$). Too few out-of-office BP tests were ordered to identify additional predictors of who was referred for testing. A review of provider documentation showed that none of the six patients received adequate training in conducting HBPM (i.e. frequency of monitoring, appropriate positioning during monitoring etc.). Nonetheless, a chart review of subsequent visits revealed that 3 of 6 patients completed HBPM as ordered. All 3 patients had normal BP readings outside of the office, and BP medications were not initiated in these patients.

CONCLUSIONS: In an urban hospital-affiliated primary care setting serving an ethnically diverse patient population, out-of-office BP testing was rarely ordered. Even when ordered, there were gaps in how HBPM was implemented. To achieve the benefits of hypertension screening guidelines, efforts are needed to understand barriers to ordering and completing ABPM and HBPM, and interventions are needed to increase test ordering.

TIMELY FOLLOW-UP WITH A MULTI-DISCIPLINARY TEAM REDUCES 30-DAY READMISSIONS AND ASSOCIATED COSTS IN A LARGE ACADEMIC PRACTICE Rachel H. Kon; Emily Cetrone; William Clay. University of Virginia, Charlottesville, VA. (Control ID #2705924)

BACKGROUND: Almost 1 in 5 Medicare patients is readmitted within 30 days, estimated to cost taxpayers 17 billion dollars annually. Many readmissions are preventable, but studies looking at interventions to reduce readmission have shown mixed results. Our objective was to determine if timely hospital follow-up with a multi-disciplinary team, including a clinical pharmacist, would reduce 30-day readmissions and costs in a large academic clinic.

METHODS: University Medical Associates (UMA), an internal medicine resident clinic, serves 15,000 patients annually. Residents hold clinic 1 week each month, so timely follow-up is a common issue. Starting in January 2016, UMA patients discharged from UVA receive an appointment at the new discharge clinic within 2 weeks. The patient meets with the multidisciplinary team (a clinical pharmacist, a nurse, and resident and faculty physicians) to review the hospitalization and medications. We conducted a retrospective cohort study. All UMA patients discharged from UVA between January and December 2016 were eligible. The study group included any patient who attended a discharge clinic appointment. Our comparison group consisted of UMA patients who had at least 1 admission in 2016 but did not attend the discharge clinic. Demographic differences between the groups were compared with chi-square testing. Incidence rate ratios were calculated for inpatient days after index discharge between the groups.

RESULTS: 127 unique patients attended the clinic in 2016. Our comparison group had 840 patients. There were no significant differences in distance from clinic, index admission length of stay, Elixhauser score, or proportion taking high-risk medications. The Charleson index and LACE scores were significantly higher in the clinic group relative to controls. All analyses controlled for demographic differences in race, gender, age, and pay scale, as well as Charleson index and LACE score. In the 30 days following index discharge, logistic regression indicated that clinic patients were less likely to be readmitted than the comparison group, $b = -.49$, (95% CI = −1.13, 0.07), OR = 0.61. Additionally, Poisson regression indicated that clinic patients spent roughly one fifth the number of days hospitalized in the 30 days after index hospitalization relative to the comparison group, $b = -1.62$, (95% CI = −2.05, −1.23) IRR = .20. 30-day direct costs for clinic patients were much less due to reduced inpatient days in the 30 days after index hospitalization.

CONCLUSIONS: Our study shows that timely follow-up with a multidisciplinary team could be effective in reducing 30-day readmission rates and costs. This could be particularly effective in a large academic practice where patients may not be able to see their PCP for several weeks following discharge, and patients have many comorbidities.

TIMING OF HOSPICE ENROLLMENT AND END-OF-LIFE UTILIZATION AND SPENDING AMONG PATIENTS WITH END-STAGE RENAL DISEASE Melissa W. Wachterman[2, 3]; Susan Hailpern[4]; Nancy L. Keating[1, 3]; Manjula K. Tamura[5]; Ann O'Hare[4]. [1]Harvard Medical School, Boston, MA; [2]VA Boston Healthcare System, Jamaica Plain, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]University of Washington, Seattle, WA; [5]Stanford University, Palo Alto, CA. (Control ID #2704961)

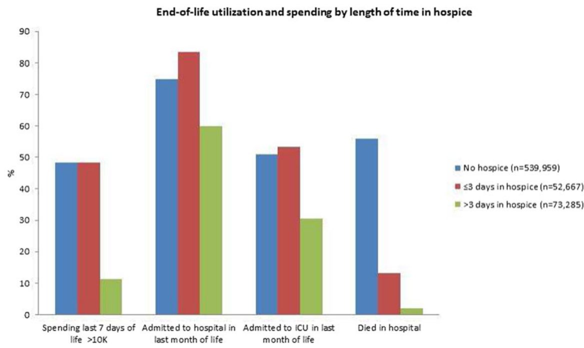
BACKGROUND: Rates of hospice enrollment in patients with end-stage renal disease (ESRD) are lower than for other serious illnesses. Because Medicare will not pay concurrently for dialysis and hospice for patients whose life-limiting illness is ESRD, these patients may also be referred to hospice in a less timely fashion. We characterized national trends in the frequency and timing of hospice enrollment among patients receiving chronic dialysis and examined the relationship between hospice use and end-of-life utilization and spending.

METHODS: Using United States Renal Data System data, we identified all hemodialysis patients with Medicare Parts A & B who died between 2000 and 2012. We grouped patients based on hospice use before death: A) no hospice, B) ≤3 days of hospice, and C) >3 days of hospice. Utilization in the last month of life was assessed for the following outcomes using Medicare claims: hospital admission, intensive care unit (ICU) use, and death in the hospital. We also assessed Medicare spending in the last 7 days of life. We used generalized linear models to compare outcomes across hospice use categories, adjusting for demographics and comorbidities.

RESULTS: Of the 665,911 decedents in our sample, 19% were enrolled in hospice at the time of death, increasing from 11% in 2000 to 26% in 2012. Among hospice enrollees, 43% were enrolled ≤3 days before death in 2000 versus 40% in 2012. Adjusted measures of spending and utilization were significantly lower for those who received >3 days of hospice than for non-hospice users (Figure, all $P < .001$). However, for patients who received ≤3 days of hospice, spending was not significantly different than for hospice non-users ($P = .97$), and hospital admission and ICU use were higher (both $P < .001$).

CONCLUSIONS: Hospice use among ESRD patients increased from 2000–2012, but nearly half of patients continued to enroll during the last 3 days of life. While longer hospice stays were associated with reductions in health care utilization and costs, shorter stays were not. Our findings suggest that efforts to improve access to hospice in this population are unlikely to result in cost

savings or changes in utilization at the end of life unless there are efforts to promote earlier referral to hospice.



TIMING OF HOSPITAL FOLLOW-UP DOES NOT IMPACT TIME TO READMISSION AMONG A POPULATION OF HIGH-UTILIZERS Colin Washington; Sara Turbow. Emory University School of Medicine, Atlanta, GA. (Control ID #2705549)

BACKGROUND: As part of efforts to improve healthcare quality while decreasing costs, hospital readmission rates are under scrutiny. Many interventions designed to decrease readmission rates have included transitions of care goals. In a population of Medicare Advantage patients, dedicated post-hospital follow-up within 7 days was shown to decrease the risk of 30-day readmissions. High-utilizer patients access healthcare services at higher rates than their peers, and are much more likely to be readmitted to the hospital. The objective of our study is to examine whether time to post-discharge outpatient follow-up has an impact on time to readmission in a population of high-utilizers at a public hospital in Atlanta, GA.

METHODS: We reviewed the charts of a random sample of 314 patients admitted 3 or more times in a calendar year between 2011–2013. We abstracted patient demographics, number of admissions, dates of admission and discharge and primary care follow-up, defined as a kept appointment with a physician or advanced practice provider in the primary care center, geriatrics, or HIV primary care clinics. An independent sample t-test was performed to compare the mean time to readmission among patients who had their first follow-up within 14 days of discharge to those who were seen after 14 days post-discharge or not seen at all. Two additional analysis were performed with cutoffs of 30 days and 60 days.

RESULTS: Patient healthcare use is presented in Table 1. There was no statistically significant difference in time to readmission among patients who were seen within 14 days of discharge compared to those who were seen after 14 days post-discharge (70.72 vs. 54.16, $p = 0.161$). Among patients who followed up within 30 days to those who did not, times to readmission were almost identical (56.27 vs. 55.75, $p = 0.949$). Finally, patients who were seen within 60 days had a shorter time to rehospitalization than patients who were seen after 60 days post-discharge, although the difference was not statistically significant (54.81 vs. 57.13, $p = 0.751$).

CONCLUSIONS: In this population of patients, time to post-discharge follow-up does not have a statistically significant impact on time to hospital readmission. There was no difference in number of hospital admissions across the three groups. This suggests that the factors driving hospital readmissions in this population are not fixable with urgent or more frequent PCP visits. The major limitation of our study was our small sample size, which prevented us from analyzing a 7-day follow-up group. Future efforts to understand factors that impact time to hospital readmission should include an examination of the influence of social determinants of health and other patient-level challenges that may not be solved with a primary care visit.

Analysis Group Healthcare Utilization

	14 day follow-up		30 day follow-up		60 day follow-up	
	≤14 days ($n = 28$)	>14 days ($n = 237$)	≤30 days ($n = 79$)	>30 days ($n = 186$)	≤60 days ($n = 140$)	>60 days ($n = 125$)
Average number of admissions	5.04	6.71	6.46	6.60	6.38	6.71
Average total number of PCP appointments (% attended)	7.82* (63.87%)	5.71* (51.00%)	7.51* (58.86%)	5.35* (49.85%)	7.04* (61.63%)	4.97* (44.17%)

TITRATED DISEASE MANAGEMENT FOR HYPERTENSION George L. Jackson[2]; Morris Weinberger[3]; Miriam A. Kirshner[2]; Karen Stechuchak[2]; Hayden Bosworth[2]; Cynthia Coffman[1]; Pamela W. Gentry[2]; Isis Morris[2]; Cynthia Rose[2]; Jennifer Taylor[2]; Carrie L. May[2]; Byungjoo Han[2]; David Edelman[2]. [1]Duke University Medical Center, Durham, NC; [2]Durham VA Medical Center, Durham, NC; [3]University of North Carolina, Chapel Hill, NC. (Control ID #2705770)

BACKGROUND: Patients who have chronic disease benefit from having the doses and types of medication titrated based upon clinical parameters, for example, higher and lower blood pressure. Similarly, these patients may also require differing intensity of disease management based upon clinical outcomes. We conducted a pragmatic clinical trial to evaluate the effectiveness of titrated disease management for patients with hypertension.

METHODS: We conducted a two-arm 18-month randomized clinical trial for patients with pharmaceutically treated hypertension for which SBP was not controlled based on clinical practice guidelines in place at the start of the study (≥140 mmHg for non-diabetic or ≥ 130 mmHg for diabetic patients). The primary aim was to compare two treatment arms in terms of impact on SBP: Arm 1 - An intervention arm using titrated disease management in which patients' hypertension control, assessed at baseline, 6 and 12 months, would be used to decide the *resource*

intensity of strategies: 1) Medium/level 1 resource intensity strategy: a registered nurse would provide monthly tailored behavioral support telephone calls + home BP monitoring; 2) High/level 2 resource intensity strategy: a pharmacist would provide monthly tailored behavioral support telephone calls + home BP monitoring + pharmacist-directed medication management; and 3) Booster (low) resource intensity strategy: a licensed practice nurse (LPN) would provide bi-monthly, non-tailored behavioral support telephone calls to patients whose SBP comes under control. Arm 2 - A comparison arm, in which an LPN would provide bi-monthly non-tailored behavioral support telephone calls (same procedures as the booster (low) resource intensity strategy component of the titrated intervention).

RESULTS: We randomized 385 Veterans. The majority (92.5%) were men, the mean age was 63.5 years, and the majority were black (61.8% black; 33.8% white; 4.5% other race). Mean baseline SBP was 143.6 mmHg and 76.6% had a baseline SBP level considered to be out of control. While the SBP (primary outcome) was reduced over 18 months in both the intervention (6.4 mmHg) and comparison (4.8 mmHg) arms, the estimated mean difference between arms was not statistically significant (−1.6 (95% confidence interval = −5.6-2.4; *p*-value = 0.43).

CONCLUSIONS: An algorithm using only blood pressure levels to determine intensity of adjuvant hypertension services does not lead to those services' generating better blood pressure outcomes. This suggests potential for the use of lower intensity telephone interventions when addressing the need to reduce blood pressure among primary care patients with hypertension, and that further research is needed to determine if there are better approaches to determining which patients with hypertension should receive advanced services.

TO ADMIT OR NOT TO ADMIT? A MULTI-INSTITUTIONAL SURVEY ON THE ROLE OF THE HOSPITALIST IN TRIAGING INPATIENT ADMISSIONS. Vijay Giridhar[2]; Sadie Trammell Velasquez[1]; Emily S. Wang[2]. [1]University of TX Health Science Center at San Antonio, San Antonio, TX; [2]University of Texas Health Science Center at San Antonio, San Antonio, TX. (Control ID #2706915)

BACKGROUND: With the increased scrutiny on the appropriateness of inpatient admissions and emphasis on efficient patient flow by hospital systems, the role of the hospitalist as a "triagist" to assess admissions from the emergency room and other outpatients setting has emerged. Despite the increasing prevalence and importance of the triagist, the skill set required is not yet defined. Our study details the differing roles and responsibilities of the triagist in a nationally distributed sample of hospital medicine and internal medicine (IM) residency programs. This information can be used to delineate the role of the triagist across multiple institutions and can assist in defining and developing a critical skill set for training IM residents.

METHODS: This is a national, multi-site survey with 11 collaborating academic institutions. Data was collected by a confidential, multi-question, mixed format RedCap survey with over 30 key questions encompassing a wide range of topics from hospitalist and residency program demographics, hospital characteristics, triage process, admission point of contact, roles and residency curriculum pertaining to triagist training. Semi-structured telephone interviews were completed to obtain further details. Data was extrapolated to graphical plots and data tables to understand current triage practices/processes.

RESULTS: The role of triaging as the admission point of contact is a faculty role greater than 75% of the time. Faculty hospitalist is the admission point of contact for the majority of the academic centers approximately 24 hours per day. Less than 50% of residency programs have a dedicated "Hospitalist/Triagist" curriculum or elective rotation. Less than 25% of all patients admitted were seen by the triagist in hospitals where the Emergency Department has admitting privileges.

CONCLUSIONS: Our study demonstrates the structure of the triagist role varies across institutions. However, with the predominance of attending physicians serving in this role rather than resident physicians, our IM residents may lack the opportunity to benefit from this training. These results demonstrate a possible gap in skills and knowledge in IM resident education and the need for further research in defining the skill set for the triagist role. In addition, there are differences in direct patient contact and patient flow depending on individual institutions and whether the emergency department has admitting privileges. This may have implications for patient safety.

TO PRODUCE OR NOT TO PRODUCE: THE CLINICAL PRACTICE GUIDELINE DILEMMAS FOR SYNTHESIZING EVIDENCE BACKGROUND Aysegul Gozu[1]; Demetrios Psihopaidas[3]; Stephanie Chang[2]. [1]AHRQ, Clarksville, MD; [2]AHRQ, Rockville, MD; [3]HRSA, Rockville, MD. (Control ID #2708335)

BACKGROUND: Clinical practice guidelines (CPG) are one of the foundations to improve patient outcomes and the quality of care. 2011 Institute of Medicine (IOM) guideline trustworthiness standards require the use of systematic review (SR) as a basis for CPG recommendations. Unfortunately, there is limited information on how CPGs develop/acquire SR evidence, what factors influence the use of any particular method, and what resources they use in developing CPGs. Our objective is to describe the advantages and challenges of different practices for developing or acquiring the SR evidence necessary for CPG development.

METHODS: We used purposive sampling to identify a rich and diverse sample of CPG developers and conducted semi-structured qualitative interviews with 9 different CPG-developing organizations in the US.

RESULTS: We identified 4 option/methods that CPG developers used in developing SRs: (1) In-house de novo production of SRs by using internal resources to produce original SRs; (2) In-house adaptation and update of existing SRs; (3) External engagement with an independent body to produce de novo SRs; and (4) Adopting existing published SRs to develop a CPG. Adopting or adapting existing SRs is preferable for CPG-developing organizations with limited staffing (often only 1–3 full time persons) due to decreased monetary and time costs. However, lack of needed information for CPG development, such as specific population-intervention specific data, use of different outcome measures, and lack of access to source data, is a potential challenge. Prior experience of panel members and staff with CPG development, the use of individual versus standing CPG panels, and the productivity of CPG panel volunteers may alter the ability of the CPG to use other methods.

CONCLUSIONS: CPG developers face multiple obstacles during development of CPG recommendations. These include balancing the desire for methodologically-rigorous SR evidence, assuring clinical relevance, meeting a variety of external requirements, time and resource limitations, and relying upon volunteer experts to develop time-sensitive SR and CPG recommendations.

TOLERANCE FOR AMBIGUITY: A TRAIT TO BE FOSTERED FOR PROMOTING WISE PHYSICIANS AND DECREASING BURNOUT

Rachel H. Kon; Justine E. Owens; Tabor E. Flickinger; Sudheer Vemuru; John Schorling; Margaret L. Plews-Ogan. University of Virginia, Charlottesville, VA. (Control ID #2705822)

BACKGROUND: A dynamic trait that may be protective against burnout in medicine is tolerance for ambiguity. Intolerance of ambiguity is the perception of ambiguous situations as a threat and conversely, tolerance for ambiguity is the tendency to approach ambiguous situations with openness and interest, working through them, rather than avoiding uncertainty. Tolerance for ambiguity has been shown to influence practice patterns, resource utilization, and leadership capacity. Preliminary evidence has linked intolerance of ambiguity to burnout. Tolerance for ambiguity may be a component of wisdom, helping physicians to navigate the complexities of testing and treatment options and accepting the limitations of medical knowledge. We conducted a cross-sectional study of medical students to assess levels of burnout, tolerance of ambiguity, and wisdom.

METHODS: All medical students at the UVA School of Medicine were sent an online anonymous survey in 2015–2016 that included the Maslach Burnout Inventory (MBI), the 7-item Tolerance for Ambiguity (TFA) scale, and Ardelt's 3-Dimentional Wisdom Scale (3D-WS). We considered high burnout to be a score of 27 or greater for emotional exhaustion (EE) or a score of 10 or greater for depersonalization (DP). Chi-square testing was used to compare MBI scores between cohorts. ANOVA testing was used to compare mean scores between year in school for 3D-WS and TFA. Pearson correlation was used to measure the relationship between MBI or 3D-WS and TFA scores.

RESULTS: 625 students were eligible and 332 responded to both MBI and TFA scales (53%). Participants had a mean age of 25 and 53% were female. Mean scores for EE were 21.15 (SD 10.34). Mean scores for DP were 6.48 (SD 5.65). Combining all years, 43.0% of students meet criteria for combined burnout. High combined burnout was significantly higher in second and third year students ($\chi^2 = 11.6$, $p = .009$), driven by EE in the second year and DP in the third year. Mean score for TFA was 22.20 (SD 6.22). Mean 3D-WS was 3.76 (SD 0.38). There was no significant difference in 3D-WS ($F = 0.970$ and $p = 0.407$) or TFA score between years in school (F 1.85 and $p = 0.138$). Those with high burnout had significantly lower tolerance for ambiguity scores (F 9.85, $p = 0.002$) at a mean of 20.98 (SD 6.25). TFA and EE burnout had a weak but significant negative correlation ($r = -0.243$, $p < 0.000$). TFA and DP burnout had a weak but significant negative correlation ($r = -0.156$, $p = 0.004$). Those with high overall wisdom had significantly higher TFA scores (F 39.80, $p < 0.000$) at a mean TFA of 25.53 (SD 5.78). TFA and 3D-WS show a moderate positive correlation ($r = 0.467$, $p < 0.000$).

CONCLUSIONS: Burnout is lower in medical students with higher tolerance for ambiguity. Students who score higher on the domains of wisdom also have higher tolerance for ambiguity. Our results suggest that promoting wisdom and tolerance for ambiguity may mitigate burnout in medical students.

TOPCARE - A MULTICOMPONENT INTERVENTION TO IMPROVE ADHERENCE TO CHRONIC OPIOID THERAPY GUIDELINES AND REDUCE OPIOID MISUSE IN PRIMARY CARE: A CLUSTER RANDOMIZED CONTROLLED TRIAL

Jane M. Liebschutz[2, 1]; Ziming Xuan[4]; Christopher W. Shanahan[2]; Marc Larochelle[3]; Julia Keosaian[1]; Daniel P. Alford[3]; Roger Weiss[5, 6]; Jeffrey H. Samet[2]; Karen E. Lasser[1]. [1]Boston Medical Center, Boston, MA; [2]Boston University School of Medicine, Boston, MA; [3]Boston University School of Medicine and Boston Medical Center, Boston, MA; [4]Boston University School of Public Health, Boston, MA; [5]McLean Hospital, Belmont, MA; [6]Harvard Medical School, Boston, MA. (Control ID #2701511)

BACKGROUND: Prescription opioid misuse has become a national epidemic. Few evidence-based clinical innovations improve monitoring of chronic opioid therapy for non-cancer pain. We tested a multicomponent intervention based on the Chronic Care Model to increase use of controlled substance agreements (CSA) and urine drug testing (UDT) while reducing opioid misuse and dosage.

METHODS: We conducted a cluster-randomized, controlled trial of 53 primary care providers (PCPs) caring for 985 patients who received >3 opioid analgesic prescriptions 21 days apart in a 6-month period at 4 safety-net primary care practices in Massachusetts from January 2014- March 2016. We randomized 25 PCPs to receive nurse-care management, an electronic registry, academic detailing and electronic tools (www.mytopcare.org) to support chronic opioid therapy. 28 control PCPs received electronic tools only. We compared patient data in the 12 months of the intervention to the prior year. The main outcomes, derived from the electronic health record (EHR), included: CSA ever in EHR, > 1 UDT in the 12 month intervention period, combination of CSA and UDT, and >2 early refills of usual opioid medication (>3 days prior to expected fill date). Secondary outcomes included termination of opioids (none in final 60 days of trial year) and > 10% decrease in mean Morphine Equivalent Daily Dose (MEDD) in mg at end of trial year. In an intent-to-treat analysis we compared proportions of patients meeting outcomes in the post-intervention year using chi-squared tests. Generalized estimating equations models accounted for clustering among patients within PCP, controlling for baseline differences.

RESULTS: At baseline, the mean patient age was 54.7 years, with 52% white, 37% black and 9% Hispanic. Patients received an average of 57.8 mg MEDD in the month prior to trial start, with no overall group differences. At one year, intervention patients had more CSA (83.5% vs. 60.9%, $p < 0.0001$, AOR 11.9, 95% CI 4.4-32.3), more UDT (79.0% vs. 54.6%, $p < 0.0001$ AOR 2.4, 95% CI 1.1, 5.2) and combination of CSA and UDT (69.8% vs. 35.3%, $p < 0.0001$, AOR 3.3, CI 1.7, 6.6). Early refills did not differ between groups (20.7% vs. 20.1%, $p = 0.75$, AOR 1.0, 95% CI 0.7, 1.7). Intervention patients were more likely to have MEDD reduced by > = 10% (32.8% vs. 22.9%, $p = 0.002$, AOR 1.6, 95% CI 1.1, 2.4). Discontinuation of opioids was more common in intervention patients but this difference was significant in only adjusted analyses (21.3% vs. 16.8%, $p = 0.08$, AOR 1.4, 95% CI 1.0, 2.1). The two largest sites implemented TOPCARE at trial conclusion.

CONCLUSIONS: TOPCARE is a promising model of team-based care to improve safety of opioid prescribing in primary care. Future studies should examine patient experience and potential unintended consequences such as illicit drug use upon termination of opioids.

TRACKING PATIENT REPORTED OUTCOME MEASURES IN A STUDENT-FACULTY COLLABORATIVE CLINIC

Shirley S. Mo[2]; Yuebi E. Hu[1]; Trevor R. Nash[1]; Shiri B. Feingold[3]. [1]Harvard College, Cambridge, MA; [2]Harvard Medical School, Boston, MA; [3]Massachusetts General Hospital, Boston, MA. (Control ID #2706881)

BACKGROUND: Patient-reported outcome measures (PROMs) are common metrics that offer a standardized assessment of health from the patient's perspective using a validated set of clinical scales. By assessing PROMs longitudinally, providers can determine whether interventions actually improve

a patient's health status. PROMs questionnaires have yet to be administered in the setting of student-faculty collaborative practices (SFCPs) or student-run clinics. In January 2015, the Crimson Care Collaborative at Internal Medicine Associates (CCC-IMA), a SFCP affiliated with Harvard Medical School and Massachusetts General Hospital, launched a platform to collect and track PROMs. The objective of this study is to report the PROMS data collected from patients at CCC-IMA. Understanding our patient population and their perceived needs will allow clinicians and volunteers to better target resources and interventions to improve the quality of care provided.

METHODS: PROMs questionnaires were administered via Apple iPads to English and Spanish speaking patients at CCC-IMA's Tuesday evening clinic from January 2015 to December 2016. Clinically validated screening instruments (PROMIS-10, PHQ-9, GAD-7, and AUDIT-0) were used to develop 32 questions that assess general physical health, mental health, alcohol abuse risk, depression, anxiety, intimate partner violence, and falling risk. The dynamic questionnaire adjusts the length and type of questions asked based on a patient's previous responses. Descriptive statistics were used to characterize the cohort answering the questionnaire and summarize the self-reported indicators described above. For each measure, patients were classified based on their numerical score for the corresponding instrument.

RESULTS: 115 patients completed a total of 177 questionnaires, completing one at each visit. This population consists of 59% male, with an average age of 40 (median 35), 31% non-native English speakers, 57% non-Caucasian, 20% reported annual household incomes of less than $15,000, and an additional 22% reporting income between $15,000 and $30,000 per year. Greater than 50% of patients reported average general physical and mental health scores. Nearly 80% reported minimal to no depression, 71% reported minimal to no anxiety, 90% were at low risk for alcohol abuse, 94% screened negative for domestic violence, and 64% reported no risk of falls. 26 and 25% of patients reported below average general physical and mental health scores, respectively. Of the cohort, 40 patients (35%), completed >1 questionnaire, and reported an average of 3 and 9% improvement in physical and mental health scores.

CONCLUSIONS: Although our patients appear to self-report their health and personal safety status similar to patients in other urban primary care clinics, continued use of PROMS will prompt thoughtful analysis, guide our use of clinical and social service resources, and allow us to longitudinally assess the efficacy of future interventions.

TRAINING ENVIRONMENTS ASSOCIATED WITH PRESENCE AND ABSENCE OF MEDICAL STUDENT RACIAL AND GENDER CLINICAL DECISION-MAKING BIASES Robert Williams[2]; Andrew Sussman[2]; Christina Getrich[1]; Miria Kano[2]; Cirila Estela Vasquez-Guzman[2]; Blake Boursaw[2]; Crystal Krabbenhoft[2]. [1]University of Maryland, College Park, MD; [2]University of New Mexico, Albuquerque, NM. (Control ID #2670624)

BACKGROUND: Research has demonstrated the presence of racial and gender biases in practicing clinicians and the role these biases may play in health disparities. We found evidence of such biases in medical students in a previous survey of 4806 seniors from 84 medical schools, using clinical vignettes in which we varied the patient race and gender. We also noted variations in the presence or absence of these biases across schools. Our current research objective was to identify modifiable aspects of the medical school training environments that would reduce the likelihood of biases.

METHODS: We conducted case studies of two clusters of medical schools, showing presence (7 schools) or absence (8 schools) of evidence of student biases in our earlier survey. During site visits to the 15 schools, we gathered quantitative and qualitative data on 24 attributes of training environments theorized to influence student attitudes, practice, or bias formation. Qualitative data were collected from key informant interviews of faculty, staff and students, and from focus groups of clinical level students. We analyzed the data using an iterative grounded hermenuetic editing approach, with five analysts identifying thematic structures. Concurrently, we used fuzzy set qualitative comparative analysis (FSCQA) to examine the data for multiple associations with the absence of evidence of biases. We focused our analysis on identifying feasible steps that schools could take to reduce biases.

RESULTS: Across the 15 schools, we interviewed 104 faculty and staff and 21 students and conducted 29 focus groups with 196 students. In the qualitative analysis, we found no attributes invariably distinguished training environments in the two clusters of schools. However, several factors were found more commonly in schools without evidence of student biases (e.g., longitudinal reflective small student groups, non-accusatory approach to training in cultural competency, etc.). The FSQCA showed that the presence of a longitudinal reflective component in the curriculum was sufficient, but not necessary to be associated with the schools without evidence of bias. Alternatively, FSQCA showed the presence (necessarily together) of attributes grouped into "formal training" (e.g., approach to diversity training) and "school priorities" (e.g., admissions preferences) or "learning environment" (e.g., faculty diversity) was sufficient to be associated with lack of evidence of biases.

CONCLUSIONS: Using two different analytic approaches, we found several potentially modifiable aspects of medical school training environments that are associated with schools whose students do not show evidence of racial and gender clinical decision-making biases. While the presence of a longitudinal reflective component in the curriculum was most strongly associated with lack of biases, several other approaches to formal and informal curriculum, communications and admissions processes were also associated with schools whose students did not exhibit biases.

TRAINING VULNERABLE PRIMARY CARE PATIENTS TO USE AN ONLINE PATIENT PORTAL Courtney Lyles; Lina Tieu; Stephen Kiyoi; Shobha Sadasivaiah; Neda Ratanawongsa; Urmimala Sarkar; Dean Schillinger. University of California, San Francisco, San Francisco, CA. (Control ID #2705238)

BACKGROUND: Patient portals, websites that provide patients and caregivers access to personal health information, are becoming ubiquitous in the US, especially with the support of Meaningful Use financial incentives. Previous research has documented substantial usability barriers, especially among patients with limited health literacy. We conducted a randomized pilot trial to determine the effectiveness of an online video-based training program to increase patient use of a portal website in a safety net healthcare setting.

METHODS: Based on our previous work documenting usability barriers to portal use, we created a website with simple instructions and 11 how-to videos for accessing features of the patient portal available in the public healthcare system in San Francisco (videos available at goo.gl/2K3X3e). We randomized 93 patients to receive: a) an in-person tutorial with a trained research assistant versus b) a link to watch the videos on their own. English-speaking patients with

at least 1 chronic condition and previous email use were eligible for the study, as the portal website was only available in English and previous research documented higher portal use among those with a chronic disease. The primary outcome was portal use (number of log-ins) at least 3 months post-training. We measured whether participants logged into the tutorial on their own. Finally, we collected baseline and follow-up survey measures to identify significant changes in participants' perceptions of the importance of the portal website, experiences with their chronic illness healthcare, and digital health literacy ratings, and to examine significant differences in the effectiveness of the training by current Internet use rates, health literacy, and other demographic characteristics.

RESULTS: The trial enrollment with complete baseline data capture was completed in September 2016. From a list of 833 provider-referred patients, we contacted 377 via phone, of which 52 declined and 186 were ineligible primarily due to lack of email use (108, 58%). Of the remaining 139 individuals, 93 participants were enrolled in the study. The mean age of the sample was 54 years, and 51% had limited health literacy; 60% were non-white, 51% were female, 25% reported speaking English less than very well. While the majority of participants used the Internet daily (77%) and reported that it was very important to access their medical information electronically (75%), over a quarter (30%) reported that they lacked the skills to use a portal website to manage their healthcare. The follow-up randomized data collection will be finished in February 2017.

CONCLUSIONS: Patients in the safety net are interested in using a portal to manage their healthcare, but many lack confidence in their ability to use it independently. Among a diverse group of patients with varying technical proficiencies, we will be able to report concrete data on how much training and support for portal use increases patient engagement with these websites.

TREATING THE PATIENT, NOT THE PROBLEM: DIVERSITY IN PERCEPTIONS OF PATIENT CENTERED CARE AMONG EARLY M1 MEDICAL STUDENTS Bruce L. Henschen[1]; Elizabeth R. Ryan[2]; Daniel Evans[1]; Ashley Truong[1]; Diane Wayne[2]; Jennifer Bierman[1]; Kenzie A. Cameron[1]. [1]Northwestern University, Chicago, IL; [2]Northwestern University Feinberg School of Medicine, Chicago, IL. (Control ID #2706508)

BACKGROUND: Teaching patient-centered care (PCC) is a key component of medical education curricula. It is unknown, however, how medical students perceive primary care, patient-centeredness, and patient-centered care. In this qualitative study, we investigate the baseline perceptions of incoming M1 medical students about primary care and patient-centered care to better inform primary care curricular development and evaluation.

METHODS: Randomly selected first year medical students in the entering Class of 2019 were invited to participate in semi-structured interviews within four months of entering medical school. We recruited a total of 38 students (20 male, 18 female). We asked participants to reflect on their perceptions of primary care by defining the concepts of "primary care" and "patient-centered care" and by indicating why "patient-centered care" may or may not be an important way for them to frame their interactions with patients. Interviews were digitally recorded, transcribed verbatim and analyzed using the constant comparative method to code, characterize emergent themes, and identify illustrative quotes.

RESULTS: Interviews lasted a mean of 24.2 min and produced over 300 pages of transcription. Students defined a primary care physician as being the "first point of contact" who cares for a patient's overall health longitudinally but only rarely discussed active management of chronic disease. PCC was defined by students as an implicit or intuitive concept; by juxtaposing it with paternalism and other motives; as involving patients and patient values in decision making; and as being jargon. Students noted that PCC is a goal or an objective to work toward as physicians and as a health system and that it can be seen as a reminder that avoids paternalism.

CONCLUSIONS: There is a diversity of perceptions about primary care and PCC among entering M1 medical students. M1 medical students tended to see a primary care physician as a 'passive gatekeeper' as opposed to one who actively manages patients' chronic illnesses, preventive care and health needs. Patient-centered care was seen as being intuitive and integral to the task of being a physician and at odds with the way students perceive that medicine was 'traditionally' practiced. Recognizing and understanding these perceptions is critical in designing or evaluating medical curricula that address primary care or patient-centered care. Authentic, longitudinal clinical experiences may have the potential to promote concepts of patient centeredness to a diverse group of medical trainees.

TRENDS AND RACIAL VARIATION IN MULTIMORBIDITY IN THE UNITED STATES Paul E. Ronksley; James Wick; Amy Metcalfe. University of Calgary, Calgary, AB, Canada. (Control ID #2695470)

BACKGROUND: The increasing prevalence of multimorbidity is a key challenge for health systems worldwide. However, little is known about the relative contribution of specific comorbidities to multimorbidity, how this has changed over time, and whether this varies by race. The objective of our study was to understand trends and racial variation in multimorbidity over a 20-year period within the United States and to describe the individual chronic conditions that differentially contribute to multimorbidity across racial groups.

METHODS: Annual data on hospitalized adults (≥18 years) between 1993–2012 were obtained from the Nationwide Inpatient Sample, representing a 20% sample of hospital discharges from across the United States. We explored trends in the proportion of inpatients with multimorbidity (as defined by ≥3 chronic conditions based on the Elixhauser comorbidity index) and stratified all estimates by five racial groups (White, Black, Hispanic, Asian/Pacific Islander, Native American). We then used population attributable fractions (PAF), adjusted for age, sex, and primary payer, to quantify the relative contribution of individual comorbidities to the outcome of multimorbidity over time and across races.

RESULTS: We analyzed data on 123,613,970 hospitalizations between 1993–2012. Over this 20-year period, the overall prevalence of multimorbidity increased from 25.7 to 47.3%. This ranged from a 23.0% relative increase in Hispanic populations to a 32.0% increase in Native American populations. Of the 30 Elixhauser comorbidities, uncomplicated hypertension was the most prevalent and increased by 22% between 1993 and 2012 in White and Native American populations. The relative change in the proportion with COPD and renal failure increased the most among Black populations (13.4 and 13.1% respectively) while depression and hypothyroidism increased the most in White populations (11.6 and 10.0% increase respectively). Adjusted PAF showed that the relative contribution of uncomplicated hypertension to multimorbidity increased for all races but had the largest contribution in Hispanic populations (27.3% in 2012). There were also large increases in the PAF for renal failure and obesity across all racial groups, though the largest relative changes were observed in Hispanic and Asian/Pacific Islander populations. In contrast, the PAF for congestive heart failure has decreased, particularly in White and Native American populations, while the PAF for cardiac arrhythmias has decreased the most in White and Hispanic populations.

CONCLUSIONS: While multimorbidity continues to increase in the United States, the relative contribution of individual chronic conditions has changed over time and varies substantially by race. In an era of precision medicine, these findings suggest the need for targeted strategies to address the medical conditions that differentially affect racial groups in an attempt to curb the burden of multimorbidity.

TRENDS IN COST-RELATED ACCESS BARRIERS AMONG NON-ELDERLY US ADULTS IN HIGH-DEDUCTIBLE VS. TRADITIONAL HEALTH PLANS, 2011–2015 Tyler N. Winkelman[2, 3]; Joel E. Segel[4]; Jeff Kullgren[1]. [1]Ann Arbor VA Healthcare System and University of Michigan, Ann Arbor, MI; [2]University of Michigan, St. Paul, MN; [3]VA Ann Arbor Healthcare System, Ann Arbor, MI; [4]The Pennsylvania State University, University Park, PA. (Control ID #2707516)

BACKGROUND: One in three privately-insured Americans are now enrolled in a high-deductible health plan (HDHP). HDHP enrollees may experience higher out-of-pocket (OOP) costs for needed care than in traditional health insurance plans. Recent policy developments, such as the Affordable Care Act's provisions on maximum OOP spending limits and coverage for preventive services without co-pays, may have benefited individuals in HDHPs more than individuals in traditional health insurance plans. However, little is known regarding trends in cost-related access barriers among Americans in each of these types of private health insurance plans.
METHODS: We used data from the 2011 to 2015 National Health Interview Survey (NHIS), an annual nationally representative survey of non-institutionalized adults in the United States. We limited our sample to adults aged 18–64 who were enrolled in a single private health insurance plan, which we classified as an HDHP (using annual IRS definitions) or a traditional plan (i.e., a private plan that was not an HDHP). Our key outcome was any reported cost-related access barrier in the last 12 months, which we defined as self-report of foregone or delayed needed care due to cost, problems paying medical bills, reduction/elimination of medication due to cost, or being very worried about paying medical bills if an illness occurred. We used a multivariable linear probability model to compare linear time trends in cost-related access barriers in HDHPs and traditional plans, adjusting for income, marital status, employment, race, gender, age, education, and number of chronic conditions (0, 1, 2 or more). We accounted for the complex survey design using Stata 14.2 and considered $P < .05$ to be statistically significant.
RESULTS: Our sample consisted of 29,164 HDHP enrollees and 72,591 traditional plan enrollees. Between 2011 and 2015, cost-related barriers declined 1.8 percentage points per year among HDHP enrollees ($P < 0.001$) and 1.0 percentage points per year among traditional plan enrollees ($P < 0.001$). Among HDHP enrollees, cost-related access barriers declined to a significantly greater degree (−0.8 percentage points; $P = 0.02$), but remained more prevalent than among traditional plan enrollees in 2015 (26.2% vs. 19.3%; $P < 0.001$).
CONCLUSIONS: Between 2011 and 2015, cost-related access barriers declined significantly for non-elderly US adults in HDHPs and in traditional plans, but to a greater extent for those in HDHPs. Despite these larger declines in cost-related barriers among HDHP enrollees, they remain at significantly higher risk for cost-related access barriers. As HDHP enrollment continues to grow, policymakers should consider taking additional steps to ensure individuals in these plans are able to afford needed care.

TRENDS IN HOSPITALIZATIONS FOR FIREARM INJURIES INFLICTED BY CIVILIANS AND POLICE ON ADOLESCENTS AND YOUNG ADULTS: U.S. PATTERNS BY RACE/ETHNICITY, 2005–2014 Frances V. Ue; Alison Alpert; Kay Negishi; Sarah Stoneking; Gina Kim; Krupa Parikh; James S. Lang; Michael McShane; Gaurab Basu; Danny McCormick. Cambridge Health Alliance, Boston, MA. (Control ID #2706669)

BACKGROUND: Young people of color are at highest risk of dying from gun violence. However, non-fatal firearm injuries are far more common and most often require hospitalization. Given the national debate about firearm violence, particularly against young people of color, we examined trends in hospitalizations for firearm injuries caused by police and civilians according to race/ethnicity of those assaulted.
METHODS: We analyzed hospital discharge data from the National Inpatient Sample (NIS) of the Healthcare Cost Utilization Project (HCUP) from 2005–2014. We used ICD-9 External Cause of Injury Codes (E-Codes) to identify all hospitalizations due to firearm injuries inflicted on people ages 15–44 years by: 1. Police (E-code, E970), "in the course of arresting lawbreakers, suppressing disturbances, maintaining order or other legal action"; and 2. Civilians (E-codes, E9650-9654), individuals who are not police. Using NIS survey weights, we tabulated the number of hospitalizations in the US yearly and stratified by race/ethnicity. We then used US Census Bureau data on the population in the ages and years studied to calculate rates of admissions/million US population per year. We compared yearly admission rates by race/ethnicity using chi-square tests and used linear regression to model hospitalization rates as a function of time.
RESULTS: Most patients with civilian-inflicted firearm injuries (CIFIs) were uninsured (35.8%), in the lowest quartile of median zip-code income (54.8%), and male (91.5%), similar to those with police-inflicted firearm injuries (PIFIs). Black people represented 51.4% of CIFIs and 27.8% of PIFIs. A total of 157,142 people were admitted for CIFIs and 4,418 for PIFIs. We found no significant difference in admissions for CIFIs between 2005 (128.5/million population [95%CI: 86.9, 170.1]) and 2014 (103.1 [95% CI: 87.6, 118.8]; p for trend = 0.15); observed increases for white and black people and a decrease for Hispanic people did not reach statistical significance. In contrast, the rate of admissions for PIFIs increased by 59.5% between 2005 (2.2/million population [95%CI: 1.5, 3.0]) and 2014 (3.5 [95% CI: 2.7, 4.3]; p for trend = 0.045). Increases were also observed in each racial/ethnic group but only reached statistical significance for white people (p for trend = 0.006). Rates of admissions for CIFIs and PIFIs were higher among black than white people. In 2014, admissions among black people were 2.8 times higher than whites for PIFIs and 20 times higher for CIFIs.
CONCLUSIONS: Hospitalizations for firearm injuries caused by civilians did not change, but those caused by police increased from 2005 to 2014. While trends for racial/ethnic minorities were not statistically significant, rates of admissions from both causes were dramatically higher among black as compared to white people. Changing policing practices and addressing other adverse social circumstances of young people, particularly those of color, may reduce hospitalizations for gun violence.

TRENDS IN INSURANCE COVERAGE AND CONTRACEPTIVE USE AMONG REPRODUCTIVE-AGE WOMEN IN THE ERA OF THE AFFORDABLE CARE ACT Mara E. Murray Horwitz; Dennis Ross-Degnan. Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA. (Control ID #2706958)
