# Urine $\pi$ -Glutathion S-transferase but not Tamm-Horsfall protein correlates with Carotid artery intima media thickness in childhood type1 diabetes

Peter Holmquist<sup>1\*</sup> and Petru Liuba<sup>2</sup>

## Abstract

**Background:** Renal disease remains a serious threat in patients with insulin-dependent (type1) diabetes. Hence its detection early in the life of patients with type1 diabetes is crucial. Several lines of evidence suggest similar mechanisms for the development of both renal and arterial disease. We sought to investigate in young patients with type1 diabetes whether  $\pi$ -Glutathione S-transferase to creatinine ( $\pi$ -GST:crea) and Tamm-Horsfall protein to creatinine (THP:crea) ratios, markers of distal tubular renal function, relate to subclinical markers of arterial disease, which appear to onset early and develop rapidly in type1 diabetes.

**Methods:** Seventy-one children and adolescents (median age and diabetes duration 14 and 6 years, respectively) with type1 diabetes for at least 6 months were assessed for timed urine levels of  $\pi$ -GST, THP, HbA1c, albumin, and plasma C-reactive protein (CRP). Carotid artery intima-media thickness (IMT), brachial artery flow-mediated dilatation (FMD), and cutaneous microvascular function were assessed by high-resolution ultrasound and laser Doppler, respectively.

**Results:** Two patients had microalbuminuria ( $> 20 \mu\text{g}/\text{min}$ ), and were therefore removed from the study population.  $\pi$ -GST:crea ratio and THP:crea showed no relationship to the demographic, diabetes, or inflammatory indices. Lower  $\pi$ -GST:crea ratio was associated with greater IMT ( $p = 0.01$ ,  $r = -0.29$ ), particularly in female patients ( $p = 0.004$ ,  $r = -0.49$ ). The association of  $\pi$ -GST:crea ratio with IMT was stronger in patients with passive smoke exposure ( $p = 0.002$ ,  $r = -0.43$ ). Among post-pubertal patients, lower  $\pi$ -GST:crea ratio was also associated with lower microvascular response to Ach (acetylcholine;  $p = 0.03$ ,  $r = 0.49$ ).

**Conclusions:** In young patients with type1 diabetes, proximal tubular dysfunction as suggested by lower levels of  $\pi$ -GST:crea ratio seems to be paralleled by changes in arterial structure and microvascular function.

**Keywords:**  $\pi$ -GST, Vascular endothelial function, Intima media thickness, Type1 diabetes

## Background

Functional and structural arterial abnormalities occur early in the life of patients with type1 diabetes [1-3]. Thickening of the arterial wall and functional disturbances in the arterial endothelium, which are more prevalent in type 1 diabetes particularly when other risk factors such as smoke exposure are present [1], may be

detected without any clear relation to the degree of glycemic control [4]. Although subtle, these changes may be detected non-invasively via high-resolution ultrasound and are seemingly at least in part responsible for the increased prevalence of cardiovascular disease in adult life [2].

In the kidney, microvascular dysfunction is thought to contribute to tubular injury [3]. Albuminuria is still the accepted standard in the diagnosis of nephropathy, and in some but not all studies was found to be associated with vascular changes [5,6]. Microalbuminuria, however,

Full list of author information is available at the end of the article

has a low sensitivity and specificity especially in young patients [7].

Novel urine biomarkers specific for different parts of the kidney have been tested for early diagnosis of nephropathy [7,8]. One of these,  $\pi$ -GST, is localized in the cytoplasm in both podocytes and parietal epithelial cells of Bowmans capsule and mostly in the distal convoluted and medullary tubules and collecting ducts [9]. Recent study showed that  $\pi$ -GST is also expressed in aortic endothelial cells [10], and may protect vascular endothelium against noxious stimuli. In adult patients, it has been found to be a predictor of kidney injury with increasing albuminuria [7]. In a male cohort of pediatric patients with type1 diabetes,  $\pi$ -GST:crea ratio was decreased [11], but increase has been reported after cardiac surgery [12].

Another putative marker of tubular dysfunction, Tamm-Horsfall protein (THP), is located in the thick ascending limb of the loops of Henle and the distal tubular cells [13]. Its urine excretion is largely regulated by sodium intake [14]. Abnormal urine excretion of THP is found already at diagnosis of type1 diabetes in children [8]. An association between cardiovascular mortality and decreased levels of urine THP in adult type1 patients has been reported [15].

Our aim was to assess whether urine levels of  $\pi$ -GST:crea ratio and THP:crea are associated in young patients with type 1 diabetes with changes in vascular structure and function.

### Subjects

Of the 184 children with type1 diabetes (duration > 6 months) enrolled in a previous study on urine excretion of GST enzymes [16], 71 were included in another study carried out within the same timeframe investigating vascular (carotid artery intima media thickness (IMT), and skin microvascular endothelial function) and inflammatory (C-reactive protein (CRP)) parameters. Exposure to environmental tobacco smoke (ETS) was assessed via questionnaire [1], and defined as occasional or regular cigarette smoking in the presence of study participants in or outside home (e.g. private or public transportation, in or around school, playground, other public places). Patients were divided into three groups: 1 = no exposure during the past year; 2 = occasional exposure, i.e. presence in a smoky environment less than once a week; 3 = weekly to daily exposure. In addition the average number of cigarettes smoked per day in or around home by patient's cohabitants was assessed as well as the number of household smokers.

Our patients are routinely treated with insulin Glargin once daily or insulin Detemir twice daily and direct-acting insulin Aspart with meals. In this cohort, nearly 15% of the diabetic children used an insulin pump with direct-acting insulin. HbA1c and blood pressure were measured four times a year upon follow-up visits.

Exclusion criteria were age below 6 years, familial hypercholesterolemia, active smoking, systemic hypertension, and albuminuria (urine albumin > 20  $\mu$ g/min). The ethical committee for human research at the Lund University Hospital approved the study (571/2004). Written and oral consent was obtained from all participants and or parents.

## Methods

### Urine and blood analyses

The method for urine  $\pi$ -GST analysis is described elsewhere [11]. Timed-over-night urine was collected at home. A specimen of urine for GST was spared with the addition of a preservative provided by the manufacturer (Biotrin International Ltd, Dublin, Ireland). Seventy-one  $\pi$ -GST urine tests were analyzed with a commercially available solid phase sandwich, immunosorbent assay from Biotrin International Ltd, Dublin, Ireland. HbA<sub>1c</sub> was measured by a high performance linked liquid chromatography (HPLC, Auto-A, Tosoh) with a normal value of 4–5.3%. U-creatinine was measured by an enzymatic calorimetric method (Hitachi Modular-P) with detection limit 0.03 mmol/L (range 0.03–53 mmol/L). Urine Tamm-Horsfall protein [17] and albumin [18] were measured by ELISA as previously described. Plasma high sensitive C reactive protein (CRP) was measured by enzyme-linked immunoassay using polyclonal antibodies (DACO Diagnostics, Glostrup, Denmark). Plasma cystatin C was measured by an automated particle enhanced immunoturbidimetric method with normal range of 0.55–1.15 mg/L [19]. Plasma creatinine was analysed by a creatininase enzyme-based analyse system (Hitachi Modular-P) with detection limit of 2.7  $\mu$ mol/L and a normal value between 5–15 years 25–68, male 60–105 and female 45–90  $\mu$ mol/L. All children had their height and weight measured. Blood pressure was taken in supine position after 5-minute rest with an arm cuff covering two third of the right upper arm.

### Assessment of carotid artery intima-media thickness

Longitudinal scans in bidimensional mode of the 1-cm long distal end of the left common carotid artery were imaged so that the lumen-intima and intima-media interfaces were clearly distinguishable. All scans corresponded to the R-wave on the ECG. Four to six scans from each individual were recorded on videotape for off line analyses of the carotid artery compliance, stiffness index and intima media thickness (IMT). The mean carotid IMT of four measurements along a 1-cm segment was calculated from each scan. Mean IMT values obtained from all scans from the same subject were averaged, and the resulted mean IMT was used for statistical analyses. All scans were taken by a single sonographer, and the analyses were performed blind to the patients' characteristics. The intraobserver variability coefficient was less than 5%.

### Cutaneous microvascular function by laser doppler with iontophoresis

Cutaneous blood flow responses to endothelium-dependent and independent agonists were assessed by using a laser Doppler multifiber probe (481-1; Perimed AB, Sweden) during transdermal iontophoresis of acetylcholine (ACh) and sodium nitroprusside (SNP), respectively, on the volar side of the forearm. The nondominant upper extremity was chosen in all patients. Anodal iontophoresis was used for ACh, whereas SNP was delivered via cathodal iontophoresis. The current was set at 100  $\mu$ A for 20 s for both drugs, based on previous work [20]. Five consecutive doses were applied for both drugs to generate dose-response curves. Baseline perfusion and changes in response to ACh were expressed as area under the curve. The intraobserver variability for skin responses to acetylcholine was 10.4%.

### Statistics

Results are given as median and range for variables with skewed distribution (see below), and as mean and standard deviations for those variables with Gaussian distribution. Spearman's correlation coefficient and analysis of variance (ANOVA) followed when applicable (i.e. significant p value) by Bonferroni posthoc test were used to assess the differences between the groups. When variable's distribution was skewed, log-transformation was used before being entered into the analysis. For statistical purpose (calculation and graphing), patients with  $\pi$ -GST below the detection limit were assigned a value of 0.05 ng/ml. Adjustment for co-variables was done with ANCOVA. Significance was accepted when  $p \leq 0.05$ . All analyses were performed using the Stat View for Windows as statistical package (USA).

### Calculations

Urinary excretion rates were calculated in relation to 1.73 m<sup>2</sup> body surface area (= Weight<sup>0.425</sup>  $\times$  Height<sup>0.725</sup>  $\times$  71.84/100) to adjust for size and gender. The ratio between the urine component and urine creatinine was used to correct for failures in timed collections. Cystatin C clearance was used to estimate glomerular filtration rate (GFR; ml/min/1.73 m<sup>2</sup> body surface area) = 84.69 \* cystatin C (mg/L) and \* 1.384 for children < 14 years [21]. Urine  $\pi$ -GST:crea ratio below 0.03 or above 1.88  $\mu$ g/mmol the lowest and the highest, respectively, in the control material, was considered abnormal [11].

### Results

$\pi$ -GST:crea ratio was available in 71 patients. Data from two patients were discarded due to microalbuminuria (urine albumin > 20  $\mu$ g/min). Demographic, diabetes, inflammatory, metabolic and renal function indexes in the remaining 69 patients are given in Table 1.

### Urine albumin excretion

With the exception of the two aforementioned patients, urine albumin was within normal range. Neither plasma cystatin C nor GFR (cystatin C clearance) showed signs of overt renal disease (Table 1). Albumin excretion rate (AER) rose with increasing age ( $p = 0.008$ ,  $r = 0.31$ ) and diabetes duration ( $p = 0.017$ ,  $r = 0.29$ ), but remained within normal range in all patients (Table 1). Neither  $\pi$ -GST:crea ratio nor THP:crea correlated with AER ( $p > 0.2$ ). HbA1c showed no association with AER ( $p = 0.6$ ), whereas patients without ETS (group 1) tended to have lower AER than those with regular ETS (group 3;  $p = 0.05$ , adjusted for age via ANCOVA).

**Table 1 Descriptive data of the studied cohort**

	Mean	Std. Dev	Count	Minimum	Maximum	Skewness	Median	IQR
Age (years)	14.7	3.5	69	7.0	20.0	-.3	14.0	5.0
BMI (kg/m <sup>2</sup> )	20.9	3.2	69	14.9	28.6	.2	20.8	4.9
Diabetes Duration (years)	6.9	4.2	69	.5	18.0	.4	6.0	6.0
HbA1c (%)	6.9	1.3	69	3.9	11.2	.5	6.7	1.6
Systolic BP (mm Hg)	112.8	10.9	69	81.0	139.0	-.1	70.0	8.0
Diastolic BP (mm Hg)	70.6	6.7	69	53.0	89.0	-.1	70.0	8.0
AER (ug/min)	2.9	2.3	69	.3	11.8	2.0	2.3	2.3
Urine THP: creatinine ratio	.9	.9	69	.0	4.4	2.0	.6	.8
Urine $\pi$ -GST: creatinine ratio	.5	.9	68	.0	6.0	4.4	.3	.6
Cystatin C (mg/L)	.8	.1	67	.4	1.1	-.6	.8	.2
GFR (ml/min)	145.1	47.6	67	79.0	373.0	2.1	141.0	43.8
CRP (mg/L)	1.8	3.2	68	.1	13.3	2.3	.5	1.4

IQR: interquartile range; BMI: body mass index; HbA1c: glycosylated hemoglobin; BP: blood pressure; AER: albumin excretion rate; THP: Tamm-Horsfall protein;  $\pi$ -GST:  $\pi$ -Glutathione S-transferase to creatinine; GFR: glomerular filtration rate; CRP: C-reactive protein.

### Urine THP to creatinine ratio

THP:crea ratio, a distal tubular marker of nephropathy, showed no relationship with any of the studied kidney and vascular markers ( $p > 0.2$ ). Also, there was no correlation between THP:crea and  $\pi$ -GST:crea ratios ( $p = 0.4$ ).

### Urine $\pi$ -GST to creatinine ratio

Among patients,  $\pi$ -GST:crea ratio was lower in males than in females ( $p < 0.01$ ). There was a weak correlation between  $\pi$ -GST:crea ratio and GFR ( $p = 0.02$ ,  $r = 0.3$ ). Neither the degree of glycemic control, as expressed by HbA1c, nor the age or diabetes duration, correlated with  $\pi$ -GST:crea ratio ( $p > 0.4$ ). CRP showed a weak correlation with  $\pi$ -GST:crea ratio ( $p = 0.03$ ,  $r = 0.26$ ).

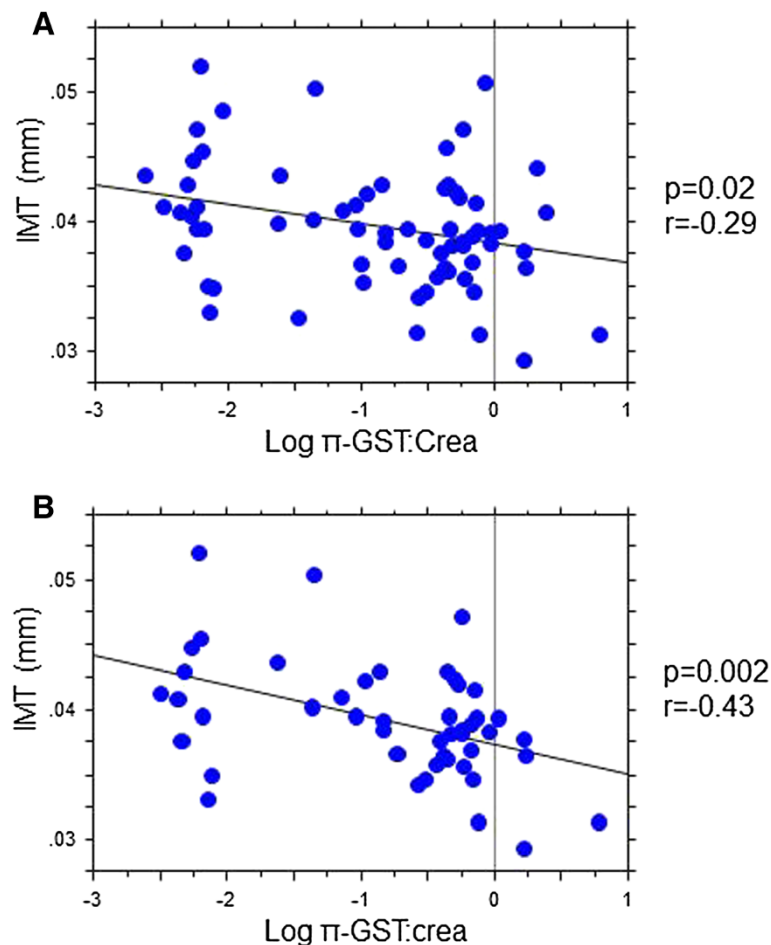

Lower  $\pi$ -GST:crea ratio was associated with greater IMT ( $p = 0.01$ ,  $r = -0.29$ ; Figure 1/Panel A), particularly in female patients ( $p = 0.004$ ,  $r = -0.49$ ). The association of  $\pi$ -GST:crea ratio with IMT became stronger in patients with ETS ( $p = 0.002$ ,  $r = -0.43$ ; Figure 1/Panel B). Among post-pubertal patients ( $>14$  years of age), lower

$\pi$ -GST:crea ratio was associated with lower microvascular response to acetylcholine (ACh;  $p = 0.03$ ,  $r = 0.49$ ; Figure 2). The responses to SNP showed no correlation with  $\pi$ -GST:crea ratio levels ( $p > 0.5$ ).

### Discussion

Using a cross-sectional design, we observed in a relatively small cohort of young patients with type1 diabetes several associations between lower urine levels of  $\pi$ -GST:crea ratio and adverse changes in carotid artery structure and cutaneous microvascular function. Female gender and exposure to tobacco smoke appear to strengthen this association. This is in keeping with some previous studies showing that girls with type1 diabetes are more prone to atherosclerosis development [22], and that exposure to tobacco smoke further increases cardiovascular risk among type1 diabetes patients [23].

The development of renal disease in type1 diabetes is often subtle especially in younger patients. The test recommended by the American Diabetes Association for

**Figure 1** Relationship of urine  $\pi$ -GST:crea ratio (log-transformed) with carotid artery intima-media thickness (IMT). Panel A: in the whole cohort of patients; Panel B: in patients with exposure to tobacco smoke.

**Figure 2** Relationship of urine  $\pi$ -GST:crea ratio (log-transformed) with mean cutaneous response to acetylcholine (Ach) among postpubertal patients (age  $\geq 14$  years).

diagnosing and monitoring diabetes nephropathy is the urinary albumin:creatinine ratio; however, this test performs poorly, with relatively low sensitivity and low specificity (7).

In view of the previous studies suggesting that vascular and kidney disease in type1 diabetes progress hand in hand [24,25], the association of  $\pi$ -GST, a novel marker of kidney disease, with increased carotid artery intima-media thickness and cutaneous microvascular dysfunction in the present study is perhaps not surprising. These two adverse vascular changes have been shown to develop early after the onset of type1 diabetes [26]. Abnormalities in peripheral arterial function and structure have been documented in both pediatric and adult cohorts with renal disease [3,27], suggesting a complex “cross-talk” between the vascular system and the kidney [28].

With the exception of this study, to the best of our knowledge, there are no further reports on  $\pi$ -GST:crea ratio in a pediatric population. In adult diabetic patients, urinary  $\pi$ -GST:crea ratio was found to rise with increasing albuminuria [7]. A similar trend was observed in adult patients with overt renal disease [13]. The cohort included in the present study is much younger and free of albuminuria, and was earlier found to have lower levels of  $\pi$ -GST:crea ratio than in healthy controls [11]. Whether age, diabetes duration, and/or stage of kidney injury could influence the urine levels of  $\pi$ -GST remains to be assessed in future studies. Maybe, since the origin of  $\pi$ -GST is renal, there is a bimodal response of kidney  $\pi$ -GST:crea ratio to diabetic kidney injury with an early decrease followed by increase as microalbuminuria occurs.

We noted a weak correlation of  $\pi$ -GST:crea ratio with the inflammatory marker CRP. Smoke exposure, diabetes duration, and poor diabetes control (HbA1c), may all be involved in the onset and progression of endothelial

damage in type1 diabetes, with release of inflammatory mediators [4,29]. Intuitively sustained injury to the vessel wall could provide a potential substrate for injury to renal tubules [30]. This could in turn, over time, lead to increase in  $\pi$ -GST excretion. Alternatively, these two processes could be unrelated to each other, although, at least based on our findings suggesting some association between  $\pi$ -GST and IMT, a common mechanism seemingly related to the diabetes milieu (e.g., inflammation, oxidative stress, and hyperglycemia) is likely to trigger both. Oxidative stress due to acutely induced hyperglycemia resulted in increased urine GST expression in a mouse model [31]. Recurrence of such events could in time lead to enzymatic exhaustion. Diabetic subjects with decreased  $\pi$ -GST activity are less likely to cope with oxidative stress and, therefore, could more easily develop generalized vascular injury and endothelial dysfunction [32].

Tamm-Horsfall protein appears to rise with increasing diabetes duration, whereas urine albumin excretion, a more conventional marker for the development of nephropathy, remains normal [33]. This may explain why in this study THP was not associated with diabetic, inflammatory or vascular markers.

*Study limitations:*  $\pi$  GST was measured in urine, not in the blood or the cytosolic of renal cells, making thus difficult the interpretation of the precise meaning of our findings. This issue needs to be addressed in future studies.

## Conclusions

In conclusion, the findings suggest that, in young patients with type1 diabetes, lower levels of  $\pi$ -GST:crea ratio correlate with changes in arterial structure and microvascular function. Future prospective studies are warranted to assess whether urine levels of  $\pi$ -GST could be used as biomarker for kidney disease in young patients with type 1 diabetes, and to clarify the above associations.

### Competing interests

The authors declare that they have no competing interests.

### Authors' contributions

PH designed the renal part of the study, carried out statistical analysis, and drafted the manuscript. PL designed the vascular part of the study, contributed to statistical analysis, and revised the manuscript. Both authors read and approved the final manuscript.

### Acknowledgments

The help from Åsa Pettersson, Renal Research Laboratory (urine testing) and Annica Maxedius (ultrasound scanning and blood sampling), and the staff of the Department of Paediatrics in Lund is gratefully appreciated. We are also grateful to Biotrin, who provided the assays for  $\pi$ -GST. The vascular part of the study was supported by grants from FAMRI, USA (PL), and the Swedish Heart and Lung Foundation (PL). Additional grant was received from Stiftelsen Samariten.
