P. Reeves: The Bacteriocins

By Peter Reeves, Ph.D., Department of Microbiology,
University of Adelaide, Australia

With 9 figures. XI, 142 pages. 1972

Cloth DM 48,-; US \$17.80

Distribution rights for the complete series for the
United Kingdom and the Traditional British Market
(excluding Canada): Chapman & Hall, Ltd., London

Prices are subject
to change without notice

The book is the first to deal comprehensively with bacteriocins, a remarkable group of substances, produced by certain strains of bacteria, and lethal for other closely related bacteria. Colicins are perhaps the best-known group and are mostly produced by strains of *Escherichia coli*.

The book appears at a time when work on some colicins is at the stage where the mode of action can really be studied at the molecular level.

The history of bacteriocins is followed from their discovery in 1925 by Professor Gratia to the recent work by Professor Nomura and others on colicin E3, culminating in the discovery that this colicin acts ultimately to cleave ribosomal RNA.

The book is written both for the general microbiologist or molecular biologist, or indeed any biologist wanting an introduction to this rapidly developing field, and also for the specialist working on some particular aspect of bacteriocins.

The basic methods of classifying bacteriocins, first evolved by Professor Fredericq, are clearly described, and an appendix gives details of the fantastic variety of bacteriocins known to exist. This provides a background to the molecular biologist of bacteriocin action, being the action of a group of proteins on sensitive bacterial cells. The chapters on chemistry, genetics and mode of action deal critically with these aspects of the molecular biology, describing the key experiments up to the recent dramatic discoveries on the mode of action of colicin E3.
