Preface

Starting from Burch and Tokarskii's experiments in 1968 [1], during the last three decades *speckle phenomena* have been extensively investigated for use in *speckle metrology*. The results of the first decade of these investigations were summarized in the first book on the subject which appeared in 1978 (R.K.Erf, ed. *Speckle Metrology*)[2].

During the second decade the field grew and was subdivided into several new metrology areas, like *particle image velocimetry* (PIV), *dynamic speckle methods*, *speckle photography*, and *speckle tomography*. The advances in CCD imaging and computer hardware stimulated the development of *electronic speckle interferometry* (ESPI) and *digital PIV* (DPIV). Holographic PIV (HPIV) and holographic speckle photography (HSP) were introduced recently into this area of metrology.

The application areas of this metrology were also essentially enlarged. Starting from surface inspection, surface displacement, vibration and strain measurements, speckle-based techniques became well established methods in solid and fluid mechanics, astronomy, informatics, and bio-mechanics. Many books have already been published in this field [3-6]. There are a number of fundamental books in very closely related fields of optical diagnostics in fluid flows [7-13]. This book is devoted to the application of speckle photography for fluid mechanical measurements.

Speckle photography nowadays is widely used for fluid mechanics measurements. As in the other applications, the work which gave rise to employing speckle photography in metrology, was the publication of the results of observing diffraction halo in two speckle-fields, registered on the same photographic plate and shifted mutually by a short distance equal to several speckle sizes [1]. The pattern of this diffraction appeared to be identical to the diffraction pattern in two orifices, and it represents the diffraction halo, modulated by Young's interferometric fringes. The distance between these fringes and the angle of their inclination with respect to a coordinate axis are determined uniquely by the shift vector of the speckle field on the photographic plate, which enables, by analysing the diffraction halo, the establishment of the magnitude of the shift with the direction remaining ambiguous. Nowadays, two different optical principles, both of which are based on the speckle technique, are used for fluid mechanical measurements.

One of the methods, *speckle velocimetry*, relies on the use of tracer particles whose motion in the plane of the flowfield is recorded on a photographic plate. To perform these measurements, the laser-light sheet is passed through the flow section, and the seed particles are photographed perpendicular to the plane of the light sheet. Thus, the velocity vectors are determined at each point in the light sheet by a point-by-point interrogation of the obtained photograph.

The second method, *speckle photography*, is based on measuring the deflection angles of the light transmitted through the flow. This technique is a *line-of-sight* method and provides information integrated along the optical path.

The first descriptions of this method were given by Köpf [14,15], by Debrus *et al.* [16], and by Mallick and Roblin [17] as early as 1972, but it was more than a decade before applications of the new technique to fluid mechanical problems were reported [18]. The state of the art of this technique is reviewed in recent publications [19,20].

It is essential that both PIV and line-of-sight speckle photography provide quantitative information for turbulent flows as well. This is due to the universal pattern of Young's interferometric fringes which remain straight and equidistant even for turbulent flows. Such interferometric patterns can be easily read into computer memory using CCD cameras. Direct optical data input into computer memory opens the way to the storage of large amounts of experimental information. This allows one to use these data in tomographic reconstruction of 3D temperature fields and to perform statistical analysis of the flowfield providing data about turbulence.

The purpose of this book is to discuss the modern possibilities of speckle photography based on automated computer-aided specklegram processing, both for the reconstruction of complex 3D refraction index fields and for the estimation of turbulence parameters in fluid mechanical measurements.

The book is divided into 10 chapters. The first six contain a description of speckle photography and the last four contain a description of the application of speckle photography to fluid mechanical measurements. According to this the first chapter (Introduction) contains a very short description of speckle photography, the second one is devoted to diffraction theory, and the third one to speckle statistics. This is a theoretical introduction to speckle photography. The next three chapters are introductions to the experimental technique. The fourth chapter contains the description of speckle generators, light sources, and recording methods for speckle photography. The fifth one contains a description of basic optical schemes for obtaining specklegrams, whereas the sixth one deals with the automated specklegram treatment. The last four chapters are devoted to a discussion of density (temperature) measurements in laminar flows, velocity measurements, and estimation of turbulence parameters in turbulent flows. The last chapter contains a description

of speckle tomography, the most promising approach in the tomography of complex phase objects.

The original idea of writing this book was a result of an early attempt to translate into the English language the author's book entitled *Speckle Photography For Fluids Flows Measurements* and published by Nauka i Technika Press, Minsk in 1989 (in Russian) [21]. However, during the decade that has passed since that time, a great number of new results in the field have been obtained. Major progress was observed in the measurement of turbulence parameters and in speckle tomography. These results and approaches occupy a significant part of this book.

For a long time the author's team has had close scientific contacts with Professor Wolfgang Merzkirch's team at the University of Essen. Many measurements were made jointly and many joint projects were developed during the last 15 years. The author is very proud of these relations and would like to express to Wolfgang Merzkirch his deepest gratitude for the friendship and scientific leadership in this very interesting 'speckle field'.

A number of grants and joint projects were very important for the development of the speckle photography technique at the Heat and Mass Transfer Institute, Minsk, Belarus. One of the first is the grant of the International Science Foundation (Soros Fond) RWB 000 as well as the subsequent grant of the Soros Fond and Belorussian Government (RWB 300). I am deeply grateful to the INTAS Foundation for grant INTAS 93-0344 and personally to Professor Clive Greated, Co-ordinator of this project. A number of publications were prepared under the scope of this project and scientific ties have been established between the Heat and Mass Transfer Institute and the University of Edinburgh. During the last decade, joint research projects on speckle photography were developed also with the University of Poitiers under guidance of Professor F. Fisson and Professor J.-B. Saulnier. Last but not least is NATO grant HTECH.LG 961001, scientific co-ordinator Professor W. Merzkirch, which allowed us to extend contacts with Essen University.

I am happy to express my appreciation and thanks to all my colleagues and friends who encouraged and supported me their help in preparing this manuscript, and especially to Prof. P. Arroyo, Drs. C. Gray, G. Blinkov, D. Vitkin, U. Wernekinck, and E. Lavinskaya.

Table of Contents

1. Introduction	1
1.1 Two schemes of speckle formation	2
1.2 Original way of specklegram treatment	4
2. Diffraction Theory of Speckle Photography	7
2.1 Maxwell's equations	7
2.2 Fresnel and Fraunhofer diffraction	10
2.3 Fourier transform	17
2.4 Diffraction at single apertures	18
2.5 Diffraction at regular and chaotic structures	21
2.6 Diffraction in the image plane	23
3. Statistical Properties of Speckle Patterns	27
3.1 The probability density function	27
3.2 The spatial structure of the speckle field	32
3.3 Dynamic speckle statistics	36
3.3.1 Statistical properties of dynamic speckles in the diffrac- tion field	36
3.3.2 Time and spatial averaging of speckle pattern	39
4. Speckle Field Generation and Recording	43
4.1 Speckle generators	43
4.1.1 Angular distribution of scattered light	44
4.1.2 Speckle statistics	49
4.2 Light sources for speckle generation	50
4.3 Photographic recording	52
4.3.1 Photographic emulsions	53
4.4 Electronic recording	57
5. Basic Optical Schemes for Obtaining Specklegrams	61
5.1 Speckle photography	61
5.1.1 Speckle photography of in-plane surface displacement (deformation)	62
5.1.2 Speckle photography of a 'transparent' medium	72

5.2	Speckle interferometry	78
5.2.1	Speckle interferometry with a reference beam	79
5.2.2	Speckle shearing interferometry	82
5.2.3	Electronic speckle pattern interferometry (ESPI)	84
6.	Specklegram Treatment	85
6.1	Point-by-point specklegram analysis	85
6.1.1	Formation of Young's fringes	87
6.1.2	Filtering and removing the diffraction halo	88
6.1.3	Fourier transform techniques	90
6.1.4	Walsh transform	91
6.1.5	Autocorrelation technique	92
6.1.6	Crosscorrelation technique	93
6.1.7	Phase iteration method	93
6.1.8	Directional ambiguity	94
6.1.9	Automated system for specklegram analysis	94
6.1.10	Parallel processing	96
6.2	Optical processing of specklegram	97
6.2.1	All-digital processor	97
6.2.2	1-D optical compression	98
6.2.3	Hybrid optical-digital processor	99
6.2.4	Anamorphic optical processor	99
6.2.5	All-optical processors	100
6.3	Spatial filtering	103
6.3.1	Optical filtering of double- and multiple-exposure specklegram	103
6.3.2	Filtering of single exposure specklegram	107
7.	Density (Temperature) Measurements in Laminar Flows	109
7.1	Rays tracing through refractive index field	109
7.1.1	Refractive index in fluid flows	110
7.1.2	Refraction of light in a density field	112
7.2	Density (temperature) measurements by speckle photography	116
7.3	Current trends in speckle photography of fluid flows	122
8.	Velocity Measurements	129
8.1	Planar velocity measurements	130
8.1.1	Light sheet formation techniques	131
8.1.2	Particle image and speckle modes	134
8.1.3	Directional ambiguity	135
8.1.4	Liquid crystal PIV	137
8.1.5	Auto- and cross-correlation analysis	138
8.1.6	Statistical flowfield analysis	138
8.2	Measurements of 3D velocity fields	140
8.2.1	Stereoscopic particle image velocimetry	140

8.2.2	Holographic particle image velocimetry	143
8.3	Dynamic speckle method	145
9.	Measurements of Turbulence Parameters: Scalar Fields . . .	149
9.1	Refraction in a turbulent field	150
9.1.1	Statistics of the refractive index	150
9.1.2	Ray tracing through a turbulent field	154
9.2	Spatial correlation analysis by speckle photography	156
9.2.1	Shadowgraphy of turbulent flows	156
9.2.2	Reconstruction of correlation functions	157
9.3	Turbulence structure visualization in flows with strong anisotropy	163
9.3.1	Speckle photography of shock tube generated flow	164
9.3.2	Results of the diagnostics	165
9.4	Single exposure technique	168
9.4.1	Experimental set-up	169
9.4.2	Diffraction halo analysis	170
9.4.3	Experimental verification	173
10.	Speckle Tomography of Transparent Objects	179
10.1	Abel and Radon inversions	182
10.2	Radon, Fourier and Hartley transforms	187
10.3	Tomography algorithms	189
10.3.1	Algebraic reconstruction technique, ART	189
10.3.2	Fourier transform algorithms	191
10.3.3	Back projection algorithm	195
10.3.4	Convolution back projection algorithm	195
10.3.5	Regularization-based technique	197
10.3.6	Ultra low projections tomography algorithms	199
10.3.7	Data smooing and interpolation	200
10.4	Performance of CT algorithms	201
10.5	Experiments	204
